findings, genetic testing results in this population of high-risk patients. Methods: We created a 6-month database (07/01/2022-12/31/2022) of women at high risk for breast cancer across a single health system with a diverse patient population. Data collected included self-identified race, TC score, mammography and MRI imaging findings, and genetic testing. Stratification analysis was performed using SAS Software 9.4. Results: A total of 496 women were included, with mean age of 47 years. The mean TC score was 23%. Compared to Black women, White women had higher rate of heterogeneously dense, fibroglandular density or fatty imaging on mammogram (p=0.0113). Among all women who had a breast MRI, 30% had abnormal findings. More White women had abnormal findings on MRI than Black women (33.0% vs 23.5%, p=0.1066). Regarding genetic consults, more White women than Black women attended appointments with genetics (45.4% vs 34.5%, p=0.0293). Additionally, 47.1% of White women pursued genetic testing compared with 35.5% of Black women (p=0.0193, RR 1.15, 95% Cl 1.03-1.30). Among those who had genetic testing, 53.1% of Black women were found to have genetic mutations (both VUS and pathogenic) compared with 40.8% of White women (p=0.1209). Patients with a TC score of 40% or higher were 83% more likely to have abnormal MRI findings than those with TC scores of less than 40% (RR 1.83, 95% Cl 1.10-3.03). Conclusions: These data demonstrate significant disparities in genetic testing and imaging findings between White and Black women in high-risk breast cancer clinic. White women were more likely to have genetics appointments and undergo genetic testing than Black women. Despite this, Black women had a higher proportion of genetic mutations among those tested. Additionally, patients with higher TC score (>40%) were more likely to have abnormal MRI findings, emphasizing the importance of comprehensive screening in high-risk individuals. These results underscore the importance of high-risk breast cancer clinics in educating patients about breast cancer and opportunities for risk reduction. They also demonstrate the critical need for equitable access to genetic counseling and testing services to ensure that all high-risk patients receive appropriate and timely care. Further research with a larger dataset and over a longer time frame is needed to better understand and address these disparities in high-risk breast cancer patients. Research sponsor: None.

P4-02-22: Temporal Changes in Breast Cancer Reproductive Risk Factors Among Women in Southwest Nigeria: Data from The Nigerian Breast Cancer Survey

Gideon Dosunmu, Olasubomi Omoleye, Mihai Giurcanu, Dezheng Huo, Olufunmilayo I. Olopade

Background: The incidence of breast cancer in Sub-Saharan Africa (SSA) has surged by 247% from 1990 to 2019, with a notable prevalence among women under 50 years of age. The understanding of evolving risk factors has however remained heavily reliant on data and guidelines extrapolated from High Income Countries (HIC), which may not accurately reflect the unique epidemiological profiles in Nigeria and other Low to Middle Income Countries (LMIC) in SSA. Given the stark mortality rates amidst rising incidence, our study

aims to refine the understanding of the trend of breast cancer risk factors in low-income countries using the Nigerian Breast Cancer Study (NBCS) data.

Methods: This is a retrospective study using the NBCS database consisting of 2314 healthy Nigerian women aged 18 and older enrolled between 1998 to 2017. Participants were grouped into six birth cohorts: <1940, 1940-49, 1950-59, 1960-69, 1970-79, and ≥1980. The primary dependent variables were age at menarche, thelarche, number of pregnancies, parity, and duration of breastfeeding. Descriptive statistics was employed to assess reproductive characteristics, while univariate regression models explored the relationship between reproductive risk factors and birth decade. Trend analyses were conducted to identify significant changes across the cohorts.

Results: The average age at menarche decreased from 16.1 years in women born before 1940 to 15.1 years in those born after 1980 ($p < 0.001$). The mean age at thelarche was centered around 13 years across cohorts. However, regression analysis indicated a slightly increasing trend in thelarche age over time (coefficient = 0.090, $p = 0.001$), with decade of birth explaining a very small portion of the variability (R-squared = 0.0048). This slightly increasing trend in thelarche age is not consistent with the sharp decreasing trend in menarche age. This discrepancy is difficult to explain physiologically and warrants further investigation. The number of pregnancies per woman similarly declined, from an average of 7 in the pre-1940 cohort to 4 in the post-1980 cohort ($p < 0.001$). Parity trends mirrored this decline, with a significant reduction over time ($p < 0.001$). The mean age at first live birth remained consistent at approximately 23 years across cohorts. The mean duration of breastfeeding per child also decreased from 18.3 months for those born before 1940 to 14.8 months for those born after 1980 ($p < 0.001$).

Conclusion: Our study provides important insights into the temporal changes in reproductive health risk factors among Nigerian women across various birth cohorts. Although some of our findings indicate shifts that might parallel trends observed in HIC, it is important to highlight notable differences such as events like thelarche and menarche which occur approximately 2 to 3 years later in the Nigerian population compared to their counterparts in HIC. There are also discernible differences in breastfeeding duration and parity trends. Future studies will evaluate the role of genomic and environmental risk factors in the etiology of breast cancer in Nigerian women. This study underscores the need for population-specific risk assessment tools to accelerate progress in breast cancer prevention in LMICs.

P4-02-23: RISK-REDUCING MASTECTOMIES FOR BREAST CANCER IN BRAZILIAN PATIENTS UNDERGOING GERMINATIVE MULTIGENE PANEL TO BREAST CANCER: impact of results on the decision of conduct

Bárbara Duarte, Christine Elisabete Rubio Alem, Ana Elisa Ribeiro da Silva Cabello, Sandra Regina Campos Teixeira, Cesar Cabello dos Santos

Introduction: Hereditary breast cancer accounts for 20% of breast cancer cases in Brazil. The cumulative risk of breast cancer in patients with germline genetic mutations in high-risk genes can reach 70-80%. Identifying high-risk patients allows for adequate screening, as well as offering risk-reducing surgeries when indicated. Risk-reducing the risk of breast cancer by more than 90% and significantly impacts a woman's quality of life. In Brazil, few institutions provide services aimed at the population at high risk for breast cancer. Objective: To evaluate the behavioral changes of high-risk patients regarding risk-reducing mastectomy (RRM) before and after receiving genetic testing results, and to identify the main influencing factors on decision-making. Methods: A prospective cohort study conducted between 11/2021 and 10/2022 included women under surveillance at the high-risk outpatient clinic of the State University of Campinas. These women were asymptomatic but had a family history of breast and/or ovarian cancer diagnosed at <45 years, met NCCN high-risk criteria, or had a personal history of breast cancer and at least one relative with breast, ovarian, and/or prostate cancer. Patients completed a questionnaire and underwent genetic testing. After receiving the results, they received appropriate guidance based on the examination result. Results: A total of 373 women were included, with 188 (50.4%) having no personal history of breast and ovarian cancer, and 185 (49.6%) having such a history. In the pre-genetic testing analysis, 173 (54.1%) patients were considering risk-reducing mastectomy, while 147 (45.9%) were either not interested or unable to respond at the time. After the test, 42.2% of patients wanted the surgical procedure, with a change in behavior observed in 26.2%, mainly from "yes" to "no/I don't know" (35.3%) ($p<0.001$). Genetic testing yielded positive results in 29.7% of patients, more frequently in those with a personal history of cancer (36.9% vs. 22.7%) ($p=0.012$). Among the 90 patients with positive results, 62 (68.9%) agreed to undergo RRM, while 22 (24.4%) remained unwilling to accept RRM, regardless of the positive test result. Genetic testing influenced the decision in 11 out of the 90 patients (11.2%) who changed their opinion from "no" to "yes" after a positive test, while 14.9% changed to "no" after a negative test, and 40.4% remained inclined towards surgery regardless of the result being normal ($p<0.001$). Significant influencing factors for pre- and post-genetic testing behavioral change (towards undergoing surgery) in multivariate analysis were positive genetic testing results (OR 2.94, $p<0.001$), personal history of cancer (OR 2.7, $p=0.008$), and ages between 40-49 (OR 2.07, $p=0.008$) and ≥ 50 (OR 3.47, $p<0.001$). Conclusion: The Brazilian high-risk population utilizing the public health system shows a greater inclination towards desiring risk-reducing mastectomies. However, when genetic testing and counseling are conducted, behavioral changes are observed, especially when the result is positive. This underscores the influence of genetic testing as a prevention strategy and optimization of healthcare system resources.

P4-02-24: Frequency of HER2-low status among patients with breast cancer and germline BRCA1/2 pathogenic variants

Ana Maria Ulbricht Gomes, Luciana Auresco, Renata Colombo Bonadio, Graziela Zibetti Dal Molin, Benedito Mauro Rossi, Debora de Melo Gagliato Jardim, Vanessa Petry, Laura Testa,

Allyne Queiros Carneiro Cagnacci, Jennifer Thalita Targino dos Santos, Maria del Pilar Estevez-Diz, Rodrigo Guindalini

Background: The antibody-drug conjugate trastuzumab deruxtecan (T-DXd) has significantly improved survival outcomes among breast cancer (BC) patients with low expression of HER2 (HER2-low) as determined by immunohistochemistry. Since then, understanding the frequency of this condition in different scenarios became relevant to guide therapeutic strategies. In sporadic BC, around 60% of hormone receptor (HR) positive and 30% of HR negative tumors are classified as HER2-low. BRCA1/2-mutated breast cancers have distinct biology, with an enrichment of triple-negative breast cancer in patients with germline BRCA1 pathogenic variants (PVs), while luminal B-like tumors are common in those with germline BRCA2. Given these particularities, the objective of the study was to evaluate the frequency of HER2-low status among BC patients carrying germline BRCA1/2 (gBRCA1/2) PVs.

Methods: An observational study was conducted to evaluate patients with a germline BRCA1/2 PVs diagnosed with breast cancer. Patients were treated between 1995 and 2024 in three oncologic centers. Electronic records and pathology reports were reviewed to collect data on demographic, clinic and pathologic features. HER2-low status was defined as immunohistochemistry +1 or +2 with a negative in-situ hybridization.

Results: Ninety-three patients with breast cancer and a germline BRCA1/2 pathogenic variant were identified, with 59 having a BRCA1 PV (63.4%) and 34 a BRCA2 PV (36.5%). Triple-negative breast cancer occurred in 47% of the cases, while 44% were hormone receptor-positive HER2-negative. Only two patients had HER2-positive breast cancer.
The median age at diagnosis was 40 years (18.5 - 69.2 years), and the majority of the patients had early-stage tumors (10.7% stage I, 47.3% stage II, 20.4% stage III), with only three patients with stage IV disease. The most frequent histological type was ductal carcinoma (82%), followed by lobular carcinoma (9%); histological grade 3 was observed in 61% of the cases.
Among patients with triple-negative breast cancer, 17.8% of the tumors were HER2-low. Among those with hormone receptor-positive HER2-negative breast cancer, the proportion of HER2-low was 29.0%. Overall, HER2-low status was present in 19.4% and 26.9% of the BC from germline BRCA1 and BRCA2 PVs carriers, respectively.

Conclusion: The HER2-low status occurred in a lower proportion in BRCA1/2-mutated BC patients in this cohort, compared to what was previously described in the literature for sporadic BC patient, both in HR negative and HR positive tumors. Additional studies are required to understand particularities of hereditary tumors in terms of the frequency of HER2-low status when samples of multiple tumor sites are evaluated as well as the frequency of HER2-ultralow since these conditions can also guide the use of targeted therapy with T-DXd.

P4-02-25: Dietary-Restriction Genes as Modulators of Breast Cancer Risk Through Metabolic Pathways

Yiyin Zhang, Yingying Dai, Shu Wang

Background: Breast cancer is a prevalent malignancy among women, exhibiting significant heterogeneity due to complex genetic and environmental interactions. Despite advances in treatment, challenges such as recurrence and drug resistance persist. Dietary Restriction (DR) has emerged as a lifestyle intervention with potential anti-cancer effects, primarily through modulation of metabolic pathways and immune responses. However, the impact of DR-related genes on breast cancer risk remains underexplored.
Methods: This study utilized differential expression analysis from the TCGA breast cancer database to identify significant genes intersecting with the DR gene set ($p < 0.05$). We conducted KEGG and GO enrichment analyses to elucidate the roles of these genes in breast cancer pathogenesis. Employing Mendelian randomization, we assessed the causal relationships between DR-related genes and metabolic indicators (LDL, TG, HDL, BMI, and waist circumference), identifying key genes involved. Additionally, protein-protein interaction networks were analyzed to explore molecular interactions, followed by drug prediction and molecular docking studies to evaluate therapeutic potential.
Results: Our differential expression analysis identified 86 DR-related genes significantly associated with breast cancer. Co-localization analysis revealed that seven of these genes shared the same SNP loci with metabolic indicators. Previous studies have established that metabolic indicators (LDL, TG, HDL, BMI, and waist circumference) can influence breast cancer incidence; our co-localization study clarified that specific DR-related genes can affect breast cancer risk through shared SNP loci with these metabolic indicators. KEGG and GO enrichment analyses indicated that these specific DR-related genes influence breast cancer development via regulation of longevity-associated pathways and lipid metabolism. Furthermore, protein-protein interaction network analysis uncovered several core regulatory nodes. Through drug prediction and molecular docking analysis, we identified perfluoroundecanoic acid, perfluorohexane sulfonic acid, perfluorononanoic acid, perfluorodecanoic acid, and rifampicin as potential therapeutic agents with high binding affinity to these genes.
Conclusions: This study elucidates the causal relationship between DR-related genes and breast cancer risk, highlighting potential therapeutic targets and candidate drugs through their effects on metabolic markers. These findings provide new directions and scientific evidence for precision treatment in breast cancer, with the potential to advance personalized treatment strategies and enhance lifestyle-based clinical management.
Keywords: Breast cancer; Mendelian randomization; Dietary restriction (DR)-related genes; Metabolic markers.

P4-02-26: CHEK2-Associated Cancer Risk Beyond 1100delC: Insights from a Northeast Brazilian Cohort

Mariana Macambira Noronha, Valbert Oliveira Costa Filho, Pedro Robson Costa Passo, Flavio Henrique Cantanhede Ximenes, Leonardo Saraiva Pontes, Duílio Reis da Rocha Filho, Gina Zully Carhuancho Flores, Aline Carvalho Rocha, Cristiane de carvalho Coutinho Farias, Ormando Rodrigues Campos Junior, Lorena Alves Oliveira da Silva, Paulo Zattar Ribeiro, Ingrid Hariman Fonseca da Cunha, Georgia Fiuza Alencar Araripe, Igor Veras, Mauro Cabral de Rosalmeida, Leandro Jonata de Carvalho Oliveira, Adriana Pires, Paulo Henrique Walter de Aguiar, Virginia Moreira Braga, Antônio Bitu dos Santos Filho, Leticia Queiros Campelo Maia, Lincoln Medeiros Dantas de Aguiar, Josmara Ximenes Andrade Furtado, Cárilla Carrascoza Caramuru, Emmanuel Filizola Cavalcante, Everardo Leite Goncalves, Carlos Alberto Barbosa Neto, Gabriel Sampaio Feitosa, Eric Lima Freitas Mota, Ígor Giordan Duarte Jorge, Izaberen Sampaio Estevam, Letícia Pinheiro Amorim, Paulo Eduardo de Oliveira, Kevin Lucas Silva Ribeiro, Natália Couto Monteiro Feitosa, Juliana Pinho Da Costa Leitao, Karla Sorandra Felipe de Oliveira, Danielle Calheiros Campelo Maia, Francisco Pimentel Cavalcante

Introduction: CHEK2 is known to be a moderate-penetrance breast cancer gene, with a lifetime risk of 20–40%. Recent studies demonstrated that pathogenic and likely pathogenic (P/LP) variants in this gene are associated with the risk of other cancers, like colorectal, kidney, and thyroid cancer. However, most of what we know about CHEK2 is from the 1100delC pathogenic variant, a founder European variant. We describe the distinct phenotype of 13 families from the state of Ceará, in the northeast of Brazil, that harbors rare P/LP variants in CHEK2, with unique tumor types, rarely described as associated with germline CHEK2 variants. Materials and methods: This cross-sectional study examines patients from a private oncology clinic in Ceará – a northeast state of Brazil - who met clinical criteria for Hereditary Predisposition to Breast and Ovarian Cancer (HBOC). The molecular analyses were from commercial multi-gene cancer panel genes from accredited laboratories between 2018 and 2023. Sequencing was conducted using next-generation sequencing (NGS) capture panels, which included 27 to 84 genes depending on clinical suspicion. The primary endpoint was to describe the prevalence of CHEK2 P/LP variants as well as sex, age at diagnosis, family phenotype, and geographic distribution. Results: From 1055 patients, 141 (13.4%) harbored a germline P/LP variant in HBOC genes, and of these, 13 (9.2%) had a P/LP variant in CHEK2. Subsequently, family members of these 13 individuals were analyzed. In total, 57 individuals were included all descending from lineages that exhibited segregation of these CHEK2 variants. Only three distinct P/LP variants were identified on CHEK2: c.349A>G, c.846+1G>C, and c.593-1G>T. The mean age of this cohort was 52 years (range 20-85). The majority was female (64.9%), with a history of one neoplasm (77.2%), and from the northwest of Ceará (57.9%). Across the 13 families analyzed, 9 (69.2%) had the c.846+1G>C mutation, while 3 had the c.349A>G mutation (23.1%), and only one had the c.593-1G>T mutation (7.7%). Interestingly, all families from the northwest were carriers of c.846+1G>C, while most families with c.349A>G were from the south of Ceará. The most frequent type of cancer was breast (40.9%), followed by

papillary thyroid cancer (9.1%), colon (7.6%), melanoma (6.1%), kidney (6.1%), prostate (6.1%), hematological (4.5%), testicular (3.0%), gastric (1.5%), lung (1.5%), hepatocarcinoma (1.5%), head and neck (1.5%) and sarcoma (1.5%). The variant c.593-1G>T accounted for one breast cancer, while the c.846+1G>C variant was enriched by papillary thyroid cancer, with 26.7% of the cases. Likewise, c.846+1G>C presented a distinct phenotype, with enrichment of melanoma (8%), prostate (8%), and testicular cancer (4%). Conclusion: This study highlights the importance of investigating CHEK2 variant impacts across diverse populations, as genetic influences on cancer phenotypes may vary significantly by genetic background and geographical location.

P4-02-27: Do High-Risk Breast Cancer Patients Belonging to Ethnic Minority Groups Undergo Adequate Genetic Testing for Early Detection and Treatment

Zachary C Bitan, Shani Fruchter, Fardeen Bhimani, Yu Chen, Sheldon Feldman, Jessica Pastoriza, Anjuli Gupta, Maureen McEvoy

Abstract: Background: Approximately 15% of women diagnosed with breast cancer have a familial history of the disease. Women with a first-degree relative are twice as likely to develop breast cancer. Early detection can confer a 99% chance of survival at five years. Numerous studies underline the Importance of genetic testing, however, there is limited literature on the use of genetic testing in ethnically and socioeconomically diverse populations. Therefore, our study aimed to analyze whether high-risk patients in our population with a documented family history of cancer received referrals to medical genetics before their breast cancer diagnosis.

Methods: A retrospective chart review was conducted on patients diagnosed with breast cancer between 2018 to 2023 from a single institution. All demographic data, family history, pathology, and genetics were collected.

Results: A total of 636 breast cancer patients with a familial cancer history were identified. Of the patients diagnosed with breast cancer, 414 (65.0%) cases were detected through routine mammography screening, and 207 (32.5%) patients discovered their cancer through palpation of a tumor. Out of the 636 patients, 226 (35.5%) of them had a first-degree relative with breast cancer. Of those with a first-degree relative, 49 (21.9%) were diagnosed with DCIS, 93 (42.0%) with stage I, 27 (12.0%) with stage II, 10 (4%) with stage III, and 2 (0.88%) with stage IV breast cancer. Overall, 43.3% of patients with familial cancer history received referrals to medical genetics, with 4.1% referred before their breast cancer diagnosis and 39.4% postdiagnosis.

Conclusion: Only 4.1% of patients with a family history of cancer received genetic consults before diagnosis. Early detection is crucial and identifying pathogenic variants can alter screening protocols. We propose a dual approach involving education and systemic modifications to increase genetic testing in high-risk patients. Automated electronic medical record prompts and primary care physicians' recognition of family history can aid in identifying high-risk patients.

P4-02-28: Decisional challenges regarding risk-reducing surgery for BRCA1/2 and PALB2 women

Catarina Relvas, Sofia Fragoso, Madalena Machado, Margarida Pereira, Bernardo Pereira, Berta Lopez, José Duarte, Sidónia Santos, Hugo Nunes, Fátima Vaz

Women with hereditary breast and ovarian cancer syndrome (HBOC) have an increased risk of breast (BC) and ovarian cancer (OC) (absolute risk > 60% and 39–58% for BRCA1-2 respectively). Options for risk management include surveillance and risk reducing surgery (RRS). Previous data reported up to 90-95% BC risk reduction after RR bilateral breast surgery (RRBBS). RR salpingo-oophorectomy (RRSO), besides a risk reduction effect on OC, impacts on overall survival for BRCA1/2 women. At present, most early BC patients with a known BRCA1/2 or PALB2 pathogenic variant discuss breast RRS during their primary surgical plan.
In this study we reviewed the Multidisciplinary Group (MD) decisions regarding cancer survivors (excluding BC women during primary treatment) and individuals with no previous cancer diagnosis, highly motivated for RRS. Between August 2020 - December 2023, 216 (215 F; 1 M) pts (median age 49 yrs) were discussed in the MD group. Genetic testing (GT): BRCA1/2 (69%), PALB2 (5%), other genes (19%) and GT not positive (7%). Cases: 114-healthy women, 97-CA survivors (6 with advanced CA) and 5 considered ineligible for RRS (1-NF1; 4-not positive GT).
Healthy women: the MD group agreed on RRBBS, RRSO or both in 37, 42 and 35 cases, respectively. After further individual discussion 5 (14%RRBBS), 2 (5%RRSO) and 6 (17% both) women refused RRS. Four RRBBS women (3 BRCA2; 1 PALB2) were diagnosed with unilateral BC in the preoperative MRI, 1 RRSO women had OC diagnosis previous to surgery. Surgical specimens of interest (5): 1- lobular invasive BC (pT1bN0), 2- DCIS, 2- STIC (1 bilateral).
Survivors were mostly (84/87%) BC survivors. While considering RRBBS, RRSO or both in 17, 49 and 25 cases, respectively, 2 (12%RRBBS), 2 (4%RRSO) and 3 (10% both) pts refused RRS. Regarding the 6 pts with advanced CA, 4 had sustained CR and RRS was agreed. Four pts (3 early BC) relapsed before RRS. Surgical specimens of interest (7): 1- multifocal BC (pT1cN1mi(sn)); 2- high grade serous fallopian tube CA (1 stage III); 4- STIC.
The decision of RRS is a challenge that should measure the competing risks, either regarding age of primary prevention for healthy women, or regarding risk of relapse versus another cancer. This decision should be as tailored as possible to each patient, respecting their individuality and preferences.

P4-02-29: Epigenetic aging as a tumor marker for predicting breast cancer susceptibility

Su Yon Jung

DNA methylation (DNAm)–based marker of aging, referred to as 'epigenetic age' or 'DNAm age' is a highly accurate multi-tissue biomarker for aging, associated with age-related disease risk, including cancer. Breast cancer (BC), an age-associated disease, is associated with older DNAm age and epigenetic age acceleration (age accel) at tissue levels. But this raises a question on the predictability of DNAm age/age accel in BC development, emphasizing the importance of studying DNAm age in pre-diagnostic peripheral blood (PB) in BC etiology and prevention. We included postmenopausal women from the largest study cohort and prospectively investigated BC development with their pre-diagnostic DNAm in PB leukocytes (PBLs). We estimated Horvath's pan-tissue DNAm age and investigated whether DNAm age/age accel highly correlates with risk for developing subtype-specific BC and to what degree the risk is modified by hormones and lifestyle factors. DNAm age in PBLs was tightly correlated with age in this age range, and older DNAm age and epigenetic age accel were significantly associated with risk for developing overall BC and luminal subtypes. Of note, in women with bilateral oophorectomy before natural menopause experiencing shorter lifetime estrogen exposure than those with natural menopause, epigenetic age accel substantially influenced BC development, independent of obesity status and exogeneous estrogen use. Our findings contribute to better understanding of biologic aging processes that mediates BC carcinogenesis, detecting a non-invasive epigenetic aging marker that better reflects BC development, and ultimately identifying the elderly with high risk who can benefit from epigenetically targeted preventive interventions.

P4-02-30: Germline Mismatch Repair Gene Mutation (MLH1) in Breast and Endometrial Cancer: A Case Report

Marygrace Margie Mesina, Frances Victoria Que, Rachelle Maravilla

Background: Lynch syndrome is an autosomal dominant, inheritable genetic disorder that predisposes affected individuals to the development of malignancies such as endometrial and colorectal cancer. This condition is primarily attributed to pathogenic germline variants, particularly in mismatch repair genes. While certain literature suggests a potential link between Lynch syndrome and breast cancer, the association remains ambiguous and requires further investigation.
Case Presentation: This report presents a case of a 52-year-old female who has been diagnosed with a double primary malignancy. The patient has a strong family history of colon cancer among her first-degree relatives.
Eleven years prior (in 2012), she was diagnosed with early-stage breast cancer, Stage I, estrogen receptor (ER) and progesterone receptor (PR) positive, HER2/neu positive. For this condition, she underwent definitive surgery and completed adjuvant systemic therapy with trastuzumab, docetaxel, and carboplatin. Trastuzumab was administered for one year,

and endocrine therapy with tamoxifen was given for five years.
In 2023, the patient began experiencing back pain accompanied by vaginal spotting. A PET CT scan revealed multiple hypermetabolic, axial, and appendicular skeletal metastases, along with multilevel lytic changes in the vertebrae, ribs, and pelvic bones, including a soft tissue component in the right pubic ramus. A biopsy of the pubic ramus indicated findings consistent with a primary breast origin, ER progesterone receptor PR negative, and HER2/neu positive. A transvaginal ultrasound further revealed a thickened endometrium. Transcervical resection of the endometrium led to a histopathological diagnosis of endometrial adenocarcinoma, endometrioid type, FIGO grade 2.
Given the patient's oncologic profile, genetic counseling and testing were conducted. A pathogenic mutation in the MLH1 gene was detected.
The association of breast cancer with Lynch syndrome remains a subject of ongoing debate. Previous literature has reported no conclusive evidence of an increased risk of breast cancer among individuals with Lynch syndrome compared to the general population. Nevertheless, recent studies suggest a potential increased risk of breast cancer in those with germline mismatch repair mutations. However, the rarity of this condition presents a significant challenge in confirming the correlation between breast cancer and Lynch syndrome on a larger scale. Given these limitations, an individualized approach is recommended.
Conclusion: This paper emphasizes on the importance of genetic counseling and genetic testing in the understanding the behavior of malignancies. This approach may aid oncologists to a comprehensive risk assessment that will serve as a guide in appropriate recommendations on screening methods for early detection, and its implications in employing preventive measures as deemed necessary. There is potentially life-saving information that may be derived in this clinical context. Hence, future studies may aid clinicians to a better understanding of tumor biology and the potential role of mismatch repair genes in breast cancer carcinogenesis, and ultimately, heighten awareness of this condition.

P4-03-01: Alarming levels of obesity and overweight in Brazilian women with early-stage ER+ breast cancer in adjuvant endocrine therapy

Daniele Assad-Suzuki, Danielle Laperche-Santos, Fernanda Cesar Moura, Sulene Cunha Sousa Oliveira, Andrea Kazumi Shimada, Renata Arakelian, Anna Luiza Zapalowski Galvão, Bruno Santos Wance de Souza, Amanda Guimarães Castro, Monalisa Ceciliana Freitas Moreira de Andrade, Yuri Cardoso Rodrigues Beckedorff Bittencourt, Maria Cristina Figueroa Magalhães, Poliana Albuquerque Signorini, Daniela Jessica Pereira, Angélica Nogueira-Rodrigues, Romualdo Barroso-Sousa

Background: Adiposity and the presence of overweight/obesity are associated with mortality in general and also with mortality and recurrence related to breast cancer. This study aims to evaluate obesity and overweight levels in Brazilian women with early-stage ER+ breast cancer in adjuvant endocrine therapy and its relations with clinical and

demographic charactheristics.
Methodology: Women with a history of early-stage ER+ invasive carcinoma of the breast on adjuvant ET for at least 6 months were invited to participate of this study. Body Mass Index (BMI) were assessed according to the cutoff points proposed by the World Health Organization (1998). Adherence, quality of life, sexual dysfunction and return to work were also assessed. Patients were stratified according to Body Mass Index (BMI (Eutrophy: 18.5 to 24.9kg/m^2, Overweight: 25 to 29.9kg/m^2 and Obesity: >=30kg/m^2). To investigate statistically significant differences between groups, Pearson's Chi-Square tests were used. To evaluate the relationship between variables and BMI in patients with breast cancer, multinomial logistic regression analysis was used.
Results: From June 2021 to March 2024, 557 women from 11 Brazilian institutions were recruited. Mean age was 62 y.o , mean tumor size was 2.14 cm, mean duration of ET was 3.1y. A total of 27% of patients were obese, 42% were overweight and 30.8% had eutrophy. Women with higher education had a lower prevalence of obesity (26%) compared to those with lower education (31%) ($p = 0.03$). The presence of comorbidities had a highly significant association with BMI, with a higher prevalence of comorbidities among obese women (33%) compared to those with ideal weight (24%) ($p < 0.001$). Patients treated in public hospitals had a higher prevalence of obesity (35%%) compared to those treated in private hospitals (20%) ($p < 0.001$). Patients in stage III were more likely to be obese (odds ratio = 2.88, 95% CI: 1.55-5.33, $p < 0.001$) compared to those in stage I. There was no significant association between BMI and variables such as age ($p = 0.97$), ethnicity ($p = 0.35$), marital status ($p = 0.98$), and duration on endocrine therapy ($p = 0.17$). Better QLQ C30 - Physical Functioning was associated with a lower chance of obesity (odds ratio = 0.95, CI95%: 0.93-0.97, $p < 0.001$) and overweight (odds ratio = 0.96, CI95 %: 0.94-0.98, $p < 0.001$). Arm Symptoms also showed a significant association with obesity (odds ratio = 1.01, 95% CI: 1.00-1.02, $p = 0.005$), but not with overweight (odds ratio = 1.00, 95% CI: 0.99-1.01, $p = 0.082$). In multivariate analysis, stage III disease (OR 1.72), prior lumpectomy (OR 7.2), prior mastectomy (OR 2.7), axillary lymphonode dissection (OR 2.8) and use of concomitant medication (OR 1.8) were related to obesity.
Conclusions: Only a third of the women evaluated in the study had an adequate BMI, leading to a worrying risk of morbidity such as cardiovascular disease and risk of breast cancer relapse. Some characteristics related to obesity, such as its greater presence in patients treated in the public service and in women with a lower level of education, lead to the hypothesis that economic factors may be related to this disease.

P4-03-03: Outcomes and Survivorship in Geriatric Breast Cancer Patients with Chemotherapy Dose Reduction.

Huy Nong, Ahmed Elkhanany

Background: Neoadjuvant and adjuvant chemotherapy is a cornerstone of treatment for high-risk breast cancers. Geriatric patients with frailty, poor performance status and multiple co-morbid conditions may not tolerate standard dosing regimens of chemotherapy

per clinical guidelines and may require dose reduction in order to complete therapy. However, previous studies have shown that dose reduction in chemotherapy in geriatric patients have led to poor outcomes and decreased overall survival.
Methods: This retrospective cohort reviews all geriatric patients (ages > 65 y.o.) who received chemotherapy for early-stage and locally advanced breast cancer over. RDI was calculated as the ratio of delivered to planned chemotherapy dose intensity. The primary outcome was low RDI, defined as RDI < 85%. Multivariable logistic regression was used to evaluate the association between baseline variables and low RDI. Survival probability was estimated using the Kaplan-Meier method, and the log-rank test was used to compare overall survival. Clinical data regarding patients' tumor subtype, stage, biomarkers, performance status, chemotherapy regimen, co-morbidities and clinical outcomes were recorded.
Results: In our population of geriatric breast cancer patients who received chemotherapy, 65% of patients had low RDI. Low RDI < 85% did not have any immediate clinical difference between patients with RDI > 85% at time of analysis. Patients with RDI < 85% were more likely to have multiple co-morbidities such as HTN, DM, CHF and CKD. Regimens containing taxanes and anthracyclines led to more toxicities compared to non-taxane and anthracycline based regimens
Conclusions: Geriatric breast cancer patients receiving chemotherapy are more likely to have dose reduction with low RDI due to multiple co-morbidities. Clinical outcomes were comparable between patients who had low RDI and high RDI with no significant difference in outcomes. Taxane and anthracycline based regimens led to more toxicities in geriatric breast cancer patients.

P4-03-04: Effect of a Weight Loss/Exercise Program and Hormone Therapy on Peripheral Inflammatory Markers in ER+ Breast Cancer Survivors

Martha Kato, Constanza Martinez, Karla Pfaeffle-Palomo, James Cleary, LB Irigoyen, M. Beatriz Currier

Background: Obesity and chronic systemic inflammation are known factors affecting mortality and cancer recurrence in breast cancer survivors (BCS). Lifestyle interventions like diet and exercise can mitigate systemic inflammation; however, their efficacy with concomitant hormone therapy remains unclear. Peripheral blood inflammation markers, such as neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and systemic immune-inflammation index (SII), hold promise as indicators of chronic inflammation but require further exploration in the breast cancer population. Hormone therapies, including tamoxifen (TAM) and aromatase inhibitors (AI), may influence inflammation differently, with TAM possibly exerting cardioprotective effects and AI showing mixed evidence regarding cardiovascular risks. This study aims to investigate the impact of a 12-week weight loss/exercise program and hormone therapy on peripheral inflammatory biomarkers among ER+ BCS.
Methods: A retrospective chart review identified 37 ER+ BCS who completed a 12-week

weight loss/exercise program consisting of supervised aerobic and resistance training exercise sessions twice weekly, and weekly balanced dietary counseling. Baseline and post-intervention assessments included anthropometric measures, body fat percentage, and laboratory results obtained within 1 week of initial and post-intervention visits, which included NLR, PLR, and SII measured as platelet count x neutrophil count/lymphocyte count. Statistical analyses included normality assessment, log10 transformation for non-normally distributed data, paired and independent t-tests for normally distributed data, and Wilcoxon signed-rank and Mann-Whitney U tests for non-normally distributed data. ANOVA assessed changes within and between groups.
Results: Participants included 36 females and 1 male ER+ BCS, mean age of 56 ± 9 years; 28 Hispanic, 9 non-Hispanic. BCS were categorized into 3 groups based on hormone therapy: TAM (N=11), AI (N=16), and no hormone therapy (N=10). No significant differences were observed in anthropometric measures or body fat distribution between the 3 groups. Age significantly differed between groups ($p = 0.046$), with the TAM group notably younger (51 ± 8 years) than AI group (60 ± 7 years) or no hormone therapy group (56 ± 10 years). TAM and AI BCS had a significantly lower baseline measure of SII ($p = 0.020$) and NLR ($p = 0.009$) compared to BCS on no hormone therapy. Post-weight loss/exercise program intervention: All BCS groups had a significant reduction in SII ($p = 0.022$), while NLR ($p = 0.026$) was significantly reduced in the TAM and no hormone therapy group. Additionally, all participants demonstrated significant reductions in weight (–2.5 kg ± 3.2, $p < 0.001$), body mass index ($p < 0.001$), waist circumference ($p < 0.001$), and % body fat ($p = 0.003$).
Conclusion: Our findings suggest that the 12-week weight loss/exercise program significantly reduces systemic inflammation and improves body composition parameters in ER+ BCS. Surprisingly, our study revealed that patients receiving hormone therapies, including TAM and AI, exhibited significantly lower baseline levels of peripheral inflammatory biomarkers compared to those on no hormone therapy. This unexpected finding underscores the potential beneficial impact of hormone therapy on modulating chronic systemic inflammation in ER+ BCS. The reduction of systemic inflammation may provide an additional mechanism through which hormonal therapy mitigates cancer recurrence in breast cancer patients. The lower levels of inflammatory markers in the TAM and AI groups highlight the importance of considering hormone therapy status when assessing inflammatory profiles in breast cancer patients.

P4-03-05: Effect of Phesgo® on Time Toxicity in Breast Cancer Patients

Minori Antoh, Haruru Kotani, Rikako Ogawa, Maho Kusudo, Aya Nakazawa, Rie Komaki, Yuka Endo, Ayumi Katakoka, Akiyo Yoshimura, Masaya Hattori, Masataka Sawaki, Fumikata Hara

Background: Time toxicity is the time spent in medical facilities, such as outpatient, travel, waiting, infusions, laboratory tests and hospitalization for any disease. Time toxicity can be an important information for treatment selection because it affects the patient's daily life such as work, housework and childcare not only for advanced cancer patients but also for early cancer patients. However, time toxicity is generally not evaluated in oncology trials.

Phesgo® is a fixed-dose combination of pertuzumab and trastuzumab for subcutaneous injection. It was approved by the U.S. Food and Drug Administration (FDA) on June 29, 2020, and has been available in Japan since November 22, 2023, with insurance coverage. The initial dose is administered subcutaneously over 8 minutes and the maintenance dose is administered over 5 minutes, which is a shorter administration time than the intravenous infusion of pertuzumab and trastuzumab, and is expected to reduce time toxicity.
Methods: We retrospectively reviewed patient background, medical condition, time spent in the hospital, time from confirmation of implementation to start of administration, and adverse events in patients with HER2-positive breast cancer treated in our hospital who switched from intravenous pertuzumab/trastuzumab to the fixed-dose combination for subcutaneous injection. Hospitalization time was defined as the time from outpatient admission to billing. Time from confirmation of initiation to start of administration was defined as the time from the physician's decision to initiate in the electronic medical record to the start of the first drug administration at the chemotherapy center. We compared the time of the last administration of intravenous pertuzumab/trastuzumab with the time of the first administration of the fixed-dose combination for subcutaneous injection.
Results: Between December 2023 and April 2024, 37 patients with breast cancer were administered subcutaneous injection, of which 24 were cases in which was switched from intravenous administration. The median age was 61.5 years (37-71 years), 5 patients had early breast cancer and 19 patients had advanced recurrent breast cancer. The mean hospital stay was 4 hours 19 minutes for intravenous administration and 2 hours 24 minutes for subcutaneous injection ($P<0.001$). The mean time from confirmation of dosing to initiation was 1 hour 11 minutes for intravenous administration and 45 minutes for subcutaneous injection ($P<0.005$). New adverse events after switching included injection site reactions (pain, redness, swelling) in 20 patients (83%) and infusion reactions in 1 patient (4%). One patient switched back to intravenous administration due to injection site pain. There was one case of a phone call regarding an injection site reaction after subcutaneous injection, but no unscheduled visits were observed.
Discussion: The fixed-dose combination for subcutaneous injection significantly reduced the time spent in the hospital compared to intravenous administration, suggesting a reduction in time toxicity. The reduction in hospital time was greater than the reduction in administration time, which may be due to the reduction in dispensing time. Evaluation of time toxicity is considered useful information for shared decision making for patients.

P4-03-06: A Single-Center Review of the Impact of an Integrated Women's Health Clinic for Breast Cancer Patients Who Received Cancer-Directed Treatment

Deanna Huffman, Danielle Collons, Ameilia Jerrnigan, Michelle Loch

Background: With increasing survival of breast cancer patients, women are subjected to the long-term side effects of their treatment and remain at risk for additional cancers. A meta-analysis showed that women with breast cancer have a 3.5-fold higher risk of developing

sexual dysfunction than women without cancer, which can lead to reduced quality of life. 1-2 A retrospective study of over 500,000 patients with breast cancer showed an increased risk of second breast cancer and other primary cancers when compared to the general population. We created GARNET (Gynecologic Survivorship and Preventative Care after Cancer Treatment) as a tool to address these issues in patients receiving care for breast cancer. Through this study we hope to describe the role of this novel clinic in a safety net hospital providing care for underserved patients in New Orleans, LA.

Methods: Data was collected via retrospective char review of women enrolled in GARNET. To be included, women had to carry a diagnosis of breast cancer from January 1st, 2021 (at the initiation of the clinic) through May 30th, 2024 at University Medical Center in New Orleans, Louisiana. Patients who received any cancer-directed treatment, including surgery, radiation therapy, chemotherapy, immunotherapy and/or endocrine therapy were included. Male patients and those who did not attend GARNET were excluded. Continuous data was summarized with means and standard deviations or medians.

Results: In total, 38 women were evaluated in GARNET during the study period. Mean age was 57.9 years; 8(21.0%) were White/Non-Hispanic, 27 (71.0%) were Black, 2 (5.2%) were Hispanic and 1 (2.6%) was Asian. Most patients used Medicare or Medicaid as insurance (24 patients, 63.2%); 12 (31.6%) patients had private insurance, and 2 (5.3%) patients were uninsured. Of the treatment types patients received, 35 patients had surgery, 23 recieved chemotherapy or immunotherapy and 31 were had radiation. Once evaluated in GARNET, 28 patients (73.7%) had an updated cervical cancer screening. Of those who did not, 4 patients exceeded the recommended age to continue screening, 3 patients cervical cancer screening was no longer indicated due to lack of cervix, 2 patients were referred for cervical cancer screening but did not yet complete it, and 1 did not have screening for unclear reasons. A review of top complaints showed that patients sought care for cervical cancer screening (52.6%) vaginal bleeding (26.3%), other vaginal complaints such as dryness, itching or discharge (13.2%), ovarian cancer screening in BRCA carriers (5.2%) and contraception (2.6%)

Discussion: Patients who received treatment for breast cancer need Chemotherapy or hormonal treatment can induce early menopause which can lead to genitourinary atrophy and psychological distress that impact a woman's sexual health. A 2016 study even showed that breast surgery has a negative impact on sexual function, independent of other treatments. Additionally, it is the consensus opinion that premenopausal women receiving treatment for breast cancer are at increased risk of endometrial cancer due to estrogenic effects of tamoxifen on endometrial tissue. Women with breast cancer are also at increased risk for additional cancers for not entirely understood reasons.

Treatment in a medical oncology office is focused on cancer treatment and surveillance. Our patients social and financial barriers often prevent them from seeking care, which led to the development of GARNET. This preliminary study showed that our patients who utilized GARNET received care for cervical cancer screening, as well as vaginal bleeding or discharge, ovarian cancer screening and contraception, among others. We hope to continue to expand referrals to GARNET to evaluate the benefit to our patients and to further inspire integrated care for women's health for those underdoing cancer care.

P4-03-07: Implementing Quality of Life assessment in breast cancer patients in India

Madhuri Taranikanti, Archana Gaur T, Roja Reddy Katta, Farheen Fatima, Vishesh Gumdal, Vidya Ganji, Kalpana Medala, Madhusudhan Umesh, Nitin Ashok John

Introduction: Breast cancer is on the rise in India and is the leading cause of cancer incidence in women. Indian Council of Medical Research - National Centre for Disease Informatics and Research report accounted for 13.5% of new cancer cases and 10% of cancer-related deaths in 2020 with higher burden in more developed states of India. The impact is seen on Quality of Life (QoL) attributed to physical, psychological and social factors . Breast cancer is a distinctive entity as it hampers physical appearance of women besides living with the fear of outcome . Treatments include chemotherapy, radiotherapy, breast surgeries all significantly influencing QoL in survivors . Depression, fertility-issues, economic burden and social issues negatively affect quality of life. European Organization for Research and Treatment of Cancer (EORTC) QoL Questionnaires-Core-30 and Breast-23 (QLQ-C30 and QLQ-BR23) are valid and reliable tools to assess QoL in breast cancer survivors (12,13,14,15). Due to high patient load in India and insufficient manpower, routine assessment of QoL in breast cancer patients is a challenge with scarce data from this part of the world. Objective: To administer QLQ-C30 and BR23 questionnaires to breast cancer patients receiving treatment at the tertiary hospital Cancer Unit to differentiate QoL among patients in varying stages of the disease and treatment.
Methodology: 175 female breast cancer patients registered in the cancer unit in the last one year with a diagnosis established at least 6 months ago were included and other gynecological cancers were excluded. After obtaining written consent, QLQ-C30 a 30-item cancer specific questionnaire designed to measure QOL and QLQ-BR23 a 23-item breast cancer specific questionnaire were administered together. The assessment comprised of nine domains (physical, role, cognitive, emotional, social, fatigue, pain, nausea and vomiting) in QLQ-C30 and five domains (body image, sexuality, arm symptoms, breast symptoms, and systemic therapy side effects) in BR23. The impact on QoL was based on the Global Health Status (GHS), Physical functioning (PF), Emotional functioning (EF), Fatigue (FA) and Pain (PA) scores.
Results: Mean age of the patients was 49.65 (±9.94) years with a mean duration of breast cancer of 2.17 (±1.61) years. 11.54% of patients did not receive counselling for various reasons. Correlation was established between GHS and PF [r=.69, p=.00001]; EF [r=.32, p=.02]; social functioning [r=.38, p=.005]; body image [r=.36, p=.01]; future perspective [r=.3, p=.03]. Analysis of PF, EF, Pain and Fatigue scores were performed based on whether treatment included only chemotherapy or was combined with radiation and surgery. Those who received only chemotherapy had better functional status compared to those with combined therapy. The symptom scale variables were negatively correlated with global health status. The study shows a higher decrease in physical functioning levels compared to other functional parameters due to factors like pain, chronic fatigue, balance impairment and lymphedema associated with breast cancer treatment. In alignment with PF scores were fatigue, pain, insomnia and appetite scores which were relatively higher.

Conclusion: With an ever increasing incidence of breast cancer in India, QoL assessment can be a valuable tool for incorporating effective management strategies. The overall quality of life was reasonably good indicating presence of positive health ecosystem. Efforts were fruitful in recruiting participants implying high feasibility of such assessments. The findings form the basis for evaluation of predictive variables that impact quality of life in future while also boosting the confidence of patients, their families and stakeholders involved in patient services. QoL assessments in routine breast cancer care is recommended for better management and good clinical outcomes.

P4-03-08: Pre- and post-diagnostic healthy lifestyle and cardiovascular disease among breast cancer survivors

Qiang Liu, Tengteng Wang, Qiaoli Wang, Yujia Lu, Mengxi Du, Jae H. Kang, Molin Wang, Eric B Rimm, Stephanie A. Smith-Warner, Michelle D Holmes, A.Heather Eliassen, Jing Wang, Mingyang Song, Edward Giovannucci

Background Cardiovascular disease (CVD) is an important cause of death among breast cancer survivors. The relationship between pre- and post-diagnostic healthy lifestyle and CVD risk among breast cancer survivors is unknown.
Objectives To examine the associations of pre- and post-diagnostic healthy lifestyle score (HLS), defined by diet, alcohol consumption, smoking status, physical activity and body mass index, with the risk of CVD incidence and mortality among breast cancer survivors.
Methods We prospectively followed for CVD incidence and mortality among 11,448 participants with confirmed diagnosis of invasive breast cancer enrolled in the Nurses' Health Study (NHS) (1984-2020) and NHSII (1991-2019) who were free of CVD before breast cancer diagnosis. Diet and lifestyle factors before and after breast cancer diagnosis were repeatedly assessed nearly every 2 to 4 years.
Results Over 124,687 person-years of follow-up, we documented 872 new-onset CVD events and 3675 overall deaths, of which 488 (13.3%) were specifically due to CVD and 1,310 (35.6%) were due to breast cancer. After multivariable adjustment, both higher pre- and post-diagnostic HLS were associated with a lower risk of CVD-specific incidence and mortality. Compared with women with the lowest cumulative average post-diagnostic HLS (0-2), the multivariable-adjusted hazard ratios (HRs) for participants with the highest score of 5 were 0.56 (95% CI: 0.32-1.00) for CVD incidence, and 0.66 (95% CI: 0.45-0.97) for CVD mortality (all p trend<0.0001). Participants who had an unhealthy pre-diagnostic lifestyle but improved to an HLS (3-5) after breast cancer diagnosis had a lower risk of both CVD incidence (HR: 0.69, 95% CI: 0.52-0.92) and CVD mortality (HR: 0.75, 95% CI: 0.53-1.07) compared with those continuing an unhealthy lifestyle during both periods. Participants maintaining a healthy lifestyle during both pre- and post-diagnostic periods showed the strongest inverse association, with HR of 0.57 (95% CI: 0.46-0.69) for CVD incidence and 0.50 (95% CI: 0.38-0.65) for CVD mortality. Each point increment of post-diagnostic HLS was associated with a 14% lower risk of CVD incidence (p=0.007), and a 14% lower risk of CVD mortality (p=0.01).

Conclusions and relevance Independent of pre-diagnostic lifestyle, a post-diagnostic healthy lifestyle was associated with a substantial, graded lower risk of CVD-specific incidence and mortality among breast cancer survivors. These findings underscore the clinical importance for health care practitioners managing breast cancer survivors to consistently promote adherence to healthy lifestyle behaviors, highlighting the opportunity to leverage the changeable moment even for those with an unhealthy lifestyle before cancer diagnosis.

P4-03-09: Breast Cancer Long Survivorship Program Experience in Mexico City

Laura Kay Lagarde-Santillan, Montserrath Alvarado-Hernández, Eucario León-Rodríguez, Yanin Chavarri-Guerra

Background: Breast cancer survivors may experience a significant burden of side effects from cancer therapies. Timely management of such effects, including strategies to promote health and wellness among breast cancer survivors, is an unmet need in low- and middle-income countries, where cancer care is centered on diagnosis and active treatments. Our aim is to describe clinical characteristics and outcomes of women with a personal history of breast cancer included in a long-term breast cancer survivorship program at a third level hospital in Mexico City.
Methods: Women with a personal history of breast cancer who completed cancer treatment and have a disease free survival period more than 5 years are referred to the Long-term Breast Cancer Survivorship Program at the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán in Mexico City. The program offers monitoring and management of long side effects, including lymphedema, cardiovascular diseases, bone health, and cancer screening, vaccination recommendations, psychosocial and nutrition support, health and wellness education, and geriatric assessment screening (G8 tool). Disease -free survival is defined from the time after completion of treatment (excluding endocrine therapy) up to the last visit.
Results: From October 2023 to June 2024, 32 women with a personal history of breast cancer were included. Median age was 69.5 years (range 48-88). The mean disease-free survival time was 11 years (range 5-21). Breast cancer stage distribution at diagnosis was Stage I in 18.75% (n=6) , Stage II in 28.1% (n=9) and Stage III in 50% (n=16) of cases. The most common histological subtype was Invasive ductal carcinoma in 68.75% (n=22), followed by an unspecified subtype in 12.5% (n=4), ductal carcinoma in situ 6.25% (n=2) and others 12.48% (n=4). Breast cancer treatment included: unilateral mastectomy in 53.1% (n=17), breast-conserving surgery in 43.75% (n=14), bilateral mastectomy in 6.25% (n=2), radiotherapy in 62.5% (n=20), chemotherapy in 78.5% (n=25) (69.56% taxanes and 78.26% anthracyclines), anti-Her2 therapy in 6.25% (n=2) and endocrine therapy in 84.37% (n=27). At the time of evaluation, the following comorbidities were recorded: hypertension in 53.12% (n=17), dyslipidemia in 46.87% (n=15), overweight and obesity in 59.37% (n=19), hypothyroidism in 34.37% (n=11), diabetes mellitus in 28.12% (n=9), prediabetes in 15.62% (n=5), depression or anxiety in 34.37% (n=11), and obstructive

sleep apnea in 6.25% (n=2). Lymphedema screening was positive in 15.6% (n=5) (defined as ≥2cm difference between arms), 18.75% (n=6) reported pain and 9.37% (n=3) had abnormal G8 scores. Bone health screening was completed in 79.31% (n=23) with, 43.47% (n=10) diagnosed with osteopenia and 39.13% (n=9) with osteoporosis. Adherence to cancer screening for cervical cancer was 92% (n=25), for colorectal cancer 78.12% (n=25) and for breast cancer 90% (n=30) of cases, with no abnormal result reported. About 18.75% of women (n=6) reported consuming dietary supplements and herbs.
Conclusion: The breast cancer long survivorship program in Mexico City provides comprehensive care for breast cancer survivors, addressing their medical and psychosocial needs, and monitoring potential long-term side effects. Our findings reveal a notable prevalence of overweight, obesity and other comorbidities among survivors, underscoring the necessity for lifestyle interventions. Through its multidisciplinary approach, the program strives to improve survivors' quality of life and overall well-being, emphasizing the significance of continual support and monitoring in survivorship care.

P4-03-10: Body image and sexuality concerns among young women with breast cancer in a Mexican Population

Saul Campos-Gomez, Andrea Ovando-Trujillo, Karen A. Campos-Gomez, Janeth Esquivel-Gutierrez, Ana Maria Mendoza-Avila, Maricela Garcia-Garces, Diego Jimenez-Guarneros, Rodrígo Serrano-Ortiz, Jesus Rivera-Cortez, Miguel Machado-Reyes, Rigoberto Dolores-Velazquez, Elvia Fernandez-Perez, Israel Salazar-Vizuet, Guillermo Pacheco-Cuellar, Cristina Rodríguez-Acosta, Nelly Ramirez--Román

Background: The diagnosis and treatment of breast cancer involves changes in personal, family, social, professional and sexual relationships. Younger breast cancer survivors confront a distinct set of treatment-related challenges that have a significant influence on their quality of life and psychological well-being. Although there is often a profound and distressing impact of treatment on self-image andsexual function, women rarely receive any attention for these issues
Purpose: The goal of this study was to investigate the prevalence of body image and sexual issues in the first months after breast cancer diagnosis and treatment in women aged 50 and younger.
Methods: We used the EORTC QLQ-B23 questionnaire in 50 patients diagnosed with early breast cancer at our centre. Sexual concern outcomes including poor body image, poor sexual functioning, poor sexual enjoyment, and sexual inactivity were investigated. Data were obtained prospectively over the perior of 2016 to 2021. Multivariate generalized estimating equation models were used to examine associations with sexual concerns after diagnosis, adjusting for age, sociodemographic, tumor, treatment, and clinical features.
Results: A sample of 50 patients was selected, aged 24-48 years old, with a median age of 40.8 years, who had undergone breast cancer surgery, 22% by conservative surgery. 84% were premenopausal, 16% were perimenopausal. All patients were treated with chemotherapy for neo or adjuvancy. Body image and sexual problems were experienced by

a substantial proportion of women in the early months after diagnosis. More than half of the women experienced two or more body image problems some of the time (56%), or at least one problem much of the time (26%). 52% of patients were quite or very sad and depressed since starting treatment. 62% of patients believe that the treatment has worsened their body image. Among sexually active women,51% reported that during treatment their sexual relations were not satisfactory. 40% believe that their sexual desire has decreased since diagnosis.
Conclusions: Difficulties related to sexuality and sexual functioning were common and occurred soon after diagnosis of breast cancer; they appear to be frequent and insuffiently handled. Addressing these issues is essential to improve the quality life for young women with breast cancer.

P4-03-11: Patient and health care provider perspectives on oral versus intramuscular endocrine therapy for locally advanced or metastatic breast cancer

Rebecca Speck, Spencer Schaff, Gale Harding, Nalin Payakachat, Jincy John, Aarti Chawla, Christine Agius, Shakeela W Bahadur, Kathryn E Hudson, Mohammed Jaloudi, Ritesh Parajuli, Gregory A Vidal, Elizabeth D Bacci

Background: Next generation oral selective ER degraders (SERDs) have been designed to improve efficacy and tolerability and may serve as an alternative to intramuscular (IM) fulvestrant for the treatment of ER+, HER2- locally advanced or metastatic breast cancer (MBC). Thus, it is important to understand perspectives on the benefit and burden of oral and IM endocrine therapy (ET) from both patients and health care providers (HCPs).
Methods: This US-based qualitative interview study recruited female patients with MBC treated with both oral ET and fulvestrant within the past 3 years and HCPs (medical oncologists and oncology nurses). One-on-one semi-structured interviews focused on four concepts: preference, benefits, burdens, and adherence to oral and IM ET. Patients spoke directly about their own personal experience with both types of administration, while HCPs provided their perspectives based on their clinical practice experience. Interviews were conducted by a third-party vendor and occurred September 2023 through May 2024. Interview transcripts were analyzed in ATLAS.ti through an iterative process and followed a qualitative analysis plan.
Results: An asterisk is used to denote responses that are not mutually exclusive. Of the 22 patients interviewed, 64% preferred oral ET, 27% preferred IM ET, and 9% had no preference. Of the fourteen patients that preferred oral ET, they did so for convenience (71%)*, non-painful administration (36%)*, and fear of needles (21%)*. Six patients preferred IM ET due to ease of monthly administration. The benefit of oral ET reported by the greatest proportion of patients was convenience (86%)*, followed by belief that the treatment is working (32%)*. The benefit reported by the greatest proportion of patients for IM ET was belief that the treatment is working (64%)*, followed by not having to

remember to take it (36%)*. Patient reported burdens to oral ET included side effects (59%)*, remembering to take medication (32%)*, insurance (23%)*, and reminder of diagnosis (18%)*. Patient-experienced burdens to IM ET were injection site pain (91%)*, side effects (82%)*, and having to travel for monthly appointments (45%)*. Nearly all patients (91%)* reported it was easy to take their oral ET, whereas 32%* reported it was easy to receive the IM ET. Of the 20 HCPs interviewed (medical oncologists=10, oncology nurses=10), nearly all (90%) perceived patients to prefer oral ET. All HCPs stated patient convenience is a benefit of oral ET, and patients not having to remember to take medication is a benefit of IM ET. HCPs also reported inadequate insurance coverage (55%)*, side effects (40%)*, and compliance (30%)* to be perceived burdens of oral ET, and that pain (85%)* and travel (70%)* were burdens of IM ET. HCPs' perception of ease of administration was equivalent for both oral and IM ET, 80% reporting they were both easy.
Conclusion: Among patients with MBC that have been treated with both oral and IM ET, the majority prefer oral ET and report that convenience of an orally administered medication was considered a key benefit and the leading reason for preference of oral ET. Injection site pain and the need to travel for monthly appointments for IM ET were reported burdens from patients and perceived as burdens from HCPs. Notably, although most HCPs reported ease of administration for both oral and IM ET, only a third of patients interviewed reported that it was easy to receive IM ET.

P4-03-12: How do Arab World Breast Cancer Survivors feel about De-escalation of Treatment?

Rita A. Sakr, SAWA breast cancer survivors

With the improved selection of patients during the past decades, we are seeing a real trend towards de-escalation of treatment in special settings of breast cancer because of less or no benefit on survival of those previously recommended surgeries or treatments. In the Arab world, patients are tending to be more influenced by familial factors in addition to cultural factors and certain concepts such as "more is better and safer" when it comes to treatment. The aim of our study is to investigate how breast cancer survivors would feel about de-escalation of breast cancer treatment thus try to help with the educational awareness and change of unhelpful concepts.
Members of SAWA breast cancer survivors group living in United Arab Emirates were invited to share their opinion regarding the de-escalation of breast cancer treatment. They were informed about the latest studies and then were separately invited to share their opinion regarding the de-escalation of breast surgery, axillary surgery, as well as protocols of radiotherapy, chemotherapy and endocrine therapy. So far, twenty-six patients aged between 38 and 59 years attended the interviews and separately replied to the questions that were about feeling safe about de-escalation of breast cancer treatment, or unsafe about de-escalation, or wishing to follow the recommendations of doctors without sharing opinion. Three patients felt a little bit confused and preferred to reply later. Regarding breast surgery, one third of the patients felt unsafe about de-escalating lumpectomy and

16% of patients felt unsafe about de-escalating mastectomy. Almost 42% of the patients said they would just follow the recommendations of doctors. Regarding axillary surgery, 20% of patients felt unsafe about de-escalating sentinel lymph node biopsy whereas 60% of patients would simply follow the recommendations. All of them were very happy with de-escalating complete axillary clearance. As for the adjuvant treatment, the majority of the patients (96%) were very happy with de-escalation of radiotherapy protocols. The majority of patients (67%) were also very happy with de-escalation of chemotherapy protocols and more interestingly, they expressed their happiness with de-escalation of endocrine therapy too.
Thanks to the development of biology towards an improved selection of patients and to the availability of more medical treatments, the reduction of surgery and radiotherapy is continuing in all settings of breast cancer treatment. In addition, the de-escalation was shown not to impact locoregional recurrence rate and overall outcome. Implementing those new recommendations will surely need to start by standardization of the information given to patients by the doctors. It should also involve patient in making the treatment decision especially when omission of a treatment is suggested. In the Arab World region, the concept of "more is better" in addition to the familial and cultural influence can drive patients sometimes against the recommendations and guidelines. By consequence, the opinion of breast cancer survivors who have been through most of the treatment plans can be of great guidance and value. In the first part of our study, most of the patients were very happy with de-escalating the treatments where side effects can really affect their daily life and womanhood: axillary surgery, radiotherapy, endocrine therapy. However, a small but non negligeable number of patients still felt unsafe about de-escalating surgery including mastectomy and sentinel lymph node biopsy.
Awareness campaigns involving beast cancer survivors can be of great value for changing the misguiding concepts, with a special focus on educating healthcare society, patients and families about the benefits of de-escalating treatments in a specific tailored way. Less can be better.

P4-03-13: Machine learning-based sentiment analysis related to Trastuzumab Deruxtecan in online forums

Nawale Hajjaji, Elnaz Sherafat, Djamel Zitouni, Benjamin Guinhouya

Background: New antibody drug conjugates (ADCs) have significantly improved the outcomes of breast cancer patients. However, this class of therapy has side effects including interstitial lung disease, digestive disorders, alopecia, fatigue, which can impact patients' quality of life. Although patients' tolerance collected within clinical trials and real-world studies reported acceptable and manageable tolerance, the feelings expressed by patients and their relatives outside the medical context is not known. People are increasingly searching for support, advice or answers online. An analysis of the posts about Trastuzumab Deruxtecan (T-DXD) could provide additional insight to better understand patients' experience with this ADC. In this study, we performed a sentiment analysis on

large amounts of information shared online.
Methods: The online narratives related to T-DXD posted on US-based platforms, one dedicated to a breast cancer community (Breast cancer.org) and the other a wide social platform (Reddit), were extracted to conduct a sentiment analysis. Breast cancer.org is a large non-profit supportive community of breast cancer patients with more than 83000 users. Reddit gathers thousands of online communities and more than 16 billion posts/comments. Machine learning techniques and models were used to identify and extract sentiment-bearing words based on a lexicon. These words were then assigned polarity values and frequencies within the corpus. Additionally, advanced natural language processing (NLP) methods through computational linguistic software was used to perform detailed analysis of nuanced sentiment categories within the forum discussions, including the identification and analysis of side effects mentioned by users.
Results: Although T-DXD cancer indications are expanding, as of 5th July 2024, only 271 comments related to T-DXD were found on the breast cancer forum out of a total of thousands posts and 1477 posts on Reddit out of a total of million posts. Most posts about T-DXD identified on the breast cancer forum were associated with positive sentiments (56%) while most posts on Reddit were negative (59%). To draw a comparison, the number of posts related to chemotherapy (n=240) was similar to the number of posts related to T-DXD on the breast cancer forum with a trend toward positive sentiments (55%) for chemotherapy. Among the 61248 posts related to chemotherapy on Reddit, 47% were positive and 43% negative. Comments about immunotherapy were also mostly negative (62%) on Reddit. The main side effects related to T-DXD and frequently reported on Reddit were nausea, vomiting, and constipation, while those on the breast cancer forum were nausea and tiredness.
Conclusion: Experiences and opinions about T-DXD are shared on social networks. The sentiment analysis content differed according to the platform and the users' profiles with more positive post in a dedicated breast cancer online community.

P4-03-14: A review of the evidence for survival benefit of six lifestyle medicine interventions in breast cancer patients

Laura Wright, Preeti K. Sudheendra

There are currently four million breast cancer survivors in the United States and the number is expected to substantially increase in the decades to come. Oncologists are regularly managing issues of survivorship during periods of surveillance and the topic of prevention of cancer recurrence is a central theme of many outpatient oncology visits. Patients often seek counsel on tangible ways to reduce their risk of breast cancer recurrence and are met with generic suggestions to live healthfully. Overwhelmingly, clinical trials point toward substantial benefit of the adopting the six pillars of Lifestyle Medicine in a comprehensive cancer survivorship program to improve disease-free survival and all-cause mortality. These six pillars include 1) social connection, 2) physical activity, 3) whole food and plant-based nutrition, 4) stress management, 5) restorative sleep, and 6)

avoidance of risky behaviors or toxins. In a review of the breast cancer literature, we present evidence for survival and quality of life benefit in breast cancer patients with the implementation of these six pillars of Lifestyle Medicine. Socially integrated patients and those who undergo cognitive behavioral therapy for management of stress were found to live longer and have better perceived quality of life than patients who are isolated or experiencing heightened anxiety. Collectively the literature is also clear that ongoing smoking and consumption of >6 grams of alcohol per day as a breast cancer survivor significantly increases risk of death from breast cancer. Finally, prospective and retrospective studies have shown that the maintenance of a healthy body weight with adequate nutrition through dietary interventions, aerobic and resistance exercise, and balanced circadian sleep, particularly in postmenopausal women, improve breast cancer mortality. These data suggest that breast cancer patients would benefit from a comprehensive Lifestyle Medicine approach to survivorship. Consensus on survivorship programming is currently lacking. We submit that formal implementation of programs that include each of these six pillars of Lifestyle Medicine could significantly impact cancer mortality and morbidity.

P4-03-15: Clinical characterization of taxanes chemotherapeutic regiments-induced peripheral neurotoxicity and establishment of a risk model

Bin Yang, Yongge Ji, Zhenhua Zhai

Objective: To describe the clinical characteristics of chemotherapy-induced peripheral and neuropathy (CIPN) occurring in patients receiving paclitaxel-based chemotherapeutic agents, and to explore the feasibility and risk modeling of age, gender, body mass index (BMI), and clinical characteristics such as hemoglobin, vitamin D, Chinese medicine identification of body mass, anxiety state, and depression state at baseline prior to chemotherapy as predictive factors for the risk of CIPN in cancer patients.
Methods: 1. This study was a prospective, single-centre, observational cohort study, which included patients who were diagnosed with malignant tumors by pathology and received chemotherapy containing paclitaxel-based single-agent or combination regimens for the first time from March 1, 2023 to November 30, 2023 in the Department of Breast, Head and Neck Oncology of the First Affiliated Hospital of Jinzhou Medical University. Strictly following the inclusion screening criteria, 90 patients were finally included in this study. Firstly, the risk factors with strong correlation were screened by reading related literature and Meta-analysis: age, cumulative dose, number of cycles, BMI, vitamin D, and paclitaxel-based chemotherapy regimen. Patients' basic information (e.g. gender, menstrual status, previous history of psychoneurological drugs, marital status, education, residence, type of work, etc.), information related to clinical medication and treatment (e.g. chemotherapy regimen and drug dosage, etc.), laboratory test indexes (white blood cell count, haemoglobin, vitamin D, etc.), and assessment of quality of life (anxiety mood state, depressive mood state, and whether or not they suffer from insomnia, etc.) were collected.

In addition, in order to optimise the model, two innovative indicators were added to the study: Chinese medicine identification of body mass and absolute count of lymphocyte subpopulations.

2. The investigators recorded the details of peripheral neurotoxicity during chemotherapy and follow-up into the electronic medical record system, and based on the complaints, symptoms, and signs related to CIPN after the application of paclitaxel-based chemotherapy and to determine whether the patients developed CIPN, the patients were classified as 0-IV using the grading criteria of CIPN grades specified in the National Cancer Institute Common Terminology Criteria for Adverse Events, version 5.0 (The National Cancer Institute Common Terminology Criteria for Adverse Events version 5.0 (NCI-CTCAE V5.0) was used to classify CIPN into five grades, ranging from 0-IV, and two scales were used: the European Organization for Research in Cancer Therapy (EORTC) Peripheral Neurotoxicity Quality of Life Questionnaire (EORTC Quality of Life Chemotherapy Induced Peripheral Neuropathy20, EORTC QLQ-CIPN20) and Functional Assessment of Cancer/Gynecologic Oncology Neurotoxicity Scale (Functional Assessment of Cancer Therapy/Gynecologic Oncology20). Therapy/Gynecologic Oncology Group-Neurotoxicity questionnaire (FACT/GOG-NTX) to assist in assessing the severity of CIPN and its impact on quality of life, and the Insomnia Severity Index (ISI) to assess patients' sleepiness. Index , ISI) was utilized for the assessment of patients' sleep status, and the Hospital Anxiety and Depression Scale (HADS) was utilized to assess patients' anxiety status and depression status. In order to verify whether patients' age, gender, BMI, and hemoglobin, vitamin D, Chinese medicine identification of body constitution, anxiety mood state, and depression mood state before chemotherapy were risk factors for the occurrence of CIPN.

3. In this study, data were analyzed using the presence or absence of CIPN as the study outcome indicator. SAS_JMP11.0 and R4.3.1 software were used to statistically analyze the acquired data, and the Jordon index of the receiver operating characteristic curve (ROC) curve was used to select the optimal cut-off value of the laboratory test indicators, and the differences were first analyzed by the Pearson's chi-square test or Fisher's exact The Pearson chi-square test or Fisher's exact test was used to analyze the differences, and then binary logistic one-way regression analysis was used (continuous variable: binary variable because the outcome variable was dichotomous and had a nonlinear relationship with the independent variable; dichotomous variable: chi-square test or Fisher's exact test) to filter out the risk factors associated with the occurrence of CIPN between the groups, and then binary logistic multifactor regression analysis was used to derive the risk factors associated with the occurrence of CIPN. factor regression analysis to derive independent risk factors for the occurrence of CIPN.

4. The column-line graph (nomogram) model for predicting the risk of developing CIPN was plotted using R4.3.1 software, the discriminatory power of the model was evaluated by the area under the ROC curve, the goodness of fit of the model was examined using the Hosmer-Lemeshow test and the GiViTI Calibration Belt, and the Bootstrap re-sampling method (1,000 times) was used Internal validation was performed, and Decision Curve Analysis (DCA) was used to evaluate the clinical applicability of the model.

5. The assessment of the degree of sensory-motor impairment before and after the

occurrence of CIPN was statistically analyzed using the chi-square test and paired-samples t-test, and the assessment of the efficacy of herbal fumigation treatment was statistically analyzed using the chi-square test or Fisher's exact test, with $P < 0.05$ considered statistically significant.

Results: 1. The overall incidence of CIPN in this study was about 48.9%, the main chemotherapy regimen was paclitaxel alone or in combination, the age of patients who did not develop CIPN was 51.47 ± 11.84 years, and the mean ± standard deviation of the age of patients who developed CIPN was 54.16 ± 9.98 years, and in a subgroup of patients who developed CIPN, the tumor lymph node metastasis stage (Tumor Node Metatastasis , TNM) stage II in 18 (41.86%), the majority of patients 43 (97.73%) received at least 4 cycles of chemotherapy, and among the female patients who developed CIPN, 28 (68.29%) were in postmenopausal status. Of the types of paclitaxel, CIPN occurred with albumin-bound paclitaxel in 21 (47.73%), Eastern Cooperative Oncology Group (ECOG) physical status score of 1 in 27 (61.36%), and BMI ≥25 kg/m2 in 17 (38.64%); 9 (20.45%) had a previous history of psychoneurotics; 38 (86.36%) had a partner in their marital status; 32 (72.73%) lived in towns and cities; 24 (54.55%) had an education level of junior high school or below; 20 (45.45%) were retired in their job type; 23 (52.27%) did not experience anxiety states; 23 (52.27%) did not experience anxiety states; and 20 (52.27%) did not experience anxiety states. (52.27%); 31 people (70.45%) showed depressive mood states; 25 people (56.82%) were assessed as not suffering from insomnia; Chinese medicine identification of constitution: 14 people (31.82%) with blood stasis, 12 people (27.27%) with qi deficiency, 7 people (15.91%) with qi depression, and 11 people (25%) with other constitutions; and the vitamin D level deficiency was 28 people (71.79%).

2. In 44 patients (48.9%) who developed CIPN, univariate logistic regression analysis showed that: history of previous psychoneurotics, menstrual status, place of residence, anxiety mood state, depression mood state, presence of insomnia, leukocyte count, lymphocyte count, hemoglobin, CD3+ (total T-cells), CD16+CD56 (NK-cells), CD3+AC (absolute total T-cell count) were all significantly correlated with the development of CIPN in patients after chemotherapy. Multifactorial logistic regression analysis showed that: postmenopausal patients, P=0.0067; chemotherapy baseline depression score ≥8, P=0.0018; low baseline leukocyte count (≤6.64×109/L), P=0.0399; low hemoglobin (≤134g/L), P=0.01; and high CD3+ (total T cells) (>70%), P= 0.023 were independent risk factors for developing CIPN.

3. Based on the results of binary logistic single-factor and multifactor regression analyses of the screened risk factors plotted on a column-line graph, the area under the curve of the model was 0.908, indicating that the model was well differentiated ($P < 0.0001$); the Hosmer-Lemeshow test showed that the model was well fitted (P-value of 0.339, $P > 0.05$). Bootstrap resampling method 1000 times internal validation and GiViTI Calibration Belt showed that it did not fall within the 95% confidence interval both showed that the model had a good fit, and the DCA curve was used to evaluate the clinical applicability of the model, and the clinical decision curve was higher than the two extreme curves, thus indicating that the model predicted the net clinical benefit better, and that the model had a greater application in practice The value of the model in practice is also greater.

4. The clinical characteristics of the occurrence of CIPN showed that: acute CIPN occurred in 6 people (13.64%), chronic CIPN occurred in 38 people (86.36%), according to the NCI-CTCAE5.0 classification: 28 people (63.64%) had Grade I, 16 people (36.36%) had Grade II, and Grade III and above did not occur; the site of CIPN only symptoms in both hands were 24 (54.55%), symptoms in both feet only were 12 (27.27%), and symptoms in both hands and feet were 8 (18.18%). To assess the degree of damage to sensory and motor nerves in the event of CIPN: the results of the two-point discrimination test indicated that before the patient developed CIPN, 19 patients (43.18%) passed 7/10 times and 25 (56.82%) did not pass 7/10 times, and after the development of CIPN, 7 patients (15.91%) passed 7/10 times and 37 (84.85%) did not pass 7/10 times. of 37 patients (84.09%), P=0.0028; Purdue nailboard test results indicated that the left-handed nailboarding time before the occurrence of CIPN was 56.2±6.26s, and the left-handed nailboarding time after the occurrence of CIPN was 57.5±9.23s, P=0.422; and the right-handed nailboarding time before the occurrence of CIPN was 55.26±5.05s, and after the occurrence of CIPN the right-handed Nail plate time was 56.78±4.62s , P=0.0015.In the assessment of the occurrence of CIPN scale, the occurrence of CIPN in patients was dominated by sensory nerve disorders, and motor nerve disorder symptoms and autonomic disorders were less frequent, and the scores of the severity of the occurrence tended to increase with the increase of chemotherapy cycles.The change of the FACT/GOG-NTX scores in patients with the occurrence of CIPN and the EORTC QLQ-CIPN20 scale score trends were more consistent. At subsequent follow-up of CIPN in patients who used herbal medicine after CIPN occurred versus those who did not, 16 (36%) of the overall population who developed CIPN were not in complete remission by the date of the last follow-up.

5. In this study, the efficacy of herbal fumigation was initially explored. 15 (34.09%) of the patients who developed CIPN underwent herbal fumigation, and only 1 (6.67%) remained unrelieved of CIPN symptoms as of the follow-up date. Of the patients who did not use herbal fumigation, 14 (48.28%) had remission of CIPN symptoms and 15 (51.72%) remained symptom free. The rate of CIPN remission was higher in patients who received herbal fumigation compared to those who were not treated with herbal fumigation (93.33% vs 48.28%), P=0.0034.

Conclusions: 1. The high incidence of CIPN caused by paclitaxel-based chemotherapeutic agents (48.9%) and its impact on the adequate amount and duration of chemotherapy, as well as the efficacy and quality of life of the patients, need to be of great clinical importance.

2. Menopausal status, white blood cell count, haemoglobin, CD3+ (total T-cells), and depressed mood state are independent risk factors for the development of CIPN after chemotherapy with paclitaxel analogues.

3. The validation of the logistic multifactorial risk prediction model constructed in this study was established; the model evaluation indexes, including differentiation, calibration, decision curves, and internal validation results, met the requirements; and the application of the column-line diagram of the CIPN risk prediction model was easy, which provided a reference for the clinical prediction of the risk of CIPN occurring in zymosan-based chemotherapeutic drugs and the clinical intervention.

4. Clinical assessment, observation and follow-up of the clinical features of the occurrence of

CIPN may help clinicians to inform their knowledge prior to administering paclitaxel-based chemotherapeutic agents to their patients in order to detect, assess and intervene in a timely manner in the occurrence of this side effect.
5. Through the preliminary exploration, it was observed that herbal fumigation showed a clear preliminary efficacy in patients with CIPN, and it is necessary to continue to expand the sample size in the next study to explore the efficacy of herbal fumigation in graded prophylactic treatment.

P4-03-16: Comparison of analytical and prognostic performance among various Artificial Intelligence models for Tumor Infiltrating Lymphocytes scoring in Triple Negative Breast Cancer: An independent validation on a prospective cohort

Nikolaos Tsiknakis, Joan Martinez Vidal, Johan Staaf, Ana Bosch, Anna Ehinger, Emma Nimeus, Roberto Salgado, Yalai Bai, David L. Rimm, Johan Hartman, Balazs Acs

Introduction: Tumor-infiltrating lymphocytes (TILs) have become a significant biomarker during recent years, showcasing its predictive and prognostic potential for early and metastatic triple-negative breast cancer (TNBC). However, pathologist-read stromal TILs (sTILs) remain a semi-quantitative biomarker, susceptible to inter-observer variability. With the surge in Artificial Intelligence (AI) research, various automated approaches have been proposed to score TILs with the promise to overcome the limitations of manual assessment. However, there is a lack of studies comparing different AI models in both analytical and clinical validity with respect to mimicking the challenges of clinical practice.
Methods: In this study, we aimed to investigate the variability among ten AI-based TILs scoring models (seven own-developed machine learning models in QuPath –KNN, Random Forest, Neural Network– and three pre-trained deep learning models –HoverNet Graham et al. Medical Image Analysis 2019, CellViT Hörst et al. Medical Image Analysis 2024, Abousamra et al. Frontiers in Oncology 2022–) with respect to their analytical and clinical validity on internal and external validation sets. The development cohort consisted of diagnostic tissue slides of 79 women with surgically resected primary invasive TNBC tumors diagnosed between 2012 and 2016 from the Yale School of Medicine. An independent prospective set comprising of 215 TNBC patients from Sweden diagnosed between 2010 and 2015, with 4 years median follow-up, was used for assessing the models' clinical validity. The gold standard of this study regards manual sTILs scoring from two expert pathologists.
Results: Moderate correlation in analytical validity (Internal validation set: Spearman's r= 0.72-0.84, $p<0.001$; External validation set: Spearman's r=0.63-0.73, $p<0.001$) is demonstrated across AI methodologies and training strategies. Training on progressively increasing number of samples improved the correlation with sTILs in internal (10 patients:r=0.79, 20:r=0.81, 30:r=0.82, 40:r=0.84, 50:r=0.83, $p<0.001$) but not in the external validation sets (10:r=0.70, 20:r=0.68, 30:r=0.70, 40:r=0.68, 50:r=0.73, $p<0.001$). HoverNet & CellViT achieved the second highest correlation with sTILs in the internal validation set

(r=0.83, p<0.001) but second and third to worst in the external validation set (r=0.67 & r=0.64, p<0.001). Variabilities in the distribution of TILs scores were identified across models. Interestingly, eight out of ten models (KNN, RF, NN and HoverNet), even less extensively trained ones, showed statistically significant prognostic potential, with similar and overlapping hazard ratios (HR) in the external validation cohort (Cox regression based on IDFS-endpoint and dichotomized TILs scores at 10%, HRadjusted=0.38-0.50, p<0.047). For reference, manual sTILs demonstrated a HRadjusted=0.43 (p=0.003).
Conclusion: Most AI TIL methods demonstrated similar and statistically significant clinical validity, which we believe may be attributed to the intrinsic robustness of TILs as a biomarker. The analytical discrepancies between the AI models should not be overlooked; rather, we believe that there is a need for a large and diverse clinical benchmark dataset to be used for independent model validation ensuring the comparability and reliability of AI tools before integration into the clinical practice.

P4-03-17: Enhanced spatial detection of post-neoadjuvant breast cancer minimal residual disease by tissue-based Cancer Personalized Profiling by Deep Sequencing.

Julia Ransohoff , Mia A. Carleton, Sofia Miron Barroso, Gregory Bean, Alisha Maltos, James Ford, George Duran, Michael Khodadoust, Melinda L. Telli, Ash A. Alizadeh, David M. Kurtz

Background: Circulating tumor DNA (ctDNA) is undetectable after neoadjuvant chemotherapy (NAC) in most breast cancer patients with residual disease, limiting its utility to inform adjuvant treatment. The current standard-of-care for assessing NAC response is pathologic evaluation of resection tissues. Many patients without histologically detected post-NAC disease, however, go on to recur, and many with significant gross residual disease are cured, highlighting the need to more accurately quantify low-burden post-NAC MRD, when adjuvant treatment decisions are made.
Methods: We describe spatial post-NAC MRD detection by tissue-based Cancer Personalized Profiling by Deep Sequencing (t-CAPP-Seq), profiling tissue-based MRD (tMRD) in breast and lymph node resection tissues. Using personalized oligonucleotide hybrid capture panels derived from whole exome sequencing (WES) along with a fixed panel of recurrently mutated and biologically relevant breast cancer genes, we established spatial tMRD detection across numerous spatially catalogued samples per case using barcode mediated error suppression and a Monte Carlo statistical framework. We compared tMRD to pathologic detection in matched samples and described patterns of quantitative tMRD measurement that predict recurrence risk.
Results: We followed a median of 36 (range: 1-112) single nucleotide variants (SNVs)/case derived from WES and a fixed panel of 56 common breast cancer genes spanning 225kb across 29 tumors representing a range of breast cancer subtypes. Nine (33%) and 10 (37%) tumors harbored TP53 and PIK3CA mutations, respectively. We genotyped 797 individual spatially resolved post-surgical specimens spanning these cases (median 24 post-treatment blocks/case, range: 12-46) and established strong concordance between genomic and

histologic MRD detection (considering histology as the gold standard, sensitivity=78.8%, specificity=83.3%), with excellent classification of histologic status by tMRD (AUC=0.92). tMRD positive samples undetected by pathology had lower mean allele frequencies (AFs) than those detected by both methods ($p<0.001$), suggesting a superior limit of detection by tMRD. With a cohort median progression-free survival (PFS) of 140 months, we identified 8 progression events, including two local recurrences adjacent to a tMRD-positive surgical margin that was histologically negative for invasive carcinoma. One of these recurrences was identified post-mastectomy in a pathologic complete response case. Both tMRD positive margins contained missense PIK3CA SNVs that were absent from the pretreatment tumor, representing identification of targetable (alpelisib, capivasertib) post-NAC driver lesions that were selected under the pressure of chemotherapy. In the overall cohort, higher mean tMRD AF across the resection tissues was associated with inferior PFS (HR 1.29, 95% CI 1.08-1.55, $p = 0.004$). We defined tMRD high status as a mean case AF >3%, which predicted inferior PFS ($p=0.034$) and identified four genes (CSPP1, POLE, DNAAF4, PCNT) containing SNVs in post-NAC tissues that were significantly correlated with inferior PFS across the cohort (Cox proportional hazards model, $p<0.05$).
Conclusions: Here we introduce t-CAPP-Seq, a novel tMRD detection platform that outperforms surgical pathology for MRD assessment, quantitatively and spatially profiling patterns of genomic lesions under the selection pressure of treatment that are associated with clinical progression. We anticipate tMRD-based interventional adjuvant approaches will motivate movement of molecularly targeted therapies into the adjuvant setting, leading to superior survival outcomes and challenging current treatment paradigms.

P4-03-18: Chimerizing the HER2 receptor for functional and immunologic studies with αHER2 antibody-drug conjugates

Julia Steele, Justin M. Balko

Background: αHER2 antibody-drug conjugates (ADCs) have revolutionized the treatment of HER2+ breast cancer, prompting numerous clinical trials investigating different combinations and indications. However, a translational gap exists between preclinical data and clinical results due to a paucity of existing models. This stems from the fact that trastuzumab, the antibody backbone of the 2 FDA approved αHER2 ADCs (trastuzumab deruxtecan (T-DXd) and trastuzumab emtansine (T-DM1)), does not bind to rodent HER2. Thus, most preclinical studies employ in vitro or immune-deficient (e.g. xenograft) models, limiting investigations of ADC function, immunologic effects, toxicity, and resistance. To address this issue, we developed a treatment-sensitive, chimeric mouse HER2 tumor model (termed HER2X) that is capable of binding to trastuzumab, while avoiding growth suppression and immunologic selection in vivo, a limitation of existing models.
Methods: The HER2X receptor was generated by substituting 3 salient amino acids from the trastuzumab binding region of human HER2 into the mouse HER2 receptor. AlphaFold and NetMHCpan4.1 were utilized to predict protein structure and murine neoantigen production of the HER2X receptor, respectively. We transduced the HER2X receptor into

EMT6 murine cancer cells and determined their ability to bind trastuzumab using a labelled trastuzumab antibody. To evaluate the immunogenicity of the HER2X model, we orthotopically inoculated immunocompetent and athymic nude syngeneic mice with parental, mouse HER2, human HER2, and HER2X-expressing tumor cells. After 17-18 days tumors were analyzed via flow cytometry to assess HER2 expression and immune cell infiltrates. To evaluate the in vivo sensitivity of the model to ADC treatment, immunocompetent mice were inoculated, as above, with parental, mouse HER2, and HER2X-expressing EMT6 cells and treated intravenously with T-DXd (weekly). The combinatorial benefit of αPD-L1 with T-DXd was also assessed in these tumor models via weekly combinations of T-DXd, αPD-L1, and trastuzumab.
Results: The predicted protein structure of HER2X preserved the general structure shared by both mouse and human HER2, but the trastuzumab binding loop of HER2X resembled that of human HER2 after in silico chimerization. The HER2X sequence also eliminated all predicted neoantigens of the fully human sequence on a murine background, permitting use of this model without concern over tumor rejection or artificial immunologic activity. The HER2X receptor was further able to bind to trastuzumab while retaining the mouse HER2 backbone sequence. In vivo, the HER2X tumor model avoided the growth suppression and immunologic selection of the full length human HER2 receptor ($p< 0.0001$ human HER2+ tumors vs. mouse HER2+ controls, n= 5-15). Upon in vivo T-DXd treatment, we observed a significant and HER2-dependent increase in survival and tumor response in HER2X tumors ($p<0.0001$, n=9-10). T-DXd response also resulted in immunologic memory formation and resistance to rechallenge with HER2X tumor cells (4/5 complete responders [80%]). Finally, αPD-L1 and T-DXd combination treatment further increased survival and response compared to either monotherapy in HER2X tumors ($p< 0.05$, n=5).
Conclusions: The HER2X tumor model is a novel and rigorous system for functional and immunologic studies with αHER2 ADCs. The HER2X receptor permits binding of trastuzumab-based drugs in immune competent models without inducing background immunogenicity associated with human HER2. We credential this model by demonstrating its sensitivity to T-DXd and combinations with immunotherapy, as well as T-DXd's ability to elicit an adaptive immune response. Overall, this model is an innovative advance to study αHER2 ADC function, bridging the translational gap between preclinical and clinical studies.

P4-03-19: Plasma-based prediction of prognosis, receptor status and organ involvement among patients receiving antibody-drug conjugates for metastatic breast cancer

Paolo Tarantino, Morganti, Rosario Vega, Francisco Pardo, Sandra Cobo, Melissa E. Hughes, Ross Kusmick, Kalie Smith, Guillermo Villacampa, Fara Brasó-Maristany, Mercedes Marín-Aguilera, Georgia Suggs, Molly Skeffington, Simone Buck, Kerry Sendrick, Abigail Recko, Katherine Junkins, Hajer Rahoo, Oleguer Castillo, Sarah Sammons, Antonio Giordano, Ana Garrido-Castro, Nabihah Tayob, Charles M. Perou, Joel S. Parker, Patricia Villagrasa, Laia Paré, Nancy U. Lin, Heather Parsons, Ana Vivancos, Aleix Prat, Sara M. Tolaney

Background: Trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan (SG) are approved antibody-drug conjugates (ADCs) for individuals with metastatic breast cancer (MBC). Multiple treatments are available in this setting, and prognostic and predictive biomarkers are needed to help understand tumor biology and guide treatment choices. The DNADX assay, utilizing innovative machine learning techniques, analyzes plasma tumor DNA to evaluate complex phenotypic features. This includes a 5-class subtype classification and multiple genomic signatures, which provide insight into the tumor biology in MBC (Nat Commun. 2023).
Methods: We included patients with MBC who received single-agent T-DXd or SG at Dana-Farber Cancer Institute. DNADX was applied to plasma samples collected prior to initiating the ADC. The primary objective was to investigate the association between the DNADX 5-class group classification (Tumor Fraction-low [TF-low], copy-number aberration-flat [CNA-flat], Luminal-high, Proliferative, and Basal-related) and overall survival (OS) from start of the ADC. Secondary objectives included correlating DNADX, time to next treatment (TTNT) and site of metastases. Statistical methods included uni- and multi-variable Cox models, logistic regression models, and Student's t-tests. Clinical variables considered included timing of biopsy, ER and HER2 IHC status, number of prior lines of chemotherapy, and type of ADC.
Results: Among 160 patients (38.1% ER+/HER2-, 36.3% ER-/HER2-, 25.0% HER2+, 0.6% unknown), 85 (53.1%) received SG and 75 (46.9%) received T-DXd. The median number of prior lines of chemotherapy was 2 (range 0-10). A total of 160 plasma samples were analyzed, of which 115 (71.87%) collected within 4 months and 45 (28.13%) >4 months from ADC start. DNADX subtypes were as follows: TF-low 36.9%, CNA-flat 1.2%, Luminal-high 27.5%, Proliferative 19.4%, and Basal-related 15.0%, suggesting significant biological heterogeneity.
Median OS in the entire study population was 11.0 months. The DNADX 5-subtype classification was significantly associated with OS ($p<0.001$) and TTNT ($p=0.005$) after adjusting for clinicopathological variables. The median OS for Luminal-high group, the proliferative subtype and the Basal-related subtype were 20.2, 9.7 and 8.9 months, respectively. Compared with the Luminal-high group, the Basal-related subtype and the proliferative subtype were associated with worse OS (HR 2.25 95% CI 1.13-4.46, $p=0.020$, and 2.61, 95% CI 1.14-4.99, $p=0.023$, respectively) independently of type of ADC and clinical ER status. Patients with high (vs. low) expression of the DNADX progesterone receptor signature, which is associated with Luminal A biology, were more often pretreated with ≥3 lines of ET (45% vs 15%, odds ratio=6.54, $p=0.001$), independently from HER2 and ER status. High expression of the DNADX ER signature as a continuous variable was associated with ER IHC status (AUC=0.81, $p<0.001$). Additionally, specific DNADX signatures were associated with the presence of liver, bone, and brain metastases (all $p<0.05$). High (vs. low) expression of DNADX signatures associated with Basal-like biology was linked with the presence of brain metastases (55% vs 20%, odds ratio=4.89, $p=0.027$), independently from HER2 and ER status.
Conclusions: Plasma-based DNADX analysis prior to starting ADC treatment in MBC demonstrates significant biological and prognostic diversity beyond ER and HER2 status.

Furthermore, DNADX may facilitate the identification and monitoring of clinical features, including endocrine therapy sensitivity, as well as the specific organs affected by metastatic disease.

P4-03-20: Molecular characterization of estrogen receptor (ER)+/HER2- breast cancer unveils a biologically and clinically distinct entity with ERBB2 hemizygous deletion (ERBB2del)

Paolo Tarantino, Xintao Qiu, Rong Li, Albert Grinshpun, Hersh Gupta, Melissa E. Hughes, Gregory Kirkner, Lynette Sholl, Bruce E. Johnson, Matthew L. Meyerson, Andrew D. Cherniack, Yijia Jiang, Ningxuan Zhou, Nancy U. Lin, Henry W. Long, Sara M. Tolaney, Rinath M. Jeselsohn

Background: Among patients with ER+/HER2- breast cancer (BC), IHC-defined HER2-low and HER2-0 tumors do not appear to significantly differ molecularly (Tarantino P. et al. Nat Comm 2023). However, this may be due to lack of sensitivity of IHC, which is currently used to select patients for T-DXd treatment, despite major diagnostic challenges. To better characterize the biologic correlates of HER2-low expression, we analyzed molecular profiles by quantitative ERBB2 mRNA expression and characterized the features of tumors harboring ERBB2del, for which resistance to T-DXd has been suggested.
Methods: Genomic, transcriptomic and proteomic data from ER+/HER2- BCs were analyzed from the METABRIC, TCGA (early BC) and MSK MetTrospism (metastatic BC, MBC) databases. Genomic landscapes, gene expression and HER2 protein expression were compared between subgroups based on HER2 mRNA tertiles (ERBB2-low, -intermediate, -high), by HER2 IHC score (IHC 0, 1+, 2+/not amplified) and by ERBB2del. Further validation was conducted in two DFCI cohorts, including patients with HER2- early BC with tumors tested for OncotypeDX between 1/2018 - 12/2022 and patients with MBC with tumors that had undergone next-generation sequencing (NGS) between 7/2013 - 12/2020.
Results: All ER+/HER2- BCs from the METABRIC (n=1298), TCGA (n=524) and early DFCI (n=971) cohorts exhibited some degree of ERBB2 mRNA expression. In both METABRIC and TCGA, the ERBB2 mRNA high group was enriched in pathways related to ER signaling (Hallmark estrogen response early), while the ERBB2 mRNA low group was enriched in genes involved in cell proliferation (Hallmark E2F targets, MYC targets) and immune response (Hallmark allograft rejection, TNF signaling via NF-kB, IFN-α response, IFN-γ response). At the genomic level, PIK3CA mutations were enriched in the ERBB2 mRNA-intermediate and -high groups (both $p<0.01$), whereas TP53 mutations were enriched in the ERBB2 mRNA-low subgroup ($p<0.001$). Notably, ERBB2del were common in the ERBB2 mRNA-low group of both METABRIC and TCGA (35% and 54%), but less frequent in the ERBB2 mRNA-intermediate and -high cohorts (METABRIC: 9% and 4%; TCGA: 14% and 5%). No significant difference in the distribution of PIK3CA, TP53 and ERBB2del was noted between HER2 IHC subgroups.
Among tumors with ERBB2-low mRNA, >90% of ERBB2del tumors had a concurrent TP53 heterozygous deletion (TP53del), compared with only 25-36% of non-ERBB2del tumors

(both on chromosome 17). ERBB2del tumors were found enriched in the expression of genes related to cell proliferation and immune response, while non-ERBB2del BCs were enriched in genes related to ER signaling. ERBB2del tumors were found scattered across HER2 IHC subgroups (30.7% of IHC 0, 23.9% of IHC 1+, 15.8% of IHC 2+), had lower ERBB2 mRNA and HER2 protein levels, lower ER signaling and higher expression of proliferation genes within each HER2 IHC category.
In the DFCI cohort of ER+/HER2- MBC with clinical NGS (n=749), the prevalence of ERBB2del was 14.3%, with 87.9% of ERBB2del tumors having concurrent TP53del. A significant difference in overall survival (OS) was observed between ERBB2del vs. non-ERBB2del tumors (33.8 vs 47.8 months, p=0.037), irrespective of the presence of TP53del, whereas no difference in OS was observed by HER2 IHC score (p=0.26). Similarly, in the MSK MetTrospism cohort (n=883), patients with ER+/HER2- MBC and an ERBB2del had worse OS (16.4 vs 30.8 months, p<0.0001), while the presence of TP53del was not associated with OS (32.1 vs 34.2 months; p=0.62).
Conclusions: ERBB2del are frequent events in ER+/HER2- BC that are characterized by low ERBB2 mRNA levels, and are associated with TP53del, higher proliferation and immunogenicity, lower ER signaling and HER2 protein expression, and decreased OS in the metastatic setting.

P4-03-21: Limiting Over- and Under-Treatment of DCIS: Ten Year Breast Recurrence Rates with Personalized Management Utilizing the 7-Gene Biosignature as Compared to Clinicopathologic Factors Alone

Frank Vicini, Chirag Shah, Pat Whitworth, Rachel Rabinovich, Sheila Weinmann, Michael C. Leo, Fredrick Warnberg, G. Bruce Mann, Steven C. Shivers, Karuna Mittal, Troy Bremer

Purpose: Clinicopathologic (CP) factors, including age, grade, and tumor size have been considered to guide the management of ductal breast carcinoma in situ (DCIS) to minimize over- or under-treatment. However, these CP factors have failed to identify a low-risk group with little to no benefit from radiation therapy (RT) or a high-risk group with a high risk of recurrence even after RT. We compare the impact of utilizing a 7-gene biosignature (DCISionRT) to risk stratify patients as compared to standard CP factors.
Methods: Women (n=926) from four published international DCIS cohorts treated with BCS with negative margins +/- RT were categorized as CP low-risk or high-risk using age (>70 or <50), grade (1-2 vs 3), size (≤ or > 2.5 cm). Women were classified as DS (DCISionRT Score) Low Risk (DS≤2.8, no Residual Risk sybtype, RRt) or High Risk (DS>2.8 +/- RRt) using the 7-gene biosignature and stratified by the CP factors. Rates of ipsilateral breast recurrence (IBR) and benefit or lack of benefit with RT were evaluated for low-risk, high-risk CP as compared to DS Low Risk and DS High Risk.
Results: On average, 61% of patients with individual low-risk CP factors (78%, n=133 of age >70, 56%, n=356 of size ≤ 1 cm, 51%, n=101 of grade 1, and 57%, n=218 of grade 2) were re-classified as DS High Risk. Although CP low risk patients showed significant RT benefit, when re-classified as DS Low Risk patients, no significant RT benefit was noted for age >70

(HR 1.19, p=0.71), size ≤1 cm (HR 1.09, p=0.90), grade 1 (HR 1.61, p=0.70), or grade 2 (HR 0.93, p=0.92), with a corresponding average 10-yr IBR rate of 4.9% (2.3%-6.8%) without RT vs. 5.9% (4%-7.1%) with RT. In contrast, when CP low risk patients were re-classified as DS High-Risk patients, a significant RT benefit was noted for age >70 (HR 0.15, p=.02), size ≤1 cm (HR 0.23, p<0.001), grade 1 (HR 0.22, p=0.04), or grade 2 (HR 0.32, p=0.01), with a corresponding average 10-yr IBR rate of 21% (18.3%-20.3%) without RT vs. 5.4% (3%-7.4%) with RT. On average, 27% of patients with individual high-risk CP factors (42% (n=88) of age <50, or 16% (n=10) of size >2.5 cm, 22% (n=75) of grade 3) were re-classified to DS Low Risk, and IBR rates did not differ significantly by RT receipt for these re-classified patients. High-risk CP patients with concordant DS High Risk classification did benefit from RT for age <50 (HR 0.35, p=0.04), size >2.5 cm (HR 0.17, p=0.02), and for grade 3 (HR 0.19, p<0.001), with a corresponding average 10-yr IBR rate of 34% (27.9%-38.5%) without RT vs. 11% (9.1%-12.4%) with RT.
Conclusions: The 7-gene predictive DCIS biosignature more reliably identified patients with low 10-year IBR rates and no significant RT benefit than traditional CP factors as well as those with elevated long term IBR rates that benefited from RT with substantial crossover for low and high risk clinicopathologic patients, respectively. The use of DCISionRT allows for more personalized and accurate risk stratification, preventing the under- and over-treatment of patients with suspected “low-risk” or “high-risk” DCIS based on current clinicopathologic factors.

P4-03-22: Inhibiting JNK signaling enhances the antitumor efficacy of macrophage-targeting agents in triple-negative breast cancer by inducing an immunoactive tumor microenvironment

Xuemei Xie, Takashi Semba, Young J. Gi, Yujia Qin, Ba Thong Nguyen, Bharat S. Kautal, Youping Deng, Jangsoon Lee, Naoto T. Ueno

Background: Triple-negative breast cancer (TNBC) has a unique tumor microenvironment (TME) that contributes to tumor progression and affects responses to immunotherapy. c-Jun N-terminal kinase (JNK), part of the MAPK pathway, plays a crucial role in inflammation and tumor progression and has been targeted in clinical trials for treating inflammation-related diseases and solid tumors. Indeed, JNK inhibitor (JNKi) BMS-986360 is currently being tested alone and in combination with chemotherapy or nivolumab in advanced solid tumors (NCT05625412). Our recent study showed that JNK promoted TNBC tumor growth and metastasis by creating an immunosuppressive TME via macrophage-derived CCL2 in preclinical models. Therefore, in this study, we tested our hypothesis that JNKi enhances the antitumor efficacy of macrophage-targeting agents in TNBC.
Methods: The correlation of JNK signaling activity with the immune status of the TME in TNBC was analyzed using the TCGA dataset (n = 191). The antitumor efficacy of JNKi (BMS-986360, a reversible orally active pan-JNKi; or JNK-IN-8, a covalent pan-JNKi) combined with macrophage-targeting agents (pexidartinib or sotuletinib, both of which are orally active CSF-1R inhibitors) was assessed using immunocompetent syngeneic models of

E0771 (M1 macrophage-enriched TME, sensitive to immune checkpoint inhibitors [ICI]), PyMT-M (M2-macrophage-enriched TME, partially sensitive to ICI), and 4T1.2 (neutrophil-enriched TME, resistant to ICI). The treatments' effects on immune cell tumor infiltration were determined by flow cytometry.
Results: To investigate the role of JNK signaling in regulating the immune landscape of the TME in cancer, we have developed a phospho-JNK (pJNK) gene signature to infer JNK phosphorylation status by gene expression. Using this pJNK gene signature and TCGA dataset, we found that high JNK (JNKhi) signaling activity was associated with high counts of Tregs and cancer-associated fibroblasts and low counts of CD8+ T cells, M1 macrophages, and neutrophils in TNBC tumors. TNBC tumors with JNKhi signaling activity were enriched with pathways regulating angiogenic and fibrotic stroma, e.g., Wnt and TGF-β signaling, which are the major inflammatory pathways involving tissue fibrosis and tumor progression. These results demonstrate a strong correlation between JNKhi signaling activity and an immunosuppressive TME in TNBC. Since JNK promoted an immunosuppressive TME in TNBC through macrophage-derived CCL2, we next investigated whether inhibiting JNK signaling enhances the antitumor efficacy of macrophage-targeting agents in mouse models. Compared with monotherapies, BMS-986360 or JNK-IN-8 plus pexidartinib or sotuletinib significantly reduced tumor growth in immunocompetent syngeneic TNBC models (E0771, PyMT-M, and 4T1.2; $P < 0.01$). Furthermore, compared with monotherapies, JNKi combined with pexidartinib reduced counts of Tregs and M2 macrophages and increased counts of M1 macrophages and cytotoxic CD8+ T cells in both E0771 and PyMT-M tumors. These results suggest that combination of JNKi with macrophage-targeting agents reduces tumor growth by inducing an immunoactive TME.
Conclusion: JNKi can potentiate macrophage-targeting agents in TNBC by inducing an immunoactive TME. This finding highlights the need to conduct further studies of combining JNKi with immunotherapy to capitalize on JNK's immune regulation of the TME and the potency of JNKi in synergistically improving the efficacy of immunotherapy for TNBC.

P4-03-23: Preclinical investigation for the mechanisms of action of PARP inhibition in combination with trastuzumab deruxtecan (T-DXd) in triple negative breast cancer (TNBC)

Gonzalez-Gonzalez, Adrian; Guo, Zhanfang; Xiao, Shan; Hoog,Jeremy; Ma, Cynthia X.
Washington University in St. Louis, School of Medicine, Oncology Department

Background: TNBC represents a significant challenge due to its aggressive clinical course and the lack of targeted therapy. Chemotherapy remains the mainstay of systemic treatment option, however resistance is common in TNBC. Next generation antibodies-drug conjugates (ADCs) have demonstrated improved efficacy compared to traditional chemotherapy as a result of more effective tumor delivery of cancer therapeutics. Two ADCs, both employing a topoisomerase 1 inhibitor payload, including Sacituzumab Govitecan (SG) and T-DXd, have received FDA approval for the treatment of metastatic TNBC. However, resistance is

evitable. Recent data indicated the potential of adding PARP inhibitor to SG or T-DXd in improving tumor control. We aim to understand the underlying mechanisms of action for the combination strategy, focusing on the T-DXd and olaparib combination.

Method: We conducted preclinical studies to assess the anti-tumour activity of T-DXd and the PARP inhibitor Olaparib, either alone or in combination, compared to the vehicle treatment, in four TNBC cell lines (MDA-MB-231, WHIM 12, HCC1806 and BT549) in vitro and four HER2-low TNBC PDX patient derived xenograft (PDX) models: WHIM2, WHIM6, WHIM12 and WHIM30 (BRCA1 mutant), and one HER2-zero PDX model (WHIM21) in vivo.

Results: In both in vitro and in vivo models, the addition of olaparib to T-DXd enhanced DNA damage and apoptosis, demonstrated by increased pH2AX and cleaved PARP, respectively. The combination therapy showed synergistic anti-tumor effect in vitro and was most effective in inhibiting tumor growth in vivo. Interestingly, combination therapy potently reduced or blocked cell migration and mammosphere formation in vitro. This was accompanied by reduced expression of epithelial-mesenchymal transition (EMT) inducers including Snail, Slug and Twist1 by Western blot. In addition, T-DXd alone increased the expression of the stress response controller ATF4, which was prevented by the addition of Olaparib. Furthermore, Olaparib combined with T-DXd inhibited the expression of MTOR. Subsequent screening of additional TNBC PDX models identified two TNBC PDX models (WHIM3 and WHIM4), which were relatively resistant to T-DXd monotherapy, was resistant to the combination with Olaparib. Additional studies including proteogenomic analysis and functional HRD assessment by RAD51 foci and markers of replication stress of baseline and on-treatment samples of these PDX models will be presented to further understand the mechanisms of resistance.

Conclusion: PARP inhibition enhances the DNA damaging and apoptotic effect of T-Dxd as expected. The findings of reducing EMT and stress response may also contribute to the enhanced anti-tumor effect. However resistance to the combination exists. Ongoing proteogenomic analysis will provide further insight into the mechanisms of action for the combination therapy.

P4-03-24: Septin 9 isoform expression and response to taxane treatment in breast cancer patients

Jacob Essif, April Risinger, Kate Lathrop, Rebecca Thompson, Virginia Kaklamani, Marcela Mazo, Jessica Jones, Saba Shaikh, Jo Ann Meekins, Kyrsten Kawazoe

Drugs that disrupt the microtubule cytoskeleton, such as the microtubule stabilizing taxanes, are regularly used in the treatment of breast cancer in both the neoadjuvant and adjuvant setting. However, there are currently no molecular biomarkers that are used to guide which patients will respond to taxane treatment. Septins, a class of small GTPases, interact with both microtubules and actin to functionally link these cytoskeletal

components and regulate cell biological processes shown to be critical for the invasion and migration of cancer cells. In particular, septin 9 (SEPT9) directly interacts directly with microtubules through an N-terminal domain on the longest isoform, SEPT9 isoform 1, which is sufficient to promote migration and invasion of breast cancer cells in vitro. Additionally, both SEPT9 isoform 1 and SEPT9 isoform 3 have been shown to play a role in taxane resistance in vitro, but the possible role in clinical taxane resistance had not been studied. We hypothesized that the relative expression of SEPT9 isoforms in breast tumors could play a role in their response to treatment with microtubule-targeted chemotherapy, specifically to taxanes in the neoadjuvant setting.
We performed a prospective clinical trial to correlate the expression of SEPT9 isoforms in breast tumors with pathological response to taxanes in the neoadjuvant setting. Pretreatment levels of SEPT9 isoforms, as well as other genes associated with clinically relevant drug resistance mechanisms, including the MDR1, ABCG2, and ABCG11 drug efflux transporters and the βIII-isoform of tubulin, were determined from FFPE biopsy samples using Biomark multiplexed PCR. RNA was isolated from 3 scrolls per patient biopsy sample using the Puregen automated RNA extraction platform. Expression was normalized between patients referencing actin using the ΔCt method and the average expression for each gene was set at 1. Protein levels of total SEPT9 as well as isoforms 1 and 3 were also determined by immunohistochemistry and quantified by calculating the cytoplasm and nucleus H-scores using the Aperio eSlide Manager analysis. Patients were treated in the neoadjuvant setting with either paclitaxel (dose dense or weekly), docetaxel or nab-paclitaxel. The expression of markers was reevaluated in the post-treatment surgical samples of patients who did not have a complete pathological response. We found that the expression of SEPT9 isoforms and drug resistance genes differed amongst the pre-treatment patient samples and are determining the correlation of initial SEPT9 isoform levels with pathological response to taxane treatment as well as whether SEPT9 isoform expression changes after treatment with taxanes. Preliminary results suggest that higher initial SEPT9 isoform 3 levels correspond with better tumor response to taxane treatment compared to those with lower initial SEPT9 isoform 3 levels and that total SEPT9 and SEPT9 isoform 1 levels decrease after taxane treatment while SEPT9 isoform 3 levels increase after taxane treatment. Overall, the data support the hypothesis that the relative expression of SEPT9 isoforms in breast tumors plays a role in their response to treatment with taxanes in the neoadjuvant setting.

P4-03-25: Actionable gene alterations affecting the PI3K/AKT and MAPK signaling pathways in breast cancer

Gargi D. Basu, Karen White, Cynthia A. Flannery, Paige E. Innis, Satish Seerapu, Jean-Paul De La O, Joyce O'Shaughnessy

Background: The MAPK and PI3K/AKT signaling pathways are known drivers of breast cancer (BC) tumorigenesis. They are increasingly important as targets for therapeutic intervention such as capivasertib-fulvestrant for HR+HER2- BC with PIK3CA/AKT1/PTEN

alterations, or dabrafenib–trametinib for solid tumors with the BRAF V600E mutation. The goal of this study was to determine the frequency and co-occurrence of actionable gene alterations affecting these signaling pathways in BC.
Methods: The study retrospectively reviewed results of tumor-normal, whole-exome, whole-transcriptome testing using the OncoExTra assay in tumor samples from patients with BC. Thirty-one genes were considered, 13 in the PI3K/AKT pathway and 18 in the MAPK pathway. Actionable alterations were defined as those with associated FDA-approved targeted therapies in any cancer type, with evidence for matched therapies, or required for clinical trial eligibility.
Results: A total of 2387 tumor samples (66.1% HR+HER2-, 15.0% HER2+, 14.7% TNBC, 4.2% unspecified) were included. PI3K/AKT pathway gene alterations were present in 48.2% (1150/2387); MAPK pathway gene alterations were present in 15.4% (367/2387). Of these, 222 samples (9.3% of the cohort) had alterations in both pathways. The frequency of PI3K/AKT pathway alterations varied by BC subtype (p<.0001), occurring most often in HR+HER2- BC (884/1577; 56.1%) and least often in TNBC (97/352; 27.6%). Among the 1577 HR+HER2- BC samples, alterations in PI3K/AKT pathway genes PIK3CA, AKT1, and PTEN were found in 718 (45.5%), 84 (5.3%), and 128 (8.1%), respectively. Most samples with alterations in these genes (814/872; 93.3%) had only one gene involved. PIK3CA alterations were significantly more common in local/regional samples vs metastatic sites (43.4% vs 34.9%; p=.0089). The converse appeared true for PTEN (4.6% vs 5%) but was not significant (p=.0758). AKT alterations were present in 4.6% of local/regional and 4.7% of metastatic sites (p=.9671). In the MAPK pathway, MAP3K1 and MAP2K4 alterations were present in 196 (8.2%) and 63 (2.6%) of all BC samples, respectively, compared to KRAS or BRAF activating mutations, which were found in only 37 (1.6%) and included just one instance of V600E. Alterations in TSC1, TSC2, or NF1 were found in 75 samples (3.1%) with no co-occurring alterations.
Conclusions: More than half of BC tumor samples had potentially actionable genomic alterations affecting either the PI3K/AKT or MAPK pathways. In HR+HER2- BC, actionable alterations in PIK3CA, AKT1, and PTEN were generally present independently rather than co-occurring. These findings support a comprehensive testing approach that interrogates a large number of genes to maximize the number of patients identified who might benefit from targeted therapies. In addition, the presence of MAP3K1 and MAP2K4 alterations warrants further investigation, as these may represent targets for MEK inhibitors.

P4-03-26: MINDY1 role and exceptional response to CDK inhibitors in metastatic breast cancer

Eleni Balla, Yi Li, Kyriaki Papadopoulou, John T. Nguyen, Zikun Zhou, Anna Koumarianou, Eleni Galani, Rania Romanidou, George Fountzilas, Evangelia Razis, Angelos Koutras, Leonidas Bleris, Elena Fountzilas

Background: Patients exhibiting exceptional response to targeted treatments represent a unique opportunity towards identifying predictive biomarkers of response. The

introduction of edits into the genome using Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) creates cancer models that can unravel the mechanisms driving tumorigenesis and response to drug agents. The study aimed to identify candidate molecular alterations associated with exceptional response to CDK inhibitors (CDKi) and validate their effects using genome editing.
Methods: Patients with ER-positive, HER2-negative advanced breast cancer treated with CDKi and endocrine combination therapy at Departments of Oncology-affiliated with the Hellenic Cooperative Oncology Group (HeCOG), were included. Exceptional response was defined as either complete response (CR) to the treatment regimen or partial response (PR) for 3 years, per physician's assessment. Formalin-fixed paraffin-embedded (FFPE) tumor tissue samples, obtained prior to CDKi administration from these patients were retrospectively collected. Whole-exome sequencing (WES) was performed to analyze tumor mutational landscape of exceptional responders to CDKi. Using CRISPR-mediated genome editing, a breast cancer cell model harboring a patient-specific SNP and the negative control were prepared, and subsequently evaluated for their responsiveness to palbociclib. Transcriptomic and proteomic analyses were conducted to uncover alterations in network interactions, between the two cell lines, elucidating the exceptional response to CDKi.
Results: Overall, 12 women identified as exceptional responders, initiated CDKi treatment from March 2017 to February 2020; median age at diagnosis was 46 (range, 37 to 78). All patients had received the CDKi as first-line treatment; most commonly palbociclib (10 patients, 83.3%). Based on physician assessment, 50% of patients achieved CR with the combination therapy. After a median follow up of 65 months, 10 patients are still alive, and 7 are still receiving treatment with CDKi in combination with endocrine treatment. WES results with adequate mapped reads and acceptable technical characteristics in both tumor and control blood samples were obtained from 6 of 12 patients. A set of germline and somatic single nucleotide polymorphisms (SNPs) commonly shared in this cohort was identified. The focus was on MINDY1, a member of the MINDY family of deubiquitinases (DUBs), known as a deubiquitylase of ERα in breast cancer, the common SNP among all 6 patients. Utilizing CRISPR-based genome editing, a breast cancer cell model harboring a specific MINDY1 SNP was engineered, and their response to palbociclib was subsequently evaluated. Depletion of MINDY1 transcripts through RNA interference with short-hairpin RNA, increased sensitivity to palbociclib in both cell lines, confirming that MINDY1 protein is involved in molecular pathways related to palbociclib response. The functional role of MINDY1 rs771205 was also investigated by combining transcriptomic and proteomic data. Our data demonstrated that the MINDY1 rs771205 SNP, which causes an amino acid substitution, while it does not impact the respective transcript and protein levels, alters the MINDY1 protein's interaction network.
Conclusions: The Rs771205 single mutation alters the MINDY1 protein's interaction network, sensitizing cells to palbociclib. Our study sheds new light on the underlying mechanisms driving exceptional response in patients with ER-positive, HER2-negative advanced breast cancer treated with CDKi and endocrine combination therapy , demonstrating that it is an opportune moment to invest attention and resources towards probing the underlying mechanisms of exceptional response in cancer patients.

P4-03-28: Validation of an AI-based solution for breast cancer risk stratification using routine digital histopathology images

Abhinav Sharma, Sandy Kang Lövgren, Kajsa Ledesma Eriksson, Yinxi Wang, Stephanie Robertson, Johan Hartman, Mattias Rantalainen

Introduction: Stratipath Breast is a CE-IVD marked AI-based solution for prognostic risk stratification of breast cancer patients into high- and low-risk groups, using haematoxylin and eosin (H&E)-stained histopathology whole slide images (WSIs). In this retrospective validation study, we assess the prognostic performance of Stratipath Breast in independent breast cancer cases.

Material and methods: This study included patients (N=2719) diagnosed with primary breast cancer at two healthcare locations in Sweden. The patients were stratified into low- and high-risk groups by Stratipath Breast using H&E stained WSIs from the surgically resected tumours. The prognostic performance was evaluated using time-to-event analysis by multivariable Cox Proportional Hazards analysis with progression-free survival (PFS) as the primary endpoint. Further, we evaluated the prognostic performance of the continuous slide score from the Stratipath Breast by stratifying patients into 5-level risk groups based on the 5-equally sized bins of the continuous slide score defined by quantiles.

Results: In the clinically relevant ER+/HER2-oestrogen receptor (ER)+/human epidermal growth factor receptor 2 (HER2)- patient subgroup, the estimated Hazard Ratio (HR) associated with PFS between low- and high-risk groups was 2.76 (95% CI: 1.63-4.66, p-value < 0.001) after adjusting for established risk factors. In the ER+/HER2- Nottingham histological grade (NHG) 2 (intermediate risk) subgroup, the HR was 2.20 (95% CI: 1.22-3.98, p-value = 0.009) between low- and high-risk groups. For 5-level patient risk stratification based on the continuous slide score, we observed the adjusted HR for PFS of 3.88 (95% CI: 1.43-10.52, p-value = 0.008) comparing between the lowest- and highest-risk group in ER+/HER2- patient subgroup.

Conclusion: The results indicate an independent prognostic value of Stratipath Breast in both the general breast cancer population, in the clinically relevant ER+/HER2- and subgroup and the NHG2/ER+/HER2- subgroups. Improved image-based risk stratification of intermediate-risk ER+/HER2- breast cancers provides information relevant for treatment decisions of adjuvant chemotherapy and has the potential to reduce both under and over-treatment, shorten lead times, and reduce costs compared to molecular diagnostics.

P4-03-29: Patient reported anxiety levels during ctDNA surveillance in early stage triple negative and hormone positive breast cancer

Devora Isseroff, Nathalie Wiesendanger, Adriana Kahn, Daniel O'Neil, Michael Cohenuram, Anca Bulgaru, Kathleen Fenn, Johanna LaSala, Kert Sabbath, Neal Fischbach, Jane Kanowitz, Robert Legare, Michael DiGiovanna, Andrea Silber, Tara Sanft, Sarah Schellhorn, Himanshu Sethi, Ekaterina Kalashnikova, Samuel Rivero-Hinojosa, Minetta Liu, Ian Krop, Eric Winer, Wei Wei, Maryam Lustberg, Lajos Pusztai, Mariya Rozenblit

Background: Growing evidence has demonstrated that circulating tumor DNA (ctDNA) is a sensitive and specific assay for predicting distant recurrences from breast cancer (BC). Patients with detectable ctDNA after neoadjuvant chemotherapy have a higher risk of distant recurrence compared to patients with negative ctDNA testing. Further, ctDNA positivity precedes clinical metastatic relapse by 10.5-12 months (mos) on average. SignateraTM (Natera, Inc.) is a tumor-informed and commercially available ctDNA assay that has been CMS-reimbursed for stage IIB and higher BC since 2023. It is unknown whether ctDNA testing influences BC patient anxiety or physician decision-making. In this study, we describe patient reported anxiety levels using the Patient-Reported Outcomes Measurement Information System (PROMIS) and assess physician decision-making using a provider decision assessment tool (PDAT) in the setting of an institutional registry for patients who underwent ctDNA surveillance during routine follow-up.

Methods: This is a single institution observational study of ctDNA surveillance in patients with early stage hormone receptor positive (HR+) or triple negative BC (TNBC) with residual disease after neoadjuvant treatment. ctDNA was assessed using the Signatera assay at baseline (prior to adjuvant therapy in ER+ disease or following surgery in TNBC) and every 6 mos for 2 years or until clinical evidence of recurrence. Patients with positive ctDNA were re-staged with scans as deemed appropriate by the treating physician. Patients were invited to complete an anxiety questionnaire using the PROMIS every 6 mos, online, or in clinic. Treating physicians were invited to complete a PDAT at the time of ctDNA test results. Mean scores on the PROMIS and PDAT were calculated at baseline and 6 mo intervals. Higher PROMIS scores correspond to higher anxiety levels. This planned interim analysis is at 50% of recruitment (n=48). T scores will be analyzed and reported at final analysis.

Results: 48 patients (TNBC n=29, HR+ n=19) were enrolled in the surveillance study, with mean age of 52 years (range 24-84). ctDNA results are available for 45 participants at baseline, and 25 at 6 mos. Seven patients, 6 TNBC (4 stage IIB and 2 stage IIIB disease), and 1 HR+ (stage IIB) had positive ctDNA. Five (11.1%) were positive at baseline and two (8%) turned positive at 6 mos. Three of the 7 (42.9%) ctDNA positive patients, all TNBC, had detectable metastatic disease on imaging at the time of ctDNA positivity. PROMIS results are available for 40 patients at baseline and 23 at 6 mos. PROMIS mean total scores were similar at baseline and 6 mos (44.5 vs 42.5, p=0.648) for the whole group, in ctDNA negative

patients (44.7 vs 42.1, p=0.488), and in ctDNA positive patients (42.3 vs 40.5, p=0.508). PDAT mean scores were also similar at baseline and 6 mos (41.2 vs 41.1, p=0.588). PROMIS data is available for 3/4 participants with ctDNA positive / imaging negative results and showed a small increase in anxiety levels at 6 mos vs baseline (32 vs 30, 48 vs 38, 49 vs 44).

Conclusion: To our knowledge, this is the first study to report on patient reported anxiety levels associated with ctDNA surveillance in early stage BC. At this interim analysis, no statistically significant difference in patient reported anxiety was seen at 6 mos compared to baseline. Average anxiety scores were similar to the US general population (average 50, standard deviation 10). The majority of ctDNA results were negative; among patients with positive ctDNA testing, small increases in anxiety levels were detected, but the sample size was limited. PDAT scores remained stable. This interim analysis suggests that ctDNA surveillance may not adversely affect patient anxiety. However, further follow up and future randomized trials are needed.

P4-03-30: GPR56/ADGRG1 promotes the progression of triple-negative breast cancer by enhancing PKM2/LDH-mediated glycolysis via the PI3K/AKT/mTOR/HIF-1α pathway

Haizhu Chen, Wenhao Ouyang, Xingbin Hu, Ziyan Zhang, Zhenjun Huang, Daquan Wang, Ying Wang, Herui Yao

Objective: Despite increasing evidence suggesting that G protein-coupled receptors (GPCRs) may play a critical role in tumor development, their exact roles and related mechanisms in breast cancer remain largely elusive. This study aimed to comprehensively investigate the prognostic value of 33 adhesion GPCRs in breast cancer, identify key GPCRs associated with prognosis, and further explore the specific biological functions and mechanisms of these key GPCRs in breast cancer.
Methods: This study utilized transcriptomic sequencing data from the TCGA and three GEO breast cancer cohorts to explore the relationship between 33 adhesion GPCRs and RFS using Cox regression analysis. GPR56 (also named as ADGRG1) was identified as a key GPCR associated with prognosis. Pathway enrichment analyses, including GO, KEGG, GSVA, and GSEA, were performed to explore the potential biological functions of GPR56. Additionally, immunohistochemistry was conducted to validate the clinical significance of GPR56. Finally, in vitro cell experiments were conducted to verify the biological functions and related mechanisms of GPR56 in triple-negative breast cancer (TNBC).
Results: Among the 33 adhesion GPCRs, only GPR56 was significantly associated with relapse-free survival (RFS) across all four cohorts and was identified as an independent adverse factor affecting both RFS and overall survival. GPR56 was overexpressed in TNBC tissues compared to normal breast epithelial tissues and was clinically associated with high invasiveness in breast cancer. GO and KEGG analyses showed that the high GPR56 expression group was significantly enriched in biological processes and pathways such as

cell division, DNA replication, and the cell cycle. GSVA and GSEA analyses indicated that the high GPR56 expression group was significantly enriched in carcinogenic pathways such as glycolysis and PI3K-AKT-mTOR. In vitro experiments demonstrated that knockdown of GPR56 inhibited the proliferation, migration, and invasion of TNBC cells. Furthermore, GPR56 promoted TNBC cell proliferation, migration, and invasion by activating glycolysis. Mechanistically, GPR56 regulated the expression of key glycolytic enzymes PKM2 and LDHA. Through literature reports, bioinformatics analysis, and experimental validation, we found that GPR56 activated the PI3K/AKT/mTOR signaling pathway. Consequently, HIF-1α, a downstream target of the PI3K/AKT/mTOR pathway, was upregulated, leading to transcriptional regulation of PKM2 and LDHA, and fostering PKM2 and LDHA-mediated glycolysis, thereby facilitating the malignant progression of TNBC.
Conclusions: GPR56 was overexpressed in TNBC and correlated with poor prognosis. GPR56 promoted the proliferation, migration, and invasion of TNBC cells. Mechanistically, GPR56 activated the PI3K/AKT/mTOR signaling pathway, promoting downstream HIF-1α expression and activating PKM2 and LDHA-mediated glycolysis. GPR56 may serve as a potential prognostic marker and therapeutic target for breast cancer, offering new insights for the precision treatment of breast cancer.

P4-04-01: Disparities in the dissemination of new breast cancer treatments in the United States

Jennifer Caswell-Jin, Marissa Reitsma, Hao Tang, James Dickerson, Shannon Phillips, Allison W. Kurian, Becky Staiger, Jeremy D. Goldhaber-Fiebert

Background: The introduction of novel treatments and treatment approaches for breast cancer has reduced breast cancer mortality and unnecessary toxicity. As care improvements develop, it is crucial to understand whom they reach. We used insurance claims data to analyze the dissemination of four major trends in breast cancer treatment into the population.
Methods: We used SEER-Medicare data to study four changes in the treatment of local and regional breast cancer in patients diagnosed between 2010 and 2018: (1) adjuvant paclitaxel-trastuzumab (APT) for patients with HER2+ local disease, (2) pertuzumab for patients with HER2+ regional disease, (3) increasing use of neoadjuvant chemotherapy for patients with triple-negative or HER2+ regional disease, and (4) decreasing use of adjuvant chemotherapy for patients with hormone receptor-positive, HER2-negative regional disease. Patients who received no systemic therapy were excluded. We used multilevel logistic regression to identify demographic (age, comorbidity, race/ethnicity, rurality, median income of residence census tract [low, middle, high]), tumor (hormone receptor status), and care (NCI vs other academic vs community hospital, breast cancer specialization of treating oncologist) factors associated with receipt of updated care. Breast cancer specialization of a physician was defined by terciles as the proportion of breast cancer patients among their patients in SEER-Medicare with colon, lung, or breast cancer. 95% confidence intervals are shown.

Results: We identified 2,385 patients with localized HER2+ breast cancer; 1,937 patients with regional HER2+ breast cancer; 3,742 patients with regional triple-negative or HER2+ breast cancer; and 14,611 patients with regional hormone receptor-positive, HER2-negative breast cancer. In these respective populations, from 2010 to 2018, use of the APT regimen increased from 31% (24-38%) to 73% (67-78%), pertuzumab from 0% to 70% (65-75%), neoadjuvant chemotherapy from 24% (19-28%) to 61% (57-66%), and adjuvant chemotherapy decreased from 37% (34-39%) to 26% (24-28%). In multivariate analyses, higher median income of residence census tract of the patient and greater specialization level of treating oncologist were significantly associated with receipt of updated care for all four trends in breast cancer treatment. Additionally, greater cancer specialization of hospital type was associated with receipt of updated care for the APT regimen, pertuzumab, and neoadjuvant chemotherapy. We develop a model that, after adjusting for patient and clinical characteristics, estimates the probability of receiving updated care, according to tumor subtype and stage, for a SEER-Medicare patient from a low-income area treated by an oncologist with low breast cancer specialization vs one from a high-income area treated by an oncologist with high specialization: for APT, 40% (37-42%) vs 76% (75-77%), for pertuzumab 28% (25-32%) vs 63% (60-66%), for neoadjuvant chemotherapy 24% (23-26%) vs 56% (54-57%), and for omission of adjuvant chemotherapy 62% (60-63%) vs 72% (71-73%). In this model, specialization alone substantially mitigates the disparity: for example, a patient from a low-income area treated by an oncologist with high specialization has an estimated 63% (59-67%) probability of receiving appropriate APT.
Conclusions: This study reveals disparities in the dissemination of major advances in breast cancer treatment across the SEER-Medicare population from 2010-2018. Patients from lower-income areas, cared for at community hospitals, and treated by oncologists with less breast cancer focus were less likely to receive updated care. These results provide important context for targeting efforts to ensure all eligible patients benefit from the latest advancements in breast cancer care.

P4-04-02: Implementing Decision Aid Use and Shared-Decision Making in Breast Cancer Screening: A Scoping Review

Rama Alkhaldi, Neha Pathak, Victoria Mintsopoulos, Rouhi Fazelzad, Sarina Schrager, Patricia Villain, Noah Ivers, Michelle B. Nadler

Background & Objective: International guidelines vary in recommendations on the starting age for mammography screening for women at average breast cancer risk; however, all note the importance of shared-decision making (SDM) from age 40 and older. Decision Aids (DAs) are evidence-based materials demonstrated to facilitate SDM and improve decisional conflict. The integration of SDM/DA into routine clinical practice is crucial to support patient-informed choice; however, little is known related to the implementation of SDM and/or DA into the clinical setting.
Methods: This scoping review was conducted according to JBI guidelines and reported using PRISMA-ScR. [RF1] Nine bibliographic databases were searched from January 2010 to May

2023 to identify studies using any SDM and/or DA tool or intervention used to implement SDM/DA regarding breast cancer screening. The studies could target either care providers or women at average risk of developing breast cancer and must include at least one implementation outcome (acceptability, adoption, appropriateness, fidelity, feasibility, penetration, sustainability). Studies that focused primarily on the decision-making process were included, whereas those that aimed only to increase breast cancer screening were excluded. Study selection and data extraction were conducted using Covidence with two independent reviewers using the Oxford Implementation Index. We extracted information on study design, intervention details, primary outcome of the study, frameworks used to develop DAs, and all results related to implementation outcomes[MN2] . Each study was coded as efficacy, effectiveness, or implementation. Intervention strategies were coded using Expert Recommendations for Implementing Change (ERIC) and strategies used to change clinical behaviours and support implementation outcomes were coded using Behaviour Change Techniques (BCTs).
Results: The search yielded 10,383 records of which 22 studies met the inclusion criteria, 2 targeting providers, 16, targeting patients, and 4 targeting both. Studies were classified as follows (provider cohort; patient cohort): efficacy studies (0/6, 0%; 8/20, 40%), effectiveness studies (4/6, 67%; 10/20, 50%), and primary implementation studies (1/6, 17%; 1/20, 5[MN3] %). In the provider cohort, acceptability was assessed in 6/6(100%), adoption in 2/6(33%), feasibility in 2/6(33%), appropriateness in 1/6(17%), and sustainability in 1/6(17%). In the patient cohort, acceptability was assessed in 20/20(100%), feasibility in 3/20(15%), appropriateness in 3/20(15%), adoption in 1/20(5%). In both cohorts, acceptability was the most evaluated implementation outcome(100%), while penetration and fidelity were never assessed. DAs demonstrated moderate-to-excellent acceptability, requiring the use of visual aids and plain language to facilitate understanding in patients. BCTs commonly employed to increase SDM/DA included shaping knowledge, natural consequences, and comparison of outcomes. ERIC strategies frequently used included developing and distributing educational materials; there were limited strategies related to increasing uptake amongst clinical providers. Common barriers to SDM/DA use in the provider cohort included time constraints and lack of SDM training.
Conclusions: DAs are effective in assisting with SDM related to breast cancer screening and existing DA's in the literature appear acceptable; however, these tools/techniques can only help if they are used as intended. More primary implementation studies, focused on implementation fidelity, adoption/penetration, and sustainability are required, especially targeting providers, to evaluate and understand the optimal strategies for implementation of SDM and DA in these healthcare settings.

P4-04-03: Establishment of an Inflammatory Breast Cancer Program: A Quality Improvement and Research Effort

Heather LeFebvre, Doreen Agnese, Heidi Basinger, Lynne Brophy, Mathew Cherian, Min-Jeong Cho, Tameka Dillard Oneal, Jacob Eckstein, Julia Garrett, Margaret Gatti-Mays, Noel

Huber, Sachin R. Jhawar, Kai Johnson, Steven Kalister, Amy Kerger, Nadine Myers, Samila Obeng-Gyasi, Jill Osborn, Ko Un Park, Dionisia Quiroga, Lindsey Radcliff, Kimberly Saxton, Roman Skoracki, Eric Young, Daniel G. Stover

INTRODUCTION: Inflammatory breast cancer (IBC) is an aggressive, poor-prognosis subset of breast cancer. Given its rarity and solely clinical criteria for diagnosis, patients with IBC may face delays in diagnosis and appropriate clinical care. IBC patients significantly benefit from a multidisciplinary diagnostic and treatment approach. Therefore, care delivery pathways and concentration at high-volume centers may be advantageous for timely diagnosis and initiation of treatment. Additionally, because IBC is rare, these patients are underrepresented in breast cancer research and clinical trials. We describe the creation of a multidisciplinary IBC Program aimed at expediting intake, standardizing care delivery, improving patient outcomes, and increasing research activities.
METHODS: An ad hoc IBC working group of key stakeholders including representatives from surgical oncology, medical oncology, radiation oncology, plastic surgery, radiology, oncology rehabilitation, nursing, patient experience, scheduling, administration, and patient advocates, was formed. A systematic review of high-volume IBC programs was conducted including meeting with the leadership of these IBC programs and reviewing best practices, guidelines, and research operations. An internal assessment was done through retrospective review studies, including internal scheduling processes, timelines to multimodality treatment, and outcomes.
RESULTS: Evidence-based clinical practice guidelines for IBC patients were developed and institutionally approved. These included the creation of IBC patient-specific order sets for guideline-concordant testing and procedures as well as creating clinic visit note templates. A new patient scheduling decision tree was created to facilitate expedited scheduling of patients with symptoms suspicious of IBC or an IBC diagnosis. A process improvement cycle was established to review access and timely scheduling of new IBC patients. An IBC education module was created and disseminated to providers across the health system. Our website was updated to include the IBC Program and specific details about IBC, and an IBC patient brochure was created and distributed. As part of this effort, a set of program quality metrics that have been shown to impact patient outcomes was established, and a quality assurance dashboard was built. For example, since launching the IBC Program in 2022, 30 new IBC patients have been seen (previously averaged <5 IBC patients per year) and the average time from receipt of referral to new patient appointment was 5 days. To address research gaps, an IBC research working group was established to offer IBC-specific tissue and blood collection for translational studies. Prior to the dedicated research effort (2008-2021), only 18 IBC patients had enrolled in our breast cancer translational research biorepository with one blood sample per patient. Since the implementation of the IBC Program in 2022, we have enrolled 34 IBC patients and collected 106 blood samples to date.
CONCLUSION: Through systematic methods with a multidisciplinary approach, we successfully created and implemented an IBC program at our tertiary-care academic institution. Ongoing efforts involve tracking quality measures, subsequent quality improvement cycles, and expanding IBC-specific research. The program is fulfilling an unmet need of a rare but complex patient population.

P4-04-04: Leveraging Technology to Improve Access to Clinical Trials in Underrepresented Populations within a Safety-Net Institution

Melissa Howell, Dedra L. Preece, David E. Gerber, Jerry D. Henderson, Kalyani Narra

Background: Clinical trials should be accessible to all patients regardless of race, ethnicity and socio-economic status. In the US, Blacks constituted 4-6% and Hispanics 3-6% of participants in cancer therapeutic trials despite representing 15% and 13% of people with cancer. US Food and Drug Administration draft guidance from April 2022 calls for the improvement of clinical trial enrollment of participants from historically excluded racial and ethnic populations. Safety-net healthcare systems like John Peter Smith Health Network (JPS) in Tarrant County, TX, serve predominantly racial ethnic minorities. At JPS, recruitment into oncology therapeutic clinical trials remains pitifully low. Efficiently identifying patients who meet eligibility criteria in an understaffed, busy clinic in the non-academic setting has been a challenge. Referral responsibility lands on overwhelmed providers or outside companies who lack the ability to effectively screen patients. Therefore, we piloted a program leveraging the expertise of our Information Technology business intelligence (IT) team to support our clinical research team to improve recruitment efforts for an oncology trial.
Methods: Collaboration between IT and research teams was established on 5/1/24 with a goal to identify patients for this trial: EMBER-4: A Randomized, Open-Label, Phase 3 Study of Adjuvant Imlunestrant vs Standard Adjuvant Endocrine Therapy in Patients who have Previously Received 2 to 5 years of Adjuvant Endocrine Therapy for ER+, HER2- Early Breast Cancer with an Increased Risk of Recurrence. This study was obtained by JPS via the Cancer Prevention and Research Institute of Texas Clinical Trials Network Award (CPRIT-CTNA) partnership. Using the inclusion and exclusion criteria and applying the Microsoft Structured Query Language (SQL) Service Management Studio software, queries and parameters were developed and run against the Epic Clarity database of patients seen by 15 providers spanning medical oncology, radiation oncology and survivorship clinics, to extract the requested dataset of potentially eligible patients.
Results: IT team identified 123 potential eligible patients (pre-screened) for EMBER-4 research study as of 6/5/24. EMBER-4 was open for accrual at JPS on 6/18/24. A roster of pre-screened patients' next scheduled clinic appointments was also provided by the IT team. Of the 9 pre-screened patients in the first week, 4 qualified for Ember-4, and successfully enrolled two Hispanic patients. 1 of the remining 2 patients is slated to be enrolled into Ember-4 in the third week. Manual screening of all patients in providers' clinics with a high proportion of breast cancer is performed weekly in the first month to validate IT list. Validation efforts have reflected that the current list from the IT collaboration has indeed included all possible patients for EMBER-4 trial. Pre-screening has been completed on 47 of the 123 potential patients thus far. Our efforts have yielded an additional 4 eligible patients for enrollment in the next 6 weeks for a total of 8 patients meeting all eligibility criteria within the first 9 weeks.
Conclusion: These efforts have empowered the clinical research team with statistics regarding diversity among study populations and ability to better track and engage all

appropriate patients for the EMBER-4 study. Leveraging the IT team's expertise to collaborate with clinical research team is a novel method: it has resulted in precision screening capabilities with immediate possibility of increasing enrollment in therapeutic oncology research studies. This method of patient identification can be done in tandem with opening clinical research studies and will be used for future studies at JPS not only in oncology but other specialties as well. We plan to introduce this concept to other CPRIT-CTNA sites.

P4-04-05: Enhancing Clinicians' Knowledge and Competence Regarding the Use of Antibody Drug Conjugates (ADCs) in HER2+ Advanced Breast Cancer: Impact of Continuing Medical Education

Tamima Ashraf, Erika P. Hamilton, Komal Jhaveri, Sarah Donahue, Emily Kitterman; Samantha Hynes, Meghan Coulehan

The emergence of antibody drug conjugates (ADCs) has considerably improved outcomes for patients with HER2+ advanced breast cancer. In light of recent advancements, clinical guidelines have also been updated to reflect how to sequence ADCs in patients progressing on first-line therapy, trastuzumab deruxtecan being the preferred second-line option. As timely treatment sequencing to the next line of therapy is crucial to extend survival in patients who are progressing on current line of therapy, education is needed to improve clinicians' understanding of how to optimally sequence ADCs in practice, balancing their efficacy and safety, in order to improve long-term patient outcomes. In order to bridge knowledge and competence gaps regarding the use of ≥2nd line ADCs in patients with HER2+ advanced breast cancer, we developed a continued medical education (CME) curriculum aimed at improving clinicians' understanding of: how the latest evidence on ≥2nd line ADCs may impact treatment decision-making; what factors to consider to optimize the use of ADCs in practice; and how to mitigate treatment-related side effects.
A CME-certified educational curriculum featuring three 20-minute interactive webinars titled "A HER2-Positive Breast Cancer Proficiency Series: Expert Insights on Evolving Data, Sequencing/Patient Selection, and Adverse Event Management With Antibody-Drug Conjugates", presented by two oncologists and a nurse practitioner, were launched between February 27 to March 14, 2024. Learners could participate in three different ways- 1) attending virtually, 2) watching the replay following the launch of each event, or 3) by watching the enduring (online) highlights following the completion of all three events. Changes in knowledge and competence were measured using pre- and post-test learner analysis. Intent to change practice and potential patient impact were also measured. Data collection is ongoing.
As of June 25, 2024, a total of 784 learners participated in the virtual live setting and 2,752 in the enduring setting, with the leading learner specialties being oncologists (62% in virtual live setting and 44% in enduring setting). A subset of learners (n=65 in virtual live setting and n=460 in enduring setting) completed pre- and post-test assessments. Baseline knowledge was lowest regarding awareness of guideline-recommended sequencing and

safety considerations. Post-education, learners demonstrated a positive change in knowledge/competence related to: clinical profiles of ADCs in ≥2nd line for HER2+ advanced breast cancer (37% in virtual live setting and 41% in enduring setting); optimal sequencing of ADCs (38% in virtual live setting and 32% in enduring setting); and management strategies for common treatment-related side effects (15% in virtual live setting and 42% in enduring setting). Of the learners, about 80% intended to make changes to their practice based on the activity. Based on learners' self-report of the number of patients seen per week, this program potentially impacted 25,437 patient interactions. More than half of the learners also expressed interest in receiving further education related to guideline/evidence updates on ADCs in patients with HER2+ advanced breast cancer. Our interim findings showed that i) CME was effective in improving knowledge and competence among clinicians related to the use of ADCs in ≥2nd line for HER2+ advanced breast cancer and ii) an ongoing need/interest among clinicians to learn more about this topic.

P4-04-06: Connecting Care: Telemedicine Breaks Barriers for Low-Income Brazilians Battling Breast Cancer

Gabriel D'Alessandro, Yedda Nunes Reis, Mila Trementosa Garcia, Daniela Zaros Guimarães, Roberta Amparado Miziara, Flavia Consolmagno Silveira, Mayara De Cassia Benedito Andrade, Emily Rie Yoshizato, Jonathan Yugo Maesaka

Introduction: Telemedicine stands out as a potential tool to promote equity in healthcare, particularly in low-income communities. By facilitating remote access to health professionals, it might help to overcome economic and geographic hurdles, increasing disadvantaged populations' access to medical care. This approach significantly contributes to a more inclusive, fair, and accessible healthcare system. The impact of implementing a protocol for remote consultations in a socially vulnerable population with breast cancer is particularly relevant, as patients require multiple hospital visits throughout their long treatment journey.
Objective: Evaluate, through the implementation of a protocol for remote consultations, the impact on equity in healthcare access for a low-income population with breast cancer.
Method: This is a prospective cohort study designed to evaluate patients' satisfaction with telemedicine consultation, in a tertiary public cancer center in Brazil. Due to the socioeconomic characteristics and the limited access to high end technology and digital literacy of the study population, all teleconsultations were conducted over the telephone. Sociodemographic data and information regarding patients' transportation to the hospital were collected. Also, a validated Likert-based questionnaire was applied to all participants to assess the quality of care provided. The study was approved by the local ethics committee (CAAE no. 68518523.0.0000.0071), and all participants signed an informed consent form.
Results: Our population consisted of 93 women, with a mean age of 57.3 years, the majority being white (51.6%) and married (35.5%). Over a third of the population (34.3%) did not

complete elementary school and 6.5% had no formal education. Regarding family income and work life, 64.4% had earnings of up to 2 Brazilian minimum wages (620.00 USD), while 25.8% were unemployed. Among those currently employed, 35% did not miss a day of work due to the remote consultations. Almost the entire population had some access to technological resources: 93.5% had internet access, 90.3% owned a mobile phone, and 51.6% had an email address. Regarding transportation to the hospital, 55.8% of individuals used public transportation. On average, approximately US$4 was spent per hospital visit, with expenses potentially exceeding US$20 (3.2%). This amount represents more than 3% of the average family income (2 minimum wages). The approximate travel time to the hospital was 60 to 90 minutes for 19.4% of patients, potentially exceeding 2 hours for 8.6%. As observed, the average distance to the hospital was 12.8 km, with a maximum of 39 km. We had 94 responses from the Likert-based questionnaire from 117 teleconsultations (some patients had more than one consultation, and they could answer a new questionnaire at every teleconsultation), with an average score of 4.65 (maximum of 5). The average Net Promoter Score (NPS) for telephone consultations was 79.8, within the range of excellence (75 to 100).
Conclusion: The implemented remote care protocol appears to be a useful tool, yielding a high level of patient satisfaction. This study also addresses the financial burden of vulnerable patients during its journey to treat breast cancer in Brazil. Therefore, adopting an appropriate remote care protocol is particularly valuable during the challenging journey faced by low-income patients with limited technology literacy who have been diagnosed with breast cancer.

P4-04-07: Harnessing Cognitive Engineering to Understand Breast Cancer Patient Decision Making

Megan Salwei, Barbara Voigtman, Janelle Faiman, Carrie Reale, Shilo Anders, Matthew Weinger

Introduction: As the number of available treatment options for breast cancer increases, decision-making for patients has become complex. Patients often struggle to make decisions as treatment options can vary in terms of short- and long-term side effects, risks of recurrence, and impact on daily life.1 Numerous decision aids have been developed to support patient decision-making.2 However, sustained implementation and use of these tools remains limited. We propose that cognitive engineering approaches, such as naturalistic decision making (NDM), can provide a deeper understanding of how patients make treatment decisions, which can improve the design of decision support tools. Naturalistic decision making (NDM) is a theoretical perspective and methodological approach used to understand how people make decisions in the real world. Originally developed to understand decision-making of expert firefighters during crises, NDM approaches have been used to understand complex decision-making across domains including the military, offshore oil rigs, and healthcare.3,4 In this study, we used an NDM approach, the critical decision method (CDM), to gain an in-depth understanding of how

breast cancer patients make treatment decisions following diagnosis.

Methods: We conducted CDM interviews,5 with breast cancer patients diagnosis in the last 12 years. CDM interviews aim to understand critical or difficult events by unpacking the event using structured probes. One researcher conducted each interview over Zoom. We started each interview by asking the patient to reflect back on the beginning of their cancer journey and what they remember about their diagnosis. We then drew a timeline and asked the patient to relay the different treatments they considered or underwent for breast cancer. We then asked "Can you think of a time during your breast cancer journey when you had to make a difficult decision?" and probed patients about that decision. We continued asking patients about their treatment decision-making as time allowed. Each interview was audio-recorded and transcribed. A researcher and a patient advocate coded each interview and created a decision requirements table,6 which detailed the decisions made by the patient, what made that decision challenging, what strategies and information they used, and what their goals were at the time. We then met to discuss and come to consensus. Once a decision requirements table was created for each transcript, we developed aggregate tables and identified key themes.

Results: We conducted 20 interviews, averaging 57 minutes each; patient age ranged from 42 to 81 years. Patients described an average of 8 decisions that they made following breast cancer diagnosis. Despite many patients facing the same decisions (e.g., mastectomy vs. lumpectomy), we found variability in which decisions were most difficult for patients. We identified 11 categories of difficult decisions for patients including whether to receive chemotherapy, getting genetic testing, stopping a medication due to side effects, and deciding where to receive treatment. Patients reported feeling time pressure and urgency to make treatment decisions and a fear of regretting their decisions. We found that patients' firsthand experiences from friends who had cancer influenced their treatment decision-making. Given the heterogeneous nature of breast cancer treatment, this often presented a barrier to decision-making as patients expected to have the same experience and treatment options as their friends. Patients expressed variable goals when making treatment decisions, which often changed throughout their treatment journey.

Conclusion: In this study, we explored how breast cancer patients made treatment decisions using NDM methods. This cognitive engineering approach revealed intricacies in the decision-making process of patients that will be valueable for improving the design of decision support tools. Next steps include collaborative design with patients to develop a tool that supports the broad spectrum of treatment decisions made across the patient journey.

P4-04-08: Delays from Self-Detection to Treatment of Breast Cancer in the South Fluminense Region: A Cross-Sectional Analysis

Heloisa Resende, Leandro Ladislau, Vinícius de Queiroz Aguiar, Nataline Freitas de Azevedo Santos, Rafael Angelo Pinto de Souza, Filippe Rocha Mello, Frederico da Rocha Mello, Caio Miranda Oliveira, André Mattar

Background: Long waiting times (WTs) to begin treatment after breast cancer (BC) diagnosis have been reported in the Brazilian public health system. However, there is a paucity of data regarding strategies that encompass women that look for primary care units due to self- perceived breast abnormalities up to the point of diagnosis. We have conducted a cross-sectional study to describe WTs from self-perception breast abnormalities to diagnosis and from diagnosis to the initiation of cancer treatment in the South-Fluminense region.
Methods: A retrospective study was conducted by assessing medical reports of all BC patients registered at a High Complexity Oncology Assistance Unit (Unidade de Alta Complexidade em Oncologia, UNACON) from October 2021 to September 2023. Sociodemographic, clinicopathological, and WTs data were collected. WTs were subdivided into categories: 1) Waiting time (WT) from self-perception of breast abnormalities to the first imaging test (WT1); 2) WT from imaging test to core biopsy (WT2); 3) WT from biopsy collection to report release (WT3); 4) WT from biopsy report release to the first medical visit at UNACON (WT4); 5) WT from the first medical visit to the first treatment (WT5); 6) WT from the first imaging test to the first treatment (WT6); and 7) WT from breast biopsy report release to the first breast cancer treatment (WT7). The inclusion criteria required that WT data be recorded. All analyses were conducted using Python version 3.9 and p-values were adopted at 5% level of significance in all tests. The study was approved by Institutional Review Board, Coeps of Fundação Oswaldo Aranha CAAE 79726824.1.0000.5237.
Results: A total of 322 cases were registered at UNACON, with 300 meeting the inclusion criteria. The median age was 59.0 years (95% CI 57.49- 60.51). Among patients, 143 (47.66%) were married, 163 (54.34%) were non-white and 117 (39.00%) were employed. In terms of educational level, 106 patients (35.33%) had an elementary school education, 100 (33.33%) had a high school education, and 28 (9.33%) had a university degree.
The clinical stage at the diagnosis were 20 patients (6.67%) at stage 0 (in situ), 63 (21%) were at stage I, 117 (39%) were at stage II, 75 (25%) were at stage III, and 13 (4.33%) were at stage IV.
The following WTs (median) have been found: WT1 was 59.0 days, (CI 95% 42.0 to 65.0); WT2 was 59.0 days (CI 95% 50.0 - 68.0); WT3 was 13.0 days (CI 95% 12.0 - 14.0); WT4 was 29.0 days (CI 95% 27.0 - 30.0); WT5 was 65 days (CI 95% 58.0 -71.0); WT6 was 185.0 days (CI 95% 174.0 - 202.0) and WT7 was 99.0 days (CI 95% 92.0 - 108.0).
We observed a difference in WT1 between white patients 50 days versus non-white patients 60 days (p=0.04). Additionally, we observed in WT6 a difference of having a high school education 169 days compared to 225 days for those with only an elementary school education (p=0.01).

Conclusion: Timely diagnosis in BC is a critical goal to be reached for public health in Brazilian population. Brazilian law established a 60-day interval to begin treatment after diagnosis, however this interval has been frequently longer, as we demonstrated in our results. Additionally, the WT from self-perception abnormalities to diagnosis is excessively long, meaning that focusing solely on the WT after diagnosis provides an unrealistic view of the overall timeline. Variables such as race and educational level may further exacerbate disparities within the system.
By characterizing delays in diagnosis procedures and treatment beginning in the region, our data highlight weak points in the public health system. To recognize and plan a symptomatic woman directed strategy aligned with offering diagnosis procedures at an only one unit care might short WTs promoting timely diagnosis and treatment for BC. These insights can help local government managers to redirect actions to improve oncological care.

P4-04-09: Supporting the Knowledge Translation of Exercise Recommendations for People with Bone Metastases using Experience-based Co-Design

Diego Malon Gimenez, Kelcey A. Bland, Sarah E. Neil-Sztramko, David M. Langelier, Kirstin N. Lane, Alana Chalmers, Rhoda Dinardo, Nicole Prestley, Sarah Weller, Shabbir Alibhai, Lauren Capozzi, Janet Papadakos, Karen McDonald, Jane Copp, Margaret McNeely, Leah Lambert, Christine Simmons, Alan Bates, Kristin L. Campbell, Michelle B. Nadler

Background: Historically, people with bone metastases have been advised to limit exercise due to the risk of adverse events, such as fractures. In 2022, the International Bone Metastases Exercise Working Group published evidence-informed recommendations indicating that regular exercise can enhance physical function and quality of life in these patients, and the risk of skeletal events should be weighed against potential health benefits. Barriers remain to the adoption of these recommendations into clinical practice, including lack of knowledge about how to exercise safely and uncertainty where to find guidance for exercise advice. This project aims to collaborate with knowledge users (KUs) through an experience-based co-design (EBCD) process to develop knowledge translation (KT) products and a dissemination plan to facilitate the uptake of exercise recommendations for people with bone metastases.
Methods: Three KU groups were engaged using EBCD: 1) patient/family partners; 2) oncology healthcare providers (physicians, nurses, allied health professionals); and 3) community-based exercise professionals (physiotherapists, exercise physiologists). Through facilitated meetings, ideas for KT products were generated, prioritized, and co-created, and a dissemination and evaluation plan was developed. A survey of exercise professionals was used to collect further information on professional development (PD) preferences.
Results: Twenty-nine KUs participated in four engagement sessions (n = 10 patient/family partners, n = 9 healthcare providers, and n = 10 exercise professionals). The prioritized KT

products for development were: 1) a patient education handout; 2) patient education videos; 3) a health information form (HIF); and 4) professional development (PD) materials for exercise professionals and healthcare providers. The HIF was designed to easily collect pertinent health and oncology-related patient information that would be necessary for an exercise professional when developing exercise prescription/recommendations. A total of 183 international exercise professionals completed the PD survey, with 80% indicating that more PD resources were needed for bone metastases, focusing on exercise safety, feasibility, and prescription considerations. Over 80% of respondents found the purpose of the HIF form was easy to understand and over 75% rated the content as excellent or very good. Our dissemination and evaluation plan included a combination of targeted social media, direct connections with key organizations, presentations, and promotion through the Canadian Cancer Society and its channels. All these products are hosted on the Bone Metastases & Exercise (BMD) Hub (bit.ly/BMEhub). In the first 30 days post-launch, the BME Hub had 5,243 views from 2,407 unique users. Full engagement results will be available at the time of conference.
Discussion & Conclusion: Collaborating with KUs through EBCD has enabled the development of diverse KT products that are more likely to be useful and acceptable to the intended audience than those designed by researchers alone. Thus far, use of the Hub has been promising; further evaluation of reach, usage, and partnership indicators of the KT products and dissemination plan will be evaluated.

P4-04-10: Improving early breast cancer care coordination - Digital care pathway: Implementation and Pivotal Results

Sónia Oliveira, Leonor Fernandes, Diana Simão, Carlos Vitorino, Susana Nunes, Clara Sampaio, Joana Raposo, Helena Xavier, Sara Pires, Clara Jasmins, Ana Andrade, Manuela Martins

Introduction: Care coordination has no consensus definition. A systematic review (McDonald KM.) purposed a broad definition: "Care coordination is the deliberate organization of patient care activities between two or more participants (including the patient) involved in a patient's care to facilitate the appropriate delivery of health care services. Organizing care involves the marshalling of personnel and other resources needed to carry out all required patient care activities and is often managed by the exchange of information among participants responsible for different aspects of care." In 2007, Vanhaecht et al. defined the term ‘care pathway’ or ‘pathway’ as follows as “A care pathway is a complex intervention for the mutual decision-making and organisation of care processes for a well-defined group of patients during a well-defined period. The aim of a care pathway is to enhance the quality of care across the continuum by improving risk-adjusted patient outcomes, promoting patient safety, increasing patient satisfaction, and optimizing the use of resources.”
Methods: In 2023 a non-fixed time but phase-oriented Early Breast Cancer Care Pathway was developed in the Breast Cancer Clinic of a University Hospital. In the first phase,

interviews with breast cancer experts (medical oncologist, breast cancer surgeons, nurses, pathologist) were performed. The model was developed and the experts were requested to validate the pathway. The second phase, was testing the developed model and characterized patients (pts) included prospectively in the first 6 months, 26thOct 2023 to 30th April 2024. Time to treatment initiation (TTI) was defined as days (d) from diagnosis (using the most recent tumor board as a surrogate for diagnosis) to first treatment (surgery or systemic therapy).
Results: During 2023, using UpHill's® software it was possible to provide seamless patient journeys with automation and patient communication. Professionals can access a shared history of all actions executed for each patient as well as the expected next steps permitting a fast recognition of patient current status and forecast future needs. Go live was 26th October 2023. Here we report the first 6 months experience. The digital pathway permits real time data collection in an automatic way. 593 pts entered the pathway with a breast cancer sign/symptom warranting further investigation, of these 162 were discussed at least once in a tumor board. In 62 pts a surgery was performed and 27 pts started treatment at the Oncology Day Care Unit. In predefined key points UpHill's® software interprets the information sent by pts to automate decisions (post-surgery and post medical oncology day care session). Median TTI was 32d, 14d and 34d for medical treatment and surgery, respectively. There were 88 automatic generated interactions that resulted in 62 pts responses (70,5% response rate, rr); post-surgery 55 automatic generated interactions that resulted in 35 responses (63,6% rr); post medical oncology day care session 16 automatic generated interactions that resulted in 14 responses (87,5% rr).
Conclusion: There is the need to ensure Health systems to simplify access and reduce operational barriers to initiating treatment. Studies of interventions to simplify access, ease navigation and reduce barriers are warranted to diminish the potential harm to pts. Real time automatic data collection has the advantage to provide high quality data with minimal human effort. Automate actions eliminates repetitive tasks permitting focus on actions that truly depend on human reasoning. Clinical pathways are one of the main methodologies to organize and coordinate care processes but the methodology needs to be further improved. It is a complex intervention and our model needs to be developed and continuously followed up.

P4-04-11: Managing Wait Time Between Surgery and Treatment Initiation Plan in Patients with Breast Cancer: a Mixed-method Approach

Wissam Saliba, Enam Alsrayheen, Yoana Fuentes, Francesco Dellorusso

Oncotype DX test (ODX) is a genomic testing that is considered a standard of care requirement for a subset of breast cancer (BC) patients, meeting specific histopathological criteria, facilitating informed decisions regarding their personalized systemic treatment. However, the conventional process for ordering this test often delays the initiation of systemic therapy, as it was only ordered after the first Medical Oncology Consultation. This study evaluates a novel initiative implemented at a medium-sized cancer center providing

care for rural and underserved communities in Nova Scotia-Canada. The initiative aimed at minimizing the time interval between surgery and treatment onset, through a phone call by the Medical Oncologist (MO) directly engaging the patient, explaining the test and treatment options, securing their consent for immediate ordering. Employing a mixed-method design, this study assessed wait times at various intervals along the patient's journey from surgery to treatment initiation. Qualitatively, semi-structured phone interviews were conducted with purposefully selected 11 breast cancer patients to explore their experiences and satisfaction with the MO's communication regarding the ODX test, focusing on achieving patient-centred care and alleviating distress during the waiting period.
Results reveal that 180 breast cancer patients underwent ODX testing between July 2018 and July 2022, 55% via the standard pathway and 45% through the new intervention. Median wait time from surgery to ODX result availability decreased significantly from 60 [IQR: 49-70] to 46 [IQR: 31-91] days (p-value < 0.001). While the median wait time from MO referral to chemotherapy onset decreased from 50 [IQR: 40-82] to 43 [IQR: 40-63] days, it was not statistically significant (p-value = 0.5). However, there was a notable two-week reduction in median wait time from referral to radiation therapy initiation (p-value = 0.09). Importantly, the median wait time from the initial consultation with the MO to the chemotherapy consent date decreased from 24 to 0 days (p-value < 0.001), indicating immediate consent for chemotherapy treatment during the first consultation. Qualitative findings underscored patient satisfaction with the new intervention, particularly appreciating the clear and mindful information provided by the MO, even through remote discussion. In conclusion, this intervention effectively reduced the interval between surgery and ODX results, facilitating expedited treatment initiation and enabling informed decision-making at the time of the initial consultation. Using plain language during remote discussions further enhanced patient satisfaction and understanding of treatment options, emphasizing the significance of effective communication in patient care. Using this intervention can also enhance ODX utilization in rural communities.

P4-04-12: Covid 19 pandemic: effects on the diagnosis and treatment of breast cancer in two large teaching hospitals in the city of São Paulo - Brazil

Marcia Silva, Vanessa Monterio Sanvido, Vinicius Aquino Correa, Tayre Arataque, GrasileaA Benini Santos, Gil Facina, Afonso Celso Pinto Nazario

Objective: To evaluate the impact of the COVID 19 pandemic on the diagnosis and treatment of breast cancer in São Paulo - Brazil. Methods: Observational, analytical, cross-sectional, retrospective study, in which patients treated at the Mastology Outpatient Clinic of the Escola Paulista e Medicina - Universidade Federal de São Paulo (EPM-UNIFESP) and the Mastology Outpatient Clinic of Hospital Santa Marcelina Itaquera with diagnosis of breast carcinoma, from March to December 2019 and from March to December 2020. Results: In this study, information from 361 patients was considered. time from diagnosis to the start of radiotherapy () and endocrine therapy (p=0.019) between the two periods. In the pre-

pandemic period, a higher percentage of patients with tumors smaller than 2 cm (T1) was observed (30.2% versus 19.1%; p=0.019); on the other hand, during the Covid 19 pandemic period, there were higher percentages of patients with tumors larger than 5 cm (T3) (17.7% versus 8.7%; p=0.019). The presence of massively compromised axillary lymph nodes (N2) was greater during the pandemic period (8.0% versus 14.3%; p = 0.288). Reconstructive surgeries were less common during the pandemic. Endocrinotherapy was more indicated in the pre-pandemic period (60.2.6% versus 32.0%; p<0.001), as well as radiotherapy in the conventional form (56.0% versus 29.0%; (p <0.001) as in hypofractionated (13.0% versus 3.2%; (p<0.001). Neoadjuvant chemotherapy was more frequent during the Covid 19 period, that is 38.3% versus 25.7% (p< 0.038). The time between diagnosis and the start of treatment in the pre-pandemic period was 139.8 ± 109.2 days, with a median of 94 days (23.0 - 596.0 days) and in the pandemic, 162.7 ± 112.5 days and the median was 165.0 days (16.0 - 544.00 days); with a median of 388.0 days and during the pandemic, 249.5 days, with a median of 274.0 days (p<0.001). In relation to the start of chemotherapy, an average of 378.2 days was observed. pre-pandemic period and 327.5 days during the pandemic, with medians of 373.0 days and 311.5 days, respectively. In relation to the start of endocrine therapy, we found an average of 239.9 days and 182.0 days. median 160.3 and 113.0 days, respectively when comparing the pre-pandemic and during the pandemic periods. Conclusions: The Covid 19 pandemic had an impact on the diagnosis of breast cancer, a fact evidenced when we observed the highest rate of clinically advanced tumors and clinically positive axillary lymph nodes, causing a direct influence on the prognosis and treatment of patients. At the same time, due to the possible occupancy of hospital beds, it influenced therapeutic options, such as a reduction in surgeries using oncoplastic techniques and neoadjuvant chemotherapy, but allowed for a shorter time interval between diagnosis and the start of radiotherapy and adjuvant endocrine therapy. or neoadjuvant, the latter being a new therapeutic possibility

P4-04-13: Single-center Relative and Cause-Specific Survival in Breast Cancer

Patrick Neven, Annouschka Laenen, Geert Silversmit, Nancy Van Damme, Hava Izci, Christine Desmedt, Chantal Remmerie, Anne Deblander, Sileny Han, Maxime Van Houdt, Ann Smeets, Ines Nevelsteen, Caroline Weltens, Hilde Janssen, Adinda Baten, Jelle Verhoeven, Yannick Van Herck, Françoise Derouane, Giuseppe Floris, Chantal Van Ongeval, Renate Prevos, Helen De Boodt, Machteld Keupers, Valerie Celis, Hans Wildiers

Background: In cancer, cause-specific survival (CSS) and relative survival (RS) aim to quantify net survival but both estimates differ due to differences present in both methodologies. CSS may be miscalculated if cause of death is misinterpreted while RS requires accurate life tables for the background population. Such differences in survival outcome might be important when data are used to allocate health care decisions. We compared RS to CCS in breast cancer patients recently treated with contemporary therapies in our center.

Methods: We included consecutive patients, all stages, all tumor types, with an unilateral invasive breast cancer diagnosis, assigned to UZ Leuven on the basis of main treatment during the period 2014-2018. Local and systemic therapies were given according to institutional guidelines. Using medical files, we verified the vital status until March 1st, 2022; if a patient died, the cause of death was verified. We used unadjusted data as 'case mix' adjustment is not needed when considering single-center outcome results. The 5 year unadjusted RS was calculated as the overall observed survival for patients with a given cancer diagnosis divided by the expected survival of a similar group of patients from the general population using the Ederer II method. The cumulative incidence function was used for estimating the unadjusted 5 year BCSS. Analyses have been performed using SAS software (version 9.4 of the SAS system for Windows).
Results: For the period 2014-2018, 2326 patients (median (IQR) age 59yr (50-70)) were included in the analysis. At diagnosis, 6.4% were metastatic and 46.4% had a very early pathologic stage; 3.6% (y)p 0 and 42.8% (y)p IA-B. 89.8% were operated, 73.7% primary and 16.1 after neo-adjuvant therapy; 27% and 82.8% received adjuvant chemo- and radiotherapy respectively. Cause of death was unknown in 10 patients. On March 2022, 7.7% died of breast cancer and 87.4% were alive. The 5-yr unadjusted breast CSS was 92.7% (95% CI: [91.5, 93.7%]) and the 5-yr unadjusted RS was 95.4% (95% CI: [93.8,96.8%]). This concludes in our series a 58% lower breast cancer mortality using the 5-yr RS (4.6%) as compared to the 5-yr BCSS (7.3%) based on medical files.
Conclusion: Using different approaches to estimate the 5 year net survival in our series confirmed a difference between RS and BCSS. We confirm that cancers like breast cancer with available early screening policies and a high survival have better RS than CSS.

P4-04-14: Economic analysis of germline genetic testing to assess for hereditary breast cancer: a systematic review

Heather Johnson, Deborah Hartzfeld, Mary Linton Peters, Jade Xiao, Bhakti Mody, Carol Kirshner, Feyza Sancar, Brandie Heald, Joyce Kong, Jecinta Scott, Gebra Cuyún Carter

Introduction: Germline genetic testing (GGT) is included in clinical guidelines and has steadily increased in use to inform treatment decisions for breast cancer patients and those with genetic predisposition. The expanding implementation has magnified the influence of GGT on the economics of breast cancer care worldwide. The objective of this systematic review was to evaluate the economic impact of GGT among adults diagnosed with breast cancer, those at increased risk of breast cancer, and in the general population.
Methods: This analysis was part of a broader study following PRISMA methodology. PubMed-Medline and Embase were searched for manuscripts published after January 2013 that reported the clinical, economic, and humanistic outcomes of GGT in patients with breast cancer and those at risk of breast cancer. The present analysis summarizes a subset of articles specifically addressing the economic value of GGT.
Results: The initial search, inclusive of all outcomes, identified 10,198 studies. Of the 231 articles extracted for data analysis, 30 studies evaluated economic outcomes. Twenty-four

of these were cost-effectiveness analyses related to testing for hereditary breast cancer; the remaining six studies were cost comparison analyses or budget impact models. Of the 24 cost-effectiveness studies, five were multinational and evaluated the cost-effectiveness of GGT in 12 countries (US, UK, Germany, Canada, Norway, Netherlands, Spain, Israel, India, Brazil, China, and Malaysia). The US (n=10) and the UK (n=7) were studied most frequently; however, there was notable heterogeneity derived from different international healthcare systems and varying patient populations. The studies modeled the effect of testing patients diagnosed with breast cancer (n=7) or breast/ovarian cancer (n=1), testing individuals with an increased risk of breast cancer (n=6), and population-specific genetic screening (n=10). Both single-syndrome (BRCA1/2; n=17) and multigene testing strategies (n=7) were investigated. Thirteen studies employed a Markov model. Close to half of the studies (n=11/24) considered cascade testing, and almost all (n=22/24) considered risk-reducing surgery (breast and/or ovarian). All studies were analyzed from a payer perspective; six used both payer and societal perspectives. Studies evaluated cost-effectiveness against various willingness-to-pay (WTP) thresholds. Each study found at least one cost-effective strategy for all countries and perspectives. Four studies presented GGT strategies that were cost-saving.
Conclusions: This analysis presents the economic impact of GGT for hereditary breast cancer syndromes with global representation and a range of testing strategies. In all settings, the analyses found GGT to be cost-effective, supporting the positive economic impact of GGT for hereditary breast cancer. Opportunities for further exploration include the added value of cascade testing and use of multigene panels, as well as the evaluation of economic impact from the patient perspective.

P4-04-15: Oncofertility and Breast Cancer: An Analysis of Perception and Practices Among Specialists

Erika Bushatsky, Andressa Candido, Maria Eduarda Scheidt, Hector Gramulia, Cicilia Rodrigues, Renata Meneguetti

Introduction: Worldwide, breast cancer is considered the most common cancer among women, with advanced treatments improving survival chances. In this context, the importance of preserving fertility stands out, seen as an influencing aspect in the post-treatment quality of life for patients in reproductive age. This study aims to understand the perception of specialist doctors about oncofertility, addressing the barriers for its implementation and identifying areas for improvement. Methodology: This was an observational study, wich used an electronic questionnaire developed from literature review. The questionnaire was distributed to oncologists and breast specialists active in Brazil, through online platforms, aiming to evaluate knowledge about oncofertility, current practices, and barriers faced in preserving the fertility of breast cancer patients.
Results: The questionnaire on oncofertility was answered by 276 Brazilian doctors, with a majority of 67.4% women and 63.3% doctors under 40 years old. The majority of them (78.6%) were specialists, with 70.7% of clinical oncologists, and 33.7% of doctors working

in the oncology area for more than 10 years. Most doctors worked in the Southeast region (70.7%) and 52.9% worked in both public and private oncology centers. The patient's gestational desire was the main incentive to discuss fertility (43.8%). Regarding knowledge in oncofertility, 77.9% of doctors felt well informed about the subject, with specialists (81.6%) outnumbering residents (64.4%) in this aspect. Around 68.7% of the specialists stated that they usually consulted international guidelines related to the topic. Regarding fertility preservation practices, such as ovarian suppression with GnRHa and cryopreservation, 72.4% of specialists stated that they had knowledge on the subject, and 82.6% considered cryopreservation as the most effective method. In their practice, 77.9% of the interviewees reported addressing oncofertility, a fact that was more common among specialists (83.4%) compared to residents (57.6%). Among those who did not address it, 61 participants, the main barrier was the lack of access to fertilization techniques in public health (80.3%). The majority of specialists (86.6%) were not resistant to procedures that delay chemotherapy, and 98.9% denied personal barriers against fertility preservation. The cost of fertility preservation practices was considered high by 62.0% of the doctors, especially among residents (74.6%) versus specialists (58.5%). The structural distance from fertilization centers was considered a barrier for 24.3% of doctors. Regarding recommendations for young patients with gestational desire, 63.0% suggested ovarian suppression and/or cryopreservation as a possible modality of fertility preservation. Controlled ovarian stimulation was considered safe for all patients by 56.2% of the experts. Regarding the use of ovarian suppression with GnRH during chemotherapy, 70% of specialists described its use in practice. The majority of professionals (69.2%) did not consider pregnancy after cancer as a factor that increases the risk of recurrence, while 68.5% judged as safe the temporary interruption of endocrine treatment. Furthermore, 84.4% considered assisted reproduction techniques as safe options as well. Significant differences about the perception of pregnancy after cancer could be seen between residents and specialists. Among the experts, breast specialists and oncologists diverged in the safety of ovarian stimulation and in the indication for ovarian suppression. Opinions varied minimally by region of activity, highlighting the uniformity in the general view about treating oncofertility. Discussion: The results indicate a growing awareness about the importance of oncofertility, although there are significant challenges related to access and professional education. The majority of the interviewees showed knowledge about oncofertility, but there was a significant difference in knowledge between specialists and residents, indicating the need to integrate this topic into medical training curricula. Cryopreservation was considered the most effective method of fertility preservation, but challenges in its applicability include the structural distance from specialized fertilization centers and the lack of knowledge about current available techniques, especially in less developed regions. Although most professionals were willing to discuss fertility preservation strategies in their clinical practices, there were significant barriers, such as cost and the lack of adequate infrastructure. The study also highlights the importance of patients' gestational desire as a motivating factor for addressing fertility during oncological treatment. The research reveals the need to improve communication about fertility risks and available preservation options, in addition to addressing challenges related to cost and

access to knowledge in oncofertility, suggesting that targeted educational strategies are necessary to promote informed and uniform practices. Conclusion This study highlights the importance of oncofertility in clinical practice for young patients with breast cancer, identifying significant barriers that need to be overcome in an underdeveloped country. Greater emphasis on physician education and improved access to fertility preservation techniques is recommended.

P4-04-17: TFX06 shows remarkable safety and extracranial and intracranial efficacy in patients with ER+ /HER2- breast cancer in a phase 1 study

Charles Ding, Jian Zhang, Wenxing Qin, Yang Chen, Zhiye Zhang, Yuping Sun, Hongqiang Guo, Yehui Shi, Zhaojian Fu, Jia Song, Douglas D. Fang, Wei Sha

Background: TFX06, a third-generation oral CERAN/SERD, demonstrated favorable safety and PK profile, as well as encouraging antitumor activities both extracranially and intracranially in patients with ER+/HER2- breast cancer (Fu Z, et al., 2023 SABCS annual meeting). A multicenter Phase 1a/b study (CTR20230789) is currently recruiting in China to further evaluate PK, safety and efficacy in previously treated patients with ER+/HER2- locally advanced and/or metastatic breast cancer.
Patients and Methods:
TFX06 tablets were orally administered once daily (QD) at 60/100/150/200 mg in dose escalation cohorts and recommended dose for expansion (150mg, QD) was used in dose expansion study every 28 days of treatment cycle until disease progression or intolerable toxicity. As of the cutoff date, this Phase 1 study enrolled 24 patients at median age of 60 years (range 34-74) with a ECOG score of 0-1. Eleven out of 24 patients (45.8%) carried estrogen receptor 1 (ESR1) mutations (ctDNA). 77% of patients enrolled had visceral metastasis diseases in liver, lung or both, and 11% of patients had brain metastasis. Median number of prior endocrine therapies were 2 (1-4) including fulvestrant (33.3%), CDK4/6i (54.1%) and combination of both (29.1%) and a median number of chemotherapies was 2 (0-3). Tumor assessments by investigator according to RECIST v1.1 were performed every eight weeks.
Results: All 24 patients in this study completed dose-limiting toxicity (DLT) observation period, and no DLT was observed. TFX06 was well tolerated. Treatment-related AEs experienced in >10% of patients were hypertriglyceridemia (25.6%), anemia (20.1%), AST elevation (20.1%), blood lactate dehydrogenase increase (16.3%), and ALT increase (14.0%), all of which were Grade 1/2. Photopsia and gastrointestinal toxicities seen in other SERD studies were not observed in this study across all dose cohorts. Out of 24 response evaluable patients, 4 confirmed partial responses and ORR was 16.7%, CBR was 42%. Of three patients with brain metastases showed reduction of brain metastases greater than 70% and one of the three had disease progression with PFS of 9 months. The other two are still in treatment with their PFS at least 8 months. Exposure data (Cmax and AUC) of TFX06

in patients showed a linear relationship with doses.
Conclusions: Based on the preliminary results, 150 mg QD dose expansions are ongoing. TFX06 demonstrated rather favorable safety profile and compelling antitumor activity for those extensively treated patients. Durable intracranial antitumor activities were also observed in all 3 patients enrolled with brain metastasis.

P4-04-18: AI based Thermalytix for management of Breast Pain in Primary Care

Siva Teja Kakileti, Geetha Manjunath

Introduction: Breast pain is the most common breast complaint presented to general practitioners (GPs) and the leading cause of referrals to breast units. Although the correlation between breast pain and breast cancer is low, the high volume of these referrals often results in over-investigation, potentially delaying the diagnosis and treatment of women with actual breast cancer. Thermalytix is an artificial intelligence-based breast imaging tool that uses advanced machine learning over high resolution thermal scans to generate a breast cancer risk score (B-Score). In this study, we assess whether Thermalytix can be utilized to effectively manage patients presenting with breast pain, thereby reducing subjectivity in referrals to upstream diagnostic pathways.
Methodology: This is a post-hoc analysis of data from prior clinical studies of Thermalytix, involving a total of 1187 women. The reference standard was the final diagnosis obtained from the available reports of mammography, ultrasound, and biopsy. Exclusion criteria included women below 18 years of age, women with a history of breast cancer, and those pregnant or lactating. For this analysis, women presenting with breast pain alone as a complaint was used as inclusion criterion. The performance of Thermalytix was evaluated within this subset of the population using B-Score for triaging. Further, we estimated the optimal criterion for vascular score (an output generated by Thermalytix to characterize the vascular asymmetry in the breasts) for improving B-score computation of Thermalytix using a receiver operating characteristic curve.
Results: Of the 1187 women, 157 (13.2%) women had reported pain alone as a complaint. Of these 157 women, 13 women were diagnosed with breast cancer. Thermalytix resulted in a sensitivity, specificity, NPV and PPV of 76.9%, 85.4%, 97.6%, and 32.3% respectively, using B-Score. When the vascularity criterion is set to the optimal point at Youden's Index, the sensitivity, specificity, NPV and PPV were 92.3%, 80.6%, 99.1% and 30%, respectively.
Conclusion: Currently, management of women presenting with breast pain complaints in primary care requires clinical judgement towards a 2 week wait time. In this paper, we present a non-invasive imaging tool called Thermalytix that can be used for triaging women with breast pain in an objective manner.
Acknowledgements: We would like to thank Dr. Deepak Kumar and Dr. Sanjiv Ahluwalia for their valuable discussions and feedback on this study.

P4-04-19: Characterizing Nanomechanical Properties of Skin and Soft Tissue in Postmastectomy Implant Reconstruction

Papa Diogop Ndiaye, Mark Victor Schaverien, Victor Joseph Hassid, Paul L. Shay, John William Shuck, Mark Warren Clemens, Jessie Zexi Yu, Austin Y Ha, Gregory Reece, Margaret Jane Roubaud, Alexander Francis Mericli, Mark Villa, Ashleigh M. Francis, David Matthew Adelman, Donald Baumann, Joani Marie Christensen, Ryan Dickey, Philip Hanwright, Sahil Kuldip Kapur, Jonathon Bryce Edward Olenczak, Aysegul A Sahin, Edna Paredes, Ahmed Jizawi, Gitika Srivastava, Tia Darwich, Soufian Lasli, Jacqueline Tilley, Tobias Appenzeller, Sara Nizzero, Marko Loparic, Marija Plodinec, Smith,Benjamin

Background: Implant-based postmastectomy breast reconstruction carries a significant risk of complications, including an aproximately 10% rate of implant loss following postmastectomy radiation therapy. While prior radiation, diabetes, and obesity are recognized risk factors, the impact of the quality of skin and soft tissue on these outcomes is not well understood. Currently, no biomarkers are available to guide decisions between implant-based and autologous tissue reconstruction. Mechanical alterations of skin tissue have been shown to be a hallmark of inflammation and thus we hypothesize that detection of this in standard of care samples may provide an early assessment for failure risk.
ObjectiveThis study aims to characterize the nanomechanical properties of skin and soft tissue in patients undergoing postmastectomy implant reconstruction, and evaluate correlations between these properties and clinical outcomes, including implant loss and patient-reported quality of life. The overall goal is to detect the nanomechanical changes that are predictive of implant failure in breast cancer mastectomy reconstruction surgery patients.
Methods: This data comes from 36 evaluable study subjects from an on-going single center prospective observational study currently taking place in MDACC (NCT06584396), enrolling female patients post- prevention or curative mastectomy, who elected postmastectomy breast reconstruction. Part of the fibrous capsule resection (often containing scar) removed during the breast implantation replacement surgery is analyzed using the ART-1 Nanomechanical Phenotype System, which provides a spatial nanomechanical characterization of clinical samples. For each sample, an average of 15 maps is measured, with 400 indentation points per map, totaling 6000 data points per sample. Clinical and patient reported outcomes are being collected through chart review and a validated BREAST-Q assessment for quality of life. Tissues are further annotated by pathologists and the nanomechanical signature of each sample is correlated to the presence and pathological features of scars.
Results and Conclusions: Overall the nanomechanical signature of these samples presents distinguishing features when compared to other studies such as breast cancer and normal breast tissue. While the nanomechanical signature of breast tumor is typically multi-peak and heterogeneous, the stiffness of the skin/scar tissues presents a single tail corresponding to a continuously heterogeneous stroma with stiffer profiles compared to normal breast and breast cancer tissues. The adhesion energy channel also presents a single asymmetric population with a much narrower distribution when compared to both normal

breast tissue and breast cancer tissue. The dissipation profile is focused at very low values, whereas both normal breast and breast cancer tissue present much higher dissipation values.
As we continue to enroll for this on-going study, we are compiling interim outcome evaluation of surgical outcome. Overall, this provides a baseline characterization of reconstruction tissues which supports the further development of Nanomechanics-based biomarkers for reconstruction failure/success prediction in postmastectomy settings.

P4-04-20: Contrast-enhanced mammography-guided biopsy enhances early detection of breast cancer through precise target selection in extensive suspicious microcalcification diagnosed in screening mammography

Wai-Shan Chung, Yun-Chung Cheung, Chi-Chang Yu, Shin-Cheh Chen, Tai-Ming Ko

Background: Contrast-enhanced mammography (CEM) is a modern technique that can reveal a relevant malignant lesion through contract enhancement in the mammography image. In a background of extensive microcalcifications of mammography, contrast-enhanced mammography-guided biopsy (CEM-Bx) can help locate the suspicious microcalcification for targeted sampling for an early diagnosis of breast cancer. The diagnostic outcome of CEM-Bx has not yet been reported in previous literature.
Purpose:
Our study aimed to discover the clinical utility of CEM-Bx for the diagnosis of breast cancer in female patients with extensive suspicious microcalcifications reported in screening mammography.
Materials and Methods: This is a prospective study that included female candidates with extensive suspicious microcalcifications shown in screening-base mammography. Among all the included candidates, no mass lesions were noted in physical examination, sonography, or mammography. Then, they received a CEM image after screening mammography recalled. Candidates without enhancement in CEM underwent conventional mammography-guided (MG-Bx) biopsy for suspicious microcalcification as the standard-of-care group. On the other hand, candidates with enhancement in CEM underwent CEM-Bx as the study group. Wilcoxon rank-sum test was employed to analyze the outcome of CEM-Bx to MG-Bx for cancer diagnostic rate (CDR). This project was funded by the National Science and Technology Council of R.O.C [MOST 111-2314-B-182A-047] and approved by the institutional review board of Chang Gung Memorial Hospital (202102180A3).

Results: A total of 61 female candidates with extensive suspicious microcalcification noted in their screening mammography were included in this study from November 2021 to November 2023. Twenty-six candidates received CEM-Bx, while thirty-five candidates received MG-Bx. There was no significant difference in the presentation of microcalcification morphology or distribution in the CEM-Bx and MG-Bx groups. CEM-Bx

with associated enhancements were diagnosed as cancer in 73.08% (n=19/26) of the study group, and no cancers were diagnosed in the standard-of-care group without associated enhancement. The overall CDR of CEM-Bx and MG-Bx was 31.4% and 20%, respectively. There was a significant difference in CDRs between CEM-bx and MG-bx. The CDR of CEM-bx was 81.8% in regional microcalcifications, while 66.7% in segmental or diffuse distributions was 66.7%.

Conclusion: The cancer diagnostic rate is significantly higher by CEM-Bx with associated enhancement than MG-Bx without enhancement. Contrast-enhanced mammography-guided biopsy technique should be considered as a solution for the target selection in patients with extensive suspicious microcalcifications to further enhance the early detection of breast cancer in population-based screening mammography.

P4-04-21: Frozen gloves can prevent chemotherapy-induced nail pigmentation of the hand in early-stage breast cancer patients: a prospective self-matched case-control study

Fei Xu, Kuikui Jiang, Jianwen Chen, Junping Zhang, Moke Deng, Simei Shi, Qiulian Lin, Shusen Wang, Hanmu Chen

Background: Nail pigmentation occurs in approximately 90% of patients treated with anthracyclines, cyclophosphamide, and taxanes, but approaches to prevent the melanonychia were absent. We aimed to evaluate the efficacy of frozen glove (FG) treatment for the prevention of the nail pigmentation in early-stage breast cancer patients. Methods: This was a prospective, phase II, single-center, self-matched case-control study in early-stage breast cancer patients who planned to receive anthracyclines, cyclophosphamide or taxanes. The primary end point was the incidence of severe nail pigmentation and the other end points included the degree of nail pigmentation, the incidence of nail pigmentation, the onset time of nail pigmentation, other cutaneous toxicity, neurotoxicity, and patient comfort. Due to the lack of NCI-CTCAE standard for melanonychia, we evaluated it by a scoring system based on the area (0 for no change, 1 for less than 1/3 , 2 for 1/3 to 2/3, and 3 for more than 2/3 of the nail plate) and the color (0 for no change, 1 for light, 2 for gray, and 3 for black) of nail pigmentation. Severe nail pigmentation was defined as area score plus color score ≥5. Two investigators independently examined the nails of participants and scored the most severe nail. The patient wore a FG on one hand from 30 minutes before chemotherapy until 30 minutes after chemotherapy, and the other hand remained unprotected as the control.

Results: Between July 2022 and June 2023, 42 early-stage breast cancer patients were enrolled. The median follow-up was 13.7 months (IQR: 11.7-16.7). The median number of chemotherapy cycles was 6 (IQR: 4-8). Treatment with a single chemotherapy course was associated with higher risk for nail pigmentation and severe nail pigmentation, with odds

ratios of 43.21 (95% CI: 14.50 to 128.76, p<0.01) and 2.82 (95% CI: 2.16 to 3.68, p<0.01), respectively. Thought there was no significant difference in the incidence of pigmentation between FG-protected hands and control hands, the area score and the total score of the FG-protected hands were significantly lower than those of the control hand ($p < 0.005$) from the third FG treatment. Additionally, the color score of the FG-protected hands was significantly decreased from the fourth FG treatment ($p < 0.005$). The rate of severe nail pigmentation was significantly lower in FG-protected group compared with that of control group at the eighth FG treatment (42.11% vs 73.68%, p=0.049). The odds ratio for severe nail pigmentation in the FG group compared to the control group is 0.34 (95% CI: 0.16 to 0.71, p<0.01). The median onset time of nail pigmentation of FG-protected group and control group was 39 days and 30 days after the initiation of chemotherapy, respectively, with no significant difference. There was no significant difference in other skin toxicity and neurotoxicity between two groups. Only one participant was dissatisfied with the FG treatment, and no patient withdrew from this study due to cold intolerance.

Conclusion: FG significantly reduces the nail pigmentation induced by anthracyclines, cyclophosphamide, and taxanes in early-stage breast cancer. Our study provides an effective and well-tolerated method to prevent melanonychia and may improve patients' quality of life.

P4-04-22: Impact of screening mammography on breast cancer outcomes in women aged 80 and over

Siu-Yuan Huang, Makaelah Murray, Angelique Rubio, Nneoma Okoro, Mina Sedrak, Nicholas Jackson, Mediget Teshome, Susan A. McCloskey, Nimmi S. Kapoor

Introduction: While the risk of breast cancer increases with age, screening mammography guidelines are lacking for women of advanced age and often factor in life expectancy estimates. We sought to identify differences in outcomes among newly diagnosed breast cancer patients aged 80 or older who were undergoing routine screening mammography versus those who were not screened.
Methods: 249 patients who were diagnosed with breast cancer at age 80 or older at a single institution from 2013-2020 were identified retrospectively. Patients with a previous diagnosis of breast cancer or those with incomplete records were excluded. Data was collected on patient demographics, comorbidities, timing of mammography, symptoms, tumor characteristics, treatment, and outcomes. Characteristics of the screened group were compared to the unscreened group with Chi-square and t tests. Kaplan-Meier survival analysis and log-rank testing was done to compare overall survival and disease-free survival.
Results: Among 177 patients with breast cancer included, 77 had mammographic screening within 2 years of diagnosis, and 100 were un-screened. Mean age at breast cancer diagnosis was 83 (80-98), and the two groups did not significantly differ in race/ethnicity, Area

Deprivation Index, tumor receptor status, nodal sampling, or receipt of endocrine therapy, adjuvant chemotherapy, or radiation. Compared to the screened group, the un-screened group was more likely to have invasive disease ($p = 0.009$), larger tumors (2.9 cm vs 1.6 cm, $p < 0.001$), higher grade tumors ($p < 0.001$), and more advanced stage ($p < 0.001$). More patients in the screened group underwent breast conserving surgery, while more patients in the un-screened group either had mastectomy or did not undergo surgery (both $p = 0.001$), and more un-screened patients received neoadjuvant chemotherapy ($p = 0.003$). The screened group had a significant benefit in disease-free survival (DFS) (HR 0.553, 95% CI, 0.380-0.802, $p = 0.002$) and overall survival (HR 0.427, 95% CI, 0.206-0.887, $p = 0.018$). Conclusions: Patients aged 80 or older with breast cancer who were undergoing screening mammography had significantly improved disease-free survival and overall survival compared to those with breast cancer who were not screened. This suggests that the benefit of screening mammography persists in advanced aged women and updated breast cancer screening guidelines are needed.

P4-04-23: Reverse-sequence Endoscopic Versus Conventional Open Nipple-Sparing Mastectomy with Implant-based Breast Reconstruction: A Single-center Prospective Cohort Study (RECO study)

Tianyuan Li, Qing Zhang, Yanyan Xie, Huanzuo Yang, Kawun Chung, Hui Dai, Xiaoman Cao, Zhenggui Du

Background: Minimal-access nipple-sparing mastectomy (NSM), including endoscopic- or robotic-assisted NSM, is increasingly used in the treatment of patients with breast cancer. However, traditional minimal-access NSM is time-consuming, costly, and has a steep learning curve, hindering its widespread adoption. Our team pioneered the “reverse-sequence” endoscopic nipple-sparing mastectomy(R-E-NSM), which addresses the challenges identified in previous surgeries. This study aimed to compare the clinical outcomes of R-E-NSM with implant-based breast reconstruction (IBR) and conventional open nipple-sparing mastectomy(C-O-NSM) with IBR.
Methods: In this prospective, single-center, non-randomized study, we consecutively recruited women aged 18 years or older who underwent NSM with IBR for breast cancer or risk reduction at the West China Hospital of Sichuan University from March 2021 to March 2024. Data about patients’ demographics and operative, oncological, complication details, and cosmetic outcomes were collected before and after surgery. We conducted a prespecified risk-factor analysis using mixed-effect regression to investigate the relationship between surgery type and incidence of complication. The study is registered on the China Clinical Trials Network, and the trial registration number is ChiCTR2100047862.
Results: A total of 447 patients were enrolled in this study, including 336 (75.2%) patients who received R-E-NSM with IBR and 111 patients (24.8%) who underwent C-O-NSM with IBR. The median follow-up time was 24.33 (7.27-42.07) months in the R-E-NSM with IBR group and 27.00 (7.70-42.53) months in the C-O-NSM with IBR group, respectively. The unilateral operation time of patients in the R-E-NSM with IBR group was not longer than

that in the C-O-NSM with IBR group (153.95±50.52min vs. 144.87±40.06min, P=0.09). Compared to the C-O-NSM with IBR group, the R-E-NSM with IBR group showed significantly lower rates of any complications (22.02% vs. 37.84%, P=0.001) and major complications (3.57% vs. 11.71%, P = 0.002). The Breast-Q, Ueda scale, and Harris scale in the R-E-NSM with IBR group were significantly superior to those in the C-O-NSM with IBR group (P＜0.05). The local-regional recurrence (P = 1.00) and distant metastasis (P = 0.37) were not different between the two groups. The R-E-NSM with IBR group showed significantly lower unilateral expenses (7043.84±771.16 USD vs. 7373.45±558.09 USD, P＜0.001) and hospital stay(3.24±2.86 days vs. 6.29±2.67 days, P＜0.001), respectively.
Conclusion: Compared to C-O-NSM with IBR, R-E-NSM with IBR can bring the same surgery efficiency and a sufficient cost-effectiveness ratio, lower incidence of postoperative complications, better aesthetic outcomes, and the same oncologic safety, indicating a broader application potential.

P4-04-24: Cytokeratin 19 mRNA copy number by one-step nucleic acid amplification (OSNA) in the sentinel lymph node biopsy (SLNB) as prognostic factor in Luminal early Breast Cancer (LeBC).

Maria Yeray Rodriguez Garces, Stephanie Saide Cobelas Cartagena, Beatriz Buendía Cruz, David Morales Pancorbo, Yeray Rodríguez Garcés, Juan L Bayo Calero

Background: Unlike the number of infiltrated lymph nodes, the tumor burden in the sentinel lymph nodes is not well defined as a prognostic factor.
We studied the relationship between axillary infiltration using OSNA and the results of the genomic platform in LeBC with positive SLNB.

Methods: Observational, retrospective study in LeBC with positive SLNB defined as > 250 CK 19 mARN copies by OSNA in addition to genomic risk platform (OncoType or Mammaprint) from 2018 to 2023 in our area (Huelva, Spain).
We carried out a univariate (xi-square) and multivariate analysis (binary logistic regression) that included other prognostic factors. The SPSS Statistics 22 was used for data assessment.

Results: 212 LeBC with genomic assays were analyzed, 95 patients presented positive SLNB. Median age was 56 years, 98.9% female and 67.3% were postmenopausal. According to phenotype, 73.7% were Luminal A and 26.3% Luminal B1. Regarding prognostic factors: 40% with T > 2cm, Ki67> 20% in 31.6% and grade 3 in 5.3% of cases.
In the bivariable analysis of the overall population, both Ki-67 > 20% and > 10,000 -15,000 copies of CK19 mRNA were associated with high genomic risk (p = 0.000 and p = 0.037). These results were consistent in subgroup analysis among postmenopausal patients. In the case of the premenopausal subgroup, a significant result was also obtained for patients with

a histological grade ≥ 3 (p=0.038).
In the multivariate analysis, Ki-67 > 20% is an independent prognostic factor in relation to high genomic risk OR 7.79 [95% CI (2.03-29.9), p=0.003]. OSNA and grade 3 is also related with high genomic risk but no significance achieved.

Conclusions: Tumor genomic assays may not be necessary in LeBC with positive SLNB with elevated ki 67 and OSNA values and could even be sufficient to decide on adjuvant therapy in this patients.
It would be interesting to expand the sample size to reaffirm our hypothesis and better adjust the appropriate CK 19 mRNA copy number.

P4-04-25: HER2 Assay for the Detection of Low Expressing HER2 (IHC Score 1+/0) in Circulating Tumor Cells Enriched from Peripheral Blood using the CELLSEARCH® System

Damodara Gullipalli, Thai Bui, Margaret LaCava, Zoltan Simandi, Christina Dorris, Richard G. Del Mastro

Estrogen receptor positive/Human epidermal growth factor receptor negative (ER+/HER2-) represents 70% of metastatic breast cancer (mBC) patients. ER+/HER2- mBC is a challenging disease with significant unmet clinical needs. Approximately 60% to 65% of women with mBC, who are considered HER2-negative based on immunohistochemistry (IHC) staining of a tissue biopsy, are HER2-low and an additional 20% to 25% may represent a new category of HER2-ultra-low. This is problematic, as these patients are often ineligible for effective HER2-targeted therapies. Furthermore, the disease can evolve, and the receptor status of the tumor may change, necessitating periodic reassessment. However, the current NCCN guidelines strongly discourage repeated tissue biopsies after the second line of treatment, as they are invasive, costly, and can be exacting to perform. To address this issue, advanced liquid biopsy approaches that can assess HER2 status without tissue biopsy are needed.
Using the current CLIA certified CELLSEARCH® Circulating Tumor Cell-HER2 test, Circulating Tumor Cells (CTCs) that are EpCam+/Cytokeratin+/DAPI+/HER2+, can be detected in 7.5mls of peripheral blood only to a HER2 expression level equivalent to an IHC score 3+/2+. The next generation assay, CELLSEARCH® CTC-HER2 Low, has been designed to improve sensitivity and detect HER2 expression in CTCs to a level equivalent to IHC score of 1+/0 in 7.5mL of blood. The assay has been developed using a brighter fluorophore (Phycoerythrin), conjugated to the HER2 antibody, and was tested against 6 breast cancer cell lines (SKBR3, JIMT-1, BT-483, BT-20, MCF-7, DU4475) ranging in IHC scores 3+ to 0 and the MCF-7 HER2 knockout cell line. Analytical sensitivity and specificity were found to be >85% and >90% respectively. Linearity testing, where the cell lines were spiked in 7.5mL blood, showed high levels of reproducibility across the clinical range (1000 cells to 0) with an R2 = 0.99. The CELLSEARCH® CTC-HER2 Low test meets a critical clinical need that breast cancer patients, positive or classified as negative from a tissue biopsy, in need of a

current evaluation of their metastatic breast cancer HER2 status, through any line of treatment, can do so from one blood draw using a test that can detect HER2 expression to very low levels.

P4-04-26: A New Option for post-CDK4/6is Resistance Era: Multicenter Real-world Study of Anlotinib-based Combination Therapy in Hormone Receptor-positive Metastatic Breast Cancer Resistant to CDK4/6 Inhibitors

Quchang Ouyang, Binliang Liu, Zhanhong Chen, Xiaohong Wu, Ying Zhang, Tao Sun, Fangyuan Dong, Tao Wu, Bin Shao, Yifei Chen, Lu Gan, Hong Zong

Background: Cyclin-dependent kinases 4 and 6 (CDK4/6) inhibitors (CDK4/6is) combined with hormonal therapy are the current standard frontline treatment for patients with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER-2)-negative metastatic breast cancer (MBC). However, the optimal treatment after progression on CDK4/6is remains unknown. Anlotinib is an oral multi-target tyrosine kinase inhibitor (TKI) that strongly inhibits VEGFR, PDGFR, FGFR, and c-kit. This study aimed to evaluate the safety and efficacy of anlotinib-based combination therapy in patients with HR+ MBC previously treated with CDK4/6is.
Methods: 53 patients from 8 medical centers with pathologically confirmed HR-positive, HER-2-negative MBC were retrospectively reviewed. All included patients had received at least one line of CDK4/6is therapy before disease progression prior to anlotinib-based combination therapy. Anlotinib (12 mg daily, Day 1-14 of each cycle) was administered orally to fasting patients, with dose reductions to 10 mg or 8 mg in cases of intolerable toxicity. Combination agents included eribulin, nab-paclitaxel, etoposide, capecitabine, pembrolizumab, sintilimab, or fulvestrant, among others. Hospital medical records and imaging systems were used to assess clinical characteristics. The primary endpoint was progression free survival (PFS) and secondary endpoints were objective response rate (ORR), disease control rate (DCR), and overall survival. The safety profile has also been assessed.
Results: Between January 2020 and August 2024, 53 patients were included, with a median age of 52 years (range: 32-77 years). In the 39 patients whose efficacy could be evaluated, the median follow-up was 9.2 months (95% CI, 5.03-13.37), and the median PFS was 7.1 months (95% CI, 4.90-9.30). The ORR was 30.8% (95% CI, 0.17-0.47), and the DCR was 94.9% (95% CI, 0.83-0.99), with partial response and stable disease observed in 12 and 25 patients, respectively. The most common adverse events (AEs) were alanine aminotransferase elevation (22 patients, 41.5%), anemia (17 patients, 32.1%), and leukopenia (14 patients, 26.4%). It also includes widely observed adverse reactions such as hypertension (7 patients, 13.21%), albuminuria (7 patients, 13.21%), among others. Grade 3/4 treatment-emergent adverse events occurred in 9 patients (16.7%), with the most common being aspartate aminotransferase elevation (3 patients, 5.7%). Dose reductions of anlotinib were required in 6 patients (11.3%).
Conclusion: Anlotinib-based combination therapy has demonstrated good efficacy and

acceptable safety in HR+/HER2- MBC patients previously treated with CDK4/6is, making it a viable treatment option following resistance to CDK4/6is.

P4-04-27: Next generation antibody drug conjugates targeting HER2 and TROP2: Multi-Payload Conjugates™ targeting orthogonal mechanisms of cell killing

Marco Lobba, Richard Kendall, Devin Trinter, Maxwell Nguyen, Daniel Gutierrez, Samantha Brady, Chanez Symister, Andrew Lau, Derek Garcia-Almedina, Saurabh Johri, Matthew Francis

Introduction: Antibody-Drug Conjugates (ADCs) have had tremendous impact on patient outcomes in breast cancer and are now second-line therapy for stage IV HER2 high expressing metastatic breast cancer as well as HER2 low expressing tumors. However, many patients fail to respond or relapse after treatment with ADC therapies due to tumor heterogeneity and eventual resistance to the ADC payload. We are developing next generation Multi-Payload Conjugates™ (MPCs™) that deliver targeted combination chemotherapies within a single molecule.
Method: CatenaBio has developed novel, highly stable single-molecule targeted combination therapies, MPCs™, with tunable drug-antibody ratio (DAR). Our selective conjugation platform allows the attachment of distinct payloads targeting different mechanisms of action at three unique sites on the antibody scaffold.
Results: We screened combinations of different payloads targeting several different mechanisms of cell division attached to trastuzumab as well as sacituzumab at different DARs to optimize tumor cell killing. These targeted combination ADCs demonstrated robust killing in multiple cell lines containing high and low expression of HER2 and TROP2, as well as an Enhertu resistant cell line. Additionally, these novel MPCs show potent inhibition and excellent tolerability in mouse models of tumor growth in HER2 high and HER2 low/TROP2 expressing xenograft models including models of TNBC.
Conclusion: While advances have been made in the design of ADCs to expand to previously unaddressed populations, high patient relapse and the failure of recent mono-payload ADCs in late-stage trials indicate a need for novel conjugate modalities. Multi-payload Conjugates™ offer the next step in ADC design and allow for the combination of multiple mechanisms of action in a single MPC™ that are highly effective across multiple breast cancer cell lines and target expression levels. Successfully constructed with both HER2 and TROP2 targeting antibodies, these molecules offer the potential to circumvent tumor resistance pathways and deliver deeper and more durable patient responses.

P4-04-28: PF-07248144, a first-in-class KAT6 inhibitor, in patients with HR+ HER2– metastatic breast cancer: Updated results from phase 1 dose expansion study

Toru Mukohara, Patricia M. LoRusso, David Sommerhalder, Kan Yonemori, Erika Hamilton, Sung-Bae Kim, Seock-Ah Im, Geoffrey J. Lindeman, Hope S. Rugo, Hiroji Iwata, Rachel M. Layman, Gun Min Kim, Toshinari Yamashita, Jee Hyun Kim, Fengting Yan, Toshio Shimizu, Yee Soo Chae, Timothy Clay, Rohit Joshi, Monica Mita, Mun Hui, Brian Dong, Brooke Holbrook, Sean Kent, Athanasia Skoura, Li Liu, Meng Li, Yeon Hee Park

Background: Histone lysine acetyltransferase KAT6A, and its paralog, KAT6B regulate lineage specific gene transcription via H3K23 acetylation. PF-07248144 is a novel selective catalytic inhibitor of KAT6 (6A & 6B). We report updated results (with 7 months additional follow-up) of clinical safety, efficacy, and additional subgroup analyses from the phase 1 study (NCT04606446) of PF-07248144 as monotherapy and with fulvestrant (fulv) in heavily pretreated ER+HER2− metastatic breast cancer (mBC).
Methods: Patients (pts) had metastatic ER+ HER2− mBC and had progressed after a CDK4/6 inhibitor (CDK4/6i) and endocrine therapy (ET). Pts received PF-07248144 at the recommended expansion dose (RDE) of 5 mg QD as monotherapy or with fulv. Primary objective: safety and tolerability per CTCAE 5.0. Secondary objectives: antitumor activity per RECIST 1.1 and pharmacokinetics. Exploratory objectives: Pharmacodynamics and predictive biomarkers. Circulating tumor DNA (ctDNA) and gene mutations were evaluated by Guardant 360 assay.
Results: 35 pts received PF-07248144 monotherapy and 43 pts with fulv. All 78 pts had received prior CDK4/6i and ET in the metastatic setting. 59% (46/78) had detectable ESR1 mutations at baseline.
PF-07248144 demonstrated tolerable safety profile at RDE and encouraging antitumor activity as monotherapy and with fulv. In all 78 pts, the most frequent treatment-related adverse event (TRAE) was grade (G) 1/2 dysgeusia (n=66, 84.6%), mainly G1 (n=50, 64.1%); no dose reduction and treatment discontinuation due to dysgeusia. The most frequent G≥3 TRAE was neutropenia (G3: n=29, 37.2%; G4: n=5, 6.4%), reversible and manageable with dose modification. No febrile neutropenia or G5 TRAEs.
As of 30 Apr 2024, we observed increased antitumor activity with longer follow-up (median 16.4 mos) for fulv combination (n=43). The objective response rate (ORR) was 37.2% (95% CI 23.0, 53.3), median duration of response was not reached (95% CI 7.2 mos, not evaluable), clinical benefit rate was 55.8% (95% CI 39.9, 70.9), and the median progression-free survival (mPFS) was 10.7 mos (95% CI 5.3, 13.8). Antitumor activity was observed irrespective of ESR1 (wild-type [WT] n=18, mutant [MT] n=24; ORR 33.3 vs 41.7%; mPFS 10.9 vs 10.7 mos) and PIK3CA/AKT1/PTEN (WT n=23, MT n=19; ORR 43.5 vs 31.6%; mPFS 13.7 vs 7.3 mos) mutation status.
Additional subgroup analyses revealed broad antitumor activity of PF-07248144 fulv combination in pts treated as second-line (2L) therapy (following 1L CDK4/6i + ET) or as third-line or beyond (3L+) therapy (ET, targeted therapy or chemotherapy in between; ORR 30.4% [7/23] vs 45.0% [9/20]; mPFS 13.8 vs 10.7 mos); and irrespective of primary or

secondary endocrine resistance (ORR 57.1% [4/7] vs 33.3% [12/36]; mPFS 9.0 vs 10.8 mos), presence or absence of prior treatment with fulv (ORR 60.0% [3/5] vs 34.2% [13/38]; mPFS not reported [n≤5] vs 7.5 mos), and rapid progression on prior CDK4/6i (duration of treatment <6 mos) or prior CDK4/6i treatment duration >12 mos (ORR 50.0% [2/4] vs 36.4% [12/33]; mPFS not reported [n≤5] vs 10.9 mos).
After 8-wk treatment, the median reduction in total ctDNA and ESR1 mutant allele frequency was 95.0% and 100.0%. Pts with non-detectable ctDNA after the initial 8-wk treatment had longer PFS compared with those with detectable ctDNA.
Conclusions: PF-07248144 in combination with fulv demonstrated an acceptable safety profile and promising efficacy in pts with ER+ HER2− mBC post CDK4/6i and ET. Antitumor activity was observed irrespective of ESR1 and PIK3CA/AKT1/PTEN mutation status, endocrine sensitivity or resistance, duration of prior CDK4/6i treatment (<6 mos or >12 mos), prior fulvestrant treatment, and 2L or later line therapy. These findings suggest that PF-07248144 in combination with ET may potentially overcome endocrine resistance and CDK4/6i resistance and provide a novel mechanism to address high unmet medical need in HR+ mBC after prior CDK4/6i and ET.

P4-04-29: The Impact of Race and Neighborhood on Young Breast Cancer Patients

Melanie Sheen, Caitlin Taylor, Jeff Burton, Rabia Cattie, Victoria Chung

Background: Current United States guidelines recommend mammogram screening for breast cancer (BC) to begin at age 40 for women of average risk, however diagnosis (dx) under age 40 accounts for ~7-9% of all BC cases. Patients with BC under age 40 have more aggressive cancers, present at later stages, and have poor outcomes. Factors that can negatively affect BC outcomes, regardless of age, include African-American (AA) race, Triple Negative BC (TNBC) dx, and lower socioeconomic status. Data show that AA patients with BC have increased mortality when compared to White (W) counterparts. Louisiana (LA) has one of the largest AA populations in the country at 32.8%, compared to ~12% of overall US population. When compared across the US, LA also has an exceptionally large number of high Area of Deprivation Index (ADI) neighborhoods, a variable encompassing socioeconomic status. We set out to examine the impact of race and ADI on patients with BC dx under age 40. Methods: We performed a retrospective chart review of the Ochsner Health System for all patients with a BC dx under age 40 from 2012-2022. ADI rankings are summarized as median and interquartile range (IQR) and the race-ADI association is evaluated using the Wilcoxon rank-sum test. Other continuous measures are reported as mean and standard deviation (SD), and categorical measures as frequency and percentage. Associations with race are assessed via two-sample t-tests, and chi-squared tests or Fisher's exact tests. Crude associations between outcomes (metastasis, mortality) and potential confounders of race (dx age, BMI, subtype, stage at dx) in total sample are estimated via Cox proportional hazards (PH) regression models and reported as hazard ratio (HR) for AA vs W and 95% confidence interval (CI). Three models are considered for each outcome. Model

1 (M1) includes a fixed race effect only; Model 2 (M2) adds covariates for age and BMI to M1 and is stratified by BC subtype; Model 3 (M3) additionally stratifies M2 by cancer stage at dx. All analyses were carried out using SAS/STAT software, version 9.4 for Windows. Results: A total of 719 patients were analyzed. 689 patients had ADI data. Total sample (AA =273 vs W =446) HR metastasis M1: 1.16 (0.85, 1.59), M2: 1.21 (0.87, 1.69); mortality M1: 1.20 (0.81,1.76), M2: 1.21 (0.80,1.82), M3: 1.09(0.71, 1.65) HR for patients with stage I-III (N=672; AA = 255 vs W = 417) metastasis M1: 1.23 (0.84, 1.79), M2: 1.30 (0.87, 1.94), M3: 1.27 (0.85, 1.90); mortality M1: 1.17 (0.74, 1.81), M2: 1.11 (0.71, 1.73), M3: 1.05 (0.67, 1.65). HR for TNBC subgroup stage I-III (N=207; AA = 103 vs W = 104) metastasis M1: 0.96 (0.51, 1.80), M2: 1.01 (0.53, 1.92), M3: 1.00 (0.52, 1.91); mortality M1: 1.08 (0.55, 2.17), M2: 1.20 (0.59, 2.45), M3: 1.13 (0.56, 2.31). HR stage I-III in ADI subgroups (N=643; AA = 239 vs W = 404), metastasis M1: 1.29 (0.88, 1.88), M2: 1.35 (0.90, 2.01), M3: 1.30 (0.86, 1.94); mortality M1: 1.28 (0.81, 2.00), M2: 1.30 (0.81, 2.09), M3: 1.23 (0.76, 1.98) ADI-adjusted HR stage I-III in ADI subgroups (N=643; AA=239 vs W=404), metastasis M1: 1.11 (0.73, 1.69), M2: 1.08 (0.70, 1.67), M3: 1.07 (0.69, 1.67); mortality M1: 1.02 (0.62, 1.68), M2 0.93 (0.55, 1.58), M3: 0.91 (0.53, 1.55). Highest (most deprived) ADI quartile (ADI >75): total 26.7%, AA 47.7%, W 14.3%. Lowest (least deprived) ADI quartile (ADI<25): total 9%, AA 4.3%, W 11.8%. Discussion/Conclusion: These results demonstrate that ADI is the primary driver of outcomes when compared to race, BMI or BC subtype. When incorporating ADI, differences in outcomes noted between AA and W patients diminish, especially when evaluating mortality among young women with TNBC. While there are differences in disease biology, the impact of ADI on outcomes should not be underestimated. Improvements in BC awareness, access to care, and support programs should target areas of highest ADI to improve long-term BC outcomes, especially in young populations, regardless of race.

P4-04-31: A phase Ib/II study of PARPi Mefuparib Hydrochloride (CVL218) in combination with PD-1 inhibitor plus chemotherapy in metastatic or recurrent triple-negative breast cancer (TNBC)

Jian Zhang, Rujiao Liu

Background: Triple-negative (negative for human epidermal growth factor receptor 2 [HER2] and estrogen and progesterone receptors) breast cancer (TNBC) is the breast cancer subtype with the worst prognosis. It represents approximately 15% -20% of all breast cancer cases. BRCA 1 and /or BRAC 2 mutation accounts for about 15% of all TNBC and remains poor outcomes for such patients. TORCHLIGHT trial is a randomized, double-blinded, phase 3 study assesses the efficacy and safety of toripalimab (programmed cell death-1 inhibitor) combined with nab-paclitaxel (nab-P) as a first-line treatment for patients diagnosed with metastatic or recurrent TNBC. The (progression-free survival) PFS and (overall survival) OS analysis, showed a significant improvement in PD-L1 positive (CPS ≥ 1) tumors. Phase III OlympiAD study has established the efficacy of Poly ADP-ribose polymerase inhibitors (PARPi) olaparib in patients with germline BRCA gene mutation

(gBRCAm) and human epidermal growth factor receptor 2 (HER2) negative metastatic breast cancer. Mefuparib hydrochloride (CVL218) is a second generation of PARPi with low hematological toxicity and the ability to cross the blood-brain barrier. The major purpose of this study is to explore the RP2D, efficacy and safety of CVL218 combined with PD-1 inhibitors and paclitaxel nanoparticle albumin-bound in patients with TNBC who have failed previous first-line treatment. The second endpoint of this study is to analyze the efficacy of each subgroup according to PD-L1 expression and HRD (Homologous Recombination Deficiency) mutation status.
Methods: This open- labeled, phase Ib/II clinical study was conducted in China. In phase Ib, the "3+3" principle is used to explore the RP2D of CVL218. Two dose escalation of CVL218 were preset, which are 500mg twice daily (BID) and 700mg BID. CVL218 administered orally in combination with toripalimab 240 mg on Day 1 of every 21-day cycle and paclitaxel nanoparticle albumin-bound 125 mg/m2 on Day 1 of every 21-day cycle. The first cycle (21 days) after administration was also defined as the DLT (dose-limiting toxicity) observation period. At last, no DLT was observed in the 3 evaluable subjects in the CVL218 500 mg BID dose group, and DLT was observed in 2 evaluable subjects in the 700 mg BID dose group, including creatinine increased and aspartate aminotransferase, Alanine aminotransferase increased. Therefore, the RP2D was determined as 500 mg BID. Patients in phase II cohort A were advanced TNBC with either CPS ≥ 1 or HRD gene pathogenic variants. All these patients received CVL218 (500mg BID) + toripalimab (240 mg) + paclitaxel nanoparticle albumin-bound (125 mg/m2,).
Results: From July 2023 to 15 July 2024 data, a total of 6 subjects were enrolled in Phase Ib and 5 subjects were enrolled in Phase II. The median age of the 11 subjects was 55.2 years. In phase Ib, The RP2D of CVL218 was identified as 500 mg BID. The preliminary efficacy was perfomed every 6 weeks in the first half a year and then once every 12 weeks thereafter in both phase I and II according to RECISTv 1.1. Among 11 patients, ORR (Objective Respond Rate) was 72.7% (8 PR, 2 SD), and DCR (Disease Control Rate) was 90.9%. The most common Grade 3 or higher treatment-related AEs (TRAEs) were hepatic function injury (2.6%), adynamia (1.8%), creatinine increased (0.8%), neutrophils decreased (0.8%), white blood cell decreased (0.8%), exanthema (0.8%), and peripheral sensory nerve disorder (0.8%), No Grade 5 TRAE. A total of 9 treatment-related SAEs in 6 patients (54.5%) were observed, including 2 aspartate aminotransferase increased, 2 alanine aminotransferase increased, 1 creatinine increased, 1 liver function injury, 1 adynamia, 1 neutrophils decreased, 1 fever, and 1 ventricular premature beats. All these SAEs recovered after symptomatic treatment.
Conclusion: Mefuparib Hydrochloride(CVL218) combined with PD-1 and chemotherapy appears to be well tolerated and has preliminary efficacy in TNBC patients. In this phase II study, stratified analyses will be conducted for PD-L1 expression and HRD status. In patients with BRCA 1 and /or BRAC 2 mutation TNBC, this CVL218 combination therapy is expected to further break through the clinical treatment effect.
Keywords: Triple negative breast cancer; PARPi.

P4-04-32: Clinical study of 99mTc-Rituximab combined with dyes double tracing for axillary sentinel lymph node biopsy after neoadjuvant chemotherapy for breast cancer

Hui Zhang, Minxue Zhuang, Mengbo Lin

Background and Objective: Whether sentinel lymph node biopsy (SLNB) after neoadjuvant chemotherapy (NAC) for breast cancer is an alternative to axillary lymph node dissection (ALND) remains controversial.In this study, the results of SLNB performed on patients with 99mTc-Rituximab combined with dyes were analyzed, and the application value of the double-tracing method of 99mTc-Rituximab combined with dyes in SLNB after breast cancer NAC was evaluated, the feasibility of SLNB after NAC and the clinical application of the novel tracer 99mTc-Rituximab and its value in internal mammary sentinel lymph node was discussed.
Methods: A retrospective analysis of 106 breast cancer patients who underwent post-NAC SLNB from August 2019 to August 2023 at Fujian Provincial Hospital, where SLNB was performed using 99mTc-Rituximab combined with dye imaging or dye imaging alone. The detection rate, sensitivity, false-negative rate, accuracy and the detection rate of internal mammary lymph node biopsy were compared between the two tracing methods.
Results:70 cases were included in the dual tracing group, with a detection rate of 97.14% (68/70), an average number of detected SLNs of （6.06±5.29）， a sensitivity of 92.86% (26/28), a false negative rate of 7.14% (2/28), and an accuracy of 97.14% (68/70).36 cases were included in the single tracing group, with a detection rate of 66.67% (24/36), an average number of detected SLNs of （3.17±3.073）， a sensitivity of 54.55% (11/22), a false negative rate of 45.45% (10/22), and an accuracy of 72.22% (26/36). There were significant differences in the detection rate and the average number of detected SLNs between the two groups (detection rate: P=0.004; detection number: P=0.038), but there were no significant differences in the sensitivity, accuracy, and false negative rate (P>0.05).A total of 70 patients underwent double-tracing internal mammary lymph node biopsy, and 22 patients were detected with an imaging rate of 31.42% (22/70), and a detection rate of 72.72% (16/22).
Conclusions:SNLB using radionuclide with dye double-tracing method after neoadjuvant chemotherapy for breast cancer can improve the detection rate of sentinel lymph nodes, reduce the false negative rate, and improve the prognosis.Compared with other tracers, 99mTc-Rituximab can improve the detection rate of internal mammary sentinel lymph nodes, with the characteristics of rapid clearance of injection site, less secondary lymph node imaging, and low sensitization, which can be used as an ideal tracer for further research.

P4-04-34: Use of Intravaginal Physical Energy for Treating Genitourinary Syndrome of Menopause in Breast Cancer Survivors: A Systematic Review

Nicoli Serquiz, Ayane C A Sarmento, Natalie R Almeida, Maria Luísa Nobre, Kleyton S Medeiros, Antonio C Q Aquino, Juliana D A S Camargo, Heitor D Medeiros, Beatriz B Siqueira, Ronnier Oliveira, Nícolas C Conrado, Larissa P Moura, Raphael M Carvalho, Ana Katherine Gonçalves

Background: Breast cancer survivors (BCSs) often experience more severe symptoms of Genitourinary Syndrome of Menopause (GSM). Since hormonal therapies, such as estrogen, are typically avoided in BCSs, physical methods may offer promising non-hormonal alternatives for these women. However, the efficacy and safety of these treatments remain uncertain.
Objectives: To evaluate the efficacy and safety of physical methods, including laser and radiofrequency, for treating GSM in BCSs.
Methods: We searched eight databases from their inception through July 2024 without imposing language or date restrictions. We included randomized controlled trials (RCTs) that assessed the efficacy and safety of any physical methods for treating GSM in BCSs. Two authors independently screened studies based on titles, abstracts, and full texts, applying predefined inclusion criteria. Data were extracted, and the risk of bias was assessed using the Cochrane risk-of-bias tool (RoB 2). Due to methodological and outcome heterogeneity, a meta-analysis was not feasible, and a narrative synthesis was conducted. The Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach was used to assess the strength of the evidence.
Main Results: Three RCTs, involving 185 participants and three different physical methods (microablative fractional carbon dioxide [CO2] laser, erbium photothermal yttrium-aluminum-garnet [Er:YAG] laser, and radiofrequency), met the inclusion criteria. All three studies reported improvements in dyspareunia with physical method therapies, with no significant differences compared to control groups. Vaginal Health Index (VHI) scores and quality of life (QoL) showed short-term improvements, but again, with no significant differences from control groups. Only one study evaluated sexual function using the Female Sexual Function Index (FSFI) and Vaginal Maturation Index (VMI), showing improvement in sexually active women, although this was not significantly different from the sham group. Minimal adverse events were reported. Overall, only one study had a low risk of reporting bias, while two studies raised concerns due to critical weaknesses. Confidence in the evidence is low and critical across all studies.
Conclusions: Physical methods appear to be safe for the short-term treatment of GSM in BCSs. However, due to the limited number of blinded clinical trials, the efficacy of these treatments remains uncertain. Further research, particularly high-quality RCTs with long-term follow-up, is needed.
PROSPERO Registration Number: CRD42023387680

P4-04-35: Thioredoxin-Interacting Protein (TXNIP) as a Key Regulator of Tumor Growth and Progression

Liang Liu, Jasvinder Singh, Bindeshwar Sah, Yibin Deng, Robert Clarke

Thioredoxin-interacting protein (TXNIP) plays a critical role in glucose metabolism and redox signaling, and has recently emerged as a potent inhibitor of cell proliferation in cancer. In our previous study, we demonstrated that TXNIP activation significantly suppressed MDA-MB-231 breast cancer cell proliferation in vitro and reduced tumor growth in vivo. In this study, we show that TXNIP knockdown accelerates tumor growth and metastasis in MDA-MB-231 cells in a mouse model. Conversely, reintroducing TXNIP into TXNIP-deficient HCC-1954 breast cancer cells reduced cell proliferation and migration, while increasing reactive oxygen species (ROS) production and decreasing mitochondrial respiration, membrane potential, and glycolysis. To further investigate TXNIP's tumor-suppressive mechanisms, co-immunoprecipitation and proteomic analyses identified calpastatin (CAST) as a novel TXNIP-interacting protein in both MDA-MB-231 and HCC-1954 cells. Overexpression of CAST, an endogenous calpain inhibitor, significantly promoted xenograft tumor growth in both cell lines, revealing a previously unrecognized role for CAST as a tumor promoter. Furthermore, we observed an inverse correlation between TXNIP and HER2 expression in multiple breast cancer cell lines, where HER2+ cells exhibit low or undetectable TXNIP levels. Notably, TXNIP expression was found to reduce HER2 levels in HER2+ breast cancer cell lines. These findings uncover novel TXNIP-dependent pathways that contribute to breast cancer pathogenesis, offering new insights into TXNIP's complex role in tumor biology and presenting potential avenues for therapeutic intervention.

P4-04-36: Mixed Reality-Assisted Breast-Conserving Surgery Using HoloLens 2: Initial Results from a Phase II Trial

Ryosuke Mohri, Hirofumi Terakawa, Chihiro Kawata, Yuuki Kurokawa, Yuuka Nishimura, Miki Hirata, Hiroko Kawashima, Hiroko Ikeda, Tomomi Kitahara, Hideki Moriyama, Jun Kinoshita, Noriyuki Inaki

Background: Achieving clear surgical margins in breast-conserving surgery (BCS) for early-stage breast cancer is essential to minimize local recurrence rates. Traditional imaging methods may not provide sufficient intraoperative guidance, potentially leading to positive margins and the need for additional surgeries. Mixed reality (MR) technology offers real-time, three-dimensional visualization of tumor anatomy, enhancing surgical precision. By integrating MR into existing surgical methods, it may be possible to omit certain procedures and expand the eligibility for breast-conserving surgery.
Methods: We are conducting a prospective, single-arm, phase II trial to evaluate the feasibility, safety, and efficacy of MR-assisted BCS using the HoloLens 2 in patients with stage I–II breast cancer. Eligible patients are females aged 20 years or older with invasive ductal carcinoma and an Eastern Cooperative Oncology Group (ECOG)

performance status of 0–1. Preoperative imaging includes contrast-enhanced breast MRI and CT scans, processed using VINCENT software (FUJIFILM) to create three-dimensional models of the tumor and surrounding breast tissue. These models are further integrated into Holoeyes MD software and visualized through the HoloLens 2 (Microsoft) head-mounted device.
In September 2024, three patients underwent MR-assisted BCS using this protocol. During surgery, the lead surgeon donned the HoloLens 2, which projected the 3D tumor model onto the patient's breast, accurately aligning with anatomical landmarks. This MR overlay provided enhanced spatial awareness, allowing for precise tumor excision. By incorporating this technology, certain intraoperative procedures, such as extensive palpation or additional imaging guidance, could be omitted, potentially simplifying the surgical workflow and expanding the applicability of breast-conserving surgery.
Results: All three surgeries were successfully completed without intraoperative complications. The operative times were approximately 2 hours for each case, consistent with standard BCS procedures. Intraoperative blood loss was minimal and difficult to quantify due to its negligible amount, indicating that MR assistance did not increase bleeding risks. Postoperative follow-up over three days revealed no complications such as infection or hematoma. Pathological examination confirmed negative surgical margins in all cases, with no need for secondary resections. Surgeons reported that the MR system was ergonomically acceptable after a brief training period and did not interfere with the surgical workflow. The enhanced visualization provided by the MR technology facilitated more precise resections while potentially reducing the reliance on intraoperative ultrasound or other imaging modalities.
Conclusions: Preliminary results from this phase II trial suggest that MR-assisted BCS using the HoloLens 2 is feasible and safe for patients with early-stage breast cancer. The integration of MR technology into existing surgical methods may improve surgical precision without extending operative times or increasing intraoperative risks. Minimal bleeding and the potential omission of certain intraoperative procedures highlight the practicality of this approach. Additionally, MR assistance may enable breast-conserving surgery in cases previously considered challenging, thereby offering more patients the benefits of less invasive treatment options. Ongoing enrollment and longer-term follow-up are needed to validate these findings and assess their impact on local recurrence rates and overall patient outcomes.

P4-04-37: SS Induces BRCA1 Reduction and Sensitizes Breast Cancer Cells to PARP Inhibitor Therapy

Jiaqi Chen, Yaguang Xi, Bin Yi

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) have been approved for the treatment of BRCA-mutant breast cancer and high-grade serous ovarian cancer, demonstrating significant efficacy. The presence of a BRCA mutation is critical for the

prescription of PARPi, as their mechanism is based on synthetic lethality. Previous studies have suggested using CRISPR/Cas9-mediated BRCA1 mutation strategies to restore PARPi sensitivity in BRCA wild-type cancers. While promising, this approach poses challenges for clinical implement. Sulindac sulfide, an active metabolite of the non-steroidal anti-inflammatory drug (NSAID) sulindac, has emerged as a potential agent that can enhance cancer cell death when combined with cisplatin and doxorubicin, potentially by impairing DNA repair mechanisms.

Methods: We investigated the mechanism of sulindac sulfide's regulation of BRCA1 using 26S proteasome inhibitors and RT-PCR. The efficiency of homologous recombination (HR) and DNA damage levels were evaluated using γH2AX-ubiquitin foci formation assays and slot blot assays, respectively. To assess the therapeutic potential of combining sulindac sulfide with PARPi, we conducted both in vitro and in vivo studies.

Principal Findings: Sulindac sulfide induced a dose-dependent reduction of BRCA1 through post-translational mediated regulation. Additionally, sulindac sulfide treatment in TNBC cells revealed DNA repair deficiency and increased sensitivity to PARPi therapy. This study provides a basis for further exploration of sulindac sulfide as a potential adjuvant therapy in BRCA1 wild-type cancers, particularly those resistant to conventional PARPi therapy.

P4-04-38: Real world study of racial disparities in toxicities of Antibody Drug Conjugates in advanced breast cancer treatment

Shista Priyadarshini, Justin Petucci, Avnish Katoch, Vasant Honavar, Monali Vasekar

Background: Antibody drug conjugates have revolutionized the treatment paradigm in breast cancer. Fam-trastuzumab-deruxtecan (TD) is used in unresectable or metastatic HER 2 positive and HER 2 low scenarios. In the metastatic hormone receptor positive and triple negative breast cancer, sacituzumab govitecan (SG) has also shown significant benefit. The efficacy of these drugs is well-known but data regarding racial differences in their toxicities is lacking. We analyzed real-world data to explore and contribute to the literature on racial disparities in treatment-related toxicities aiming to reduce drug failure or early discontinuation.

Methods: We utilized TriNetX, a multi-health care organization electronic health record database, to identify African American (AA) and Caucasian (C) cohorts for outcome comparison. Inclusion criteria required a C50 ICD-10-CM diagnosis code and at least one SG or TD treatment. Age, gender, and race-controlled Cox proportional-hazard Andersen-Gill models were applied to analyze time to complete each SG cycle and the time gap between TD treatments, accounting for recurrent treatment events. Multiple logistic regression was used to evaluate the association between race and toxicity outcomes (controlled for age and gender) for cytopenias, nausea, inpatient encounters, cardiotoxicity, interstitial lung disease and diarrhea. Odds ratios (OR) and hazard ratios with 95% confidence interval (CI) are

reported to estimate effect size and statistical significance.

Results: For SG 862 C, 174 AA and for TD 831 C, 145 AA met the inclusion criteria. The mean age, in years, at initiation of treatment was 59.1 +/- 12.4 for C, 56.8 +/- 12.0 for AA among SG and 61.7 +/- 12.3 for C, 57.6 +/- 12.8 for AA among TD. In both SG and TD groups, AA patients had a lower hazard and thus less likely to complete treatment cycle on time at any given time compared to C: 15% (CI: 8-22%) and 14% (CI: 8-19%) respectively. AA experienced 1.46 (CI: 1.04 - 2.07) times higher odds of having a delay longer than 7-days between 2 doses of 1st cycle SG. For TD, AA experienced a 2.7 (CI: 1.7 - 4.2) times increased odds of having a delay longer than 21-days between 3rd and 4th doses. This is associated with an increased odds (OR=7.6, p=0.008) of cardiotoxicity in AA during this time window. No other toxicities resulted in a significant difference between AA and C cohorts.

Conclusions: This study revealed critical findings regarding treatment adherence and delays among patients receiving SG and TD, specifically linked to a particular race. Among both the groups, AA patients demonstrated a lower hazard or less likely to complete their treatment cycle on time at any given point compared to C patients. Furthermore, the odds of delay was noted to be 46% higher in AA during 1st cycle of SG. The cytopenias were analyzed as probable cause but noted to be non-significant. The median number of SG cycles were 3.5 for AA and 4 for C. Interestingly, AA have 170% higher odds of having a delay between 3rd and 4th doses of TD. This correlates with a significant 7.6 times increased odds of cardiotoxicity among AA. The median number of TD cycles were 5 for AA and 7 for C. These findings emphasize the need for future research to focus on intricacies contributing to these disparities and improve patient outcomes.

P4-04-39: Excellent and Prolonged Response to Sacituzumab-govitecan in Triple Negative mBC

Elena Giontella, Elena Fiorio

Background: Triple negative breast cancer (TNBC) is defined by the absence of estrogen and progesterone receptor expression and HER2 expression. This subtype of breast cancer has the worst prognosis and the fewest therapeutic options. In recent years, there has been the advent of both immunotherapy (first in metastatic stages and then also in early breast cancer) and ADCs. Antibody-drug conjugates are used in advanced stages of the disease. In fact the ASCENT study has been shown that sacituzumab govitecan provides a significant benefit compared to single-agent chemotherpay in progression-free survival (PFS) (5.6 months vs 1.7 months) and overall survival (OS) (12.1 months vs 6.7 months) compared to single-agent chemotherapy). Therefore SG is currently used as a second-line treatment for metastatic TNBC. Additionally, the TROPICS-02 study demonstrated a benefit PFS and objective response rate (ORR) in patients with HR+/HER2- metastatic breast cancer (mBC) who had previously been treated with at least one line of endocrine therapy and two to four lines of chemotherapy.

TROP-2 expression is elevated in HER2-negative breast tumors (HR+/HR-) and correlates with poorer survival outcomes. Sacituzumab govitecan (SG) is a pioneering TROP-2-directed antibody-drug conjugate (ADC) that combines an anti-TROP-2 antibody with SN-38, a topoisomerase inhibitor linked through a hydrolysable connector.

Clinical Case: In 2021, a 57-year-old woman presented with a palpable lesion in her left breast. Diagnostic tests, including breast ultrasound and subsequent MRI, revealed a unifocal lesion measuring 4 cm and two ipsilateral axillary lymphadenopathies. A biopsy confirmed the diagnosis of ductal infiltrating carcinoma with ER expression at 9%, PgR negative, HER2 1+, and Ki67 at 40%, indicating locally advanced disease due to axillary lymph node involvement. She underwent neoadjuvant chemotherapy with epirubicin and cyclophosphamide for 4 cycles, followed by carboplatin and weekly taxol for 12 cycles. Despite the low estrogen receptor expression, carboplatin was considered due to the early triple-negative subtype. At the end of neoadjuvant chemotherapy, the patient was underwent a left mastectomy and axillary dissection, With the finding of a pathological complete response at the site of the primary tumor, but with residual disease at the axillary lymph node level. Thus, she was treated with adjuvant capecitabine and adjuvant radiotherapy.
Unfortunately, in January 2023, CT scan presented multifocal recurrence (bone, lung, liver and spleen lesions). A biopsy of a liver lesion was performed, which showed triple-negative histotype.
Since the disease recurrence occurred within 6 months after the completion of adjuvant chemotherapy, we considered the patient for treatment with sacituzumab govitecan plus denosumab (for bone metastasis). At the first follow-up, the CT scan showed a significant response in the liver and lung disease. The patient continued treatment with SG, with total body CT scans every 3-4 months showing maintained disease response. By February 2024, there was complete radiological response of the liver and lung lesions, with stable bone disease. The complete response is still maintained today, after 20 months the beginning of SG.
As adverse events, we report: grade 3 (CTCAE) neutropenia, so it became necessary prophylaxis with G-CSF; grade 1 diarrhea and grade 1 fatigue.

Conclusion: This clinical case offers significant insights. Currently, the PFS has not yet been reached at 20 months, maintaining a complete response in visceral sites and stability in bone disease, while in the ASCENT study, the mPFS was noted at 6.7 months.
The fact that there is weak estrogen receptor positivity may lead to a better response to SG and should it be classified as HR+ or TN? Could it be useful to identify any new biomarkers that may have predictive value, like Trop-2?

P4-04-40: Sentinel Lymph Node Biopsy in the Prognosis of Women Undergoing Neoadjuvant Chemotherapy for Breast Cancer Treatment including advanced Stages: A Real-World Study in a public hospital in Brazil

Rafael Machado, Marcelo Belo, Anke Bergman, Luiz Claudio Thuler

Objectives: To evaluate the impact of Sentinel Lymph Node Biopsy (SLNB) on the prognosis of women undergoing neoadjuvant chemotherapy for breast cancer (BC) treatment, including advanced stages of BC (8th Edition, American Joint Committee on Cancer - AJCC).

Methods: A retrospective cohort observational study was conducted in women diagnosed with BC, enrolled at the Cancer Hospital III of the Brazilian National Cancer Institute José Alencar Gomes da Silva (HCIII/National Cancer Institute - INCA), from January 2013 to December 2015. Patients without a primary indication for surgery, who underwent neoadjuvant chemotherapy, were included. Eligible women were followed until May 30, 2024. Data were collected from both physical and electronic medical records using a specific instrument developed for this purpose. Sociodemographic, clinical, tumor-related, oncological treatment, and prognostic variables were collected. Disease-free survival and overall survival were evaluated using the Kaplan-Meier method and Cox regression with the Stepwise Forward method. This study was approved by the Research Ethics Committee of INCA (CAAE: 06794512.3.00005274).

Results: During the study period, 918 women were eligible, with a mean age of 51.58 years (SD 11.46). Clinical stage III was the most frequent (53.5%), and most patients were classified as luminal B (52.2%) and luminal A (17.8%) subtypes.SLNB was performed in 266 women, mostly with dual-agent labeling (88.2%). In six cases (2.3%), the sentinel lymph node could not be identified, and these patients underwent direct Axillary Lymph Node Dissection (ALND). ALND was performed after SLNB in 105 patients. A median of two lymph nodes (0 to 12) were removed during SLNB, most being negative in both intraoperative analysis (74.1%) and paraffin-embedded hematoxylin-eosin (HE) analysis (67.3%).A higher frequency of SLNB with or without ALND was observed in women with cT1 and cT2 tumors, whereas ALND was more frequently performed in patients with cT4 tumors ($p<0.001$). Regarding clinical lymph node involvement, SLNB was performed in 65.8% of women with cN0, 32.7% with cN1, and 1.5% with cN2 or cN3 ($p<0.001$).A total of 37.8% of the patients had local or distant recurrence during the follow-up period, with a median disease-free survival of 87.8 months (95% CI 84 to 91), which was longer in patients undergoing SLNB (93 months) and SLNB+ALND (90 months) compared to those undergoing ALND (82 months) ($p<0.001$). In the Cox regression analysis adjusted for clinical stage and BC subtype according to immunohistochemistry, patients who underwent ALND had a higher risk of recurrence or metastasis compared to those who underwent SLNB (HR=2.27, 95% CI 1.50–3.45; $p<0.001$), as did those who underwent SLNB+ALND

(HR=1.95, 95% CI 1.18–3.22; p=0.009).Regarding Overall Survival, there were 334 deaths, with an average survival time of 102.2 months (95% CI 99 to 105), which was longer in patients undergoing SLNB (107 months) and SLNB+ALND (103 months) compared to those undergoing ALND (97 months) (p<0.001). In the Cox regression analysis adjusted for clinical stage and BC subtype, patients who underwent ALND had a higher risk of death compared to those who underwent SLNB (HR=2.52, 95% CI 1.61–3.93; p<0.001), as did those who underwent SLNB+ALND (HR=2.40, 95% CI 1.43–4.06; p=0.001).

Conclusions: This study demonstrated the safety of performing SLNB in women undergoing neoadjuvant chemotherapy, including advanced BC stages in a real-world setting of patients treated in the Brazilian Nacional Cancer Institute.

P4-04-41: The impacts of neoadjuvant or adjuvant chemotherapy on surgical complications and cosmetic outcomes of reverse-sequence endoscopic nipple-sparing-mastectomy with immediate breast reconstruction.

Kawun Chung, Yanyan xie, Faqing Liang, Zhongjian Zhu, Qing Zhang, Hui Dai, Tianyuan Li, Xiaoman Cao, Zhenggui Du

Abstract: sBackground The reverse-sequence endoscopic nipple-sparing mastectomy (R-E-NSM) combined with immediate breast reconstruction (IBR) has gained widespread attention in China, becoming a preferred surgical option for breast cancer patients. However, there is a significant gap in understanding how different chemotherapy regimens affect the outcomes of R-E-NSM with IBR. To bridge this knowledge gap, this prospective study aims to comprehensively compare postoperative complications and cosmetic outcomes of R-E-NSM with IBR among patients who received no chemotherapy (NC), neoadjuvant chemotherapy (NAC), and adjuvant chemotherapy (AC). We hope to provide valuable insights that will inform clinical decision-making and optimize patient care.
Method Patients who underwent R-E-NSM with IBR at the Breast Center of West China Hospital, Sichuan University, between April 2020 and December 2023, were stratified into three distinct groups: NC, NAC, and AC. This classification enabled a comprehensive analysis of surgical complications and cosmetic outcomes across the different treatment cohorts, providing valuable insights into the impact of chemotherapy timing on surgical outcomes and patient satisfaction.
Result: A total of 692 patients were prospectively enrolled in this study, including 241 (34.8%) patients who received NC, 113 patients (16.3%) who underwent NAC, and 338 (48.8%) who underwent AC. Compared to the other two groups, patients in the NAC group were younger (P < 0.05) and had a shorter median follow-up (P < 0.05). The AC group, but not the NAC group, showed higher rates of any complications compared to the NC group (26.6% vs. 14.2%, 2.188 [1.415-3.383], P=0.001). Specifically, the AC group had higher rates of particular treatment complications [Clavien-Dindo classification (CDC) ≥ 2] (20.7% vs.

12.6%, 1.820 [1.144-2.895], P=0.036) and surgical site infections (SSI) (18.0% vs. 8.8%, 2.240 [1.322-3.797], P=0.003). Further analysis found that these differences mainly arose more than 30 days after the surgery (any, CDC ≥ 2, SSI, P<0.05). On multivariable analysis, there were significant differences in any complications across the entire time (OR, 1.680 [95% CI, 1.015-2.711], p=0.044) and SSI that occurred more than 30 days after surgery (OR, 2.346 [95% CI, 0.991-5.556], p=0.052) between NC and AC groups. After controlling for clinical covariates, no significant differences were observed between the three groups in terms of the BREAST-Q subscales and Ueda score.
Conclusion: When performing R-E-NSM followed by IBR, administering AC but not NAC (if the surgery is done more than 21 days after NAC) may increase the incidences of any complications compared to those who do not undergo chemotherapy. As measured by breast-Q and Ueda score results, cosmetic outcomes are not affected by NC, NAC, or AC.

P4-04-42: A novel 3D-printed scaffold for patient-specific partial breast reconstruction: A Prospective, Single-Arm Clinical Trial

Lan Hou, Changjiao Yan, Mingkun Zhang, Liu Yang, Zhe Wang, Yuan Qin, Huan Zhang, Zijie Meng, Qing Yao, Rui Ling, Jiankang He, Juliang Zhang

Background: The current scarcity of appropriate breast fillers restricts the availability of breast-conserving surgery for breast cancer patients. Although breast reconstruction can be conducted following a mastectomy, the existing methods for reconstruction are constrained. Three-dimensional (3D) printing technique enables the production of patient-specific and custom-designed scaffold, which may solve this problem.
Methods: A prospective, single-arm clinical trial was performed. This study enrolled breast cancer patients who were not suitable for traditional breast-conserving surgery, including primary tumors larger than 1.0 cm and less than 8.0 cm, or those presenting as multiple diffuse lesions limited to a single quadrant. 3D-printed scaffold was fabricated according to patient's own magnetic resonance imaging (MRI) one week before surgery. Patients were assigned to receive the patient-specific 3D-printed scaffolds transplantation surgery. The primary endpoint of this study is to determine the safety and cosmetic outcomes of partial breast reconstruction using 3D-printed patient-specific scaffolds. The secondary endpoints include degradation of 3D-printed scaffold, complications and satisfaction of patients received this partial breast reconstruction surgery.
Results: Between August of 2016 and August of 2023, 26 patients received partial breast reconstruction using 3D-printed patient-specific scaffolds. The median follow-up was 58.9 months (range, 29 to 88 months). Patients who received partial breast reconstruction with 3D-printed scaffolds have natural-looking and symmetrical breasts after surgery. One year after operation, mild depression at the implantation site was observed in four patients (15.4%). This number increased to seven (26.9%) after two years of surgery. No flap necrosis or ischemia was observed in the nipple and areola area in all patients. Hematoxylin & Eosin showed that fibrous connective tissue, fibroblast cells and blood vessels were observed inside/around the scaffold after one year of surgery. The average degradation rate

of 3D-printed scaffolds is 54.07% at 12 months, 74.48% at 24 months, 86.94% at 36 months, 87.36% at 48 months, and 92.76% at 60 months. The breast satisfaction score rating by Breast-q scale is 68.5±15.7 at 6 months, 65.4±14.2 at 12 months, and 62.8±15.9 at 24 months.
Conclusion: This is the first report of 3D-printed biodegradable scaffolds for breast reconstruction. Partial breast reconstruction using a 3D-printed scaffold presents a viable alternative for breast cancer patients who are not suitable candidates for conventional breast-conserving surgery, yielding promising outcomes.

P4-05-01: Retrospective Analysis of fam-Trastuzumab Deruxtecan Treatment in Advanced Breast Cancer Patients: Real World Experience at Mayo Clinic in Arizona (2022-2024)

Drake Alton, Somanshu Sharma, Farah Raheem, Felipe Batalini, Claire Yee, Jenna Hoppenworth, Roberto Leon Ferre, Lida Mina

Background: Fam-trastuzumab-deruxtecan (T-DXd) was first approved for metastatic breast cancer disease with iHER2 3+ positivity by IHC and/or FISH amplification . Subsequently, it gained FDA approval for HER2 low disease. Recent clinical trials demonstrated significant benefits in a broader patient population, including those with HER2 ultra-low disease potentially expanding its use in more than 85% of patients with advanced breast cancer. Treatment-induced interstitial lung disease (ILD) associated with T-DXd remains a concern that poses unique challenges for the treating oncologists. Understanding the prevalence, characteristics, and risk factors of ILD with T-Dxd in real world clinical settings is crucial for improving patient outcomes .

Methods: In this retrospective study, we included patients with advanced breast cancer treated with T-DXd at the Mayo Clinic Comprehensive Cancer Center in Arizona from July 1, 2022 to January 31, 2024. The electronic medical record extract tool (SlicerDicer) was utilized for patient identification and data collection. Data was collected on patient demographics, breast cancer subtype, treatment course, ILD diagnosis and treatment. The objectives of this retrospective review was to identify the rate of and risk factors for developing ILD with T-DXd. Analyses were conducted using SAS version 9.04. Continuous variables were summarized using median and interquartile range (IQR). Categorical variables were described using frequencies and proportions. Kruskal-Wallis tests and Fisher's exact tests were used to assess the differences between patients with and without ILD.

Results: A total of 64 patients with breast cancer who received at least one dose of T-DXd were identified. Most patients were females (96.9%) and white (82.8%). Approximately, 10.9% of patients were Black and 6.3% were Asian. 40.4% had HER2+ disease, 59.6% had HER2 low disease. Pulmonary comorbidities included asthma (25.8%), history of pneumonitis (9.7%), COVID-19 infection (3.2%), and COPD (1.6%), with 35.9% of patients having a prior history of smoking. Of the 64 patients who received T-DXd, more than 20%

of patients required at least one dose reduction of TDXd with 14.1% requiring 1 dose reduction and 6.3% requiring 2 dose reductions because of side effects. 8 developed ILD (12.5%). The median age at ILD diagnosis was 56.6 (IQR, 55 - 66) Patients who developed symptoms presented with cough (42.9%), shortness of breath (57.1%), and had a median spO2 87% (IQR, 85-89%). The median time to ILD development was 197 days (IQR, 165 – 634). Ground-glass opacities and consolidations were commonly seen on imaging (75% and 50%, respectively). Of the 8 patients diagnosed with ILD, 3 were hospitalized during their presentation. Of these, 2 were required to be admitted to the ICU and were then released from the hospital and 1 patient transitioned to inpatient hospice. All patients with ILD were treated with high dose corticosteroids and none of them were rechallenged with T-DXd. Analysis of demographics data between patients with vs. without ILD revealed that there is no difference between the two groups with the exception of race. Race was an independent predictor of ILD, with 4 out of 53 vs. 2 out of 7 vs. 2 out of 4 patients developing ILD in the White vs. Black vs. Asian patient population with a significant p-value of 0.0178.

Conclusion: In this study, the incidence of ILD with T-DXd was 12.5%. Demographic differences were not significant, except for race. However, due to the small sample size, we should be cautious when extrapolating these findings. Larger studies are needed to confirm these results and identify additional risk factors for ILD in real-world clinical settings. Recognizing risk factors can guide monitoring and improve guidelines for managing ILD in breast cancer patients receiving T-DXd.

P4-05-02: Strategies for premedication and neutropenia prophylaxis in sacituzumab govitecan treatment of patients with triple-negative breast cancer: multicenter insights

Miroslawa Puskulluoglu, Malgorzata Pieniazek, Joanna Streb, Manuela Las-Jankowska, Marek Ziobro, Renata Pacholczak-Madej, Paulina Kilian-Van Miegem, Agnieszka Rudzinska, Aleksandra Grela-Wojewoda, Aleksandra Łacko, Michał Jarzab, Anna Polakiewicz-Gilowska

Background: Sacituzumab govitecan (SG) is approved for use in the second line and beyond for advanced triple-negative breast cancer (TNBC), improving survival outcomes compared to standard chemotherapy. As demonstrated by the ASCENT trial and real-world data, typical adverse events (AEs) of SG include myelosuppression, diarrhea, nausea, vomiting, or hepatic toxicity. Premedication strategies should address these AEs. In patients with specific AEs, additional prophylaxis, such as granulocyte colony-stimulating factor (G-CSF), may be required. The purpose of this study was to evaluate premedication policies, adjustments, and G-CSF application in patients with TNBC treated with SG.

Materials and Methods: In this ambispective multicenter cohort study (five oncology units in Poland), we collected data on the prophylactic application of G-CSF and initiation and modification of premedication with various agents during SG treatment in patients who

completed SG therapy for any reason by April 2024 and received at least one full SG cycle (day 1 and day 8). We evaluated the use of drugs such as acetaminophen, corticosteroids, atropine, H1/H2 blockers, 5-hydroxytryptamine 3 (5-HT3) receptor antagonists, neurokinin-1 (NK1) receptor antagonists, filgrastim, and pegfilgrastim/lipegfilgrastim. Adverse events were assessed according to the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI-CTCAE) version 5.0.

Results: Fifty female patients met the inclusion criteria. The median age at treatment initiation was 52.6 years, and the median number of SG cycles completed was 4 (cycle 4, day 8). During the first cycle, 47 patients (94%) received 1 gram of iv acetaminophen, while 3 patients did not receive it throughout their treatment. All patients received steroids (typically 8 milligrams of iv dexamethasone) and 5-HT3 antagonists (usually 8 milligrams of iv ondansetron). One patient required the addition of NK1 antagonists (aprepitant at typical doses for 3 days) in later cycles. Thirty-six patients (72%) received H1 blockers (2 milligrams of iv clemastine), with one patient receiving it in later cycles due to a hypersensitivity reaction. Thirty-eight patients (76%) received H2 blockers (40 milligrams of oral famotidine), with none requiring its addition in later cycles.
18 patients (36%) received G-CSF as primary prophylaxis starting on day 2 or 3 of cycle 1 due to a prior history of neutropenia or febrile neutropenia. However, as many as 40 patients (80%) required G-CSF as primary or secondary prophylaxis throughout the SG treatment. Typically, filgrastim was administered for 3-4 days starting at day 2-3 and for 5 consecutive days starting at day 9-10 (or pegfilgrastim/lipegfilgrastim as a single dose on day 9-10 in 10 patients). G-CSF was usually initiated due to grade 3 neutropenia, with a median onset after cycle 2, day 1. None of the patients received subcutaneous atropine on cycle 1, day 1, but 3 required it before subsequent cycles due to grade 3 diarrhea. In 6 patients, various schedules and types of steroids were used for secondary prophylaxis of neutropenia, and in 1 patient for thrombocytopenia.

Conclusions: The majority of patients received prophylaxis with acetaminophen, H1/H2 blockers, steroids, and 5-HT3 antagonists. SG AEs are well-known and predictable, resulting in similar prophylactic approaches for majority of patients. The most significant disparities were related to G-CSF application in primary and secondary prophylaxis. Patients typically required G-CSF initiated as early as during the second cycle of SG. The use of steroids as secondary prophylaxis for neutropenia remains controversial and should be avoided. Only a few patients required atropine as secondary diarrhea prophylaxis.

P4-05-03: Acceptability and feasibility of early cancer physiatry consultation in management of aromatase inhibitor-induced musculoskeletal symptoms (AIMSS) in early-stage hormone receptor positive breast cancer

Oday Elmanaseer, Arun Kumar, Ami Chitalia, Eric Wisotzky

Aromatase inhibitors (AIs) are the mainstay of adjuvant therapy for postmenopausal hormone receptor (HR)-positive breast cancer (BC). AI-induced musculoskeletal symptoms (AIMSS) are a common side effect seen in up to 50% of patients, leading to discontinuation in 20-30%. This non-adherence is an independent predictor of mortality. While guidelines for AIMSS management are lacking, exercise, physical therapy, and acupuncture offer benefit, and pharmacologic options exist. However, preventative measures remain unexplored. Physiatrists, physicians who specialize in physical medicine and rehabilitation, can employ conservative measures that may help to treat and/or prevent AIMSS. This study evaluated the feasibility and acceptability of early physiatry consultation for AIMSS.

Methods: Patients with early-stage HR-positive BC starting AI therapy were enrolled in this prospective study. Patients underwent baseline physiatry consultation before AI initiation, followed by visits at 6 weeks, 3 months, and 6 months. Primary objectives were feasibility (determined by appointment attendance) and acceptability (measured by the validated Treatment Acceptability and Preference (TAP) score at 6 months), a mean TAP score above mid-point scale of 2, deems the intervention acceptable.

Results: 25 patients enrolled in this prospective study. 76% were African American, and 24% were Caucasian. The mean age was 66.2 years. The mean BMI was 28.2. 100% of patients attended all physiatry clinic visits, demonstrating the intervention is feasible. The average TAP score of the cohort was 2.7 (SD +/- 0.9) indicating that early physiatry consultation is acceptable. During physiatry visits, diagnostic imaging was performed in 24% of patients and 40% were offered referral to physical therapy. 2 patients were offered bracing, 2 patients received injections, 3 patients were given prescription medications, and 6 patients were offered over the counter (pain) medications. More than 50% were prescribed topical NSAIDS.

Conclusion: Early cancer physiatry consultations are feasible and acceptable for BC patients on AI therapy. A larger prospective study with a control group is needed to evaluate if this multidisciplinary approach can reduce AIMSS, thus promoting adherence and potentially improving survival outcomes. Physiatry consultation can offer counseling and diverse pharmacological/non-pharmacological interventions for AIMSS management.

P4-05-04: Evaluating the ePRO-based follow-up system (Pink Ribbon Diary) on quality of life and treatment adherence in patients with breast cancer receiving CDK4/6 inhibitors (JPRO-B)

Rie Ozeki, Hideo Shimizu, Kotaro Iijima, Misato Okazaki, Ayumi Watanabe, Sachiko Taka, Kouji Yamamoto, Junichiro Watanabe, Mitsue Saito, Goro Kutomi

Introduction: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) improve the prognosis of estrogen receptor-positive (ER+) HER2 negative (HER2-) advanced breast cancer (ABC) patients, however, our concerns are treatment-related toxicities ≥ Grade 2 during treatment, decrease of QOL and influence on adherence to medication. We have recently developed an electronic patient-reported outcome (ePRO), the Pink Ribbon Diary (PRD), that allows patients to record their medication and their physical conditions easily to detect side effects as early as possible, in order to maintain treatment adherence and QOL. We investigated the clinical efficacy of the PRD in patients with ER+HER2-ABC undergoing CDK4/6i-based therapy.

Methods: Seventy patients were enrolled in this single-center, randomized, open-label, placebo-controlled, phase II trial. Patients with ER+HER2-ABC receiving oral CDK4/6i-based therapy were assigned 1:1 to either arm A using the ePRO system or arm B receiving usual care. Participants in arm A were required to record their medication taken and physical conditions daily for 3 months, and report adverse events weekly using PRO-CTCAETM. Participants in arm B were also asked to answer to questions about adverse events using PRO-CTCAETM at monthly visits during the three-month period. All participants were asked to complete to the EORTC QLQ-C30 at their monthly visits and were administered an adherence questionnaire survey before and after the study. The primary endpoint was the change in global health status/QOL (EORTC QLQ-C30) from baseline to 3 months.

Results: Sixty-five participants were eligible for data analysis. Three months global health status/QOL score went from 64.8 to 67.4 in arm A, a change from baseline of 2.6 points (N=32), and from 65.7 to 64.1 in arm B, a change from baseline was -1.5 points (N=33) (P=0.4552). In a post questionnaire, 96.9% of patients reported that the PRD was easy to use, with the most useful feature of the PRD being the ability to record medication (81.3%). All also indicated that communication with their health care providers in the PRD helped patients feel more relief and motivated to take treatment.

Conclusions: The use of the PRD, while not significant, tended to improve QOL, and support patients in taking their medications, indicating that communication with health care providers leads to safe medication use.

P4-05-05: Investigating the Efficacy and Safety of a Dose-Dense Paclitaxel, Cyclophosphamide with Trastuzumab in Stage I-III Human Epidermal Growth Factor Receptor 2 (HER2) Positive Breast Cancer

Jairam Krishnamurthy, Lina Elsayed, Elizabeth Reed, Shivani Modi, Pavan Tandra, Mehmet Copur, Kaeli Samson

Background: The evolution of systemic therapies has improved outcomes for patients with human epidermal growth factor receptor 2 positive (HER2+) breast cancer. Nonetheless, the tolerability and safety profile of systemic therapies represent an area for further improvement. Here we report the results of a phase 2 trial evaluating a non-anthracycline, non-platinum adjuvant treatment regimen for patients following initial surgical resection.

Methods: We enrolled patients with stage I or II HER2+ breast cancer who underwent upfront surgery to receive adjuvant treatment with 6 cycles of dose-dense Paclitaxel, cyclophosphamide and Trastuzumab (PC-H) every 2 weeks, followed by 13 cycles of maintenance trastuzumab every 3 weeks to complete 52 weeks of treatment (comprising 19 cycles). The primary objective was to determine the safety and feasibility of adjuvant PC-H measured by the completion rate and the frequency and the grade of adverse events, using National Cancer Institute Common Terminology Criteria. The secondary objective was to estimate relapse-free survival and overall survival.

Results: Between 2010 and 2019, a total of thirty-nine patients were enrolled. Of those, 34 patients (87.18%) completed the planned treatment. Sever adverse events of grade 3 or 4 occurred in 27 patients (69.23%), including 3 patients (7.69%) with grade 3-4 decrease in ejection fraction. At median follow up of 5.6 years, all 39 patients were alive. The 5-year relapse-free survival was 94.30% (95% CI: 75.3-100).

Conclusions: PC-H regimen demonstrated overall safety and efficacy, yielding high rates of relapse-free survival among patients with early stage (HER2+) breast cancer.]

P4-05-06: The role of music therapy, guided meditation and acupuncture in attenuating chemotherapy-induced cognitive impairment in breast cancer.

Jules Cohen, Gaurav Sharma

Background: Breast cancer treatment, particularly chemotherapy, is known to cause cognitive impairment, often referred to as "chemo fog" or "chemo brain," which can persist for months to years after treatment has been completed. Currently, there are no proven options to attenuate the development of cognitive impairment in chemotherapy patients.

Some non-pharmacological interventions that may help alleviate chemotherapy-induced cognitive impairment include music therapy, guided meditation (or mindfulness), and acupuncture. Music therapy has been shown to activate cortical areas in the brain that help with emotional processing and stress while acupuncture is hypothesized to promote neuroplasticity, reduce inflammation and improve cerebral blood flow. Guided meditation has been shown to improve memory and executive function potentially by preventing neuronal loss during chemotherapy. Acupuncture, guided meditation and music therapy have all shown promise in alleviating cognitive and emotional symptoms in those with mild cognitive impairment and dementia. Their efficacy in addressing chemotherapy-induced cognitive impairment (CICI) in breast cancer patients remains underexplored.

Objective: This study aims to evaluate the effectiveness of music therapy, guided meditation and acupuncture in mitigating cognitive impairment in breast cancer patients undergoing chemotherapy. We hypothesize that these complementary interventions will blunt any cognitive impairment in patients receiving neoadjuvant and adjuvant chemotherapy.

Methods: Participants will be randomly assigned to one of four groups: (1) guided meditation and music therapy; (2) guided meditation and acupuncture; (3) music therapy and acupuncture; and (4) no intervention. Cognitive function will be assessed using a PROMIS NIH questionnaire across domains related to anxiety, depression, cognition, fatigue, sleep, companionship, and emotional support. Data will be analyzed to compare the efficacy of the intervention groups against each other as well as against the control group.
Results: We anticipate that the combined intervention of acupuncture and music therapy will result in significant improvements in cognitive function compared to other interventions and the control group. We believe that the domains most likely to be affected include anxiety, depression, cognition, and emotional support. We anticipate that the (1) guided meditation and music therapy and (2) guided meditation and acupuncture intervention groups will also show improvements in cognitive function compared to the control group.

Conclusions: The study aims to provide evidence that the combination of acupuncture and music therapy offers a novel, non-pharmacological approach to alleviating chemotherapy-induced cognitive impairment in breast cancer patients. If successful, these interventions could be incorporated into standard supportive care practices, improving the overall quality of life for patients suffering from cognitive deficits post-chemotherapy. Further research will be needed to fully understand the underlying mechanisms and optimize treatment protocols to attenuate chemotherapy-induced cognitive dysfunction.

P4-05-07: Estimating Clonal Hematopoiesis Prevalence in Women with Breast Cancer: A Meta-Analytic Approach Stratified by Age

Pedro Robson Costa Passos, Valbert Oliveira Costa Filho, Mariana Macambira Noronha, Roberta Taiane Germano de Oliveira, Duílio Reis da Rocha Filho, Leonardo Saraiva Pontes, Francisco Pimentel Cavalcante, Eduardo Araújo Costa Lima, Cecília Dias Caminha Gentile, Gabriel Fontenelle Costa, Júlia Matos Dubanhevitz, Saulo Rabelo Costa, João Luiz Lima Pinheiro, Eduarda Severo Alvarenga, Fabrícia Cardoso Marques, Danielle Calheiros Campelo Maia, Francisco Pimentel Cavalcante, Silvia Maria Meira Magalhães, Ronald Feitosa Pinheiro

Introduction: Clonal hematopoiesis (CH), characterized by genetically distinct blood cell subpopulations arising from somatic mutations, becomes more prevalent with age and is linked to higher risks of hematologic malignancies and cardiovascular diseases. In breast cancer (BC), the relationship between CH and cancer-related mutations is an emerging area of study, as the genetic interplay between these mutations and cancer development is puzzling. CH-related mutations have been shown to alter solid tumor microenvironment and are speculated to significantly influence angiogenesis, which could underscore CH as influential to BC development and progression. Moreover, cytotoxic treatments' myelotoxic effects on this parameter are not fully understood. This meta-analysis synthesizes data on CH incidence in women with BC, estimating its prevalence and helping elucidate the necessity of a specific CH screening in this population.

Methods: We searched the PubMed, EMBASE, and Cochrane databases for studies reporting the prevalence of somatic mutations related to CH in women with BC. For studies providing data at both baseline and during treatment, we selected the treatment data to account for possible treatment effects. To account for age-related differences, as this highly influences CH incidence, we stratified the data into three groups: young (≤40 years), characteristic (41-69 years), and older (≥70 years) patients. We excluded studies that did not report the mean or median age of patients, had a variant allele frequency threshold for CH mutations lower than 0.02 (2%), or only made composite assessments with other tumors available. Proportions of CH incidence were pooled using a meta-analysis of proportions with logit transformation, performed in the software R.

Results: Three full articles and five abstracts were included in the meta-analyses. Of these, five studies had patients with a mean or median age in the characteristic group (41-69 years), which had an estimated CH incidence of 15% (95% CI: 13%-17%). Two studies focused on older populations (≥70 years), with an estimated CH incidence of 55% (95% CI: 42%-68%). Only one study focused on younger women (≤40 years), with an estimated CH incidence of 4% (95% CI: 3%-6%). The subgroup differences were evident in the forest plot and confirmed by moderator analyses ($p < 0.001$ for all comparisons).

Conclusion: Our meta-analyses underscore the prevalence of CH in women with BC, which closely mirrors statistics and age-related tendencies observed in the general population. Our data reaffirms age as a significant factor in CH development. This research does not show evidence supportive of CH specific screening for BC populations, although it reinforces

the standard investigation in older patients. Nonetheless, specific treatments or risk factors may make investigation in younger ages valid. Further research, spanning different age groups and treatment modalities, is crucial for advancing our understanding of CH in BC and optimizing therapeutic interventions.

P4-05-08: Impact of antiemetic prophylaxis on maintaining dose intensity of trastuzumab deruxtecan in HER2-positive advanced breast cancer

Junghoon Shin, Ji-Yeon Kim, Jin-Seok Ahn, Yeon Hee Park

Introduction: Maintaining dose intensity is crucial for optimizing outcomes in patients with HER2-positive advanced breast cancer (ABC) treated with trastuzumab deruxtecan (T-DXd). Nausea and vomiting are among the most frequent adverse events associated with T-DXd and often lead to dose reductions, potentially compromising efficacy. While T-DXd is classified as moderately to highly emetogenic, clinician education on appropriate antiemetic prophylaxis is crucial, especially given the extended treatment duration due to its remarkable efficacy. This analysis investigated the impact of guideline-recommended antiemetic prophylaxis in the first cycle on maintaining T-DXd dosing over time.

Methods: Data from patients with HER2-positive ABC treated with at least two cycles of T-DXd were extracted and analyzed from the clinical data warehouse of Samsung Medical Center. Patients were grouped based on the use of a guideline-recommended triple antiemetic regimen (TAR) in the first cycle of T-DXd. The TAR consisted of either the fixed combination of netupitant/palonosetron (NEPA) or the combination of an NK1 receptor antagonist (RA) and a 5-HT3 RA plus dexamethasone. The proportions of patients requiring a reduction from the 5.4 mg/kg starting dose of T-DXd to 4.4 mg/kg and 3.2 mg/kg were calculated for both TAR and non-TAR groups.

Results: Between June 29, 2022 and May 5, 2024, 59 patients with HER2-positive ABC received a median of 7 cycles (range, 2–30) of T-DXd. The median age at initiation of T-DXd was 55 (range, 28–79). Prophylactic TAR was administered to 49 (83%) patients in the first T-DXd cycle: 46 with NEPA and 3 with other NK1 RA and 5-HT3 RA combinations. Ten patients (17%) initially received either a 5-HT3 RA alone (n=9) or no prophylaxis (n=1). Patients who received TAR in cycle 1 were less likely to require T-DXd dose reduction to ≤4.4 mg/kg (24% vs 50%, p=0.133) or ≤3.2 mg/kg (0% vs 10%, p=0.169), with a significantly greater magnitude of dose reduction observed in patients who did not receive TAR in cycle 1 than those who did (P=0.011). Following an institutional policy change favoring NEPA due to the high incidence of nausea and vomiting with other regimens, 8 of 9 patients initially on a 5-HT3 RA alone and 2 of 3 patients initially on other NK1 RA and 5-HT3 RA combinations switched to NEPA. At the data cutoff, no patients discontinued T-DXd due to intractable nausea and vomiting; 44 (75%) patients continued to receive T-DXd, while 8 (14%), 4 (7%), and 2 (3%) patients discontinued due to disease progression, death,

or pneumonia/pneumonitis, respectively. One patient was lost to follow-up after cycle 2.

Conclusion: These results highlight the previously unreported finding that administering guideline-recommended TAR prophylaxis facilitates maintaining the dose intensity of T-DXd throughout treatment. Using an appropriate upfront antiemetic regimen when initiating T-DXd is critical to optimize patient outcomes.

P4-05-09: ERIBULIN'S ARCANE ODYSSEY: UNRAVELING STEVEN JOHNSON SYNDROME (SJS) /TOXIC EPIDERMAL NECROLYSIS (TEN) IN METASTATIC BREAST CANCER

Arti Goel, Sudeep Gupta, Prabhat Ghanshyam Bhargava, Seema Gulia, Sushmitha Rath, Shalaka Joshi, Tabassum Wadasadawala, Dileep Hoysal

Abstract: Eribulin mesylate is a non-taxane inhibitor of microtubule dynamics belonging to the halichondrin class of antineoplastic drugs. It is a novel agent that inhibits the microtubule growth phase without affecting the shortening phase, causing tubulin sequestration into non-productive aggregates. Eribulin is used as monotherapy in heavily treated metastatic breast cancer patients resistant to taxane or anthracycline-based chemotherapy. Common Grade 3 or 4 adverse events with Eribulin include neutropenia (52%), leucopenia (23%), thrombocytopenia (19%), and peripheral neuropathy (35%). Cutaneous manifestations with Eribulin are uncommon. However, Steven Johnson Syndrome (SJS) / Toxic Epidermal Necrolysis (TEN) is a rare and severe mucocutaneous reaction characterized by extensive necrosis and detachment of the epidermis, often triggered by medications. Here we present a case of SJS/TEN caused by Eribulin in a woman with Metastatic Breast cancer.
Introduction: A 55-year-old post-menopausal hypothyroid woman was diagnosed with triple-negative breast cancer (TNBC) with metastasis to the liver and non-regional nodes. She was found to be refractory to anthracycline, docetaxel, capecitabine, and platinum agents and was thus planned for Eribulin monotherapy as a third-line agent. On day 11 of Cycle 1 of Eribulin at 1.4 mg/m^2, she presented with high-grade fever and a rash over her torso and arms, which gradually spread to approximately 80% of her body surface area. Further examination revealed Grade 2 oral mucositis as per the Common Terminology Criteria for Adverse Events (CTCAE) v5.0. The rash initially presented as targetoid lesions involving the torso and then gradually covered up to 80% of the body surface area, sparing the scalp. Later, the rash became confluent and formed flaccid bullae, but the Nikolsky sign was negative. She had a persistent high-grade fever with temperatures reaching up to 104°F. All infective workup evaluations were negative. Her lab parameters suggested Grade 2 transaminitis, Grade 2 hypokalaemia, and hyponatremia as per CTCAE v5.0. Blood culture and swab culture from the skin lesions were negative. She was non-neutropenic throughout the course. A skin punch biopsy of the largest lesion on her back showed trans-epidermal neutrophilic infiltration, suggestive of a drug-induced hypersensitivity reaction. Ruling out

other infective etiologies and considering the temporal relationship between initiating Eribulin therapy and the development of the rash, she was clinically diagnosed with Stevens-Johnson Syndrome (SJS) / Toxic Epidermal Necrolysis (TEN). Further probing confirmed that her drug history did not indicate any alternative medications intake. Due to persistent high-grade fever, she was started on empirical antibiotics, meropenem, and teicoplanin. As there was no clinical improvement over 24 hours, she was started on dexamethasone at 24 mg/day. Over 15 days, with gradual tapering, her skin lesions healed by more than 75% from baseline. She was discharged in a hemodynamically stable condition. On her first follow-up visit after 15 days, her lesions had healed, with mild hyperpigmentation persisting over her face and arms.

Conclusion: SJS/TEN is a life-threatening mucocutaneous reaction that typically is not associated with chemotherapy. We present a case of SJS/TEN where the drug eribulin was identified as the causative agent. Despite the high mortality rate of TEN (>30%), our patient successfully recovered, likely due to the prompt recognition of the syndrome, immediate discontinuation of the causative drug, and timely treatment with steroids. This case underscores the critical importance of considering SJS/TEN in any patient presenting with an extensive, desquamative rash following eribulin chemotherapy. Quick intervention can be the difference between life and death, highlighting the need for vigilance and rapid response in managing adverse drug reactions.

P4-05-10: Outcomes of Chemotherapy-Induced Peripheral Neuropathy (CIPN): Psychological Impact and Predictive Modeling

Carla Bou Dargham, Ken B. Johnson, Anukriti Sharma, Alper Sen, Bihua Bie, Emily E. Rhoades, Courtney Hershberger, Mei Wei, Lynn Henry, G. Thomas Budd, Joseph Foss, Daniel M. Rotroff

Introduction: CIPN from taxanes involves numbness, tingling, or burning or shooting pain in the hands and feet. In some patients, these effects are debilitating and can interfere with treatment, leading to taxane dosing changes or discontinuation. The aim of this study was to use a machine-learning approach to build a predictive model of CIPN from clinical data and patient reported outcomes (PRO) collected before taxane treatment. The study hypothesis was that predictive model of CIPN would identify patients that would develop CIPN.

Methods: In a multicenter observational study, breast cancer patients receiving taxane treatment were invited to participate over 12 months period. PRO were collected at seven visits before (visit 1), during (visits 2-4), and after (visits 5-7) taxane treatment. The outcomes included assessments of CIPN, anxiety, and depression. The EORTC QLQ-CIPN20 was used to evaluate the presence and severity of CIPN. Moderate to severe CIPN was defined as an 8-point increase from baseline. Anxiety was measured using Generalized Anxiety Disorder 7-item scale (GAD-7). The GAD-7 score was interpreted as no (0-4), mild (5-9), moderate (10-14) and severe (15-21) anxiety. Depression was measured using PHQ8.

PHQ8 depression raw scores are categorized as follows: none (0-2), mild (3-5), moderate (6-8), and severe (9-12). Wilcoxon-ranked sum tests were used to explore differences in patient reported outcomes between time points and between patients that did and did not develop CIPN. P values were adjusted using a False Discovery Rate (FDR) approach. Using machine learning, a Random Forest model, based on 500 trees and three variables per split (randomly selected features for each decision point), was built using clinical features before taxane initiation to predict CIPN. Features included GAD7, PCS (Pain Catastrophizing Scale), PHQ-8, BPI (Brief Pain Inventory), PROMIS physical and sleep scores, dietary habits, baseline CIPN scores, age, race, smoking status, chemotherapy regimen, CCI (Charlson Comorbidity Index), and BMI. Model accuracy was assessed using Out of Bag (OOB) error analysis, providing an unbiased estimate of the generalization error.

Results: From January 2021 to February 2024, 400 patients were enrolled. Clinical and PRO data from visits 1 through 7 were used in this analysis. 241 patients completed all 7 visits, out of which 182 developed CIPN while receiving taxanes. For the patients who completed all 7 visits (241), median anxiety scores dropped from 4 (IQR = 1-7) at baseline to 2.3 (IQR 1-5.3) (FDR P = 7.1 x 10-9) during treatment and 2.3 (IQR 0.3-5) (FDR P = 7 x 10-10) after treatment. While on treatment, median anxiety scores were 2.5 (IQR = 1-5.9) and 1.5 (IQR = 0.4-3.5) (FDR P=.03) for patients with and without CIPN. The PHQ8 depression scores were analyzed at baseline for all 400 patients. Median raw PHQ8 depression scores at baseline were 4 (IQR 2-7) and 3 (IQR 1-5) (FDR P = 0.03) for patients with and without CIPN. Using data from visit 1 (baseline visit before taxane therapy), the Random Forest model's ROC predictive accuracy was 0.72 in identifying patients that would develop CIPN. Of all the clinical and patient reported outcomes, BMI, age, anxiety scores, and depression scores were the most influential in predicting CIPN.

Conclusion: While on taxane treatment, although anxiety and depression scores were statistically different between patients with and without CIPN, scores in both groups suggested no clinically relevant anxiety or depression.
Model prediction of CIPN was poor suggesting that clinical and PRO data alone may be inadequate to predict CIPN. Future work is warranted exploring the use of molecular biomarkers to improve model accuracy.

P4-05-11: Physical changes caused by low-dose Tamoxifen therapy

Daniel Hendler, Sivan Agranat, Olga Ulitsky, Matan Ben-Zion Berliner, Ofer Rotem, Yinon Gilboa, Rinat Yerushalmi

Background: Ten-year data of the phase III trial TAM-01 showed that low-dose Tamoxifen reduced recurrence of invasive breast cancer and ductal carcinoma in-situ.
Purpose: The first objective of the study was to learn about the gynecological and other side effects caused by low-dose Tamoxifen therapy in daily practice. A second objective was to report disease outcome.

Methods: The study group consisted of women with DCIS who received low-dose Tamoxifen and did their follow-up at Davidoff Center in Israel. Consecutive patients from July 2019 to July 2021 were enrolled. The endometrial thickness, uterine fibroid and uterine polyps were assessed by gynecological US. General potential side effects were assessed by a questionnaire.
Results: A total 33 patients were enrolled. 23 of them were included in the study. The median follow-up was 50 months (38, 60). The median age at diagnosis was 51 (40,66) years. 8.6% of the women were referred to an endometrial biopsy or polypectomy during the study period, none of them discovered malignancy. The median endometrial thickness before the treatment with Tamoxifen was 4 (2,9) mm, the median maximal endometrial thickness during the treatment with Tamoxifen was 8 (4,15) mm. New symptoms were developed during the treatment, 47% of the women reported hot flashes, 43% leg cramps and 37.5% of premenopausal women reported prolongation of the menstrual cycle. One (4.3%) of the women developed DCIS recurrence.
Conclusions: Low-dose Tamoxifen therapy is associated with increased endometrial thickness, formation of new endometrial polyps, and general side effects such as hot flashed and leg cramps.

P4-05-12: A meta-analysis of adverse events associated with anti-PD-1 therapy

Balazs Gyorffy, Janos Tibor Fekete

Anti-PD-1 therapies have revolutionized cancer treatment by significantly improving clinical outcomes. However, the safety profile of these therapies remains a critical concern. This meta-analysis aimed to evaluate the correlation between anti-PD-1 therapy and the occurrence of adverse events (AEs).
We systematically analyzed data from ten studies, encompassing a total of 4,379 patients treated with anti-PD-1 agents and 3,720 control subjects. The statistical platform available at www.metaanalyisonline.com was used for data analysis. Using a random effects model with the Mantel-Haenszel method, we observed a statistically significant increase in the risk of AEs in the anti-PD-1 cohort compared to controls (risk ratio: 2.15, 95% CI: 1.39 - 3.32, $P<0.05$). Despite the observed association, substantial heterogeneity was detected among the studies ($P<0.01$, $I^2 = 95\%$), indicating variability in the magnitude and direction of effects. Funnel plot analysis and Eggers' test revealed potential publication bias (intercept: 3.85, 95% CI: 1.39 - 6.3, P=0.015). Additionally, a Z-score plot indicated that the cumulative sample size (n=8,099) did not reach the optimal threshold for a definitive conclusion (n=24,056 at a significance = 0.05, type II error level = 0.2, and minimal clinically relevant outcome = 30%).
These findings highlight the importance of continuous monitoring and reporting of AEs in patients undergoing anti-PD-1 therapy to ensure a comprehensive understanding of its safety profile. However, currently available studies show considerable heterogeneity and insufficient number of cases, suggesting the need for extensive further research.

P4-05-13: The quality of life of women after treatment of breast cancer is lymphostasis as a life-changing complication.

Marha Mukueva, Mukueva M.I, Soynov A.V., Sharavina M.V., Vorotnikov V.V., Andreeva V.A., Kopytich I.V., Abdugaffarov S.A., Mchedlidze T.G., Tsalko S.E., Tkachenko A.V., Voronov M.V., Gugnina A.S.

Relevance: Lymphedema (lymphostasis) is an edema of the hand characterized by the accumulation of fluid in the intercellular space, which develops as a result of dysfunction in the lymphatic system. Lymphedema develops in about 40% of patients within 8-10 years after surgical treatment in the volume of axillary lymphadenectomy. In the case of axillary lymphadenectomy in combination with radiation therapy, the risk of lymphedema in some cases reaches 60%. Also, even in the case of a biopsy of "signal" lymph nodes, the risk is 4-5%. Complete Decongestive Therapy (CDT) is a method of treating lymphedema (lymphostasis), which is currently considered the "gold standard" in the treatment of lymphedema in Europe and the United States. This method involves a special lymphatic drainage massage and banding the upper limb with the subsequent wearing of compression knitwear.

Research methods: Materials and methods: Two doctors and 2 nurses have been specially trained in our surgical department to introduce conservative techniques into practice. 30 patients who had previously received treatment in our center and who were diagnosed with stage 2-4 lymphostasis using ICG lymphography, lymphoscintiography, volumetric measurements, physical examination were examined. The main complaints of patients are the feeling of heaviness and schedule in the upper limb on the side of the operation, swelling of the upper limb, dysfunction of the upper limb on the part of the operation, recurrent erysy inflammation. The average volume difference between a healthy hand and a hand in which lymphostasis developed was 5-6 cm. At the same time, there was a positive symptom of Stemmer and Pitting test on the affected arm.

Results. Patients were given courses of complex physical anti-edema therapy. The number of courses ranged from 5 to 10 courses. After the courses, the patients subjectively noted an improvement in general well-being in the form of a decrease in gravity in the affected limb, a decrease in puffiness, restoration of limb function. The average difference in volume between a healthy hand and a hand in which lymphostasis developed before the procedures was 5-6cm, after the procedures 1-2cm. Patients were performed a control ICG lymphography, on which positive dynamics was observed.

Conclusions: Complete Decongestive Therapy (CDT) is the "gold standard" of lymphostasis treatment, which leads to an improvement in the quality of life. This method does not create an economic burden, as it requires only specially trained medical personnel and special bandages. The high effectiveness of this method and the lack of alternative conservative methods of treatment of lymphostasis indicate the need to introduce this method of

treatment into medical standards of care for patients with lymphostasis. Mastering this technique in a surgical hospital allows you to better understand the mechanisms of lymphedema development, as well as to take timely measures for prevention through special surgical interventions and/or training of patients.

P4-05-14: Prognostic factors of one versus two pregnancy associated breast cancer

Maxim Izquierdo

Aims. The five year interval pregnancy associated breast cancer has resulted in patients with two pregnancies. Study ans assess the diferences in the prognostic factors with one and two pregnancies associated with breast cancer
Methods. Study 134 pregnancies associated breast cancer treated in the same hospital, 110 with one pregnancy associated breast cancer and 24 with two pregancies associated breast cancer. Analyze prognostic factors: estrogen receptor, progesterone receptor, human epidermal growth factor receptor 2 (HER2), histological grade and Ki67, with one and two pregancies associated breast cancer
Results. 110 patients with one pregnancy associated breast cancer, estrogen receptor is positive in 89 (80'90%) patients and estrogen receptor inegative in 21 (19'09%) patients. 24 patients with two pregnancies associated breast cancer, estrogen receptor is positive in 14 (58'33%) patients and estrogen receptor is negative in 10 (41'66%) patients (p<0'05). One pregnancy associated breast cancer is progesterone receptor positive in 76 (69'09%) patients and progesterone receptor negative in 13 (54'16%) patients (p<0'05). HER. Ki67 and histological grade there were no differences with one or two pregnancies associated breast cancer (p=ns)
Conclusion. One or two pregnancies associated breast cancer over 5 years influence estrogen receptors and progesterone receptors, and do not influence HER2, Ki67 and histological grade.

P4-05-15: EVOLVE: Harnessing the Power of AI, RWD, and Precision Education to Minimize Breast Cancer Care Disruptions

Shashi Shankar, Jeff Carter, Josh Zalis

Background: HER2-targeted therapies have significantly advanced the treatment of HER2+ breast cancer. However, many of these therapies are associated with interstitial lung disease (ILD), a rare but potentially life-threatening adverse event (AE). The perceived risk of ILD often leads to premature discontinuation of effective HER2-targeted therapies, potentially compromising patient outcomes. Better understanding of ILD incidence and management using real world data is crucial to optimize care continuity and treatment efficacy in HER2+ breast cancer patients.

Methods: Project EVOLVE, a two-part quality improvement study, integrated Novellia's AI-powered personal health record platform with Prime Education's expertise in medical education. The study aimed to uncover ILD patterns and develop targeted interventions to minimize unwarranted therapy discontinuations.
Part 1: A real-time observational study analyzed over 500,000 unique health records of HER2+ breast cancer patients using Novellia's advanced AI-enabled data modeling to identify ILD-related patterns and treatment gaps.
Part 2: Development and implementation of precision educational interventions based on Part 1 findings for patients and their treating HCPs. Patient interventions included personalized modules on cancer basics, treatment adherence, and side effect management. HCP interventions focused on patient-specific care strategies and advanced ILD management techniques.

Results: Part 1 Findings:

Only 4.17% of documented respiratory AEs were identified as ILD, lower than generally perceived risk (n=24)
Primary respiratory AEs: asthma (37.5%), common cold (20.8%), COVID-19 (8.3%)
65.79% of patients lacked COVID-19 vaccination history
Secondary survey (n=187): 67% cited fatigue as the most challenging side effect; 38% lacked awareness of cancer subtypes and stages

Part 2 Findings:
Patient Improvements (n=187):

Treatment plan adherence confidence: 72% to 89%
At-home side effect management confidence: 55% to 79%

HCP Improvements (n=275):

Correct identification of ILD as a boxed warning AE for trastuzumab deruxtecan: 19% to 47%
Confidence in individualizing treatment selection: 66% to 90%
AE identification and management confidence: 69% to 92%
Appropriate recommendation of trastuzumab deruxtecan in specific scenarios: 36% to 58%

Conclusions: Project EVOLVE demonstrated the efficacy of integrating AI-driven real-world data analysis with targeted educational interventions in optimizing HER2+ breast cancer care, particularly in managing ILD. The study revealed a lower-than-perceived ILD incidence, challenging prevailing risk perceptions. Significant improvements in HCP confidence and decision-making regarding AE management and treatment recommendations were observed. Patient outcomes improved substantially, with increased confidence in treatment adherence and side effect management. Novellia’s personalized

education approach was identified as a key benefit by 53% of patients. These findings suggest that this novel methodology effectively minimizes care disruptions due to ILD concerns, potentially improving treatment continuity and patient outcomes in HER2+ breast cancer. This innovative approach presents a promising model for addressing complex adverse events in oncology and beyond, paving the way for more personalized and effective cancer care strategies.

P4-05-16: FATTY ACID PROFILE ON RED BLOOD CELL MEMBRANE PREDICT BREAST CANCER SUBTYPE

Francisco Acevedo, Rodrigo Valenzuela, Benjamín Walbaum, Camila Farias, Catalina Vargas, Mauricio Camus, Francisco Dominguez, Marisa Abud, Lidia Medina, Tomas Merino, Carolina Ibañez, Alejandra Parada, Cesar Sanchez

Introduction. Metabolic reprogramming is a hallmark of cancer development and progression. Regarding breast cancer (BC) limited evidence assert an association between metabolic changes and its impact on BC biology and subtype. Yet no clear data has evaluated the link between lipid metabolism, measured through red blood-cell membrane (RBCm) composition, and BC subtype determination. Because RBC are the main circulating cells and 90% of its surface is membrane, the fatty acid (FA) measurement on the RBCm seems to be a good marker for FA body status and BC cell relationship with systemic normal cells. Our study sought to determine if RBCm FA profiles, determined on a routine blood sample, could predictBC subtypes in non-metastatic BC patients. Methods. A prospective study assessing FA levels (Saturated:SFA; monounsaturated: MUFA, and polyunsaturated: PUFA) on RBCm from baseline peripheral blood samples obtained in BC patients, prior systemic or local treatments. The primary objective was to determine the relationship between FA lipidomic profiles measured in the RBCm and the four main BC subtypes, defined by the IHC of diagnostic biopsy. Subtypes were classified based on estrogen receptor positive (ER) and epidermal receptor growth factor type 2 (HER2) status determinations:ER+/ HER2-, ER+/HER2+, ER-/HER2+ and ER-/HER-. Results. A total of 77 stage I-III patients with BC were included. Regarding CcClinico pathological variables measured include (age, body mass index, histological grade, Ki67 andor stage). An elevated total SFA, and lower MUFA showed a significant association with ER+/HER2- BC (p= 0.0028). No differences for total FA values were found for other BC subtypes. Regarding specific FA analysis, the concentration of PUFAs alpha-linolenic acid (C18:2n6c, linoleic (ALA), p= 0.0001), C18:3n3 (a-linolenic, p= 0.0000), C20:5n3 (EPA, p= 0.0009) and C22:6n3 (DHA, p= 0.0000) were differentially expressed based on IHC subtypes. Conclusions: RBCm FA profile determination showed a significant diagnostic potential as a biomarker for BC subtype in non-metastatic BC. Measuring FAs in RBCm could offer a convenient, minimally invasive strategy to identify BC subtypes. Further research is needed necessary to validate the performance of FAs and their thresholds using an independent dataset for cross-validation to ensure robustness.

P4-05-17: PER2 Expression as an Independent Predictor of Shorter Disease-Free Survival in Breast Cancer Patients Undergoing Neoadjuvant Chemotherapy

Gabriela Bezerra Nobrega, Bruna Salani Mota, Rodrigo Goncalves, Gabriela Boufelli de Freitas, Ricardo Hsieh, Silvia Vanessa Lourenço, Isaque da Silva Ferreira, Isabel Cristina Espósito Sorpreso, Bruna Karla Krislane Alves Costa Monteiro, José Cipolla-Neto, José Roberto Filassi, Edmund Chada Baracat, José Maria Soares Júnior

Background: The PERIOD2 (PER2) gene is a core component of the circadian clock and is crucial for maintaining daily rhythms. PER2, regulated by melatonin, is often linked to tumor development. Studies have shown that PER2 expression is downregulated in various tumors, and in vitro studies indicate that PER2 overexpression in tumor cells, including breast cancer cells, promotes apoptosis and reduces proliferation. Since melatonin interacts with estrogen receptors, hormone receptor status may influence PER2 expression. This study aimed to evaluate PER2 expression in different breast cancer (BC) molecular subtypes using immunohistochemistry (IHC) and to examine its association with disease-free survival (DFS) and overall survival (OS).
Materials and Methods: A retrospective cohort study was conducted at the Instituto do Câncer do Estado de São Paulo from January 2012 to September 2023. The study included women with stages II-III BC, who completed neoadjuvant chemotherapy (NAC) followed by surgery. Following histological and immunohistochemical analysis, samples from 100 patients were classified into the following molecular subtypes: Triple-negative, Luminal A, Luminal B, HER2 enriched, and Luminal B – HER2+. IHC reactions using the primary antibody for PER2 (C6 -sc-377290 Santa Cruz Biotechnology, Inc.) were performed and qualitatively classified as follows: absence of expression, weak/moderate expression, and strong/intense expression of PER2. Two independent researchers analyzed the IHC results. Clinical, demographical and outcome data were extracted from electronic medical records. Associations between categorical variables were evaluated using the Chi-square test. OS and DFS were assessed using the Kaplan-Meier method and the Log-Rank test. Statistical significance was defined as p-values less than 0.05.
Results: One hundred patients equally divided among Luminal A, Luminal B, HER2 enriched, Triple-negative and Luminal B – HER2+ molecular subtypes were selected. Five patients were excluded because of inadequate PER2 IHC staining. A total of 95 women were included, with a mean age of 54.4 years (range: 29-84) and a median BMI of 30.1 kg/m^2. Additionally, 14.9% were nulliparous and 54.7% were post-menopausal. Before NAC, 28.4% of patients presented with stage II BC and 71.6% presented with stage III BC. 4.2% of the patients had absence of expression of PER2, 44.2% presented weak/moderate expression and 51.6% presented strong expression. There was no difference in PER2 expression according to molecular subtype (p=0.769). After NAC,18.1% of the patients achieved pathological complete response (pCR), with a statistically significant association between pCR and molecular subtype (p=0.001). At a median follow-up time of 90.2 months (IQR 62.6-123.9) there were 31 recurrence events (32.6%) and 29 overall deaths (30.5%). There was a statistically significant association between DFS and PER2 expression (log-rank p=

0.0288). Median DFS was 56.1 months (95%CI 28.3 – NR) for patients with no expression of PER2, 48.5 months (95%CI 24.6-81.8) for patients with moderate expression and 25 months (95%CI 15.7-37.7) for patients with strong expression of PER2. In a Cox multivariate analysis, adjusting for molecular subtype, PER2 expression remained associated with DFS with an HR of 3.02 (95% CI 0.52-17.481, p=0.22) for moderate expression and an HR of 13.13 (95% CI 1.89-91.15, p=0.009) for strong expression when compared to absence of expression. There was no statistically significant OS difference according to PER2 expression in our cohort (p=0.92).
Conclusion: Our findings suggest that strong PER2 expression is an independent predictor of shorter DFS in breast cancer patients treated with NAC, highlighting its potential role as a prognostic biomarker. Further research is warranted to understand the underlying mechanisms and to explore potential therapeutic interventions targeting PER2 pathways.

P4-05-18: Modelling MHC-I downregulation in triple negative breast cancer to rescue resistance to ICB using diacylglycerol kinase inhibitors

Jacey Marshall, Justin M. Balko

Background: Immune checkpoint blockade (ICB) has recently revolutionized the treatment of triple-negative breast cancer (TNBC) and improved patient outcomes. However, most patients are intrinsically resistant and do not benefit from ICB. Moreover, no biomarkers to predict outcome have been clinically successful.
Antigen presentation by MHC-I molecules is required for CD8 T cell mediated tumor death and response to immune checkpoint blockade, e.g. a-PD-1/a-PD-L1 therapy. TNBCs downregulate MHC-I to suppress anti-tumor immunity and patients with decreased antigen presentation have worse outcomes to ICB. Thus, loss of MHC-I expression may be a candidate biomarker for lack of ICB response, and therapeutic strategies to overcome MHC-I loss are an area of high translational relevance and interest.
Diacylglycerol kinase α/ζ inhibitors (DGKis), which increase T cell activation, are being investigated to treat patients resistant to ICB. DGKis increase concentrations of diacylglycerol (DAG) in CD8 T cells by inhibiting conversion of DAG into phosphatidic acid, lowering the threshold for activation and amplifying TCR signaling and effector T cell function. We hypothesized that DGKis will improve response to ICB in TNBC with low MHC-I expression by improving CD8 T cell response to low antigen stimulation. However, modeling low MHC-I expression (as opposed to CRISPR-mediated KO) presents a technical challenge. Thus, we created a novel model of MHC-I downregulation, leveraging miRNA binding element mutations to titrate MHC-I expression. We assess changes in the tumor microenvironment and ICB response created by stepwise-decreased MHC-I expression and evaluate the potential of DGKis to treat MHC-I low tumors in combination with ICB.
Methods: We assessed the effect of DGKi/a-PD-L1 dual therapy on an MHC-I competent, baseline model of TNBC using the murine EMT6 cell line, which is moderately responsive to a-PD-L1 therapy. To model titrated levels of MHC-I downregulation in vivo, we utilized miRNA silencing-mediated fine-tuners (misFITs). We created an MHC-I null variant of EMT6

cells through knock out of beta-2-microglobulin (B2m), a required component for MHC-I expression. To create the misFITs, we reintroduced the B2m gene into the cells with the addition of varied binding regions for the endogenously expressed miR-17. Presence of an miR-17 binding region allows for miRNA-mediated suppression of B2m and thus, MHC-I. Seven different binding regions were introduced resulting in stepwise titration of MHC-I expression. To evaluate the effects of titrated MHC-I expression on tumor growth and survival, we orthotopically inoculated mice and treated weekly with a-PD-L1.
Results: In the EMT6 TNBC model, treatment with DGKi every 3 days in combination with weekly a-PD-L1 administration resulted in decreased tumor growth (Isotype control v. DGKi/a-PD-L1, p=0.0023, n=20) and doubled complete response rates from 20% in single-agent a-PD-L1 to 40% with combination therapy. Re-injection of complete responders with the original tumor cell line to assess persistence of response resulted in no tumor growth. Simultaneous bilateral injection of MHC-I null isogenic cells also resulted in significantly reduced growth, indicative of an MHC-I-independent memory response (p=0.0012, n=5-12). MisFITs representing 60%, 30%, and 10% of MHC-I levels in EMT6 cells grew at differential rates – faster with less MHC-I expression. Additionally, preliminary data demonstrates reduced a-PD-L1 benefit in mice with lower MHC-I expression.
Conclusions: We determined that DGKi/a-PD-L1 treatment enhances response in the EMT6 TNBC model and establishes a memory immune response. We have created a model of MHC-I downregulation and begun to establish how MHC-I affects a-PD-L1 response and will utilize the misFITs to assess the mechanism of resistance to response and the efficacy of DGKi/a-PD-L1 treatment in improving response to ICB in MHC-I downregulated tumors.

P4-05-19: Magnetic Resonance Elastography: A Novel Imaging tool to predict response in patients undergoing Neo-Adjuvant Chemotherapy for Breast Cancer

Aaditya Sinha, Patriek Jurrius, Anne-Sophie van Schelt, Omar Darwish, Giacomo Annio, Belul Shifa, Zhane Peterson, Hannah Jeffery, Karen Welsh, Anna Metafa, John Spence, Ashutosh Kothari, Hisham Hamed, Georgina Bitsakou, Vasileios Karydakis, Mangesh Thorat, Elina Shaari, Ali Sever, Anne Rigg, Tony Ng, Sarah Pinder, Ralph Sinkus, Arnie Purushotham

Introduction: Patients undergoing neoadjuvant chemotherapy (NACT) for breast cancer are monitored using Magnetic Resonance Imaging (MRI) with Dynamic Contrast Enhancement (DCE), the gold-standard imaging technique to assess tumour response.
DCE-MRI has a sensitivity of 80-90% but a low specificity of 37-97% when assessing complete response (CR). Although alternative methods to assess CR have been attempted, such as biopsies, no highly accurate method has been identified. Magnetic Resonance Elastography (MRE) is a non-invasive imaging technique that uses biomechanics to identify tissue alterations within the tumour during NACT. With recent discussions regarding the de-escalation of surgical treatment for breast cancer post-NACT, an accurate assessment of CR is essential.
Methods: This prospective, first-in-human study includes patients undergoing five MRI-

MRE scans at different time points during the course of NACT. Breast MRE is a 7-minute sequence added to the routine clinical breast MRI, with mechanical vibrations applied to the patient's breast via paddles attached to a gravitational driver incorporated into a Siemens biopsy coil for a 1.5T system. The tissue occupying the tumour at diagnosis on DCE imaging was defined throughout the NACT treatment. Biomechanics within these regions were quantified, primarily observing relative changes in tumour stiffness (elasticity) between pre-NACT and post-NACT (tumour stiffness ratio: TSR). Relative changes in phase angle (the phase lag between viscosity and elasticity) in the specific tumour region after the 1st cycle from pre-NACT were also observed (phase angle ratio: PAR). Post-surgical histopathology was used to determine complete and partial responders. Furthermore, a repeatability analysis was done on nine patients to assess concordance of the scans.
Results: The analysis included complete datasets from forty-one patients. After NACT, the TSR significantly decreased for complete pathological responders and increased for partial responders ($p<.001$). The PAR's post-cycle 1.1 predictive ability for a complete pathological response was also significant ($p<.001$). When TSR was combined with DCE imaging, the specificity improved considerably compared to DCE alone (43.5%→95.7%), while maintaining the high sensitivity of DCE (94.4%). The repeatability analysis demonstrated excellent agreement for elasticity (ICC=0.969, RC=8.9%) and phase angle (ICC=0.876, RC=12.6%).
Conclusion: This novel technology, which uses a combined approach including biomarkers (DCE+MRE), shows great promise as a non-invasive imaging method for assessing complete pathological response at the end of NACT. As a stand-alone method or combined with other investigative techniques to diagnose complete responses accurately and non-invasively at the end of chemotherapy, this can aid consideration in de-escalating surgical treatment. Furthermore, the information after the 1st cycle can help predict if tumours will eventually have a complete response or partial/no response; the latter may need early re-discussion in multi-disciplinary meetings to consider an alteration to their chemotherapy regimens. Further studies are required to strengthen these findings.

P4-05-20: Development and validation of a combined ultrasound-pathology model to predict axillary status after neoadjuvant systemic therapy in breast cancer

Jue Wang, Wenjie Shi, Jinzhi He, Xuan Li, Hailing Zha, Rui Chen, Lu Xu, Xiaoming Zha

Background: For patients with axillary lymph node metastasis before neoadjuvant systemic therapy (NST), axillary lymph node dissection is still the mainstream surgical procedure after NST, but this procedure will bring many complications to the patients. Currently, ultrasound-guided fine-needle aspiration (FNA) is commonly used in the clinic to determine whether the axillary lymph nodes have metastases, but the false-negative rate of FNA is too high. Therefore, there is a need for a more accurate method to assess whether axillary lymph nodes achieve pathological complete response (pCR) after NST to help clinicians make treatment decisions or even try to perform axillary de-escalation surgery for these

patients.
Methods: This study retrospectively collected data from breast cancer patients who underwent NST and were considered to have axillary lymph node metastasis at the Department of Breast Surgery of the First Affiliated Hospital of Nanjing Medical University from 2015 to 2022. The clinical information, ultrasound results and postoperative pathological results of patients were collected, and all patients were randomly divided into a training group and a validation group at a ratio of 7:3. Independent predictors of axillary pCR were screened in the training group using univariate and multivariate logistic regression analyses, and a nomogram model was developed and validated based on these factors, and then the accuracy of the model was compared with that of FNA.
Results: Ultimately, 657 patients were enrolled in this study, and after randomization, there were 460 patients in the training group and 197 patients in the validation group. Univariate and multivariate logistic regression analyses based on clinical and ultrasound factors were performed to screen clinical node stage (cN) (P =0.014), estrogen receptor (ER) status (P <0.001), human epidermal growth factor receptor 2 (HER2) status (P <0. 001), imaging regression of the primary breast tumor (P =0.011), the hilum structure of the axillary lymph nodes after NST (P <0.001), and the blood flow distribution of the axillary lymph nodes after NST (P =0.004) were independent predictors of axillary pCR, and an ultrasound-based model was developed, which had an AUC value of 0.821. Univariate and multivariate logistic regression analyses based on clinical, ultrasound and breast pathology information were again performed to screen cN (P =0.003), ER status (P <0.001), HER2 status (P =0. 009), the hilum structure of the axillary lymph nodes after NST (P <0.001), the blood flow distribution of the axillary lymph nodes after NST (P =0.003), longest diameter of breast tumor after operation (P =0. 001), vascular invasion of breast tumor (P =0.043) and Miller-Payne grade (P =0.006) were independent predictors of axillary pCR. A combined model incorporating ultrasound and breast pathology was developed, which had an AUC value of 0.883. The calibration curves, decision curve analyses, and clinical impact curves of the training and validation groups demonstrated that the discrimination ability, calibration ability, and clinical application value of this combined model were significantly better than those of the ultrasound-based model and FNA.
Conclusion: In this study, a combined model incorporating axillary lymph node characteristics under ultrasound and breast pathology to predict axillary pCR after NST is developed, validated and found to be highly accurate. This model will help surgeons select patients who are likely to achieve axillary pCR after NST and thus attempt to perform axillary de-escalation surgery for these patients.

P4-05-21: Dynamic ctDNA tracking stratifies individual relapse risk for early triple negative breast cancer patients receiving neoadjuvant chemotherapy

Qiang Liu, Shunying Li, Yudong Li, Wei Wei, Chang Gong, Ting Wang, Guangxin Li, Feng Yao, Jiang-Hua Ou, Yan Xu, Wei Wu, Liang Jin, Nanyan Rao, Yan Nie, Fengyan Yu, Weijuan Jia,

Xing-Rui Li, Jun Zhang, Hua-Wei Yang, Yaping Yang, Mengzi Wu, Qin Li, Fang Li, Yuhua Gong, Xin Yi

Background: Early Triple negative breast cancer (eTNBC) is the breast cancer subtype with the least favorable outcome. Tools to identify their individual relapse risk are in great need. Circulating tumor DNA (ctDNA) analysis is shown to predict the prognosis in breast cancer, but its utility in eTNBC remains unclear.
Patients and methods: In this prospective study, 130 eTNBC patients receiving neoadjuvant chemotherapy (NAC) were successfully enrolled. Their blood samples were taken at the baseline, post-NAC, post-surgery and during follow-up, and were subjected to tumor-guided ctDNA analysis.
Results: ctDNA positivity at post-NAC and post-surgery, but not at baseline, was associated with significantly worse prognosis. A threshold of 1.1% maximum variant allele frequency (MVAF) at baseline better stratified eTNBC patients with different relapse risk, which was validated both internally and externally. A systemic tumor burden model integrating baseline and post-surgery ctDNA was highly prognostic and independent of clinical characteristics. Combining systemic tumor burden with pathologic response identified a highly curable subgroup and a subgroup of high-risk eTNBC patients that need more effective adjuvant treatments. ctDNA surveillance during follow-up showed that the patients with negative ctDNA had 100% distant recurrence free survival (DRFS), but the ones with positive ctDNA had high relapse rate with relatively short lead time.
Conclusions: To our knowledge, this study is the first to set a ctDNA threshold in eTNBC patients to stratify their relapse risk. This systemic ctDNA analysis from baseline to follow-up demonstrates the utility of baseline ctDNA with a threshold and a systemic tumor burden model in risk stratification of eTNBC patients, which may guide future treatment escalation or de-escalation trials.

P4-05-22: Discovery of Molecules Synergistic with (Z)-endoxifen for the Treatment of Breast Cancer

Daniela Hühn, Maria Häggblad, Anastasia Shneyderman, Alexander Veviorskiy, Khadija Alawi, Mikhail Korzinkin, Alex Zhavoronkov, John R. Hawse, Oscar Fernandez-Capetillo, Sandra S. Hammer, H. Lawrence Remmel, Steven C. Quay

Background: (Z)-endoxifen is a potent selective estrogen receptor modulator (SERM) with 100-fold more potency than its parent drug, tamoxifen. It is hypothesized that (Z)-endoxifen has a dual concentration dependent mechanism of action. At lower concentrations, (Z)-endoxifen is an ER antagonist while at higher concentrations (Z)-endoxifen additionally inhibits and degrades protein kinase C beta 1 (PKCβ1). Preclinical and clinical studies in bipolar disease, ER+ breast cancer and other solid tumor types have demonstrated (Z)-endoxifen to be safe and well tolerated. Specifically, in ER+/HER2- breast cancer (Z)-endoxifen has shown promising anti-tumor activity (EVANGELINE; NCT05601004). The objective of this study was to evaluate the synergistic potential of (Z)-endoxifen by identifying new combination therapeutic solutions in breast cancer.

Methods: Insilico modeling: The artificial intelligence-driven platform PandaOmics was used to collect and aggregate omics-based gene signatures of breast cancer and (Z)-endoxifen and combine these with over 3000 small molecule perturbations from the LINCS database to predict compounds that could be synergistic with (Z)-endoxifen. All possible combinations with (Z)-endoxifen were evaluated by several ranked scores which included effects on disease signature and direction of gene expression changes, applying a gene-gene synthetic lethality component. Thus, drug pairs with highest combined scores are predicted to be potentially synergistic. Chemical screen: A total of 5251 compounds from the Drug Repurposing Library (SPECS) were screened for synergy with (Z)-endoxifen. MCF-7 cells (ER+ breast cancer) were treated with 0.5μM (Z)-endoxifen, dispensed into 384-well plates and exposed to 1 μM of compounds diluted in DMSO. After 4 days, cells were fixed and stained with Hoechst to visualize nuclei. Cells were imaged via high throughput microscopy (INCell 2200 microscope) and nuclei count was analyzed using CellProfiler. Statistical and data analysis was done using KNIME Software. All values were normalized to DMSO, no (Z)-endoxifen condition. Compounds reducing the viability of cells more than (Z)-endoxifen alone (mean viability -3x StD), and showing higher viability than Doxorubicin (10μM) combined with (Z)-endoxifen (mean viability +3x StD), were considered as hits and subjected to validation screening.
Results: Insilico modeling identified compounds with inhibitory mechanism of actions against mTOR/PI3K, tyrosine kinase, topoisomerase, HDAC and CDKs in combination with (Z)-endoxifen as potentially synergistic. To validate these results, a chemical screen was conducted in MCF-7 cells. Results from this screen yielded a total of 354 compounds with synergistic potential with (Z)-endoxifen's mechanism of action. The top-ranking compounds in the screen have mechanisms of actions centering on inhibition of DNA topoisomerase, CDK, mTOR/PI3K, AKT and HDAC. Nineteen compounds showed antagonistic activity. Ongoing studies will validate the chemical screening hits in additional breast cancer in vitro and in vivo models.
Conclusions: Based on two independent approaches, compounds used to inhibit DNA topoisomerase, CDK, mTOR/PI3K and AKT synergize with (Z)-endoxifen to induce cell death in MCF-7 cells when compared to either agent alone. Taken together, these data suggest that combination therapies with (Z)-endoxifen and agents targeting topoisomerase, CDK, mTOR/PI3K and AKT hold great therapeutic potential and should be further validated in additional model systems.

P4-05-23: Quantitative Diffusion Weighted Imaging for Predicting Response to Neoadjuvant Therapy in Patients with Inflammatory Breast Cancer

Huong Le-Petross, Jong Bum Son, Jingfei Ma, Megumi Kai, Gary Whitman, Mary Guirguis, Miral Patel, Megha Kapoor, Susie Sun, Bora Lim, Angela Alexander, Vincent Valero, Anthony Lucci, Wendy Woodward

Background and Purpose: Inflammatory breast cancer (IBC) is a rare and aggressive disease, accounting for 2-4% of all breast cancers. One third of the patients have distant metastases at initial presentation [1]. Trimodality therapy beginning with neoadjuvant systemic therapy (NAST) is associated with the best local control and survival (2). The ability to determine tumor response early in the NAST course is essential in optimizing treatment and predicting prognosis (2,3). MRI (Magnetic Resonance Imaging) is suggested to be the best modality for assessing response. Cellular changes such as cell membrane destruction or tumor lysis lead to increased water diffusivity and can be measured on MRI (4). Apparent diffusion coefficient (ADC) is a measurement of the change in water diffusivity, calculated from the diffusion weighted imaging (DWI) scans. In this study, we investigated quantitative DWI for differentiating pathological complete response (pCR) from non-pCR in IBC patients after NAST.

Methods and Materials: All patients were selected from an IRB-approved prospective IBC registry at one tertiary academic center and treated between December 2019 to November 2022. A retrospective chart review was performed to identify IBC patients with analyzable imaging and pathology records. Patients with available pre-treatment and mid-treatment MRI with DWI scans were included. Of 262 scans, 149 pre-treatment MRI, 13 outside films (OSF) without DWI, and 5 biopsy MRIs were excluded from analysis. Of the remaining 97, 27 had both pre-treatment and mid-treatment DWI with same b-values (diffusion coefficient value applied to images) available for evaluation.
All MRI exams were performed on 3T scanners (either GE Healthcare or Siemens Healthineers) using phased-array dedicated breast coils. Typical scan parameters for DCE scans were: flip angle = 12°, TR/TE ~6/2 msec, acquisition matrix = 320 x 320 x 112, FOV = 30 x 30 x 18 cm, and temporal resolution = 10 secs. Contrast agent was administered intravenously via an MR-compatible injector and flushed with 20 mL saline solution. DWI was acquired with two b-values of 100, 800 sec/mm2 and scan parameters as follows: TR/TE = 4000/70 msec, and FOV = 16 x 16 x 6.4 cm. Quantitative ADC maps were computed using a mono-exponential model. Image analysis was performed on a DynaCAD system (Invivo Corporation, Pewaukee, WI). Three regions-of-interest (ROIs) of the index breast tumor, axillary node, and thickened skin were segmented on DCE by an experienced breast radiologist (24 years). ROIs were transferred to the ADC maps and co-registered with DCE images. The quantitative ROI histogram values (median, mean, standard deviation, minimum, maximum, skewness, and kurtosis) were extracted. Statistical analyses were performed to determine the association between these measurement and the patients' pCR status and PFS.

Results: Median follow up was 14.5 months. 19 patients had non-pCR and 8 had pCR. At the time of this analysis, 20 patients were alive and 7 deceased. The median and mean ADC values of tumor was 1.326 and 1.333, respectively. Both median and mean ADC values were correlated to pCR, with p-value of 0.0074 and 0.0071, respectively. None of the remaining values associated with DWI scans of the index tumor, axillary node, and skin ROIs (standard

deviation, minimum, maximum, skewness, and kurtosis) was significantly correlated to pCR. No statistically significant correlation was demonstrated between ROI measured and PFS (correlation coefficients = -0.35 to 0.48).

Conclusion: DWI is sensitive to changes in water cellularity and has the potential to characterize early tumoral response during NAST. Histogram analyses of ADC in IBC reflects tumor heterogeneity. Our pilot study shows promise of the median and mean ADC values as imaging biomarkers for predicting pCR at mid-NAST in IBC patients.

P4-05-24: Point mutations (PM), gene amplifications (GA) and variants of unknown significance (VUS) detected by next-generation sequencing (NGS) in a real-world sample of metastatic breast cancer (MBC)

Marcus Lee, Jules Cohen

Background: The management of MBC requires NGS of tissue biopsies or ctDNA. Certain changes in the tumor genome, predominantly PM in ESR1 and PIK3CA, are targetable with FDA-approved drugs. GA, with the notable exception of ERBB2, is a common but not actionable finding on NGS. Commercial NGS report amplification of multiple genes within a sample but do not always indicate they are amplified en bloc from the same chromosomal region or amplicon. We evaluated NGS results from MBC to (1) report the prevalence of PM across a real-world cohort; (2) organize individual GA within their respective amplicons; and (3) identify VUS that may show unexpected functional significance.
Methods: We evaluated NGS from 44 tissue (Foundation One) and 17 liquid (Guardant 360) biopsies. We correlated NGS results with histological type and ER/HER2 status. We analyzed PM in oncogenes vs. tumor suppressors and compared known cancer-related PM with VUS. We analyzed co-amplified GA and grouped them into amplicons based on their genomic location.
Results: 76% (35/46) cases were ductal (IDC) and 24% (11/46) were lobular (ILC). 59% (27/46) were luminal, 32% (15/46) were TNBC and 9% (4/46) were HER2-pos. 48% (22/46) of patients had a TP53 mutation, including 93% (14/15) of TNBC, 75% (3/4) of HER2-pos and 19% (5/27) of luminal. Individual TP53 PM were rarely repeated among patients. 39% (18/46) of patients had a PIK3CA mutation, including 20% (3/15) of TNBC, 75% (3/4) of HER2-pos and 44% (12/27) of luminal. 45% (9/20) of PIK3CA were H1047R. 82% (9/11) of ILC had a PM in CDH1. ESR1 (8/27), GATA3 (6/27) and AKT1 (3/27) PM were seen in luminal but not TNBC. 7/8 ESR1 PM were Y537 or D538. GATA3 (6/35) and AKT1 (3/35) PM were seen in IDC but not ILC. RB1 PM (but not PTEN) were more common in TNBC (4/15) than luminal MBC (1/27). 25% (11/44) of patients had a VUS in KMT2D (MLL2). PM were more common in liquid (20/17) than tissue (20/40) biopsies, with 65% of liquid biopsies showing PM in TP53 (vs. 48% in tissue) and 71% showing PM in PIK3CA (vs. 39%). Multiple PM in TP53 or PIK3CA were only seen in liquid biopsies.

11q13 amplification (CCND1, FGF3, FGF4, FGF19) was seen in 9 patients, 8q24 (MYC, RAD21, LYN) in 7 and 8p11 (FGFR1, ZNF703, NSD3) in 5. 4 patients each showed amplification in 20q13 (AURKA, ZNF217, GNAS, ARFRP1) and 17q12 (ERBB2, CDK12). 11q13, 8p11 and 20q13 were seen mostly in luminal MBC. 8q24 and 12p13 (CCND2, FGF6, FGF23, KDM5A, KRAS) were seen mostly in TNBC. The most common (11q13, 8q24, 8p11) were enriched in ILC (27% of cases). 20q13 and 12p13 were only seen in IDC. 15% (6/40) were TMB-high (>=10), 23% (9/40) TMB-int (8-9) and zero MSI-high.
Conclusions: NGS of real-world patients reveals a broad spectrum of genomic abnormalities in MBC. TP53 and PIK3CA associate with TNBC and luminal MBC, respectively. Mutations in tumor suppressors are mostly distinct since there are many ways to induce loss-of-function. Mutations in oncogenes are restricted to a few hotspots associated with ligand-independent activation. Liquid biopsies detect more PM and are the only modality to detect multiple PM in the same gene. Small molecule inhibitors may demonstrate increased efficacy more against PM than GA.
Increased expression of individual amplicons is frequently related to histology or ER/HER2 expression. Commercial NGS reports do not clearly organize individual genes into distinct amplicons. Tissue biopsies preferentially detect GA. mAbs/ADCs are likely the best therapeutic candidates against protein overexpression mediated by GA. Commercial NGS assays reveal descriptive and prognostic information alongside actionable mutations and novel potential targets. Careful evaluation of NGS will improve our understanding of the genotype/phenotype relationship in real-world patients.

P4-05-25: Impact of Estrogen Receptor Targeting Drugs on a Novel Epithelial-Mesenchymal Transition Pathway in Endocrine Resistant Breast Cancer: Implications for Metastasis

Nivida Shete, Debra A. Tonetti

Background: Approximately 10% of breast cancer patients are metastatic at the time of diagnosis with a 27% survival rate. Currently, endocrine therapy, including tamoxifen, aromatase inhibitors (letrozole, anastrozole, and exemestane), Selective Estrogen Receptor Degraders (fulvestrant and elacestrant), is the standard of care for patients with estrogen receptor-positive (ER+) breast cancer. The major treatment challenge is endocrine therapy resistance and metastasis. Epithelial Mesenchymal Transition (EMT) is the process in which cells lose epithelial properties and acquire motility and mesenchymal phenotype, which leads to migration and invasion. EMT is characterized by the destabilization of adherens junctions by loss of E-cadherin at the plasma membrane. We previously reported a novel signaling pathway that is present in tamoxifen-resistant (TR) breast cancer cells. This pathway involves transcriptional repression of p120catenin by upstream regulators PKCa and FOXC2, resulting in the loss of E-cadherin at the plasma membrane (Pham, 2017). EMT features were characterized by decreased expression of epithelial markers and increased

migration and invasion.
Initially, estrogen stimulates breast cancer growth but becomes inhibitory after long-term estrogen deprivation. A novel Selective Human Estrogen Receptor Partial Agonist (ShERPA) TTC-352 is an estrogen mimic that induces unfolded protein response and shrinks the TR tumors (Molloy, 2014; Abderrahman, 2021). In this study, we investigated the impact of various ER-targeting drugs including 17b-estradiol (E2), tamoxifen, fulvestrant, and TTC-352 on the novel PKCa-FOXC2-p120catenin signaling axis. We hypothesize that ER-targeting drugs modulate the novel EMT pathway in TR breast cancer cells.
Materials and Methods: TR cell lines used in this study include PKCa overexpressing cells MCF-7/PKCa, and MCF-7:5C and represent migratory ER+ breast cancer. Migration assays were performed in response to ER ligands using Falcon Permeable inserts. Migrated cells in response to chemoattractant were stained and counted after 24 hours. Luciferase reporter assays were performed to evaluate the effect of ER ligands on p120catenin transcription. Cells were transiently co-transfected with a p120catenin promoter-reporter plasmid using renilla vector for normalization. The reporter system readout is based on FOXC2 binding to the p120catenin promoter resulting in repression of luciferase transcription. Luciferase luminescence was measured on a plate reader corresponding to p120catenin transcription. Chromatin immunoprecipitation was performed using a FOXC2 antibody (Abcam-308055) to assess FOXC2 binding to the p120catenin promoter after ER ligand treatment.
Results: E2 and TTC-352 treatment lowered FOXC2 binding on the p120catenin promoter, increased its transcription, and decreased the migration of MCF-7/PKCa and MCF-7:5C breast cancer cells compared to vehicle. E2 and TTC-352 treatment does not activate the PKCa-FOXC2-p120catenin EMT signaling axis and reduces the migratory potential of TR cells.
Conclusion and Discussion: Our findings suggest that patients with endocrine-resistant ER+ breast cancer may benefit from E2 and TTC-352 therapy by inhibiting the activation of the PKCa-FOXC2-p120catenin signaling and cell migration identified in TR cell lines. Results of the Phase I clinical trial of TTC-352 reveal a reduced side effects profile and improved progression-free survival (Dudek, 2020). Strategizing less toxic treatment options may potentially reduce metastasis and prolong patient survival with a better quality of life.

P4-05-26: MamaTrace - A cell-free DNA methylation plasma only assay for minimal residual disease detection in breast cancer

David N Buckley, Gerald Gooden, Alex Kalfa, Barbara Pockaj, Bodour Salhia

Background:Metastatic breast cancer (MBC) is an incurable disease, affecting 10-15% of breast cancer (BC) patients, with a 5-year overall survival of less than 25%. MBC arises when small populations of disseminated BC cells remain in the body after primary therapy, otherwise known as minimal residual disease (MRD). MRD is currently difficult to detect following primary therapy. Despite, improvements, there remains a need for more effective and sensitive clinical tools to identify patients with MRD following primary treatment who may benefit from additional treatment or increased surveillance. In the current study, we

aimed to develop a plasma only MRD test, based on cfDNA methylation markers specifically associated with developing breast cancer metastasis, rather than markers that may prioritize markers of tumor burden, making this approach a partially-informed MRD assay.

Methods: Blood was collected under informed consent from multiple commercial and academic sources. We constructed 6 pools of cfDNA comprising a total 43 samples from MBC patients, and 3 pools comprised of cfDNA from 39 healthy individuals. In addition, we sequenced 21 cfDNA libraries from treatment-naïve patients with stage I-III breast cancer who either developed a future recurrence (REC, N = 12) or remained disease-free survivors (DFS, N = 9). The 6 MBC pools represented all major BC subtypes (ER+/HER2-, ER-/HER2+, ER+/HER2+, TNBC). To improve model performance and represent DNA methylation patterns associated with underrepresented populations, we also included 19 samples from African American patients with triple-negative breast cancer (TNBC) across varying stages. Whole genome bisulfite sequencing (WGBS) was performed on the 9 pools and 21 individual cfDNA samples. Differentially methylated regions (DMRs) were identified between MBC versus healthy pools and between REC versus DFS samples. A total of 5077 DMRs were then used to generate a targeted methylation assay using hybridization probe capture, which was used to analyze 72 individual cfDNA samples from patients with MBC (5 stage I-III), and 83 healthy cfDNA controls. Next, we developed a binary classification model called MammaTrace to distinguish between MBC and healthy samples. To evaluate the model for MRD, we subsequently applied the classifier to assess its accuracy in distinguishing REC from DFS in patients with early-stage breast cancer prior to recurrence. Specifically, cfDNA was sequenced using the MammaTrace targeted panel at multiple timepoints from 107 patients with early-stage breast cancer who underwent neoadjuvant chemotherapy. Of these patients, 51 had blood collected 9–27 months after definitive therapy and was determined as the most predictive time point and used for landmark analysis. At the time of writing, 11 patients developed metastasis, while 40 remained disease-free. Blood samples were collected prior to recurrence for all patients.

Results: The classifier model, constructed primarily using samples from MBC patients and healthy individuals, demonstrated excellent performance in distinguishing MBC from healthy samples, achieving a ROC AUC of 0.96. For assessing MRD detection in early-stage breast cancer samples collected at least 9 months after the completion of therapy, MammaTrace achieved an ROC AUC of 0.88, correctly classifying 10 of 11 REC patients as MRD positive and 33 of 40 DFS patients as MRD negative (sensitivity = 0.91, specificity = 0.83). The 10 positive REC landmark samples were collected an average of 457 days prior to clinical recurrence.

Conclusion: MammaTrace, a plasma-only cfDNA methylation-based classifier, effectively distinguishes MBC patients from healthy individuals, and can detect MRD before clinical

recurrence, identifying high-risk patients in need of additional therapy. Prospective studies are ongoing to validate MammaTrace.

P4-05-27: Comparative analysis of TROP2 expression in tumor tissues and circulating tumor cells (CTCs) in the peripheral blood of patients with triple negative breast cancer

Dimitrios Mavroudis, Eleni Lagoudaki, Sofia Gounaki, Sofia Hatziavraam, Charalampos Fotsitzoudis, Kleita Michaelidou, Sofia Agelaki, Maria A Papadaki

Background: Trophoblast cell surface antigen 2 (TROP2) promotes breast cancer (BC) development, invasion and metastasis, with promising role as a biomarker and therapeutic target in triple negative BC. Due to the dynamic tumor evolution during disease progression, a significant discordance in tumor cell profiles is frequently observed among primary tissues and distant metastases. In this regard, analyses of circulating tumor cells (CTCs) in the peripheral blood (PB) can inform on the expression of biomarkers in real-time. In the current study we assessed in parallel the expression of TROP2 on CTCs and matched primary tumors and metastatic sites from patients with triple negative BC.

Methodology: PB was collected from 54 patients and CTCs were enriched by ficoll-density gradient centrifugation. Cytospins were immunofluorescently stained using antibodies for cytokeratins (Clones: AE1/AE3 & C11), CD45 and TROP-2 (Enzo Life Sciences); TROP2 expression on CTCs was defined as high, low or negative, by using the high TROP2-expressing MDA.MB.231 triple negative BC cell line as internal control. Matched primary (n=51) and metastatic (n=7) tumor tissue samples were evaluated for TROP-2 expression by immunocytochemistry (IHC); H-score was calculated as follows: (3 × % cells with strong intensity staining) + (2 × % cells with moderate intensity staining) + (1 × % cells with mild intensity staining), ranging from 0 to 300, and the following expression categories were defined: H-score 0 to <100: TROP2 low; H-score 100-200: TROP2 medium; H-score >200-300: TROP2 high.

Results: CTCs (CK+/CD45- cells) were identified in 12 out of 54 patients evaluated (total CTC counts: n=80; mean CTC counts per patient: n=6.7). TROP2-expressing CTCs were detected in 75% of CTC-positive patients and represented the 95% of total CTCs. Specifically, high and low TROP2-expressing CTCs were identified in 66.7% and 41.7% of patients, representing the 81.3% and 13.7% of total CTCs, respectively. Differential TROP2 expression levels (high, medium and low) were also observed in both primary and metastatic tumors, showing a great intra-tumoral heterogeneity. High TROP2 expression was identified in 58.8% and 57.1% of primary and metastatic tissues, respectively. When matched primary and metastatic tissues were analyzed, a decrease in TROP2 expression was observed [median H-Score: 172.5 (range: 11-300) versus 87.5 (range: 5-150) in primary and metastatic tissue, respectively, p=0.068)]. CTC detection in the PB was not

associated with TROP2 expression levels in primary or metastatic tissue (CTCs were identified in 13.3% and 50% of patients with high TROP2-expressing primary and metastatic tumors, respectively). Finally, there was no concordance in TROP2 expression pattern among CTCs and the respective tumor (high, low and negative TROP2-expressing CTCs were identified in 50%, 25% and 25% of patients with high TROP2-expressing primary tumors, respectively; high and low TROP2 -expressing CTCs were evident in all patients with high TROP2-expressing metastatic tumors).

Conclusions: Herein we demonstrate for the first time a significant discrepancy in TROP2 expression among CTCs, primary and metastatic tumor tissue samples in triple negative BC. A lower TROP2 expression was observed in metastatic as compared to primary tissue, while no concordance was demonstrated among CTCs and the respective tumors. The results suggest the dynamic change in TROP2 expression status among different disease sites, thus highlighting the value of using liquid biopsy as a tool for real-time biomarker assessment in triple negative BC.

P4-05-28: The cytokine profile correlates with less tumor-infiltrating lymphocytes in luminal A breast cancer

Aoi Oshiro, Eri Ishikawa, Takahiro Watanabe, Takako Kihara, Mamiko Kuroiwa, Miki Komatsu, Sayaka Urano, Masayuki Nagahashi, Seiichi Hirota, Yasuo Miyoshi

Background: Tumor-infiltrating lymphocyte (TIL) levels are prognostic and predictive factors for breast cancer. Contrary to other subtypes, most luminal A breast cancers are immune deserts; however, the underlying mechanisms are poorly understood. As the immune-related molecules cooperate in a complex network, experiments that evaluate the immune status of breast cancer need to be performed by exploring multiple molecules rather than a single molecule. In this study, we focused on cytokines, chemokines, and growth factors, which modulate immune reactions, using multiplex assays to identify cytokine profiles linked with TILs in operated breast cancers, especially focusing on the luminal subtype.
Methods: A total of 103 patients with breast cancer who underwent surgery between September 2019 and October 2023 and had available blood samples coupled with resected tumor samples were constitutively recruited. Immune-related cytokines, chemokines, and growth factors were measured in the sera of the 103 patients using a multiplex panel. TILs were evaluated in the hotspot lesions and the TIL levels were divided into high (≥50%), intermediate (≥10%, <50%), and low (<10%). All statistical analyses were performed with JMP® Pro Version 16 (SAS Institute Inc., Cary, NC, USA), and statistical significance was set at $p < 0.05$.
Results: We compared expression levels of cytokines, chemokines, and growth factors according to the TIL levels, and found that the TIL levels were significantly associated with IL-1 receptor antagonist (IL-1ra) ($p = 0.0185$), IL-8 ($p = 0.0068$), IL-12 ($p = 0.0469$), IL-17 ($p = 0.0319$), macrophage inflammatory protein-1β(MIP-1b) ($p = 0.0398$), and homodimer

of platelet-derived growth factor B (PDGF-bb) (p = 0.0360). Cluster analysis using these six variables identified six clusters related to TIL levels. Breast cancers with high TILs were most frequent in cluster 3 (9 out of 15 cases, 60.0%), followed by cluster 1 (8 out of 34 cases, 23.5%), and fewest in cluster 6 (1 out of 21 cases, 4.8%), whereas only one or three cases were present in clusters 2, 4, and 5 (p = 0.0064). The distribution of the subtypes in each cluster was also significantly different (p = 0.0009). In cluster 6, 19 of 21 (90.5%) were luminal A, and 16 of 20 (80.0%) luminal B tumors were in cluster 1. Moreover, TIL levels in each cluster were significantly different (p = 0.0064). High expression levels of IL-12, IL-17, and PDGF-bb with low levels of MIP-1b, a characteristic of cluster 6, were prominent in luminal A but not in luminal B subtypes.
Conclusion: We identified a luminal A-associated immunosuppressive cytokine signature in the circulation. The results suggest that a tumor microenvironment with high levels of IL-17 and PDGF-bb, and low levels of MIP-1b in luminal A breast cancers resulted in low induction of TILs. Our data may partially explain the low TIL levels in luminal A breast cancer.

P4-05-29: ctDNA and serum thymidine kinase activity as tools to stratify ER+/HER2- metastatic breast cancer patients treated with endocrine therapy and CDK4/6 inhibitors: preliminary results of the TIRESIAS trial

Luca Malorni, Francesca Galardi, Chiara Biagioni, Marta Paoli, Giulia Anichini, Dario Romagnoli, Agostina Nardone, Mattias Bergqvist, Grazia Arpino, Mario Giuliano, Marco Colleoni, Emilia Montagna, Lorenzo Gianni, Stefania Vittoria Luisa Nicoletti, Lucia Del Mastro, Roberto Borea, Antonino Musolino, Claudio Zamagni, Paola Poletti, Anna Cariello, Cristina Guarducci, Stefano Gabellini, Gloria Capaccioli, Ilenia Migliaccio, Luca Livraghi, Erica Moretti, Emanuela Risi, Matteo Benelli, Laura Biganzoli

Background: Patients (pts) with ER+/HER2- metastatic breast cancer (MBC) have heterogeneous response and outcome when treated with standard first-line endocrine therapy (ET)+CDK4/6 inhibitors (CDK4/6i). We and others have previously shown that either circulating tumor DNA (ctDNA) or serum thymidine kinase activity (sTKa) may represent useful tools for the prognostic stratification of these pts according to the pattern of biomarker response during the first cycle of therapy. Here, we report a preliminary analysis of the TIRESIAS trial (NCT04660435) exploring both sTKa and ctDNA and their correlations in this setting.

Methods: TIRESIAS is an ongoing multicenter trial enrolling pts receiving ET+CDK4/6i as first-line therapy for ER+/HER2- MBC per standard clinical practice. Liquid biopsy samples are taken at different timepoints including Baseline (Bas), Cycle (C) 1 Day (D) 15, C2D1, C2D15, C3D1, end of treatment of first- and second-line therapy (EOT1, EOT2). ctDNA analysis, including low-pass whole-genome sequencing (lpWGS) and mutational profiling, was done at Bas, C1D15, EOT1 and EOT2, when available. Tumor content (TC) was estimated from lpWGS by ichorCNA, using a 3% threshold for detection (TC+). Mutational profiling was obtained with a custom enrichment-based panel of 43 breast cancer related

genes integrating unique molecular identifiers; somatic variant calls (Single Nucleotide Variants and Insertions/Deletions) were detected using three tools, including Mutect2, Strelka and LoFreq, and then validated by the tool ABEMUS. maxVAF (Variant Allele Frequency) was defined as the maximum mutant allele frequency. sTKa was measured at all time-points by DIVITUM TKa using 250 DuA as cut-off for Bas and 100 DuA for the subsequent time-points. sTKa patterns (P) were defined according to C1D15/C2D1 status (+, - or indifferent): P1 -/-; P2 -/+; P3 +/indifferent.

Results: 64 pts with ctDNA and sTKa data available were analyzed, (113 timepoints with matched data). Pts had either de-novo metastatic (53%) or secondary endocrine resistance (44%) and mainly received either ribociclib or abemaciclib in combination with an aromatase inhibitor; only 5% received a CDK4/6i + fulvestrant.
At Bas, 33% (N=21) of the pts were TC+, 44% (N=28) had at least 1 protein-affecting variant detected, and 36% (N=23) had sTKa + status. At Bas, detection of a ctDNA variant was significantly more frequent in TC+ vs – (53% vs 21%, p = 0.002), with sTKa being significantly higher in pts with TC+ (p<0.001) and in those with at least one variant detected (p 0.002). At C1D15, a parallel and significant reduction in TC and sTKa, was observed, with TC and maxVAF showing a positive correlation (R= 0.77, p< 0.001). During cycle 1, 37% of the pts were categorized as sTKa P1, 38% P2 and 25% P3. At C2D15, median sTKa was significantly lower for pts in P1 vs P3 (p 0.05). At EOT1 and 2, a parallel increase in the three biomarkers was observed with the detection of 18 new variants in 10 pts.

Conclusions: ctDNA and sTKa determination give complementary information throughout the pts treatment journey. TC estimation may give useful information on the potential detectability of ctDNA variants in a given sample, potentially informing biomarker search strategies. sTKa is a reliable marker which gives a result in every patient. Dynamic assessment of sTKa during treatment is concordant with ctDNA changes and offers a cost-effective and easier alternative to ctDNA for non-invasive monitoring of early response to therapy. Dynamic patterns of sTKa response in cycle 2 may complement sTKa response in cycle 1.

P4-05-30: MUC4 downregulation by TNF blockade enhances trastuzumab deruxtecan antitumor effect in a HER2-positive breast cancer model

Sofía Bruni, Florencia Mauro, Camila Jencquel, María Florencia Mercogliano, Roxana Schillaci

Background: Trastuzumab deruxtecan (T-DXd) is indicated for the treatment of adult patients with unresectable or metastatic HER2-positive (HER2+) breast cancer who have received a prior anti-HER2-based regimen. Results from DESTINY-Breast03 demonstrated that the median overall survival in this setting was 52.6 months, showing a need for novel biomarkers and efficient agents that may improve T-DXd outcome. Furthermore, it causes adverse effects that lead to dose reduction or treatment discontinuation. We have

demonstrated that mucin 4 (MUC4) is an independent biomarker of poor disease-free survival in early HER2+ breast cancer patients treated with trastuzumab and reflects an immunosuppressive tumor microenvironment (TME). In addition, we have shown that TNF induces MUC4 expression and that soluble TNF (sTNF) neutralization with a dominant negative protein to TNF, INB03 (DN), downregulates MUC4 and overcomes trastuzumab resistance in preclinical models. Previously, we observed that administration of 1.25 mg/kg, 2.5 mg/kg or 5 mg/kg T-DXd in nude mice reduce JIMT-1 tumor growth by 37%, 61% and 83%, respectively. Administration of 1.25mg/kg + DN induces tumor reduction that mimics the effect of the 5 mg/kg dose. In this work, we explored the precise contribution of TNF-induced MUC4 expression on T-DXd antitumor effect.

Methods: The HER2+, trastuzumab-resistant JIMT-1 cells were engineered to express a doxycycline (Dox)-inducible shRNA targeting human MUC4, rendering JIMT-shMUC4 cells. These cells were injected in nude mice and, once tumors were established, animals were administered with Dox (Dox+) or not (-Dox), and treated with IgG 2.5 mg/kg, T-DXd 2.5 mg/kg (T-DXd 2.5), or 1.25 mg/kg (T-DXd 1.25), DN 10 mg/kg or the combined therapies (n=6-8/group). T-DXd and IgG were administered i.v. on days 0, 7 and 14. DN was administered i.p. twice a week for 3 weeks. Tumor growth was monitored and differences among groups were analyzed using two-way ANOVA coupled with a Bonferroni post hoc test.

Results: In JIMT-1-shMUC4 Dox- tumors, T-DXd 1.25 inhibited tumor growth by 55% vs IgG ($p<0.0001$) at day 21. Addition of DN significantly enhanced this effect (73%, $p<0.05$ vs T-DXd 1.25). T-DXd 2.5 decreased growth by 72% ($p<0.0001$) and T-DXd 2.5 + DN by 74% ($p<0.00001$) vs IgG. Of notice, T-DXd 1.25+DN inhibits tumor growth to a similar extent to T-DXd 2.5 alone. In Dox+ tumors, with silenced MUC4 expression (30-50%), T-DXd 1.25 inhibited tumor growth by 61% and T-DXd 2.5 by60% ($p<0.0001$ each, vs IgG). Addition of DN did not further increase these effects.

Conclusion: Our results suggest that MUC4 interferes with T-DXd antitumor effect when this drug is administered at a low dose (1.25 mg/kg). This detrimental effect can be tackled by blocking sTNF, which downregulates MUC4 expression and enhances-DXd therapeutic effect. MUC4 expression seems not to affect T-DXd effect when administered at a higher dose (2.5 mg/kg). As bioavailability of anti-cancer drugs can be affected by the TME, we propose that MUC4 would be a suitable biomarker to evaluate T-DXd resistance in HER2+ breast cancer, Therefore, addition of sTNF blocking agents would be an option to reinstate tumor sensitivity to T-DXd. In addition, dose reduction of T-DXd in combination with DN could be a feasible therapeutic option to reduce adverse effects.

P4-06-01: Comprehensive Analysis of Breast Cancer Treatment and Patient Characteristics in a Nationwide Cross-Sectional Study

Bela Mrinakova, Martin Suchansky, Dalibor Ondrus, Martina Ondrusova

Background: The Medi-LINE project is a nationwide multicenter cross-sectional epidemiological study focused on analyzing the medical treatment of breast cancer (BC) in Slovakia and describing the population characteristics of patients undergoing active oncological treatment. Recommended treatment guidelines for BC often vary significantly from the treatments used in clinical practice. Real-world data based on medical oncologists' decisions reflect guideline implementation, regional practices, patient preferences, and drug availability. Studies like this are essential to measure the quality of oncological care and inform pharmacoeconomic decisions, providing a clear picture of current treatment landscapes and identifying areas for improvement.
Methods: The study collected data from medical oncologists treating breast cancer patients across all regions of Slovakia. Inclusion criteria required patients to be undergoing active oncological treatment during the data collection period. Data were gathered through an online protocol designed to capture comprehensive patient information. This included demographic data, tumor characteristics (such as year of diagnosis, histological type, multifocal/multicentric status, clinical stage, hormone receptor status, HER2, PD-L1, BRCA1/2 status), and detailed treatment histories (type of treatment, treatment sequences, and history of previous breast or other cancers). Separate analyses were conducted for the male patient population. This robust data collection methodology ensured the acquisition of detailed and high-quality information reflective of real-world clinical practices.

Results: The study analyzed data from 995 patients, providing a representative cohort of the disease prevalence. The median age at diagnosis was 60 years. Simultaneous multifocal/multicentric tumors were present in 12.06% of patients. Ductal carcinoma was the most common histological type (83.71%). HER2 negative status was observed in 78.35% of patients, with 71.96% having ER+, PR+ status. PD-L1 testing was conducted only in 2.99% of patients, with a 17.24% positivity rate. BRCA1/2 testing was performed on 25.36% of patients, with 15.04% testing positive. Previous BC was found in 3.20% of patients. The average duration of medical treatment was 2.85 years post-diagnosis. Paclitaxel was the most frequently used neoadjuvant treatment, while letrozole monotherapy and the combination of letrozole and ribociclib were most prevalent in adjuvant and palliative treatments, respectively. Significant variations from recommended treatment protocols were observed. Among male patients, 20% had a history of cancer of another origin before their BC diagnosis. All male patients were equally distributed between adjuvant and palliative treatments.

Conclusions: This study offers valuable insights into real-world oncological practices and emphasizes the importance of continuous data collection. By gathering data yearly, the results can track changes in clinical practice and serve as a sensitive indicator of the efficacy

of interventions and guideline implementation. This dataset is a vital resource for research, policy-making, and pharmacoeconomic analyses, aiming to enhance patient outcomes and optimize treatment strategies.

P4-06-02: Integration of simulated triple assessment clinics into undergraduate education improves preparedness for clinical practice

Rebecca Murphy Lonergan, Anoushka Samanta

According to the Outcomes for Graduates, the General Medical Council requires students be able to safely diagnose, investigate and manage clinical presentations, however newly graduated UK doctors have shown uncertainty in practicing autonomously and confidently in clinical settings.
Undergraduate clinical attachments provide the setting for students to learn through engagement with the clinical team and supervised participation in patient care, although well-respected barrier to this include the busyness of a student's firm, the availability of adequate supervision and the quality of feedback provided. In surgery, there are additional challenges: while the majority of UK foundation doctors will rotate through at least one surgical specialty, students report fewer opportunities to engage clinical activity in surgery than in medicine, yet are expected to develop the same standard of clinical skill and competency within surgical disciplines. Simulation is one strategy to create authentic learning opportunities adjacent to the clinical environment, allowing students to integrate their knowledge with the clinical skills required in their daily practice as junior doctors in a safe, controlled environment.
UK students may have as little as one day's exposure in breast surgery. Although considered a specialist surgical field, breast examination and history-taking are skills required not just of general surgeons but also general practitioners who make up the largest proportion of the medial workforce. In our study, we investigated the use of simulated triple assessment clinics to improve undergraduate confidence and competence with diagnosis, investigation and management of breast pathology and aid preparedness for practice.
Third year students (n=20) took part in a 4- station simulated triple assessment clinic. A prerequisit was that students had not received any formal breast examination teaching prior to participation. Participants' self-reported confidence complete eight clinical tasks were assessed pre- and post-session using anonymous questionnaires, utilising Likert scales and free text questions. We also collected data on students' preferred learning environments for clinical examinations and skills: simulation versus classroom teaching.
Overall, global confidence increased significantly post-session according to statistical analysis performed using a Wilcoxon signed-ranked test ($W = 1292.5$, p-value $< 2.2e-16$).
Most marked improvements were seen in the ordering of appropriate investigations, examining patients with breast lumps and taking a focused history of a breast-related case.
Students reported a strong preference for simulated learning environments due to relevance to practical examination, links to future practice, active learning process, and increased understanding and confidence when on clinical placement.

Integrating simulated breast clinics into the undergraduate curriculum aids development of specialist and generalist clinical skills through active learning and confidence in applying clinical knowledge in, which students value highly. Student are enthused to participate when the relevance to future practice is clear. Students reported a stronger interest in a clinical career in breast surgery after attending the session.

P4-06-03: Barriers and Goals of Care Expressed by Patients Living with Advanced Breast Cancer during a Nurse Practitioner-Led Visit

Ginny Kirklin, Abbey Kaler, Akshara Singareeka Raghavendra, Bei Wang, Ashley Anderson, Cathy Harris, Faith Field, Debasish Tripathy

Significance: Advanced Breast Cancer (ABC) is incurable with limited life expectancy. The ABC Program aims to improve the quality and quantity of life for ABC patients through navigation, education, and support. During an ABC Advanced Practice Registered Nurse (APRN)-led visit, patients are guided through the cancer center resources and provides education, resources, support, managed care between departments, and helps with the clinical trial process. Before COVID-19, an ABC APRN conducted longer in-person visits at a comprehensive cancer center in the southern US. Post-COVID-19, the program held visits via video and telephone, enhanced data collection, proactively contacted patients living within 75 miles of the center, collaborated on a clinic to bridge the gaps in oncology care, and led provider education about ABC resources. Additionally, registered nurse patient navigation was implemented for all new ABC patients.
Purpose: Understand barriers to care, goals of care, and time spent addressing barriers post- COVID-19. Compare patient characteristics including demographics, barriers to care, time spent addressing barriers for patients seen by an ABC APRN prior to COVID-19 (June 2018 to February 2020).
Methods: Data were collected as part of an ABC APRN-led visit between March 2020 to May 2024. Patients were referred by clinicians or by self. Data were analyzed utilizing descriptive statistics.
Findings: The ABC APRNs saw 253 unique patients in 586 visits. The visits were held via video (85%) and telephone (11%). Most participants were female (n=251) with a diagnosis of ABC (metastatic), and a mean age of 56 years; 69% identified as White and 83% as non-Hispanic. Most patients (53%) were diagnosed one to five years ago, married (70%), employed full-time (35%), time from first ABC diagnosis to time of navigation visit was one to five years (53%), and lived within 75 miles of the cancer center (63%). Barriers identified by ABC patients: education (90%), coordination of care (81%), emotional concerns (53%), and physical concerns (32%). Of the 586 encounters, education (77%) and coordination of care (73%) were more likely discussed at each encounter. Goals of care expressed were life prolongation (39%), symptoms (28%), and treatment (27%). For 85% of visits, 40 to 60 minutes were spent assessing and addressing barriers to care. Patients seen post-COVID-19 were more likely to be African American (16% vs 11%), Asian (5% vs 2%), be employed (35% vs 30%) and be disabled due to illness (26% vs 23%). The patients

were more likely to live within 75 miles (63% vs 37%) and have a new progression of ABC (62% vs 52%). Discussion and Implications: ABC patients have significant barriers to care, necessitating additional time at visits to assess and address these barriers. An APRN-led visit allows for time to address barriers to care and promote the patient's goals of care for inclusion in their treatment plan. Education and coordination of care barriers were more likely to be found over multiple encounters. Embracing video and telephone visits not only expanded access to appointments with the ABC APRN clinic but also reduced the need for physical trips to the cancer center. As a result, patients experienced minimal disruptions to their daily lives. Longitudinal studies are needed to further describe these barriers and better articulate goals of care.

P4-06-04: Exploring Unmet Dental Care Need and Delay Due to Cost between Breast Cancer Survivors and the General Population in the United States

Jincong Freeman, Victoria Umutoni, Xinyi Li, Yong Gun Lee

Background: Breast cancer survivors have various health needs but often encounter financial challenges or barriers to care and supportive services. Oral health is an essential component of overall health and quality of life. However, research is scarce concerning dental care specifically among breast cancer survivors. This study sought to evaluate unmet dental care need and delay due to cost comparing breast cancer survivors to the general population in the US.
Methods: This study analyzed data from the 2022 National Health Interview Survey that used multistage probability sampling. Adults with a history of breast cancer were categorized as breast cancer survivors, and the general population included adults without a cancer history. To assess unmet dental care need (yes/no), participants were asked if there was any time when needed dental care but did not obtain it due to cost in the past 12 months. Dental care delay (yes/no) was defined as whether or not participants have delayed getting dental care or services due to cost in the past 12 months. We tabulated unweighted frequencies and weighted proportions. Groups were compared using Rao-Scott Chi-squared tests, followed by multivariable weighted logistic regression controlling for sociodemographic factors. Adjusted odds ratios (aOR) and 95% confidence intervals (95% CI) were calculated. All analyses accounted for complex design and survey weights.
Results: Of 24,828 adults, 644 (1.8%) were breast cancer survivors, representing a weighted sample of 4,234,520 US survivors. Survivors were older than adults in the general population (mean age: 68 vs. 46 years). Most (60.1%) identified as White, 18.2% as Hispanic, 12.5% as Black, 6.4% as Asian, and 2.9% as Other. Compared with the general population, breast cancer survivors reported a lower proportion of coverage for dental services (34.8% vs. 37.3%) but a higher percentage of having had their last dental exam or cleaning within the past year (72.6% vs. 63.5%). Overall, 12.0% (95% CI: 9.0-15.0%) of survivors reported unmet dental care need compared to 15.7% (95% CI: 15.0-16.4%) of the general population (P=0.036). The proportion of dental care delay was lower among survivors than in the general population (15.3% [95% CI: 12.0-18.7%] vs. 19.2% [95% CI: 18.5-19.9%]; P=0.039). After covariate adjustment, the odds of unmet dental care need were similar between breast cancer survivors and the general population (aOR 0.96, 95% CI: 0.70-1.31). Breast cancer survivors were numerically more likely than the general population to have delayed dental care (aOR 1.10, 95% CI: 0.83-1.56), though the difference was not statistically significant. In the same adjusted models, compared with White adults, Black adults had greater odds of unmet dental care need (aOR 1.51, 95% CI: 1.31-1.74); Hispanic adults also had greater odds of unmet dental care need (aOR 1.77, 95% CI: 1.56-2.00) and dental care delay (aOR 1.51, 95% CI: 1.35-1.69). Smoking, drinking, and having public insurance were significantly associated with greater odds of having unmet dental care need or delayed dental care due to cost.
Conclusions: In this population-based sample of US adults, unmet dental care need and

delay due to cost were prevalent in breast cancer survivors, with similar prevalence rates to the general population. Nearly two-thirds of breast cancer survivors lack coverage for dental services. There are racial/ethnic and socioeconomic disparities in dental care need and delay. Strategies and policies should consider reducing dental care costs and addressing coverage barriers to dental services among breast cancer survivors and socioeconomically disadvantaged populations. Future research should examine the impact of unmet dental care needs and delays on breast cancer survivors' quality of life and survival outcomes.

P4-06-05: Telehealth and cancer care delivery: Evaluating the impact of telehealth on patient access and treatment utilization at a comprehensive cancer center using real world data

Kelsey Natsuhara, Hope S. Rugo, Sorbarikor Piawah, Jean Feng, Travis Zack, Jie Jane Chen, Nathan Magalit, Ryzen Benson, Anobel Odisho, Alan P. Venook, Julian C. Hong

introduction: Telehealth has persisted post-COVID 19 due to its convenience, potential to improve access to care, and changes in telehealth reimbursement incentivizing its use. Data are needed to examine telehealth's impact on care utilization and patient (pt) access among diverse cancer types to inform long-term telehealth policies.
Methods: We used a deidentified clinical data warehouse to develop 2 cohorts of pts treated at our center from 2017-2019 (pre-telehealth) and 2021-2023 (post-telehealth). Data from 2020 was excluded, given peak pandemic irregularities. We included pts ≥18 yrs who completed ≥1 medical, surgical or radiation oncology visit with an associated cancer diagnosis. We strategically selected 3 disease groups with varying telehealth use: breast (low), GI (medium), GU (high). This allowed us to control for external factors (eg COVID) and better isolate the impact of telehealth. We obtained pt data (age, sex, race, zip code), visit data (new/follow-up, in-person/video, provider, department) and identified pts receiving cancer treatment (tx) at our center. We compared changes in visit distribution, sociodemographics, and tx patterns within and between disease groups pre- and post-telehealth using Chi-square and ANOVA tests.
Results: A total of 102,516 encounters and 25,123 pts pre-telehealth vs 139,309 encounters and 47,814 pts post-telehealth were analyzed. The # of unique pts seen pre- and post-telehealth increased significantly in all groups (+101% breast, +60% GI, +108% GU). Post-telehealth, the proportion of video visits (VVs) increased in breast from 1.6% to 28.2%, with most visits remaining in-person (IP; 71.5%); GI increased VVs from 1.9% to 55.3% of total visits; GU increased VVs from 3.1% to 81.4%. The distribution of visits by department, visit and provider type were similar pre- and post-telehealth for all groups. Among all groups, the proportion of pts identifying as White decreased among aggregated visit types, while the proportion of Asian and LatinX pts increased post-telehealth. In breast and GU, there was a statistically significant change in the geographic distribution of pts post-telehealth, with an increase in unique pts seen who lived in San Francisco (+7.4% breast, +3.5% GU). Post-telehealth, the % of pts who received radiation increased in breast, GI, and GU (+3.7, +2.3, +1.3). In breast and GI, the % of pts receiving infusions increased (+3.4, +1.6), but

decreased in GU (-0.6). The % of pts who underwent surgery decreased among all groups (-6.6, -4.4, -6.7).
Discussion: We evaluated 3 oncology disease-based groups with varying telehealth use to characterize the impact of widespread telehealth adoption on pt demographics and tx patterns. Total pts seen increased in all 3 groups. Notably, more pts with breast and GU cancer were seen from San Francisco post-telehealth. Given similar increases in pt volume and geographic shifts between low and high telehealth groups, this cannot be attributed to telehealth alone. Additional analyses to characterize telehealth's impact on pt access are ongoing. Regarding tx, the % of pts receiving infusions and radiation increased most in breast, which maintained the highest % of IP visits, highlighting the importance of IP visits during active tx. Limitations of our study include an inability to capture whether pts were seen via telehealth for 2nd opinions and treated locally or pts who received oral medications. This will be explored in future analyses. Study strengths include the large sample size and study design that leverages differences in telehealth use among disease groups to better isolate telehealth's impact on care patterns and pt demographics. Overall, we observed significant increases in pt volume and shifts in geographic distribution post-telehealth. Further analyses will be reported.

P4-06-06: The Etiologic Causes of Diagnostic Delay in Locally Advanced Breast Cancer: _x000B_A Multicentric Nationwide Trial

Guldeniz Karadeniz Cakmak, Enver Özkurt, Hasan Karanlık, Lütfü Doğan, Semra Günay, Pelin Basım, Müfide Akçay, Günay Gürleyik, Ali Uzunköy, Mehmet Ali Gülçelik, Taner Kıvılcım, Gültekin Ozan Küçük, Hande Köksal, Özge Gümüşay, Belma Koçer, Yeliz Ersoy, Selman Emiroğlu, Ahmet Pergel, Bartu Badak, Atakan Sezer, Sibel Özkan Gürdal, Kubilay Dalcı, Arzu Akan, Barış Morkavuk, Metin Varlı, Ali Cihat Yıldırım, Beyza Özçınar, Emine Yıldırım, Ahmet Dağ, Cihan Uras, Vahit Özmen

Purpose: Breast cancer is the most common type of cancer in women worldwide, and early detection in advanced stages is the most crucial factor in reducing mortality and improving quality of life. The aim of the presented study is to investigate patient and region-specific factors causing delays in the diagnosis and treatment of breast cancer in different geographical regions in Türkiye.
Method: A survey study has been designed to be conducted between August 2023 and October 2024 in every region, involving women who have been diagnosed with locally advanced breast cancer. The survey consists of two parts, filled out by both patients and physicians, focusing on possible delays in diagnosis and treatment. The survey form, designed in the data collection section, was filled out during face-to-face interviews conducted by trained doctors/nurses. The questions cover socio-demographic factors (age, education level, first year of marriage, marital status, occupation, menopausal status, residence, health insurance, daily exercise duration, body mass index (BMI), smoking habits, X-ray history, chronic illness, delay duration, family history of breast cancer, age range of first pregnancy, history of benign breast disease, breast self-examination,

knowledge, and regular performance status) and clinical factors (lymph node status, first symptom type, tumor location, tumor type, date and type of first symptoms noticed by patients, date of first detection, date of first medical consultation, and socio-economic factors during that period).
Results: The study included 37 centers from 7 regions of Türkiye involved in survey creation and implementation. In the initial phase, a total of 886 surveys were evaluated. The median age was 46 (22-89 years). 47% of the patients had primary school education, 18% live in rural areas, 63% knew how to perform breast self-examinations (BSE) and 51% rarely do BSE. Of the patients, 87% initially visited hospitals. 425 patients had the disease detected during screening and 543 sought medical attention within 1 month of detecting a lump. 42 cases tried alternative medicine. Factors causing diagnostic delays were reported as 21% ignorance and 17% fear of death delaying medical consultation. The examination time by specialists varied, with 574 patients examined within 1 month after detecting a symptom, 183 within 1-3 months, and 129 taking over 3 months. Mammography was performed within 1 month in 78% of patients, within 1-3 months in the rest of the cases. Other radiological imaging (ultrasonography-magnetic resonance imaging) was done within 1 month for 561 (76%) patients, and tissue biopsy for 509 (70%) patients. The most significant factor in delaying the adjuvant chemotherapy and radiotherapy process was identified as treatment side effects. In the Black Sea region, most common factors causing diagnostic delays were inability to get medical appointments and fear of losing the breast, while in the Mediterranean and Eastern Anatolia regions, fear of death, ignorance, and inability to find time due to daily tasks were prominent. In the Southeastern Anatolia, Marmara, Aegean, and Central Anatolia regions, ignorance, economic reasons, fear of death, and fear of losing the breast were listed as the primary factors.
Conclusion: More than half of the women diagnosed with locally advanced breast cancer do know how to perform BSE, but only 29% of the patients perform BSE monthly. Across geographical regions, the most common factor causing delays among patient-based factors is fear of death following ignorance.

P4-06-07: The Impact of a Multidisciplinary Quality Assurance Conference on the Management of Inflammatory Breast Cancer

Huong (Carisa) Le-Petross, Megumi Kai, Angela N Marx, Hope Murphy, Angela Alexander, Gary Whitman, Sadia Saleem, Mary Guirguis, Miral Patel, Susie Sun, Bora Lim, Vicente Valero, Anthony Lucci, MDACC Inflammatory Breast Cancer Team, Wendy Woodward

Introduction: Inflammatory breast cancer (IBC) is rare but aggressive breast cancer. With the variability in presentation, making prompt diagnosis is challenging even for the experienced physicians. Only in the last several years has a dedicated diagnostic and management algorithm been agreed upon among multidisciplinary teams at one academic institution. A weekly multidisciplinary management conference (MTC) was developed at our institution three years ago specifically for IBC patients, to provide a common platform for reviewing cases, discussion of challenging diagnoses and treatments, sharing of clinical

trial protocols, and ultimately optimizing patient care. In this abstract, we investigate the impact of the conference discussion on IBC patient management.
Methodology: All patients who were presented at the IBC multidisciplinary conference from one tertiary academic center were identified from an IRB approved registry protocol, between June 2020 to May 2024. The chart review, imaging studies, associated pathology, and conference notes were retrospectively reviewed from the institutional medical record system EPIC.
Results: 205 patients were presented at the IBC multidisciplinary team conference during the study period. The patients' age at the time of IBC diagnosis was: mean age of 50.9 years and median age of 52 years (range 26-83). Patients' demographics are : 152 (74.1%) white, 28 (13.7%) black, 10 (4.9%) Asian, 1 (0.5%) native Hawaiian or other pacific islander, and 14 (6.8%) others. Reasons for presenting at MTC include newly diagnosis or suspicion of IBC 40.8%, treated or being treated at outside facility for second opinion 24 %, treated or being treated 19.2%, and interesting case by a clinician 16%. Diagnostic imaging modalities presented or discussed included: mammography 47% of cases, breast ultrasound 58%, biopsies 13%, CT chest abdomen pelvis 20%, PET/CT 51%, brain MRI 17%, bone scan 9%, and other tests (eg. non-breast ultrasound, abdominal MRI, nuclear medicine exams, etc.) 25%. Repeat or additional biopsies were recommended in 4% of cases. At the conclusion of the conferences, recommendations were document in EPIC. Confirmation of IBC diagnosis was reported in 61% (126/205) while in 1% (2/205) diagnoses were changed or consensus was not IBC. In 45% (92/205) patients, treatment recommendation or management change were made. 47% (97/205) patients were recommended for enrollment in clinical trials.
Discussion: Multidisciplinary team conference even in rare disease such as IBC is impactful and beneficial for patients' care resulting in almost half of the patients having recommendation for enrollment in clinical trials, as well as confirmation of accurate diagnosis by a multiteam approach.

P4-06-08: Regional Disparities in Mammography Access in Brazil: The Impact on the Consolidation of Effective Breast Cancer Screening

Letícia Pinheiro Amorim, Mariana Macambira Noronha, Valbert Oliveira Costa Filho, Pedro Robson Costa Passo, Duílio Reis da Rocha Filho, Leonardo Saraiva Pontes, Eric Lima Freitas Mota, Gabriel Sampaio Feitosa, Ígor Giordan Duarte Jorge, Izaberen Sampaio Estevam, Paulo Eduardo de Oliveira, Kevin Lucas Silva Ribeiro, Carlos Alberto Barbosa Neto, Josmara Ximenes Andrade Furtado, Markus Andret Cavalcante Gifoni, Márcio Marcondes Vieira, Elvis Lopes Barbosa, Luiz Gonzaga Porto Pinheiro, Paulo Henrique Diógenes Vasques, Eduardo Araújo Costa Lima, Gabriel Fontenelle Costa, Júlia Matos Dubanhevitz, Saulo Rabelo Costa, João Luiz Lima Pinheiro, Eduarda Severo Alvarenga, Fabrícia Cardoso Marques, Cecília Dias Caminha Gentile, Juliana Pinho da Costa Leitão, Danielle Calheiros Campelo Maia, Francisco Pimentel Cavalcante

Introduction: Breast cancer (BC) is the most frequently diagnosed and lethal neoplasm among women globally and in Brazil, constituting a significant public health burden.

Mammography is the primary strategy for early detection of BC, but its effectiveness in reducing mortality is most evident in populations where adherence to the exam reaches at least 70% of the target population. In Brazil, unfortunately, there is a significant regional disparity in access to health services, raising concerns about the true effectiveness BC screening. In light of this, we aim to access the regional disparities in the consolidation of breast cancer screening, comparing the number of mammograms performed in Brazil by the five regions (North, Northeast, Southwest, South, and Midwest) between the years 2020 and 2024. Methodology: The DATASUS platform was used to collect data from the Cancer Information System (SISCAN), with analysis of the screening mammography variant according to the patient's state of residence and the year of the procedure. Additionally, data from the Brazilian Institute of Geography and Statistics (IBGE) was used to consult the target female population for screening between two thresholds: of 40 and 74 years old and 50 and 69 years old, according to the 2022 Demographic Census. Results: A total of 8,954,424 mammograms were performed in Brazil between 2020 and June 2024, with the Southeast region accounting for approximately 36.8% of this total. The Northeast region ranked second, with 30.8% of the exams, followed by the South (20.6%), Midwest (6.9%), and North (4.7%) regions. The proportion of mammograms per female population aged 40-74 years varied across regions, with the highest percentage found in the South (29.16%), followed by the Northeast (26.44%), Midwest (20.09%), Southeast (17.92%), and North (15.70%). Furthermore, when analyzing the proportion of mammograms in women aged 50-69 years, the South region achieved the highest mammography coverage rate (51.42%), followed by the Northeast (49.73%), Midwest (38.13%), Southeast (32.27%), and North (31.17%). Conclusion: The study revealed significant regional disparities in access to mammography screening across Brazil. The South and Northeast regions demonstrated the highest accessibility rates for the target population, while the North region faced alarmingly low rates. Regardless of the age range considered as the target population, the national percentages fell short of the recommended levels for adequate screening. This scenario can be attributed, primarily, to the lack of effective public policies that ensure equitable access to healthcare, a fundamental principle of Brazil's Unified Health System (SUS). This lack of equity hinders the consolidation of effective breast cancer screening nationwide.

P4-06-09: Does Age Impact Patient Involvement in Treatment Decision Making: Results from the Canadian Breast Cancer Network (CBCN) Assessment Project

Kathleen D. Swiger, Scott Richter, Bukun Adegbembo, Cathy Ammendolea

Assessing the information and support needs of Canadians diagnosed with breast cancer must be rooted in an understating of the patient. In 2022, the Canadian Breast Cancer Network (CBCN) initiated a project to identify the educational needs of Canadian breast cancer patients in order to develop tailored, focused programs and materials to fill educational gaps.
We conducted 45-minute key informant interviews (7) with patients and oncologists to

determine the needs and educational gaps of breast cancer patients. Five 90-minute patient focus groups (32 participants) were conducted to enhance the interviews. Findings from the interviews and focus groups were used to inform the questions for an online survey fielded between May 1 and June 10, 2022. Data analysis began in September 2022 and is on-going. A review of survey findings of patients under 50 years (U50) (n=131) and those 70 years plus (70+) (n=124) revealed little difference between the age groups regarding their involvement in the treatment decision making process. Both groups were more likely than not to have a healthcare provider (HCP) review their pathology report with them (71.0% of U50 vs. 73.2% of 70+); be included in the treatment decision making process (87% of U50 group vs. 86.1% of 70+) and be provided with information before treatment (72.5% of U50 vs.75.4% of 70+). The above findings are all significant at less than 0.001. In making their decision, both groups (75% of U50 vs. 80% of 70+) reported that "Efficacy of Treatment" was their primary consideration.
Age should not be a factor in whether to include patients in the treatment decision-making process. Patients, whether under 50, or over 70, can be equally involved in this process, if they choose to be. Communication between the HCP and the patient during the treatment decision-making process may build trust and understanding of the differences in treatment and follow-up and instill confidence in the overall patient experience.

P4-06-10: Impact of Online Education in Improving Clinicians' Knowledge of the Hot Topics in Breast Cancer Clinical Research

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Eloise Ballard, Jamie Habib, Giuseppe Curigliano

Background: The treatment landscape for breast cancer is evolving rapidly, with many clinical trials investigating novel treatment strategies and promising new agents. The objective of this study was to assess the effect of an online continuing medical education (CME) activity on clinicians' knowledge in latest clinical trials investigating novel and emerging therapies in breast cancer and their confidence in identifying patients suitable for clinical trials of emerging therapies.
Methods: This CME activity consisted of a 15-minute video presentation with synchronized slides. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 27th of September, 2023, with data collected through 19th January, 2024 being reported in the current study.
Results: 57 oncologists and 37 obstetricians/gynaecologists who answered all the assessment questions were included in this analysis. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge of both physician learner groups, with 150% more oncologists answering all questions correctly after

education (30% post- vs 12% pre-CME) and 38% more obstetricians/gynaecologists answering all questions correctly after education (22% post- vs 16% pre-CME). Specifically, the knowledge regarding the latest clinical trials investigating novel and emerging therapies in breast cancer increased from 50% pre- to 68% post-CME for oncologists (P<.001) and from 38% pre- to 58% post-CME (P<.001) for obstetricians/gynaecologists, respectively. Additionally, 35% of oncologists and 11% of obstetricians/gynaecologists reported increased confidence in effectively managing adverse events associated with novel ADC therapy for breast cancer, and that increase was, on average, 48% and 44% among the two physician groups, respectively.
Conclusions: This analysis demonstrates the success of a 15-minute online educational activity on clinicians' knowledge of the evolving treatment landscape in breast cancer. As more clinical data become available, it will be important to provide ongoing education to clinicians on the implications of the new data and how to translate them into clinical practice.

P4-06-11: What do patients, doctors, and payers truly value? Developing a multi-criteria decision analytic tool that assesses the value of adjuvant hormonal plus CDK inhibitors in breast cancer

Omar Castillo-Fernandez, Cristiane Martin, Maria Lim, Taysser Sowley, Mario Guardia, Jonatan Quintero, Jaime Ordoñez

Background: Multicriteria Decision Analysis (MCDA) is a collaborative process that helps clinicians, payers, and patients consider various factors such as treatment effectiveness, potential side effects, cost, individual preferences, and quality of life outcomes. This study aims to evaluate the agreement among patients, doctors, and payers regarding the factors used to assess interventions for adjuvant CDK inhibitors and hormonal therapy in breast cancer in our country. Methods: To create the rating instrument, we formed three groups – The patient group: 15 patients with non-metastatic HR-positive Her2-negative breast cancer undergoing hormonal adjuvant treatment (patient panel), a payer panel (n=3) consisting of Institute personnel with budget responsibilities, and a group of 6 breast medical oncologist specialists. These groups discussed and selected the main domains and subdomains of the instrument in meetings held from September 2023 to June 2024. The group agreement was evaluated using Kendall's coefficient of concordance (W). Results: The agreed instrument has six main domains. 1) Health outcomes, 2) Safety, 3) Public Health,4) Financial and Economics, 5) Innovation, and 6) Patient/Society. A very strong agreement among their weight was observed W=.0.95 (p=0.014). There was a weak agreement in the Safety subdomain (tolerability and medication suspension W=0.11(p=0.56) mainly because of payer evaluation. A moderate agreement was observed in three subdomains: Public Health (Severity of disease, disease burden, and proportion of patients needing adjuvant treatment) W=0.33 (P=0.36). Innovation (Another alternative available, technological innovation, value of hope) W=0.53 (p=0.20) and Health Outcomes (iDFS, cost-effectiveness, Predictability of clinic benefit, Doses optimization, OS, and Number necessary

to treat) W=0.49 (p=0.19). Domains with a strong agreement: Financial/Economics (Budget impact, return to work) W=0.99 and Patient/Society (free treatment period, tolerance, quality of life, out-of-pocket expenses) W=0.81 (p=0.062). Most of the concordance was seen between doctors and patients. Conclusion: Using the MCDA in the adjuvant setting is feasible and requires an open and comprehensive discussion among the patients, doctors, and payers. A proof-of-concept application of this tool to new adjuvant options is currently underway at our institution.

P4-06-12: Breast Cancer Hub (BCH) Case Study – Addressing Breast Cancer Challenges in Villages in India with Grassroots Sustainable Solution

Ratna Basak, Sima Basak, Rimpa Biswas, Sabarna Saraswati, Lopamudra Das Roy

Background and Challenges: The death rate to Breast Cancer is significantly higher in India due to taboo, ignorance, inaccessibility to healthcare services, proper diagnosis, and treatment management. The situation in the villages is grimmer. This populace is not only in financial constraints, struggling for daily food, with health taking a back seat, but due to geographical barriers, the hospitals equipped with cancer screening & treatment are in towns/cities, needing hours of travel for the villagers as they live in the remote far-flung areas, investing the full day to go back and forth, adding to their transport charges. It is hard for them to miss on their daily wage, and since a family member needs to accompany the suspicious case, the monetary loss adds up, eventually delaying or skipping treatment.
Missions: Breast Cancer Hub (BCH), founded by Dr Lopamudra Das Roy, aims to bridge the healthcare gap between developed and developing countries by providing sustainable grassroots solutions with 100% Free services. Since its inception in 2017, BCH has improvised guidelines to meet community needs, considering cultural stigmas and socio-economic conditions.
Breast Cancer in underserved areas: In deprived regions, accessing specialized cancer treatment is challenging. Mammogram and ultrasound screenings are rare in these areas, contributing to delayed or avoided treatments. To address this, BCH developed Breast Self-Exam (BSE) cards in 24 languages for Her and Him making it inclusive, targeting underprivileged and conservative communities. These cards, along with awareness campaigns, screening camps, and providing a holistic approach by Adopting Villages for door-to-door Cancer Screening, Treatment Aid, Counseling, Support, and Food, are part of BCH's strategy to improve early detection and adherence to breast cancer screening guidelines.
Case Study from one of the BCH adopted villages in India: Dipali Basak, a 54-year-old agricultural laborer from Huda Village, Nadia District, West Bengal, India, represents a typical case of the struggles faced by women in remote areas. With a family income of approximately $60 per month, accessing healthcare is a significant challenge. Dr Das Roy conducted a cancer awareness camp in Huda Village on August 9, 2022, where Dipali learned about BSE. On December 7, 2022, BCH team visited Dipali's home during door-to-door Cancer screening, providing BSE cards in local language and contact information.

Healthcare Journey: In October 2023, Dipali discovered a lump while performing a BSE and reached out to a BCH field worker. Despite having a government-provided health card for underprivileged families, the process of getting proper medical care was arduous. The nearest primary health center lacked imaging facilities for cancer screening, requiring BCH team to take Dipali to various hospitals, involving multiple modes of transport (Toto, Auto, Bus, Train) and long travel times. At Krishnanagar Sadar District Hospital, Dipali received treatment, but with limited specialist availability and the need for private pathology tests due to inadequate hospital facilities. Dipali underwent surgery on January 17, 2024, at Krishnanagar Hospital. Post-surgery, BCH facilitated further testing and provided comprehensive support, including covering transport and remaining treatment costs, counseling, and follow-up care. Despite facing resistance from Dipali due to treatment side effects, BCH ensured she received ongoing chemotherapy and radiation.
Broader Implications: Dipali's case highlights the systemic issues in breast cancer care in developing regions, where lack of awareness, inadequate healthcare infrastructure, and financial constraints delay or prevent treatment. BCH's unique trendsetting efforts underscore the need for revising the guidelines to address these challenges effectively, necessitating policy changes and targeted healthcare strategies to better serve vulnerable populations.

P4-06-13: Empowering the clinician and patient communities through the development of an accessible, online tool to support diagnosis of Inflammatory Breast Cancer (IBC)

Lindsey Anstine, Alexandra Erwin, Hosea Baker, Sainath Vaidhyanath, Trevor Polischuk, Anjali Patel, Brady Kazar, Kimberly Sabelko, Glendon Zinser

Inflammatory Breast Cancer (IBC) is a rare and highly aggressive form of advanced breast cancer. Compared to other breast cancers, IBC is uniquely characterized by skin changes and breast swelling often resembling a breast infection. Additionally, IBC is largely a subjective, clinical diagnosis that is challenging to identify. These issues are further potentiated by a general lack of awareness in the clinical and patient communities, further contributing to delays in diagnosis and treatment. Together, these circumstances contribute to poorer outcomes for people with IBC, who have a 5-year relative survival rate of only 39%. Thus, there is an urgent need to educate health care providers and patients about IBC and to develop tools to aid in differentiating IBC from other forms of breast cancer, enabling more accurate and timely diagnosis. To begin to address these challenges, the IBC Scoring System Online Tool (IBC Online Tool) (komen.org/ibc-calc) was developed as an easy-to-use, web-based version to help health care providers recognize and more effectively diagnose IBC. The IBC Online Tool is based on a set of proposed common diagnostic criteria identified by a panel of experts within the Susan G. Komen-IBCRF IBC Collaborative in partnership with the Milburn Foundation (Jagsi et. al. Breast Cancer Res Treat. 2022) that has recently undergone scientific validation (publication in preparation). Prior to the online version, providers had to navigate to the publication and manually calculate a score. The

IBC Online Tool provides the proposed IBC diagnostic criteria in a more convenient form, allowing clinicians to quickly calculate a patient's possibility of having IBC in the clinic. Development of the IBC Online Tool required a highly collaborative effort with medical experts, patient advocates, in-house IT experts and others to provide insights to build and test the online platform. Components of the IBC Online Tool include a user interface, reference images of IBC, supporting text to aid with response selections and user feedback surveys. In addition, a results page can be downloaded to document breast changes and/or support patients in initiating discussions with their providers about the possibility of IBC. Available in both desktop and mobile versions, the online tool enables providers to more quickly and easily assess patients for IBC, which may result in more timely diagnosis and care. To drive and support the use of this important tool, additional IBC educational materials were created including A Health Care Providers Guide to IBC, A Patient's Guide to IBC and an IBC Collaborative webpage (komen.org/ibc) to house the tool, providing important IBC information and resources for clinicians, researchers and patients. A QR code linking to the IBC Online Tool was generated and included within these resources and the QR code has been presented by IBC experts at major conferences to drive access and usage of the IBC Online Tool. This approach has been highly successful in raising awareness of this important resource, driving its use across the United States and in over 60 countries worldwide (as of June 2024). By digitizing the IBC Scoring System into an easily accessible online version, health care providers can now easily access a critical tool for IBC diagnosis in the palm of their hand. The development of the IBC Online Tool will ultimately help increase diagnostic accuracy, guide treatment decisions and improve IBC patient inclusion in clinical trials. Furthermore, Komen's IBC resources can help to support patients in conversations with their doctors ultimately leading to more timely diagnosis and improved outcomes for this rare and understudied breast cancer.

P4-06-14: Closing gaps in the diagnosis and treatment journey by a collaborative process design in a social and non-profit association in Peru

Mauricio Leon Rivera, Franco Doimi Garcia, Jose Marin San Yen Man, Steffi González Bocanegra

Knowing that in our country, 6 women die per day from breast cancer, totally preventable diseases and that none should die and that the state has been totally overwhelmed in its work, is that we will manage to make the project is carried out by the Liga Peruana Contra el Cancer (LCC), ROCHE pharmacy and the Oncological Pathology laboratory become great allies to reinforce.
According to statistics from the LCC, this institution treats approximately 50,000 patients a year. Of these patients, 4,000 (8%) present abnormal cellular changes, of which 600 (15%) have a type of invasive cancer, and of these, invasive breast cancer occupies first place in incidence with nearly 300 cases annually.
To complete the diagnosis of breast cancer, the immunohistochemistry (IHQ) test must always be performed; however, the access to this test has been subject to the patient's

ability to pay for it, with a delivery time of 1 month for the results in average. A current alternative is for patients to be referred to public institutions; however, the time for referral and for carrying out this test until obtaining the results is too long.
This entire situation has resulted in only between 10 to 20% of the patients treated in the LCC, undergoing the IHQ test, and the remaining percentage is unknown if they did so. Likewise, this institution does not know the situation of all patients after being diagnosed with breast cancer because LCC only do diagnoses and not treatments.
The first objective of this project has been to close these gaps in complete diagnosis by providing patients with the IHQ test and, if necessary, the confirmatory in situ hybridization (SISH) test, free of charge and with results within 1 week. The second objective has been to achieve a referral of these patients in an accompanied manner to the public or private hospitals that correspond to them so that they can receive the appropriate treatment according to the sub molecular type of breast cancer they present and their clinical stage.
To date, after 1 year and 8 months of starting the project, IHQ tests have been performed on 385 patients, with a cumulative HER2 positivity rate of 28.8% (111 patients), of which 85 were HER2 +++ and 26 presented the amplified SISH test. The SISH positivity rate was 31%, with 26 amplified tests out of 84 SISH tests performed in doubtful HER2 patients (HER2 ++).
Regarding the design of the collaborative process, it has consisted of three stages: contact with the patient, affiliation to the program, and accompaniment to the respective hospital to receive the corresponding treatment.
Regarding contact with the patient, a rate of 100% has been achieved, that is, all patients diagnosed to date have been initially contacted by the staff of the LCC, and subsequently by the staff of the program's call center from pharmacy.
Next step, the affiliation of patients to the pharmacy support program has reached 60% after collaborative work between the LCC, the pathology laboratory, and pharmacy lab.
Of the total number of patients affiliated with the program, 34 patients, 25 (74%) have managed to receive treatment, and 9 (26%) are in the staging process to choose the corresponding treatment, being accompanied by the pharmacy´s patient program.
Of these patients treated in the LCC, 46% have public health insurance of the ministry of health (SIS program), 43% belong to social security (ESSALUD), and the rest have private insurance (EPS) or insurance from the armed forces.
Without this project, these patients would have been left with a incomplete diagnosis of breast cancer in a timely manner, and without the corresponding treatment.

P4-06-15: Resource Utilization by Patients Living with Advanced Breast Cancer (ABC) Who Had a Nurse Practitioner-Led Visit

Ginny Kirklin, Abbey Kaler, Akshara Singareeka Raghavendra, Bei Wang, Ashley Anderson, Cathy Harris, Isabella Masso, Debasish Tripathy

Significance and Purpose: The diagnosis of ABC is life-changing and requires greater support and resource utilization compared to early-stage breast cancer patients. The ABC Program aims to improve the quality and quantity of life for ABC patients through navigation, education, and support. At an ABC Advanced Practice Registered Nurse (APRN) led visit, patients are guided through the cancer center services and provided education, resources, emotional support, managed care between departments, and informed about clinical trial opportunities and eligibility. The program reviewed resource utilization of the ABC patients seen by an ABC APRN at a comprehensive cancer center in southern US to understand what additional multi-disciplinary interventions are needed. The specific resources included emergency room and inpatients visits, therapeutic clinical trials, and completed visits to the LIMBS Clinic (Linking Internal Medicine and Metastatic Breast cancer for Success), a subspeciality clinic providing access to internal medicine services coordinated with oncology care.
Methods: Data were collected as part of an ABC APRN-led visit between March 2020 to May 2024. Patients were referred by clinicians or by self. Data were analyzed utilizing descriptive statistics.
Findings: A total of 480 patients had a total of 1,769 visits with an ABC APRN via video (94%) or telephone (6%). Participants were female (99%) and male (0.63%) with a diagnosis of ABC and a mean age of 57; 69% self-identified as white, 16% as black, and 84% non-Hispanic. Most patients (53%) live within 75 miles of the cancer center followed by 23% of patients living between 151 to 500 miles of the cancer center. Most patients (68%) had an ECOG status of 0 or 1. Fifty-six percent of patients presented to the emergency room visit (n=1,052). Of those, 48% of patients had an inpatient admission (n=587). Sixteen percent of patients were active on a therapeutic clinical trial at the cancer center, and 25% of patients had a completed visit in the LIMBS Clinic. There were 425 internal referrals including the LIMBS Clinic (n=110), Integrative Medicine (n=78), Supportive Care (n=59), Nutrition (n=42), and Physical Therapy (n=28) being the top five referrals from the ABC APRN visits. Most patients (52%) had at least one internal referral. Most incoming referrals to the ABC APRN clinic were from the Texas Medical Center site (77%) followed by a regional campus (14%) 41 miles north of the cancer center.
Discussion and Implications: People living with ABC utilize multiple resources for management of disease and treatment. Limitations include only having access to data for resource utilization at the cancer center and not resources available through the community. Additional research needs to be completed to match ABC patient needs to the type and amount of services and resources. Robust programs are needed to streamline and proactively address ABCs patient's needs.

P4-06-24: The effects of two multimodal exercise programs (face-to-face vs online) on physical and functional outcomes in breast cancer survivors: A randomized control trial.

Monica Castellanos-Montealegre, Soraya Casla-Barrio, Helios Pareja, Laura Cantero

Introduction: Extensive evidence supports the numerous benefits of physical exercise programs in cancer patients. Physical exercise has been demonstrated to reduce many of the side effects of cancer and its treatments, primarily by addressing alterations in body composition, CRF, and fatigue, all of which are associated with quality of life and survival. Despite these benefits, it is estimated that only 36% of breast cancer survivors adhere to the exercise recommendations for cancer survivors set by the World Health Organization (WHO). In this Randomized Control Trial (RCT), we examined the impact of a face-to-face oncological exercise program compared with an online oncological exercise program on body composition, CRF, fatigue, and quality of life in patients with breast cancer in stage IA to IIIB.

Methodology: Women diagnosed with primary breast cancer (stages IA to IIIB); aged 18 years or older; no more than 10 years since cancer diagnosis; and without other comorbidities that would limit their capacity to engage in exercise were included in this study. Patients assigned to the intervention group underwent a multimodal exercise program intervention for 16 weeks. This intervention was conducted both in-person at the training center and online to enhance participant adherence.

Both oncological exercise programs (online and in-person intervention) included resistance, endurance, balance, and proprioception exercises for 16 weeks, with intensity ranging from 55% to 95% of heart rate reserve (HRR). Each session lasted 75 minutes and was structured as follows: 10 minutes of warm-up involving joint mobilities, balance and proprioceptive exercises, and aerobic exercise at an intensity ranging from 55% to 75% HRR. This was followed by two 20-minute bouts of combined activities (endurance activities combined with resistance exercises) at an average intensity of 70-75% HRR with 30 to 60 second bouts of high-intensity activity of 85% to 100% HRR. The resistance exercises were developed with free weights in circuits of 6 to 8 exercises of 3x10 or 3x15, combined with endurance activities of 60% HRR. Intensity perception in resistance exercises was assessed using the Borg Scale, and endurance exercise intensity was assessed by HRR. Finally, full-body stretching was performed. The only difference between the two types of programs was the remote or face-to-face format.

Demographic data were analyzed by descriptive methods and were presented by Media and standard deviation and frequencies. Baseline analysis comparisons between groups were developed by t-test for independent samples. Final group comparisons were developed with the ANCOVA test, adjusting results by baseline assessments in each variable. Cohen's d was performed to find the effect size in the final group comparison results.

Results: 40 patients in the intervention group (mean 50.2±1.05 years old) and 34 in the control group (mean 49.48±1.88 years old) completed the study. In the intervention group, 14 (35.9%) patients participated in the online program, while 25 (64.1%) attended the in-

person sessions. The attendance rates for the intervention group were 89.5% in both instances. Specifically, for the online group, 84.02% of the sessions were conducted online, while 15.98% of the attendance occurred in person. Conversely, for the in-person intervention, 76.64% of the sessions were face-to-face, and 23.35% of the attendance was through online classes. No differences in attendance between interventions were observed (p=0.997) (table 1). In addition, no significant differences between interventions were observed in physical (cardiorespiratory fitness, functional capacity, and body composition) or emotional (fatigue and quality of life) variables (table 2).

Conclusions:
The multimodal physical exercise interventions (online and face-to-face) in this study prove to be effective not only in improving fitness and body composition, but also in promoting different exercise strategies, and improving the accessibility of exercise programs for patients far from sports centers. This accessibility is crucial in ensuring high levels of adherence to these programs and adapting the intervention to the personal situation of patients.

P4-06-25: The impact of multimodal exercise program on physical and functional outcomes in breast cancer survivors: A randomized controlled trial.

Soraya Casla-Barrio, Mónica Castellanos-Montealegre, Helios Pareja, Laura Cantero

Introduction: Despite there are considerable number and variety of physical exercise programs having demonstrated benefits in breast cancer patients (BCP), exist certain factors such as the lack of awareness and difficulty in accessing oncology exercise programs and the scarcity of qualified professionals in this field difficulted the adherence of the breast cancer survivors to the exercise recommendations by the World Health Organization (WHO). This study aimed to evaluate the impact of a multimodal oncological exercise program on these parameters in breast cancer patients at stages IA to IIIB.
Methodology: Patients contacted the research team to schedule baseline assessments at Centro Ejercicio Y Cáncer, in Madrid. Inclusion criteria for participation were women diagnosed with primary breast cancer (stages IA to IIIB); aged 18 years or older; no more than 10 years since cancer diagnosis; and without other comorbidities that would limit their capacity to engage in exercise (recent surgery or functional limitations) were included in this study. Patients with metastatic disease, undergoing chemotherapy and radiotherapy were excluded from the study. Afterward, all women were randomly assigned to one of the two groups. The intervention comprised a multimodal exercise program (online and face-to-face) for 16 weeks that included endurance, resistance, balance, and proprioception exercises, with an intensity ranging from 55% to 95% of Heart Rate Reserve (HRR). Each session lasted 75 minutes and was structured as follows: 10 minutes of warm-up involving

joint mobilities, balance, and proprioceptive exercises, and aerobic exercise at an intensity ranging from 55% to 75% HRR. This was followed by two 20-minute bouts of combined activities (endurance activities combined with resistance exercises) at an average intensity of 70-75% HRR with 30 to 60-second bouts of high-intensity activity of 85% to 100% HRR. The resistance exercises were developed with free weights in circuits of 6 to 8 exercises of 3x10 or 3x15, combined with endurance activities of 60% HRR. Intensity perception in resistance exercises was assessed using the Borg Scale, and endurance exercise intensity was assessed by HRR. Finally, full-body stretching was performed.

Results: 40 patients in the intervention group (mean 50.2±1.05 years old) and 34 in the control group (mean 49.48±1.88 years old) completed the study. Related to the program adherence was 95.23% in the intervention group and 82.93% in the control group, and the assistance rate was 85.13%. BCP in the intervention group showed significant improvements in cardiorespiratory fitness (DifMean (ΔM): 7.19 ml.kg.min; CI95% 4.50 – 9.60; p=<0.0001); fat mass (ΔM: -1.81%; CI95% -3.47 - -0.15; p=0.033); lean mass (ΔM: 5.24%; CI95% 3.74 – 6.74; p=<0.0001); functional capacity through sit -to-stand (ΔM: 5.26 number of repetitions; CI95% 2.01 – 5.26; p=0.002) and 6-minutes walking test (ΔM: 89.58 meters; CI95% 36.78 – 142.37; p=0.001); level of PA such us total METs (ΔM: 946.85 METs (min/week); CI95% 212.08 - 1681.64; p=0.012) and high intensity METs (ΔM: 419.65 METs (min/week); CI95% 37.93 - 801.36; p=0.032); Fatigue (ΔM: -3.20; CI95% -5.75 - -0.65; p=0.014)

Conclusions:
This RCT has demonstrated a multimodal exercise program is feasible and effective in significantly improving cardiorespiratory fitness, body composition, and physical function in BCP. The implementation of these new models of exercise interventions not only allows BCPs to access supervised exercise programs but also, presents high levels of adherence. These findings advocate for integrating structured exercise programs into the treatment plan for breast cancer patients, with potential long-term benefits for survival and quality of life.

P4-06-26: Fertility Preservation in Young Women with Breast Cancer in Brazil: Patient Profiles and Challenges in a Real World Scenario

Caroline Avelar, Renata Arruda Cerqueira, José Tadeu Campos de Avelar, Enaldo Melo de Lima, Rivia Mara Lamaita, João Pedro Costa Apolinário, Ianca Elirrayeth Rocha Mendes, Luísa Lazarino de Souza Campos, Neila Caroline Alves Amaral, Catharina Cançado Avelar, Paulo Henrique Costa Diniz

Introduction: Breast cancer, whose incidence among adolescents and young adults (AYA) has increased in recent years, harbors many global challenges and unmet needs. Among them, concerns regarding fertility preservation stand out. Many barriers, such as financial support, lack of timely referral and availability of cryopreservation have been identified,

which may be exacerbated in developing countries. In this study, we accessed real-world data regarding fertility preservation in Brazil among AYA breast cancer patients.
Methods: This retrospective cross-sectional observational study was conducted in a private referral network cancer center in Brazil. Breast cancer premenopausal patients aged 15 to 39 years undergoing systemic treatment between 2019 and 2023 were identified. Clinical data was obtained retrospectively from medical records. We searched for demographic and clinicopathologic characteristics and data regarding fertility counseling, funding and the practices of fertility preservation groups, aiming to map out the care among this population. Descriptive statistics were used to summarize data.
Results: In this cohort, 60 AYA breast cancer patients were identified, representing 10.9% of the disease diagnosis. Of them, 49 (81.6%) underwent chemotherapy, most with anthracycline-containing regimens (82.0%). However, only 23 (38.3%) of the patients had fertility counseling documented in their medical records. Among these referred patients, 12 (52.1%), in fact, proceeded to evaluation by the reproductive medicine team. Oocyte collection for cryopreservation was performed in 7 patients, representing 14.2% under systemic treatment. When this technique was not feasible, some patients (n=3) received LHRH agonists in monotherapy, considered a less effective method. The average time between diagnosis and the initiation of oncologic treatment was also analyzed. Among patients who underwent fertility counseling, it was 25 days (range, 7-34), a similar timeframe to those who did not (19 days, range 3-37). Considering only the patients who underwent oocyte collection, the median time was 26 days (range, 9-34). Regarding fertility preservation funding, procedures and medical expenses were not covered or reimbursed by health insurance but solely by the patient.
Conclusion: The present study shows a low rate of cryopreservation among AYA breast cancer patients who underwent systemic treatment in Brazil, although this procedure did not lead to clinically relevant delays in the initiation of chemotherapy. Potential barriers include a poor rate of fertility counseling and funding concerns. Given Brazilian economic and sociodemographic inequalities, this scenario may be even worse in the public setting and outside referral centers. This study highlights the need for standardized protocols to ensure that all AYA patients are counseled on fertility preservation from initial diagnosis. This includes integrating multidisciplinary teams, providing specific training for oncologists and other healthcare professionals and establishing automatic referrals for consultation with fertility specialists. Additionally, providing psychological support is crucial to help patients make informed decisions aligned with their future maternity desires. Thus, further studies would support national cancer care improvements among this population.

P4-06-27: "The decrease in survival of breast cancer patients during the COVID-19 pandemic"

Arely Gonzalez, Diana Vilar, Nancy Reynoso, Rafel Franco, Juan Medina, Paula Cabrera

COVID-19 tested the health system and its processes in the world, modifying primary and secondary health care for many diseases. Among the most affected were breast cancer, who

faced a delay not only in detection, but also in the start of treatments and the follow-up during this contingency.

In Mexico, the National Cancer Institute (INCan) was the only hybrid center that treated patients with cancer and COVID-19.

Cancer and COVID-19 management were a challenge from different angles, with consequences that are still difficult to evaluate. Breast cancer patients were affected by the pathology itself (COVID and cancer), by the hospital re-organization (no more hospitals in Mexico City look for patients with both diseases) and the shortage of oncological drugs (by political decisions and because the global quarantine. With this in mind, the following paper is presented.

We carried out a case-cohort study of women with breast cancer treated at the INCan between January 1, 2020, and December 31, 2021 (2,153 women). During this period, there were 151 cases of COVID-19 (defined as a patient with cancer and a positive test for SARS-CoV-2, by polymerase chain reaction (PCR) or an antigenic test). A pairing was performed with a case control ratio of 1:3, adjusted by clinical stage, molecular biology and month of care, with a total of 453 women studied.

Of our population, 20.4% of patients did not follow the indicated treatment. This had an impact on survival of the patients despite a follow-up of just 2 years, with 10.9% of deaths (66, of which 36 were secondary to the presence of COVID 19). Furthermore, there were patients who were never able to start oncological treatment after SARS-CoV-2 infection.

Regarding treatment compliance, 114 women (20.4%) did not follow the indicated treatment, 19 (17.12%) patients with COVID 19 presented disease progression, greater than that observed in the group without COVID-19 (3.01%).

Another relevant point of the findings in this study is that one of the main reasons for the delay in treatment was not directly attributable to COVID-19, but to the lack of medications. Although the worldwide stillness decreased the distribution of medicines and the demands for other medical supplies such as gloves and masks increased, this was aggravated in our country by a significant shortage of oncological medicines, derived in part from the health policies implemented in this six-year term. In this cohort, 20.4% of patients did not receive optimal treatment (due to lack of medications or lack of time). When reviewing this information, it is paradoxical that there were more women affected by the shortage of medicines than by the COVID-19 infection itself. These delays and changes in regimens due to lack of medications may have a high impact on the 5-year survival, and very possibly, on the quality of life of these women.

It is important to highlight that in this study the presence of COVID-19 was an important factor for non-compliance with oncological treatment despite not being significant, finding a trend at two years of follow-up or at the end of the initial treatment ($p=0.052$). In a subsequent study we intend to analyze the impact of COVID-19 on 5-year survival.

In our study, the prevalence of COVID-19 in patients with breast cancer was 7.11%, with a mortality of 23.8%.

The interruption, delay and multiple changes on the breast cancer treatment due to COVID-19 pandemic, modified negatively the outcome of these patients on a short term by decreasing the surveillance and arising progression case.

P4-06-28: Income and Geography: Key Drivers of Disparities in Breast Cancer Mortality

Emily McGovern, Wade Swenson, Ingrid Jacobson, Abigail Swenson, Zack Schroeder, Aquino Williams, Andrew Armstrong, Brooke Gully, Sahil Prakash, Sean Kelso

Background: Disparities in breast cancer outcomes between rural and urban populations are influenced by socioeconomic status and access to healthcare. This study examines the rural cancer gap in breast cancer survival rates, focusing on county-level geographic and income-related disparities.
Methods: Data from the SEER database (2001-2020) were analyzed, focusing on breast cancer cases. We compared observed 5-year survival rates between metropolitan (Metro) and non-metropolitan (Non-Metro) counties, as well as between counties with median household incomes above and below $50,000.
Results: Our analysis revealed a statistically significant rural cancer gap in breast cancer outcomes. Non-Metro counties consistently had lower 5-year survival rates compared to Metro counties. Additionally, counties with median household incomes below $50,000 showed significantly worse outcomes than those above this threshold. The mortality difference persisted over the entire observation period.
Conclusions: The findings highlight substantial disparities in breast cancer survival based on both county-level geographic location and income, emphasizing the need for targeted interventions and policies to improve outcomes in underserved populations.

P4-06-29: The impact of cardiovascular disease on breast cancer stage at diagnosis

Kevin Nead, Ivan Angelov, Allen M. Haas, Elizabeth Brock, Lingfeng Luo, Jing Zhao, Benjamin D. Smith, Sharon H. Giordano, Nicholas J. Leeper

Background: Cardiovascular disease (CVD) and cancer are the leading causes of mortality in the United States. Large-scale population-based and mechanistic studies support a direct effect of CVD on accelerated tumor growth and spread, including in breast cancer. Our objective was to test the hypothesis that individuals with prevalent CVD will present with more advanced breast cancers at the time of diagnosis compared to those without CVD.
Methods: We conducted a retrospective cohort study in the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked databases from 2009-2020. Participants were female patients aged 66 years or older at diagnosis of invasive breast cancer. We utilized a case-control design, based on breast cancer stage at diagnosis, propensity score matched on factors know to be related to delayed cancer diagnosis. Our full analytic cohort included 19,292 matched individuals, with median age 73 years (interquartile range 70-79), of which 86% were white and 49% had prevalent CVD. The exposure was prevalent CVD prior to breast cancer diagnosis. Our a priori hypothesis tested the odds of locally advanced (T3-4 or N+) or metastatic (M+) breast cancer at diagnosis based on prevalent CVD status.
Results: In propensity score matched, multivariable adjusted models we found that

individuals with prevalent CVD had a statistically significantly increased odds of locally advanced or metastatic breast cancer at diagnosis (OR, 1.10; 95% CI, 1.03-1.17; p=0.007). This association was observed among hormone receptor positive (OR, 1.11; 95% CI, 1.03-1.19; p=0.006), but not hormone receptor negative (OR, 1.02; 95% CI, 0.86-1.21; p=0.834) breast cancer. Our results were directionally consistent when separately examining locally advanced (OR, 1.09; 95% CI, 1.02-1.17; p=0.017) and metastatic (OR, 1.20; 95% CI, 0.94-1.54; p=0.152) disease, among all receptor subtypes.
Conclusions: Our study provides evidence that prevalent cardiovascular disease is associated with more advanced breast cancer at diagnosis. This finding may be specific to hormone receptor positive disease. Future studies are needed to confirm our findings and investigate interventions to improve patient outcomes, including personalized screening.

P4-06-30: Comprehensive Approach to Prevention: Cancer Risk Reduction and Education (CaRE) Program

Jessica Jones, Virginia Kaklamani, George McCann, Ismail Jatoi, Rachel Darling

With overall breast cancer incidence increasing, and a shift towards higher rates of premenopausal breast cancer (BC), effective risk reduction strategies are paramount for Latinx women. UTHealth San Antonio MD Anderson Mays Cancer Center (MCC) serves a majority minority community of Latinx patients, and Latinx women are more likely to hold BC adjacent diseases such as obesity and diabetes. Premenopausal Hispanic women are more likely to develop HR-negative BC. The healthcare systems within UTHSA holds a high number of Hispanic, Medicaid, low-income, and uninsured (MLIU) patients, and MCC provides care to both San Antonio but surrounding medically underserved areas (MUA). The newest guidelines recommend mammography every 2 years for women starting at the age of 40 have the potential to negatively impact Latinx MLIU since mammography preferentially detects more indolent HR-positive than higher mortality HR-negative tumors. False positives associated with breast MRI screening can lead to scan-anxiety and over-diagnosis. The novel and innovative Cancer Risk Reduction and Education (CaRE) program is a multispecialty endorsed precision prevention clinic which coordinates higher level BC surveillance for patients at higher risk of BC and integrates prevention strategies for modifiable risk factors. Herein, the following processes are shown: (i) Mission statement of program, (ii) Stakeholder engagement, (ii) BC Risk assessment models used, (iii) Site Specific treatment plan strategies for non-modifiable risk factors, (iv) Site specific treatment plan strategies for modifiable risk factors. Taken together, combined efforts from multiple stakeholders demonstrates a comprehensive program that provides personalized cancer risk assessments and will effectively reducing cancer incidence and improving long-term health outcomes. This program also sets the stage for future research opportunities to include patient outcome measures, adherence, cardio-oncology, weight loss studies, genetics, psychosocial interventions, medical education, patient education, and patient advocacy.

P4-07-01: Comparative 10-Year Survival Analysis of Breast-Conserving Surgery Versus Mastectomy in Early-Stage Breast Cancer for Young Patients

Babette Salaets, Annouschka Laenen, Thais Baert, Adinda Baten, Francoise Derouane, Christine Desmedt, Sileny Han, Hilde Janssen, Ines Nevelsteen, Ann Smeets, Maxime Van Houdt, Jelle Verhoeven, Caroline Weltens, Hans Wildiers, Patrick Neven

Abstract: Comparative 10-Year Survival Analysis of Breast-Conserving Surgery Versus Mastectomy in Early-Stage Breast Cancer for Young Patients

Introduction:Pivotal studies established that breast-conserving surgery (BCS) followed by radiotherapy is as effective as mastectomy for breast cancer treatment. Recent retrospective population-based studies suggest a potential overall survival benefit for BCS over mastectomy, particularly in older patients. In younger patients this benefit was less clear. Therefore, we evaluated 10-year overall survival and distant metastasis-free survival in patients with early breast cancer, aged up to 55 years, comparing BCS with radiotherapy to mastectomy.
Methods:We conducted a retrospective cohort study using data from UZ Leuven including female patients aged up to 55 years, diagnosed with early invasive breast cancer (pT1-2, N0-1; for those receiving neo-adjuvant therapy cT1-2, cN0-1 and ypT0-2, N0-1) between 2008 and 2012. Patients underwent either mastectomy (with or without radiotherapy) or BCS with radiotherapy. Decision for type of surgery was made based on tumor and patient characteristics, as well as patients' preference. All received systemic adjuvant therapy according to prevailing standard of care at that time. Outcomes included overall survival and distant metastasis-free survival. The Kaplan-Meier method estimated crude survival rates 10 years after diagnosis. Multivariable Cox proportional hazard regression, incorporating propensity scores, was used to correct for confounding factors (age, cT, cN, pT, pN, molecular subtype, grade, and multifocality).
Results:Of 986 eligible patients, 407 underwent mastectomy (73.5% postop radiotherapy) and 579 received BCS (100% postop radiotherapy). Average age at diagnosis was 46,4 years and median follow-up time was 12,7 years. Patients who received a mastectomy had larger tumors and were more frequently node positive. Furthermore, these tumors were often of higher grade and multifocal. Of the patients in the mastectomy group 14.0% had triple negative tumors, compared to 15.7% in the BCS group. However, the patients in the mastectomy group had more HER2-positive tumors (15.2% vs 8.6% for BCS). Adjuvant chemotherapy was administered to 60.1% of patients who underwent mastectomy compared to 41.6% of patients who had breast-conserving surgery (BCS). Alternatively, neo-adjuvant chemotherapy was given to 5.6% of patients in the mastectomy group, whereas 2.2% of patients in the BCS group.
Overall unadjusted overall survival rates (crude survival, not corrected for confounding factors) were 85.5% for mastectomy and 92.1% for BCS. Adjusted analysis showed no significant difference in overall survival, though it did seem to show a trend favoring BCS (HR 0.52 [95% CI 0.36-0.77]; p=0.001; adjusted HR 0.67 [0.43-1.06]; p=0.09). This trend

was less clear for distant metastasis-free survival (DMFS HR 0.65 [95% CI 0.46-0.92]; p=0.01; adjusted HR 0.88 [95% CI 0.59-1.32]; p=0.56).
Conclusion:Consistent with previous cohort studies, our single-center study suggests a trend favoring BCS over mastectomy in terms of overall survival for patients up to 55 years old. This trend, however, was not statistically significant after adjusting for confounding factors, highlighting the need for further investigation of this population using larger cohorts.

P4-07-02: Concordance rate of 99mTc and ICG/near-infrared light detected sentinel-symphnodes in primary breast cancer

Peter Kern, Bittner Ann-Kathrin, Kimmig Rainer, Mokas Stefanos, Hoffmann Oliver

Background: Sentinel lymph node biopsy (SLNB) by 99mTechnetium +/- patent blue has been long-time standard in SLN detection. However, the lack of nuclear sources, limited availability of nuclear medicine departments in some health providers and cost issues have led to the development of other techniques. ICG labelling and detection by near-infrared light is one of these techniques which empower surgeons to schedule their surgery independently from these prerequisites. Patients and methods: We conducted a prospective study to evaluate the concordance rate of ICG-fluorescence and 99mTc for sentinel lymph node detection of primary breast cancer. Patients, aged 18 - 80 years, with unilateral or bilateral, unifocal or multifocal/ multicentric primary breast cancer without signs of metastases were eligible for this study. ECOG status of 0-2 and life expectancy > 1 year was required. Tumor stages included are a) Tis (>= 4 cm) b) T1 c) T2 and d) T3. We applied both sentinel lymph node labelling (99 mTc and ICG) in the same patient and compared the concordance of both methods. Results: 275 pateints were elgible for interims analysis. For the first sentinel lymph node, we detected a concordance rate for both methods of 91,7 % , for the second sentinel lymphnode 81 %. 3 and 6 additional SLN were detected as first and second SLN by ICG which would not have been detected by 99mTc. After neoadjuvant chemotherapy, all sentinel lymphnodes have been detected by ICG. Conclusion: SLNB by ICG near-infrared light is a valid alternative for radioactive labelled SLN, however does reveal different SLNs as the second SLN: After neoadjuvant chemotherapy, ICG was able to detect all SLNs.

P4-07-03: LONG TERM PATIENT REPORTED OUTCOMES FOLLOWING THERAPEUTIC MAMMAPLASTY

Katherine Fairhurst, Harriet Cook, Joseph Vane-Daniel, Alison Hunter-Smith, Richard Sutton

Background: Therapeutic Mammaplasty (TM) is a safe oncoplastic surgical technique aiming to extend the boundaries of traditional breast conserving therapy (BCT) by removing larger breast volumes to reduce and/or lift the breast, without compromising cosmetic or oncological outcomes. Several systematic reviews have emphasised the paucity

of Patient Reported Outcome Measures (PROMs) following TM. This study aimed to assess the long-term PROMs following TM performed in our centre over a 17-year period.
Methods: Eligible women who underwent TM between 2005 and 2021 were invited to participate by returning the BREAST-Q questionnaire (combination of BCT and Reduction/Mastopexy modules). Surveys were returned by post or online from August to December 2023 (minimum 20-months post TM). Raw responses were transformed using Rasch conversion tables (0=worst;100=best) and descriptive summary statistics generated. Clinical outcome data was collected from digital hospital records/databases and analysed using descriptive summary statistics.
Results: Of 246 patients who underwent TM, n=21 (8.5%) subsequently required completion mastectomy, n=15 (6.1%) developed recurrence/metastatic disease and n=22 (8.9%) died. Questionnaires were returned by n=103/188 (53.4%) participants. Only n=4/103 (3.9%) participants were current smokers at the time of surgery; n=10/103 (9.7%) were ex-smokers. Neoadjuvant treatment was given to n=31/103 (30.1%) patients. Most tumours were T1 (n=53/103, 51.5%) or T2 (n=36/103, 34.9%). Only n=19/103 (18.4%) patients had immediate contralateral symmetrizing surgery at the time of TM, but a further n=34/103 (33.0%) had delayed symmetrization surgery. Few women suffered complications (n=15/103, 14.6%), all were minor and there were no peri-operative deaths. Most women received adjuvant radiotherapy (n=95/103, 92.2%); around two thirds received adjuvant endocrine treatment (n=63/103, 61.2%).
Overall, patients reported median scores of 69 (IQR 53-83.5) and 70 (IQR 54-86) for satisfaction with breasts for BCT/breast reduction modules respectively. Median wellbeing scores were physical (chest wall) 82 (IQR 66-100), physical (reduction) 72 (IQR 59-82) and psychosocial 77 (IQR 62-93) with lowest scores for sexual wellbeing 59 (IQR 36-79). Comparison was made with published long-term PROMs 12 years following immediate breast reconstruction (IBR) (Johnson et al doi:10.1093/bjs/znad276) using a minimal clinically important difference in mean scores of 4-points for satisfaction with breasts/psychosocial/sexual wellbeing and 3-points for physical wellbeing. TMs performed from 2005 to 2015 (n=40, 8-18 years previously) had significantly better mean long-term satisfaction with breasts scores (TM 72.3(BCT)/74.5(reduction) than all forms of IBR (Implant/expander 54.7; Latissimus Dorsi flap (LD) 59; Abdominal flaps 67.6). Sexual wellbeing scores were also significantly higher for TM (57.4) than for all forms of IBR (Implant/expander 44.7;LD 47.4;Abdominal 51.2). Psychosocial wellbeing scores for TM (78) were higher than both implant/expander 72.2 and LD 73.3 IBR, but comparable to abdominal flap IBR (77.6). TM physical (chest wall) wellbeing scores (80.6) were comparable to implant/expander (82.1) and LD (79.5) IBR, but significantly lower than abdominal flap IBR (87.8).
Conclusions: TM has a long-lasting positive impact on quality-of-life following breast cancer treatment. Patient satisfaction with breasts, sexual and psychosocial wellbeing may be significantly higher in the long term than all types of IBR. Physical wellbeing outcomes are comparable to both implant/expander and LD flap IBR but worse than abdominal flaps in our series.
With the now growing body of evidence suggesting BCT may also confer a survival

advantage over mastectomy, this data suggesting that overall, quality of life is better in the long term, further supports offering oncoplastic BCT preferentially whenever it is oncologically feasible.

P4-07-04: Impact of Involved Margin Status and Radiotherapy on Local Recurrence and Regional Recurrence in Patients Who Underwent Nipple Sparing Mastectomy or Skin Sparing Mastectomy with Immediate Reconstruction

Hyoung Won Koh, Ji-Jung Jung, Hee-Chul Shin, Han-Hyoel Lee, Eun-Kyu Kim

Backgrounds: A superficial margin less than 2mm from tumor is considered a risk factor for local recurrence (LR) after breast cancer surgery. For the prevention of LR and RR, radiation therapy (RT) is acknowledged as the principal adjuvant therapy. However, its role following NSM/SSM is less defined in contrast to the clear indication for RT following conventional mastectomy.
Purpose: The objective of this study was to investigate the factors associated with LR and RR to assess the impact of an involved margin and RT on LR and RR in patients who underwent NSM/SSM with immediate breast reconstruction for breast cancer.
Method: We conducted retrospective analysis of the medical records from 1675 patients who underwent NSM/SSM with immediate reconstruction for breast malignancies between 2004 and 2019. Patients who underwent NSM/SSM for recurrent disease, palliative surgery, prophylactic surgery, or delayed reconstruction were excluded. Uni- and multivariable analyses were used to assess the association of margin status, RT, and other clinicopathologic factors with LR, RR, local recurrence-free survival (LRFS) and regional recurrence-free survival (RRFS).
Result: Out of all patients, 28 experienced LR. Among the 28 LR cases, one patient had an involved margin, six patients had close resection margin (<2mm), and one patient received RT. Multivariable analysis revealed that HER2-positive subtype was a significant risk factor for LR (P=0.039) while adjuvant RT was identified to be protective (P=0.027). An involved margin status (P=0.009) and pathologic subtype including luminal B and triple-negative subtype (P<0.001) were significant risk factor associated to RR. In the multivariable model for survival, RT was the sole significant factor for LRFS showing protective effect (P=0.037). An involved margin status (P=0.021), luminal B and triple-negative subtype (P<0.001) were identified as a risk factor associated with shorter RRFS. Notably, RT did not exhibit a statistically significant association with LRFS in univariate analysis (P=0.245).
Conclusion: Tumor subtype is more strongly associated with LR compared to margin status. Additionally, RT showed protective effect against LR and LRFS. Although RT did not exhibit a direct correlation with RR, RT can be considered for LR prevention in patients with HER2-positive breast cancer or those with involved superficial margin.

P4-07-05: Breast Cancer and Local Therapy: Breast Conservation and Oncoplastic Surgery are Associated with Improved Quality of Life

Daniel Barbalho, Natalia Polidorio, Lincon Mori, Alfredo Barros, Marcelo Sampaio, Sandro Melo, Amilcar Assis, Pamela Bioni, Giovanna Miziara, Murilo Fraga, Felipe Andrade

Introduction: Breast cancer is one of the leading causes of cancer in women worldwide, and local treatment can be distressful to patients. We aimed to evaluate how different types of local treatment impact the quality of life of Breast Cancer patients.

Methods: This is a retrospective cohort study from 2017 to 2022. All Breast Cancer patients treated in our institution are followed and voluntarily invited to answer Breast-Q Satisfaction with Breasts questionnaire pre and post-operatively. Of 711 eligible patients, 349 female patients answered both pre and post-operative questionnaires, and were included in the final analysis. Patients were divided in two groups: breast conservation and mastectomy. Use of oncoplastic surgery and types of breast reconstruction were recorded. Breast-Q Satisfaction with Breasts scores collected one year after a breast oncological surgery was used as a surrogate for Quality of Life. Linear regression was used to estimate the impact of breast conservation, use of oncoplastic surgery, types of breast reconstruction, and use of radiation therapy on Breast-Q scores. All analyses were adjusted by age, education, marital status, body-mass index, T stage, N stage, tumor subtype, presence of bilateral cancer, radiation therapy, axillary surgery, presence of complications, and pre-operative Breast-Q scores.

Results: In total, 237 (68%) patients received breast-conserving surgeries, and 112 (32%) received mastectomies. All mastectomy patients received breast reconstruction and 176 (74% of breast-conserving surgeries) received concomitant oncoplastic surgery. After multivariable analysis, mastectomy was associated with lower scores compared to breast-conserving surgery (-21.3; 95%CI: -36.2, -6.4, p=0.005), oncoplastic surgery was associated with higher scores (9.2; 95%CI: 0.8, 17.6, p=0.032). There was a tendency of higher scores with the use of flaps in breast reconstruction, and a tendency of lower scores with the use of radiation therapy, but not significant. Interestingly, bilateral cancers were associated with higher scores (25.8; 95%CI: 3.6, 47.9, p=0.023). Of note, there were 6 bilateral cancers, 5 treated with bilateral mastectomies.

Conclusions: Breast-conserving surgery is associated with better quality of life compared to mastectomy. Additionally, oncoplastic surgery is associated with better quality of life compared to standard breast-conserving surgery. Patients should be counseled whenever multiple options of surgery are possible, and efforts should be made to increase the availability of trained surgeons in oncoplastic techniques.

P4-07-07: Comparative analysis of breast-conserving surgery using a 3D-printed breast surgical guide versus standard breast-conserving surgery in breast cancer patients treated with neoadjuvant chemotherapy

Ah Yoon Kim, Sae Byul Lee, Tae Kyung Yoo, Ji Sun Kim, Il Yong Chung, Hee Joung Kim, Jong Won Lee, Byung Ho Son, BeomSeok Ko

Introduction: Breast cancer remains a major health concern for women globally. During breast conserving surgery (BCS), tumor involvement in the resection margins is closely related to recurrence and prognosis. To achieve precise BCS, accurate imaging tools are essential, with MRI being the most accurate. However, for patients who have received neoadjuvant chemotherapy (NACT), determining the extent of breast cancer remains challenging. MRI has limitations in predicting the location of cancer during surgery. In this context, a 3D-Printed Breast Surgical Guide (3DP-BSG) can effectively identify the extent of breast cancer in NACT patients, enhancing surgical accuracy.
Material and Methods: This retrospective single-institution cohort study focused on female patients diagnosed with invasive breast cancer who underwent NACT. Between November 2015 and October 2021, patients received BCS with the aid of a 3DP-BSG. Personalized 3DP-BSG targeted tumors by tracking changes in breast and tumor anatomy on MRI before and after NACT. The 3DP-BCS (using 3DP-BSG) group was matched 1:2 with conventional BCS (cBCS) group.
Results: 591 patients were enrolled in this study. 197 people in the 3DP-BSG group and 394 people in the cBCS group were compared and analyzed. The median follow-up period was 43.4 months (range: 1.2-99.6 months). Pathologic complete remission with NACT was confirmed in 221 patients (37.4%). Positive resection margins were observed in 1.5% of the 3DP-BSG group and 2.8% of the cBCS group. Recurrence occurred in 8.6% of the 3DP-BSG group (0.5% of local recurrence) and 12.9% of the cBCS group (3.3% of local recurrence). The distribution of age, BMI, stage, and subtype proportions is identical between the two groups. Pathological stage and subtype are statistically significant factors that increase the recurrence rate. ($P < 0.05$) There were 3 deaths (1.5%) in the 3DP-BSG group and 11 deaths (2.8%) in the cBCS group.
Conclusion: The application of MRI-based 3DP-BSG is effective in achieving low positive margins and local recurrence in patients undergoing BCS after NACT, offering a promising approach for improving surgical outcomes.

P4-07-08: Targeted Axillary Dissection using magnetic seed placement in the axilla (mag-TAD) combined w/ dual tracer sentinel node procedure after neo-adjuvant systemic therapy (NST) in primary node pos breast cancer. Real-world evidence study in the UAE.

Ernest Luiten, Tallal Younis, Aydah Al-Awadhi, Hussam Mousa

Targeted Axillary Dissection using magnetic seed placement in the axilla (mag-TAD) combined with dual tracer sentinel node procedure after neo-adjuvant systemic therapy (NST) in primary node positive breast cancer.
A real-world evidence study of patients treated in a tertiary breast center in the United Arab Emirates (UAE).

Introduction: Patients with primary node positive breast (BC) are most often treated with NST followed by breast surgery and axillary lymph node dissection (ALND). Axillary pCR is achieved in up to 80% post NST1 . Less invasive axillary surgery as opposed to ALND is a promising surgical strategy post NST to detect remnant nodal disease while reducing morbidity and preserving oncologic safety. In a large Dutch clinical trial targeted axillary dissection (TAD) was associated with a 3.5% False Negative Rate (FNR) and a 92.8% Negative Predictive Value (NPV)2. A recent multicenter retrospective cohort study showed that in patients found to be ypNo - either sentinel lymph node biopsy (SLNB) or TAD - axillary recurrence following omission of completion-ALND was low (1.0%)3. Implementation of TAD is increasing in western parts of the world. The performance of TAD relative to ALND outside clinical trials, however, remains unknown, particularly in jurisdictions such as the United Arab Emirates (UAE) where BCs are characterized by younger age of onset, poorer biological features and more advanced disease stages4.

Methods: A retrospective cohort analysis was done, involving patients with primary node-positive BC treated with NST followed by mag-TAD plus ALND from August 2021 until March 2024 at the Breast Surgery Department of Tawam Hospital. A magnetic seed was inserted in the biopsy proven clipped primary positive node preceding surgery. Following completion of NST, surgery was carried out by a single breast surgeon, experienced in TAD. Dual tracer sentinel node procedure was carried out using either Technetium (Tc-99) or a magnetic tracer and combined with Patent Blue injection. (Neo-)Adjuvant treatment decisions were taken in accordance with NCCN guidelines. The performance of mag-TAD relative to mag-TAD plus ALND was examined.

Results: 60 patients with node positive BC underwent mag-TAD following NST. Completion ALND was omitted in 6 patients and mag-TAD yielded inconclusive results in 1 patient due to incorrect placement outside a lymph node (1.7%). Of the remaining 53, ALND was carried out during the same (n=52) or second (n=1) surgery. All patients received neo-adjuvant chemotherapy +/- targeted therapy, except for 1 patient (neo-adjuvant endocrine). Median age was 50 year (range 30-68). Clinical T-stage was cT1-2 in 56.6% (n=30) vs cT3-4 in 43.4% (n=23) while clinical N-stage was cN1 in 83.0% (n=44) vs cN2-3 in 17.0% (n=9). Breast conserving surgery was performed in 45 out of 53 patients (84.9%). Of these, 2 (4.4%) had incomplete resection necessitating additional resection in 1 patient while the other opted for completion mastectomy. Of the 53 patients, 52.8% (n=28) had HER2 positive expression and 11.3% (n=6) had triple negative disease. The median number of lymph nodes removed by mag-TAD and the consecutive ALND was 4 (range 1-16) and 10

(range 1-18) nodes, respectively. Axillary pCR was achieved in 20 out of 53 patients (37.7%). In 2 out of 22 patients with mag-TAD ypNo, a positive lymph node was found in the ALND. In 21 out of 31 patients (67.7%) with mag-TAD ypN+, additional positive nodes were found in the ALND; median 2 (range 1-11). The mag-TAD was associated with FNR 6% (95% CI: 2 - 23 %) and NPV 91% (95% CI: 72-98%).

Conclusion: In this RWE study – unique in the GCC - involving patients with high-risk node-positive BC, mag-TAD was feasible in our population with a high success rate and comparable FNR and NPV to those observed in the relevant clinical trial2. Recurrence and survival analyses will be planned. Further confirmatory studies in other jurisdictions in the region, with larger sample sizes, are warranted to confirm the favorable performance of mag-TAD observed in this single center study.

P4-07-09: Does energy device improve operative procedure and postoperative management of total mastectomy with axillary lymph node dissection?

Toshiyuki Ishiba, Mio Adachi, Sakiko Maruya, Kumiko Hayashi, Yuichi Kumaki, Goshi Oda, Tsuyoshi Nakagawa, Emi Yamaga, Tomoyuki Fujioka, Kazunori Kubota, Noriko Uemura, Horoki Mori, Naoko Iwamoto, Rikako Hashimoto, Takashi Kuwayama, Masakazu Toi, Tomoyuki Aruga

Background: Axillary lymph node dissection (ALND) is still necessary in breast surgery, although it is now less frequently employed. Although it is often experienced that increased surgeon experience and better performance of the surgical equipment used reduces operative time and blood loss, there are still few reports on the extent to which these improvements are reflected in the recent introduction of recent ENERGY devices. Furthermore, the vessel sealing effect of energy devices is expected to reduce the volume of

discharge after ALND, which is expected to improve postoperative management by reducing hospitalization period until drain removal and the number of hospital visits after discharge. In the present study, we compared cases in which surgery was performed using an electrocautery scalpel, thermal scalpels and energy device to find a difference in the operative procedure and post-operative management.
Methods: The subjects were 300 patients who underwent a total mastectomy with ALND between October 2018 and December 2022 at Tokyo Metropolitan Cancer and Infectious Center, Komagome Hospital. Their electronic medical records were retrospectively reviewed to collect data on the patient's sex, age, BMI, history of sentinel lymph node biopsy, history of neoadjuvant chemotherapy, number of lymph nodes removed, number of metastatic lymph nodes, surgical devices, and postoperative complications. The clinical path at the study center includes drain removal on postoperative day 7 and discharge on the following day. In the present study, if a seroma was detected post-discharge, it was punctured in the outpatient clinic. The total volume of drainage during hospitalization was calculated, as were the total number of seroma puncture and the total volume of punctured seromas. Surgical devices were divided into a normal device (ND) group, consisting of conventional electrocautery machines and thermal scalpels, and an energy device (ED) group, consisting of LigaSURE EXACT and Harmonic FOCUS Plus. Surgical device selection was primarily due to surgeon preference, with no differences by timing or patient factors.
Results: Operative time, blood loss, and surgical complications were examined in 266 patients (226 in the ND group and 40 in the ED group) after excluding patients with bilateral surgery or a level III dissection. The median operative time was 140 minutes and 137, and the median blood loss was 70 mL and 65 mL, in the ND and ED group, respectively. Surgical complications comprised two cases of hemorrhage and four cases of wound infection in the ND group, but the difference was non-significant. The volume of drainage and punctured seromas were then examined in 212 and 39 patients in the ND and ED group, respectively, after excluding post-discharge follow-up at other clinics, drop-outs, and patients with surgical complications. No significant difference was found between the groups in terms of BMI, sentinel node biopsy or neoadjuvant chemotherapy. The median total volume of drainage during hospitalization was 655 mL and 730 mL in the ED and ND group, respectively. The difference was non-significant ($p=0.11$), but the median total volume of punctured seromas following hospital discharge was 108 mL and 235 mL in the ED and ND group, respectively, indicating a significantly lower volume in the former ($p= 0.0114$). Hence, the median sum of total volume of drainage and punctured seromas was 763 mL and 965 mL in the ED and ND group, respectively, indicating a significantly lower volume in the former ($p= 0.020$). Furthermore, the mean number of seroma puncture after discharge differed significantly, at 2.04 in the ED group versus 2.86 in the ND group ($p= 0.0091$).
Conclusion: Surgical devices had little effect on operative time, blood loss or complications. The volume of drainage during hospitalization was also unaffected, but the volume of punctured seromas post-discharge decreased significantly when energy devices were used. This decrease was likely also to have reduced the burden on the patient as well as the surgeon.

P4-07-10: Ensuring the precise interpretation of intraoperative specimen 3D imaging is crucial in avoiding the need for additional surgery for patients.

Hannah Jeffery, Mohamed Attia, Ravindran Karthigan, Rachael Manning, Ashutosh Kothari

Introduction: 1 in 7 women develop breast cancer over their lifetime risk. 70% of women undergoing surgical intervention will undergo breast-conserving surgery (BCS). 20-25% of women who undergo BCS require at least a second operation due to positive margins on histopathology. In keeping with the guidelines of the Association of Breast Surgeons in the UK, our institution defines a positive margin as less than 1 mm of healthy tissue for invasive cancer with associated DCIS and 2mm for pure DCIS.
Intraoperative specimen radiography has become standard practice in the UK. Surgeons review 2D or rarely 3D images of the specimen intraoperatively to assess if further excision is necessary. Advanced 3D imaging using a Kubtec machine with tomosynthesis allows the evaluation of the entire height of the specimen via 1mm slices, although the 3D function is not always utilised. Some centres have specimens assessed by radiologists who opine on probable specimen margin positivity, to guide surgeons.
This retrospective review of specimen tomosynthesis images by a Kubtec 3-D system looks at whether a meticulous review of all tomography slices by the surgeon, a radiologist or a combined assessment could prevent the need for subsequent operations.

Method: A senior surgeon and a senior radiologist reviewed intra-operative specimen images in 54 patients who had undergone BCS with intra-operative specimen tomosynthesis using the Kubtec system over a year and required re-operation for positive histopathological margins. The operating surgeon initially assessed the margins as clear. The surgeon and radiologist (blinded to the pathology report) used the slice function to independently measure the shortest distance from the tumour to the edge of the specimen; their assessments were correlated with histopathology.

Results: The review included 54 specimens from 54 patients, including invasive and pure ductal carcinoma in situ (DCIS) patients, primary surgery patients, and post-neoadjuvant-chemotherapy (NACT) patients.
81 margins out of 216 (37.5%) were positive on histopathology, 44 (54.3%) of these were assessed as having involved margins by radiologists and 25 (30.9%) by surgeons using the 3D tomosynthesis function. The radiologist individually reported margins with better sensitivity (54.3% vs 30.9%) but poorer specificity (95.6% vs 100%) than the surgeon; however, there was a fair agreement between their individual interpretation (Kappa agreement 78.3%, Kappa statistic 0.26, $p<0.0001$). Dual assessment showed overall a better accuracy of 85.2% (Radiologist 80.1% and Surgeons 74.1%).
Overall, 27 (50%) patients could have avoided returning to the theatre if the images had been reported intra-operatively by a breast radiologist alongside the surgeon. At our intuition, a day case procedure for re-excising margins costs circa £3,638 per patient, saving approximately £200,000 a year.

Conclusion: If radiologists and surgeons use 3D images intraoperatively to undertake a dual assessment, the re-excision rates can be reduced by 50%. This would significantly improve patient outcomes and reduce healthcare provision costs.

P4-07-11: Intraoperative sentinel lymph node evaluation in patients with breast cancer undergoing surgery after neoadjuvant systemic therapy

Saskia Leonard, Shirley Cheng, Brendan Seto, Ashley Marumoto

Background: Current literature recommends performing an axillary lymph node dissection (ALND) for patients undergoing neoadjuvant systemic therapy (NAST) for breast cancer who have residual disease in the sentinel lymph node (SLN). Pending the results of Alliance 110202, accurate intraoperative lymph node evaluation is imperative to determine which patients are candidates for axillary dissection. There is some evidence that frozen section (FS) has a higher sensitivity than touch-prep (TP) for intraoperative evaluation of SLN for clinically node positive patients who convert to node negative in the post-NAST setting; however, the data is sparse. This study aims to compare the intraoperative techniques of touch-prep (TP) and frozen section (FS) in clinically node negative patients after NAST at a single institution.
Methods: This was a case series retrospective medical chart review of patients diagnosed with invasive breast cancer treated with NAST followed by surgery who underwent intraoperative evaluation of SLNs from 2013-2022. Patient demographics, AJCC clinical stage, tumor histology, biomarker status, lymph node features and size, surgery type and intraoperative lymph node evaluation technique by either TP or FS were analyzed for sensitivity, specificity, and false negative rate (FNR). Chi-squared or fischer's Exact test were used to determine significance.
Results: A total of 167 node-negative patients and 68 node-positive patients were included in the analysis. Overall, the sensitivity of TP was 0.46 versus 0.80 for FS (p=0.036). The specificity was 1 for both intraoperative preparations. Specimens with lymphovascular invasion (LVI) were 6.5 times as likely to have a false negative TP or FS result compared to those without LVI (46% with LVI versus 7% without LVI). Patients who were clinically node positive prior to NAST were 20 times as likely to have a false negative TP vs FS result compared to those who were clinically node negative prior to NAST (41% vs 2.7%). Age, sex, race, AJCC clinical stage, histology, biomarker status, lymph node features and size, surgery type, intraoperative lymph node evaluation technique were not associated with FNR.
Analysis of patients who were clinically node-positive prior to NAST demonstrated 13/68 patients who underwent both TP and FS evaluation, 47/68 patients underwent TP only, and 8/68 patients underwent FS only. Of the 13 who underwent both TP and FS, 38% (5/13) evaluated by TP were discordant with final pathology while 15% (2/13) evaluated by FS were discordant.
Discussion: FS of the SLN may be preferrable for clinically node-positive patients who

convert to clinically node-negative after NAST. There were no predictors of FNR. Further studies are needed to evaluate accuracy of intraoperative evaluation of SLNs after NAST.

P4-07-12: Attitudes on mastectomy in sub-Saharan Africa; a systematic literature review exploring womanhood and femininity

Mikaela Belsky

Introduction: Breast cancer mortality remains high in sub-Saharan Africa (SSA), which stands in contrast to the gradual mortality decrease in high income countries. This disparity is partly attributed to fears of mastectomy and its effects, however, mastectomy is the primary treatment modality of breast cancer in SSA. Thus, it is crucial to better understand the culture of mastectomy in these regions, so that appropriate interventions can allow for both timely treatment and sufficient support of women as they transition to a postmastectomy life. This review aims to examine existing literature on attitudes surrounding mastectomy in SSA and to further explore its impact on womanhood.

Methods: During March of 2024, a literature search was conducted on PubMed and EMBASE data sources, using key search terms such as: “mastectomy,” “breast removal,” “qualitative,” “questionnaire,” “interview, “africa,” “sub-saharan,” and the names of each sub-Saharan African country. This method was supplemented by hand searching. Inclusion criteria are as follows; 2000-2024 publication year, explicit discussion of attitudes surrounding mastectomy, sub-Saharan country study setting, and use of qualitative design or mixed methodology.

Results: The search yielded 83 nonoverlapping articles and 15 articles met inclusion criteria. The majority (n = 12) administered in-depth interviews as opposed to open-ended questionnaires. Two studies supplemented data with focus groups, and one utilized ethnography. Of note, all explicitly identified study settings were urban (n=11), and only six countries were represented. Only five studies exclusively worked with mastectomy patients; other studies often failed to differentiate between mastectomy patients and breast cancer patients in general. The most highly discussed themes fell under an overarching theme of womanhood; 1) poor body image and discomfort, 2) loss of femininity and uncertainty with one’s identity as a woman, 3) mixed impacts on intimate relationships and marriage, and 4) fears related to breastfeeding and motherhood.

Discussion: In SSA, there are many attitudes surrounding mastectomy that relate to one’s identity as a woman. These themes emphasize the idea that a breastless woman in SSA is disfigured to the point of losing her womanhood, thus imparting concerns on her capacity for intimacy and motherhood. Femininity is assigned only to those with breasts; this belief is not just held by community members, but also holds true for breast cancer patients both pre- and post-mastectomy. As supported by prior quantitative literature, the findings of this qualitative review imply that womanhood-related consequences of mastectomy are

associated with fears, delays, and even refusal of breast cancer treatment, thus likely worsening morbidity and mortality. Limitations of this review include a qualitative framework, which precludes definitive outcomes, and a dearth of broad SSA representation. Future areas of research should explore long-term impacts of mastectomy, attitudes around breast conservation and reconstruction, and postmastectomy breastfeeding trends, and the knowledge base of male partners.

P4-07-13: FACTORS ASSOCIATED WITH THE PRACTICE OF ONCOPLASTIC SURGERY AMONG BREAST SURGEONS IN BRAZIL: A NATIONAL SURVEY

Francisco Pimentel Cavalcante, Guilherme Garcia Novita, Regis Resende Paulinelli, Fabrício Palermo Brenelli, Cícero de Andrade Urban, Carlos Alberto Ruiz, Eduardo Camargo Millen, Felipe Pereira Zerwes, André Mattar, Marcelo Antonini, Patrícia Klarmann Ziegelmann, Ruffo Freitas-Junior, Antonio Tufi Hassan, Eduardo Carvalho Pessoa, Heber Salvador de Castro Ribeiro, Antonio Luiz Frasson, Vilmar Marques de Oliveira, René Aloisio da Costa Vieira

Introduction: Breast oncoplastic surgery (BOS) is an important tool in breast cancer treatment. In Brazil, since 2008, various actions endorsed by the Brazilian Society of Mastology (SBM) have stimulated the dissemination of these techniques over the years, including: (1) BOS in National and regional Congress; (2) organization of a specific oncoplasty congress; (3) support for hand-on courses and fellowship; (4) inclusion of BOS in medical residency. However, its results and the proportion of surgeons whose performs BOS, including the level of complexity, is unknown.
Materials and Methods: A structured cross-sectional web-push survey, containing 30 questions focused on the attitudes and skills of Brazilian mastologists regarding oncoplastic surgery, was sent in a hybrid way (mail, email, telephone and during the Brazilian Mastology Congress) to SBM members between July and December/2023 (n=1,759). All associates were considered eligible since the SBM list was updated in 2023, and no prior screening was conducted to assess eligibility. The response rate was calculated by the number of complete responses (80% of questions) returned. Questionnaires with a response proportion of less than 80%, but above 50%, were considered partial and did not enter the response rate calculation but were considered with sufficient information for analysis. Responses less than 50% were considered "breakoff." The questionnaire was divided into general and demographic questions, followed by questions related to breast surgery and the last part for those performing oncoplasty. The degree of practice in oncoplasty in this group was evaluated. The characteristics of professionals performing oncoplasty were compared to those who did not. For this purpose, the chi-square test was used. In variables where differences were observed and $p<0.10$, logistic regression was performed.
Results: 1089 (Response rate: 61.9%) professionals returned the questionnaire, of which 530 (48.6%) performed oncoplasty. Factors associated with performing oncoplasty were: primary surgical training (56.5% General Surgery versus 43.6% Gynecology; $p<0.001$),

secondary surgical training (51.9% Oncologic Surgery versus 47.8% Mastology versus 12.5% without other secondary training; p=0.007), male gender (53.7% Male versus 40.4% Female; p<0.001), region of Brazil (55.9% South / 53.1% North / 51.0% Midwest / 49.8% Northeast / 41.5% Southeast; p=0.009), exclusive dedication to breast surgery (53.5% 100% practice; 51.6% breast and general oncologic surgery; 26.4% breast and gynecology; p<0.001), number of breast cancer cases performed by year (65.6% >100 cases/year; 56.0% 51 to 100 cases/year; 38.2% 11 to 50 cases/year; 26.4% <10 cases/year; p<0.001). On the other hand, city size (p=0.288), practice in a teaching hospital (p=0.305), age (0.128) and private or public hospital (p=0.08) were not associated with oncoplasty. Among those practicing oncoplasty, most professionals were skilled in multiple procedures: nipple-sparing mastectomies (99%), therapeutic mammoplasty/symmetrization (96%), implant reconstruction (93%), skin-reducing mastectomies (84%), extreme oncoplasty (81%), thoracoabdominal flaps (71.5%), latissimus dorsi flap (66%), lipofilling (61.5%), breast augmentation (54.6%), and rectus abdominis flap (28.2%). Most breast surgeons developed their techniques in hands-on courses (36.7%), medical residency (32.8%) and dedicated fellowships (21.3%).
Conclusion: A high proportion of Brazilian mastologists perform oncoplastic techniques, even those with higher complexity. These results show that the SBM actions were effective and could serve as a model to be used in other countries. Knowledge of the factors associated with non-training in oncoplasty is essential for intervention strategies aiming to enhance the use of oncoplasty.

P4-07-15: Minimally Invasive Mastery: A Comparative Analysis of Endoscopic Mastectomy and Conventional Nipple-Sparing Mastectomy with Immediate Reconstruction in Patients with Early-Stage Breast Cancer - A Paradigm Shift in Breast Cancer Surgery

Voratape Kijtavee, Korawan Chandrachamnong, Anakkawee Hsiung

Introduction: Endoscopic mastectomy (EM) has emerged as a minimally invasive alternative to conventional nipple-sparing mastectomy (cNSM) for the treatment of early-stage breast cancer. This study aimed to compare the surgical outcomes, aesthetic results, and quality of life (QoL) between EM and cNSM with immediate implant reconstruction, with or without acellular dermal matrix (ADM) augmentation, in a single-institution cohort.
Methods: A retrospective review of 50 patients with breast cup A-B who underwent either endoscopic mastectomy (EM, n=25) or conventional nipple-sparing mastectomy (cNSM, n=25) with immediate implant reconstruction at Police General Hospital between January 2022 and December 2023 was conducted. The study population included patients with early-stage breast cancer without pathological lymph node involvement or those undergoing prophylactic mastectomy. Primary endpoints were operative time, incision length, and pathology outcomes. Secondary endpoints included local recurrence rate (with 1-year follow-up for EM and 2-year follow-up for cNSM) and QoL (BREAST-Q) preoperatively and at 3, 6, and 12 months postoperatively. The BREAST-Q was used to

assess differences in aesthetic results, psychosocial well-being, and sexual health between the two groups. Multivariable binary logistic regression evaluated local recurrence risk.Results: The EM group demonstrated significantly longer operative times compared to the cNSM group (mean ± SD: 125 ± 60.5 minutes vs. 105 ± 35.4 minutes, p = 0.045). The EM group had significantly smaller incision lengths (mean ± SD: 4.5 ± 0.4 cm vs. 10.7 ± 3 cm, p < 0.001). In the EM group, removed breast tissue weight ranged from 120 to 380 grams, with a mean of 220 grams and a median of 250 grams. This was not significantly different from the cNSM group (p = 0.065). All surgical margins were free of tumor in both the EM and cNSM groups. No significant differences were observed in other pathology outcomes, including tumor size, lymph node involvement. Local recurrence rates were similar between the groups at their respective follow-up time points.Patients in the EM group reported significantly higher BREAST-Q scores for satisfaction with breasts (mean ± SD: 56.6 ± 6.4 vs. 39.5 ± 8.6, p < 0.001) and psychosocial well-being (mean ± SD: 79.5 ± 11.0 vs. 58.1 ± 10.9, p < 0.001) at 12 months postoperatively. There was no significant difference in sexual well-being scores between the two groups (p = 0.034).Conclusions: Endoscopic mastectomy offers a safe and effective alternative to conventional nipple_x0002_sparing mastectomy for the treatment of early-stage breast cancer in patients with breast cup A-B, without pathological lymph node involvement or those undergoing prophylactic mastectomy. EM is associated with significantly longer operative times, smaller incisions, and comparable surgical and oncologic outcomes to cNSM. Furthermore, EM may provide superior long-term aesthetic satisfaction and QoL compared to cNSM, particularly in patients with smaller breasts or those who prioritize minimizing scarring. The use of porcine or human ADM did not significantly impact the surgical or aesthetic outcomes in either group, consistent with findings from other studies.Keywords: endoscopic mastectomy, nipple-sparing mastectomy, breast reconstruction, immediate implant reconstruction, acellular dermal matrix, surgical outcomes, aesthetic outcomes, quality of life, early-stage breast cancer, prophylactic mastectomy.

P4-07-16: First line CDK4/6 inhibitors plus endocrine therapy versus chemotherapy for HR+/HER2- metastatic breast cancer patients in real world: a multicenter YOUNGBC-30 study.

Biyun Wang, Yifan Chen, Yizhao Xie, Yuan Peng, Ning Xie, Die Sang, Xinhua Han, Yanxia Zhao, Juanjuan Li

Background: The combination of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) and endocrine therapy (ET) is widely utilized as the first-line treatment for hormone receptor (HR) positive and human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC) patients. However, there has been long debates on the choice between CDK4/6i plus ET and chemotherapy (CT), especially those with visceral metastasis or visceral crisis. Several prospective trials suggested a suspected superiority of CDK4/6i over CT, however, conclusions vary among different studies due to the complexity of treatment lines and different inclusion criteria. Here we report CDK4/6i plus ET versus CT in first line

treatment of HR+/HER2- MBC in a real-world setting.
Methods: The medical records of patients diagnosed with HR+/HER2- MBC from 2020 to 2023 in 6 institutions were retrospectively evaluated. And patients received first-line CDK4/6i plus ET or first-line CT were included in this study.
Results: A total of 339 patients were available for analysis. 244 (72%) patients received CDK4/6i plus ET and 95 (28%) patients received CT. The median PFS of CDK4/6i plus ET cohort was significantly superior to CT group (17.2 months versus 9.1 months, hazard ratio = 0.49; 95% CI, 0.36 to 0.66; P < 0.0001). Subgroup analysis showed similar results, except subgroup of patients with visceral crisis (hazard ratio =0.73; 95% CI, 0.37 to 1.43; P = 0.36) or primary endocrine resistance (hazard ratio =0.59; 95% CI, 0.33 to 1.06; P = 0.08). The median overall survival was not reached. No significant difference of grade 3 or worse adverse events was observed in two groups (25.8% vs 26.3%, P = 0.93).
Conclusions: In a real-world setting, first line CDK4/6i plus ET showed better efficacy than chemotherapy in patients with HR+/HER2- MBC, while CT and ET showed similar results in patients with visceral crisis or primary endocrine resistance. Safety profile was similar between two groups. This study provides real-world data for future clinical decision.

P4-07-19: Quality of life with palbociclib plus tamoxifen in hormone receptor-positive, HER2-negative advanced breast cancer: results from NCCH1607/PATHWAY, an Asian international double-blind randomized phase 3 trial.

Joohyuk Sohn, Kazuki Sudo, Takashi Yamanaka, Hirofumi Mukai, Naohito Yamamoto, Chi-Feng Chung, Yen-Shen Lu, Kyung-Hun Lee, Soo-Chin Lee, Tsutomu Iwasa, Hiroji Iwata, Kenichi Watanabe, Kyung Hae Jung, Yuko Tanabe, Seok Yun Kang, Hiroyuki Yasojima, Kenjiro Aogi, Eriko Tokunaga, Sung Hoon Sim, Yoon Sim Yap, Koji Matsumoto, Ling-Ming Tseng, Yoshiko Umeyama, Emi Noguchi, Tomomi Hata, Aya Kuchiba, Taro Shibata, Kenichi Nakamura, Kenji Tamura, Kan Yonemori

Background: In the PATHWAY trial, palbociclib plus tamoxifen demonstrated improved progression-free survival compared with placebo plus tamoxifen in hormone receptor-positive, HER2-negative (HR+/HER2−) advanced breast cancer. Quality of life (QOL) data was also collected and evaluated as a secondary objective. This analysis compared QOL between the two treatment groups.
Methods: Pre-, peri-, or postmenopausal women with locally advanced or metastatic HR+/HER2− breast cancer who were candidates to receive tamoxifen as first-line or second-line endocrine treatment for advanced disease were randomly assigned 1:1 to receive palbociclib–tamoxifen or placebo–tamoxifen in Japan, Republic of Korea, Taiwan, and Singapore. Patients continued to receive the assigned treatment until progressive disease (PD), clinically diagnosed symptomatic deterioration, unacceptable toxicity, death, or patient's refusal, whichever occurred first. The study was conducted as a Clinical Research Collaboration with the National Cancer Center Hospital as the regulatory study sponsor and Pfizer providing drug and financial support (NCT03423199). Patient-reported

outcomes were assessed on Day 1 of Cycles (C) 1 (baseline), 4, and 7, and at the end of treatment (EOT) using EORTC QLQ-C30 and EORTC QLQ BR23. Least-square means (LSM) changes from baseline were calculated. Kaplan-Meier Plot was used to calculate time to deterioration (TTD). A composite definition of deterioration based on death, PD, clinically diagnosed symptomatic deterioration, and minimally important difference (MID) was used for TTD. MID was defined as the increase in QOL score of 10 points or greater from baseline. Results: The EORTC QLQ-C30 and the EORTC QLQ-BR23 were completed by 88 patients in the palbociclib plus tamoxifen arm and 93 patients in the placebo plus tamoxifen arm at baseline, and by 64 (72.7%) to 80 (90.9%) patients in the palbociclib plus tamoxifen arm and by 59 (63.4%) to 79 (84.9%) patients in the placebo plus tamoxifen arm, from C4 to EOT. In the EORTC QLQ-C30, the global QOL subscale, the LSM changes from baseline for C4, C7, and EOT were -0.22 (Standard error [SE]: 1.99) and -0.92 (SE: 2.09), 2.83 (SE: 2.21) and 0.66 (SE: 2.30), and -12.31 (SE: 2.40) and -7.12 (SE: 2.21) in the palbociclib plus tamoxifen arm and in the placebo plus tamoxifen arm, respectively. The difference in the LSM between treatments at C4, C7, and EOT were 0.70 (95% CI: -5.00, 6.41), 2.17 (95% CI: -4.14, 8.48) and -5.19 (95% CI: -11.64, 1.26). For either the functional subscales or symptom scales, no notable trends or differences between the treatment arms were found in the LSM changes from baseline. In the pain symptom scale, a total of 68 patients (77.3%) in the palbociclib plus tamoxifen arm and 81 patients (87.1%) in the placebo plus tamoxifen arm had documented PD, clinically diagnosed symptomatic deterioration, or MID at the data cutoff as of 15 Sept 2022. The median TTD was 10.3 months (95% CI: 5.8, 24.4) for the palbociclib plus tamoxifen arm and 5.5 months (95% CI: 3.6, 7.6) for the placebo plus tamoxifen arm with the hazard ratio of 0.601 (95% CI: 0.433, 0.834). In the analysis of the EORTC QLQ-BR23: no notable trends or differences between the treatment arms were found in the LSM changes from baseline for either the functional subscales or symptom scales.
Conclusion: The addition of palbociclib demonstrated a prolongation of TTD in the pain symptom scale of EORTC QLQ-C30 compared with placebo. No differences were found between treatment arms in other QOL analyses. Palbociclib plus tamoxifen allowed patients to maintain QOL while experiencing delayed disease progression.

P4-07-20: Is Distance to Treating Oncologist a Potential Prognostic Real-World-Factor for Patients with HR+/HER2- Advanced Breast Cancer? Results from the Non-Interventional Study PERFORM

Michael P Lux, Georg Pfeiler, Matthias Korell, Julia Radosa, Thomas Decker, Mustafa Deryal, Thomas Fietz, Andreas Köhler, Björn Schöttker, Jochen Wilke, Jan Knoblich, Volker Petersen, Maria Dietrich, Thomas Gabrysiak, Uwe Rhein, Denise Wrobel, Reinhard Depenbusch, Isolde Gröll, Nikola Bangemann, Lutz Jacobasch, Lothar Müller, Marika Henriette Princk, Johanna Dzieran, Katja Gratzke, Martin Glasstetter, Anne Adams, Esther Glastetter, André Breitbach, Rupert Bartsch

Background: Real-world evidence (RWE) is generated to explore the safety and effectiveness of approved agents in a broad real-world population in regionally specific

health care structures. The distance to treating oncologist (DTO) is a rarely analyzed real-world factor of high interest. This real-world exploratory analysis investigated the possible influence of the DTO on patient characteristics, adverse events (AEs), therapy modifications and effectiveness.
Methods: The prospective non-interventional study PERFORM is carried out in 320 urban and rural study sites across Germany and Austria. Up to 1,900 patients with HR+/HER2- advanced breast cancer (aBC) treated with palbociclib plus endocrine therapy (ET) in the first-line setting (1L) will be enrolled. Three years after 1st patient enrollment, the 3rd interim analysis (IA3) was conducted with data cutoff in September 2023. Demographic and disease characteristics as well as socioeconomic information, including DTO, are documented at baseline. AEs and therapy modifications are continuously documented. Disease progression is evaluated according to routine clinical practice. Here, we focus on subgroups with DTO <20 km and ≥20 km with additional age-stratification (<75 and ≥75 years). Patient-, disease- and socioeconomic characteristics, AEs, therapy modifications and real-world PFS (rwPFS) rates at 6, 12, 18 and 24 months are included in this analysis. The median rwPFS and rwPFS rates are estimated using the Kaplan-Meier method. Descriptive statistics are used to summarize results. Limitations are the descriptive, exploratory, hypotheses generating character of the results, that are not necessarily transferable to other regions.
Results: An exploratory analysis of IA3 (990 patients) evaluated 854 patients who reported DTO. For 612 patients (71.7 %), DTO is less than 20 km and 242 patients (28.3 %) have a DTO of ≥20 km. The latter tend to have a slightly lower ECOG-PS (ECOG 0: 46.6% vs. 50.4%) and are younger at inclusion (median: 68.6 vs. 66.5 years). Interestingly, patients with a shorter DTO are more likely to live alone, irrespective of age (41.0 % vs. 29.5 %). Patients with a greater DTO present more often with de novo aBC (<20 km: 36.4% vs. ≥20 km: 42.1%), which is mainly driven by patients ≥75 years (<20 km: 39.3% vs. ≥20 km: 58.3%). Patients with a DTO of <20km are more likely to have visceral metastases at inclusion (<20 km 46.7% vs ≥20 km: 43.8%). In the age-stratified analysis this was more pronounced in patients <75 years (<20 km: 48.2% vs. ≥20 km: 42.9%). AEs and therapy modifications are comparable, regardless of DTO. Median rwPFS in the subgroup with ≥20 km DTO was 22.8 months (95% CI 19.2, NA). For the subgroup with <20 km DTO, the median rwPFS could not (yet) be determined (NA (95% CI 23.5, NA)). This tendency is consistently confirmed in the 6-, 12-, 18-, 24-month rwPFS rates compared to the <20 km subgroup (<20 km: 85.9 %, 73.2 %, 64.2 %, 55.1 %; ≥20km: 82.7 %, 71.0 %, 59.8 %, 46.7 %).

Conclusions: This exploratory analysis shows a trend towards poorer rwPFS rates in patients with DTO of ≥20 km compared to <20km although they had a lower rate of visceral metastases and a higher rate of de novo aBC. These results indicate that the DTO might be a relevant real-world factor influencing outcome, that warrants further analyses including PROs with a longer follow-up.

P4-07-21: Prognostic analysis of operable HR-positive HER2-negative loco-regional recurrent breast cancer; A multi-institutional Retrospective Cohort Study

Emi Tokuda, Yukinori Ozaki, Fumikata Hara, Shinsuke Sasada, Yasuaki Sagara, Masataka Sawaki, Chizuko Kanbayashi, Takashi Yamanaka, Tatsuya Onishi, Yoshitaka Fujiki, Akihiko Suto, Yuko Takahashi, Eriko Tokunaga, Tomoyuki Aruga, Rikiya Nakamura, Tomomi Fujisawa, Shigehira Saji, Hiroji Iwata, Tadahiko Shien

Background: Locoregional recurrence (LRR) after surgery in early-stage breast cancer patients is not uncommon。 Several reports suggest that LRR in hormone receptor-positive HER2-negative breast cancer (HR+HER2- BC) has a better prognosis compared to other subtypes, however, studies on the prognosis of LRR in this subtype and factors affecting it are limited.
Methods: Multicenter retrospective cohort study was conducted [te2] within the JCOG study group to assess the prognosis of HR+HER2- LRR and the factors affecting it. The study included patients diagnosed with HR+HER2- LRR at one or more sites, such as the ipsilateral breast, skin, chest wall, or regional lymph nodes following primary breast cancer surgery. All participants were free of distant metastases at LRR diagnosis and underwent radical surgery from January 2014 to December 2018.
Results:Out of 967 enrolled patients across 41 centers, 946 were analyzed. There were 504 cases of ipsilateral breast tumor recurrence only (IBTR), while 442 had LRR at sites other than IBTR (oLRR). During a median follow-up period of 62.1 months, 239 invasive disease-free survival (iDFS) events and 80 deaths occurred. The 5-year iDFS rate for all LRR cases was 75.0%, and the 5-year overall survival (OS) rate was 92.3%. The 5-year iDFS was 83.4% for IBTR and significantly lower at 66.5% for oLRR. Multivariate analysis identified several independent prognostic factors for poorer iDFS: age over 60 years (HR: 1.43, 95% CI: 1.03-1.99) at LRR diagnosis, tumors with high Ki67 (>30) or high grade (HG3) (HR: 1.65, 95% CI: 1.19-2.27), and LRR diagnosis during adjuvant endocrine therapy (HR: 2.06, 95% CI: 1.30-3.66). For OS, poor prognostic factors included age over 60 (HR: 1.76, 95% CI: 1.04-2.98) or under 40 (HR: 2.31, 95% CI: 1.05-5.13) at LRR diagnosis, and tumors with high Ki67 or HG3 (HR: 2.25, 95% CI: 1.35-3.77).
Conclusion: In this study, we investigated the prognosis and influencing factors of LRR in HR+ HER2- breast cancer using a large cohort of 946 cases, which has not been previously reported. Our findings highlight the imperative of tailored treatment strategies based on recurrence risk for HR+HER2- breast cancer patients experiencing LRR. Further randomized controlled trials are warranted to validate these strategies and improve the outcome in high-risk populations.

P4-07-22: Real world effectiveness of overall survival (OS) with palbociclib (PAL) plus (+) endocrine therapy (ET) in hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC) patients in Japan

Michiko Tsuneizumi, Tetsuhiro Yoshinami, Shigenori E. Nagai, Masaya Hattori, Hiroko Masuda, Takuho Okamura, Kenichi Watanabe, Takahiro Nakayama, Daisuke Takabatake, Michiko Harao, Hiroshi Yoshino, Natsuko Mori, Hiroyuki Yasojima, Chiya Oshiro, Madoka Iwase, Miki Yamaguchi, Takafumi Sangai, Shinsuke Sasada, Takanori Ishida, Manabu Futamura, Nobuyoshi Kosaka, Yasuaki Muramatsu, Norikazu Masuda

Introduction: PAL, cyclin-dependent kinases 4 and 6 inhibitor (CDK4/6i), + ET is a standard therapy for the treatment of HR+/HER2- ABC. Efficacy and safety of PAL + ET was shown by two randomized clinical trials, PALOMA-2 and PALOMA-3. Further, recent large real-world studies revealed effectiveness of PAL + aromatase inhibitor (AI) for HR+/HER2- ABC in routine United States clinical practice. To strengthen the real-world evidence (RWE) of PAL + ET for HR+/HER2- ABC treatment under different clinical practice and healthcare situations, we conducted observational study to evaluate the effectiveness of PAL + ET in Japanese real-world setting. Recently, we reported that the median (95% CI) OS were 68.2 months (60.8-not estimated (NE)), among patients who treated with PAL + ET in 1st line (1L) in Japanese routine clinical practice with longer follow-up after interim analysis. Here, we investigate the subgroup of real-world OS of Japanese patients treated with PAL + ET as 1L for HR+/HER2- ABC to understand the impact of OS.
Methods: In this multicenter, observational study, patients with HR+/HER2- ABC, who initiated PAL + ET from 15 December 2017 (launch date in Japan) to 31 December 2020 were enrolled. To reduce selection bias, all patients who started PAL during the above period were listed up and eligibility was confirmed. Key eligibility criteria were: 1) Diagnosis of HR+/HER2- ABC; 2) Patients received PAL + ET in 1L or 2L; 3) Patients had at least 6 months of follow up from start of PAL or died within that period. The primary endpoint was real-world progression free survival (rwPFS), and one of the secondary endpoints was OS, defined as the time from start of PAL + ET treatment to death due to any cause. We performed the further analysis, including subgroup analysis, about OS of 1L PAL + ET to investigate what factors could affect its clinical benefits.
Results: In this study, 693 patients from 20 study sites in Japan were enrolled. Among them, 426 and 267 received PAL + ET as 1L and 2L, respectively. The median age was 60.0 (range 29-87) and 482 patients (70.0%) were postmenopausal. 54.0% patients had visceral involvement and 43.3% had <12 months of treatment-free interval (TFI; defined as end date of adjuvant therapy to diagnosis date of recurrence). 295 patients received subsequent therapy out of 426 patients after PAL + ET as 1L. 60.7% (179/295) of patients received an endocrine-based regimen as first subsequent treatment; of those 23.1% (68/295) received CDK4/6i + ET, 19.3% (57/295) endocrine monotherapy, and 17.6% (52/295) ET + everolimus. After a median follow-up of 48.1 months, the following subgroup analysis was performed for OS in 1L, showing median OS (95% CI) and, survival rate at 60 months: pre-

/post-menopausal status was not reached (NR) (59.4-NE), 61.3%/68.0 months (58.5-NE), 55.6%, TFI<12 months/TFI12>months/De novo metastatic was 56.3 months (43.9-68.2), 46.1%/NR (NE-NE), 72.9%/NR (56.3-NE), 60.0%, visceral/non-visceral metastasis was 65.0 months (56.3-NE), 52.3%/NR (63.2-NE), 61.3%, liver metastasis was 46.4 months (37.2-NE), 42.8%, and bone only disease was NR (57.8-NE), 61.2%.
Conclusions: The findings of the study based on Japanese routine clinical practice further confirmed that the clinical benefits of PAL+ET is consistent regardless of patient characteristics in the real-world setting. In all subgroup other than TFI＜12 months or liver metastasis, median OS was >5 years with 1L PAL + ET, underlining the use of PAL + ET as 1L standard for ABC in the real-world setting.

P4-07-23: Preliminary safety in the inavolisib + fulvestrant + ribociclib/abemaciclib arms of MORPHEUS-pan breast cancer: A Phase 1b/2 study of efficacy & safety of multiple treatment combinations in patients with metastatic/locally advanced breast cancer

Sherene Loi, Hilary Martin, Mafalda Oliveira, Janelle Soong, Fiona Young, Clélia Cahuzac, Colby Shemesh, Chunyan Song, Kristin Kallapur, Richard Schwab, Einav Nili Gal-Yam

Background: First-line (1L) standard of care for hormone receptor-positive, HER2-negative metastatic breast cancer (HR+, HER2– mBC) is endocrine therapy + a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). However, crosstalk between the estrogen receptor, CDK4/6 and PI3K oncogenic pathways may lead to treatment resistance. PIK3CA mutations are not only associated with poor prognosis but also a predictive biomarker of response to PI3K inhibitors. The INAVO120 (NCT03006172) study showed that combining 1L inavolisib (INAVO; a highly potent and selective inhibitor of the p110 catalytic subunit alpha isoform encoded by PIK3CA) with fulvestrant (FUL) and palbociclib conferred a significant and clinically meaningful progression-free survival improvement, and numerically favorable trend in overall survival, in patients (pts) with PIK3CA-mutated, HR+, HER2– locally advanced (LA)/mBC. Abemaciclib (abema) and ribociclib (ribo) are other CDK4/6is used in clinical practice, and data showing combinability with INAVO are of great interest. We present preliminary safety data from the INAVO + FUL + abema/ribo arms of the MORPHEUS-pan BC (NCT03424005) umbrella study.
Methods: Eligible pts had PIK3CA-mutated, HR+, HER2– LA/mBC, prior therapy for metastatic disease, fasting glucose of <126 mg/dL or <7.0 mmol/L and hemoglobin A1c levels of ≤6.4%. Pts were randomized to receive INAVO (9 mg orally [PO] once daily on Days [D] 1–28 of 28-D cycles) + FUL (500 mg intramuscularly on D1 & 15 of Cycle 1, then on D1 of each cycle) + either abema (150 mg PO twice daily on D1–28 of 28-D cycles) or ribo (400 mg PO once daily on D1–21 of 28-D cycles).
Results: In the INAVO + FUL + abema arm (n = 4), one pt had received one prior line of therapy, one pt had three prior lines, and two pts had more than four prior lines. In the INAVO + FUL + ribo arm (n = 6), one pt had received one prior line, three pts had two prior lines, one pt had four prior lines, and one pt had more than four prior lines. The most

common metastatic sites (occurring in >1 pt in either arm) in the INAVO + FUL + abema arm were bone (n = 3) and liver (n = 2); in the INAVO + FUL + ribo arm, bone (n = 5), liver (n = 3), and lymph nodes (n = 2). At clinical cutoff (May 1, 2024) all pts were on study and receiving treatment. Median duration of safety follow-up was 2.9 months in the INAVO + FUL + abema arm and 2.5 months in the INAVO + FUL + ribo arm. All pts had at least one adverse event (AE). The most common AEs, occurring in >1 pt in either arm (INAVO + FUL + abema vs ribo), included hyperglycemia (4 vs 5 pts), diarrhea (3 vs 4), vomiting (2 vs 4), increased blood creatinine (2 each), nausea (2 each), cough (1 vs 2), fatigue (1 vs 2), musculoskeletal pain (1 vs 2), erythema (0 vs 2), headache (0 vs 2), and decreased platelet count (2 vs 0). Two pts in the INAVO + FUL + abema arm and one pt in the INAVO + FUL + ribo arm had grade 3 AEs. There were no grade 4 or 5 AEs, and no AEs leading to withdrawal of any treatment in either arm. All pts in the INAVO + FUL + abema arm and two pts in the INAVO + FUL + ribo arm had AEs leading to dose modification/interruption; the most common (>1 pt in either arm) were diarrhea (n = 2 in the INAVO + FUL + abema arm; n = 1 in the INAVO + FUL + ribo arm) and hyperglycemia (n = 2 in each arm). Two AEs of special interest were reported in the INAVO + FUL + abema arm (grade 2 pneumonitis, grade 3 stomatitis) and one in the INAVO + FUL + ribo arm (grade 3 hyperglycemia) per CTCAE 4.0.
Conclusions: No unexpected safety findings were observed at this early timepoint in either arm; pts remain on-study and follow-up is ongoing. Treatment-related AEs for each combination were driven by the known safety profiles of INAVO and each individual CDK4/6i. Updated data, including pharmacokinetics and data from additional participants, will be presented.

P4-07-24: Prospective Cohort Study of Abemaciclib in Combination with Endocrine Therapy for Chemotherapy-Treated HR+/HER2- Metastatic Breast Cancer

Kazutaka Narui, Kana Miyahara, Yukari Uemura, Akimitsu Yamada, Kazuhiro Araki, Fumie Fujisawa, Takahiro Nakayama, Takashi Ishikawa, Hirohito Seki, Kimito Yamada, Masahiro Kitada, Takayuki Iwamoto, Naruto Taira, Yuichiro Kikawa, Tomohiko Aihara, Hirofumi Mukai

Background: Combination therapy with cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors and endocrine therapy as the first-line and second-line treatments has already been standard therapy in patients with hormone receptor-positive (HR+) human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (MBC) based on clinical trials. On the other hand, in clinical practice, CDK4/6 inhibitors are used not only as first-/second-line but also for patients receiving prior chemotherapy in metastatic setting. However, the efficacy and safety of combination therapy in these patients remain unclear.
Patients and Methods: We conducted a multi-institutional prospective cohort study to obtain real-world evidence about the clinical efficacy and safety of combination therapy with abemaciclib and endocrine therapy for chemotherapy-treated patients with

HR+/HER2- MBC. The eligibility criteria included a history of chemotherapy after diagnosis of MBC, no recent history of CDK4/6 inhibitor treatment as the previous line, and no history of abemaciclib treatment. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival and adverse events. The preplanned subpopulation analysis comprised prior treatment history with CDK4/6 inhibitors other than abemaciclib, the number of chemotherapy regimens for HR+ HER2- MBC (one or two vs. three or more), and menopausal status (pre vs. post). We also planned the subpopulation analysis on the PFS treated with abemaciclib as maintenance therapy: defined as response of the former chemotherapy was determined as CR, PR or SD, and switched to abemaciclib and endocrine therapy for a reason other than PD.
Results: 181 patients were registered from December 2019 to November 2022. a minority of patients discontinued abemaciclib because of toxicity (13.9%) and of patient request (6.9%) without progression. Median PFS for abemaciclib in this population was 10.3 (95%CI: 8.4-12.0) months and median overall survival was 25.2 (95%CI: 12.5-18.0) months. Median number of endocrine therapies for MBC was 1 regimen. Median PFS of the patients treated with abemaciclib as maintenance therapy after chemotherapy (n=71) was 13.8 months (95%CI: 11.8-20.2). Median PFS of patients with prior treatment history with CDK4/6 inhibitor (palbociclib) (n=59) was 6.6 months (95%CI: 4.8-8.5). Patients with one or two chemotherapy regimens in the previous line (n=143) had a significantly longer PFS than those with three or more regimen (n=30) (median PFS: 10.6 months versus 6.5 months, p = 0.039). Premenopausal patients (n=40) had a longer PFS, but not significantly, than postmenopausal patients (n=133) (median PFS: 14.9 months versus 9.4 months, p = 0.073). As for safety, severe adverse events including diarrhea (6.9%), fatigue (4.6%), appetite loss (2.9%), nausea (1.7%), vomiting (1.2%), interstitial lung disease (1.2%), arthralgia (0.6%), infection (0.6%), up to grade 3, were observed during treatment with abemaciclib and endocrine therapy; these were consistent with known abemaciclib profile.
Conclusion: Abemaciclib, in combination with endocrine therapy, demonstrated considerable efficacy and manageable safety profiles in chemotherapy-treated HR+/HER2- MBC patients. Notably, the extended PFS of over one year, when abemaciclib is used as maintenance therapy after chemotherapy due to reasons other than disease progression, underscores its potential utility. Maintenance administration of abemaciclib could represent a significant advancement in MBC treatment, offering a promising option for patients transitioning from chemotherapy.

P4-07-25: Verification of a Highly Sensitive, Circulating Cell-Free DNA and Exosomal RNA RT-qPCR Assay to Monitor ESR1 Mutations from a Liquid Biopsy

Kevin Kelnar, Blaine Caughron, Holli Dale, Melissa Church, Julie R Thibert, Jamie Myers, Sarah Statt, Brian C Haynes

Introduction: At a rate of 90 new cases per 100,000 women per year, hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) is the most

prevalent subtype of breast cancer. Mutations in the ligand binding domain of the estrogen receptor gene (ESR1) are frequently the cause of resistance to aromatase inhibitor therapy. With repeat biopsy collection rarely performed after starting therapeutic treatment, early identification of ESR1 mutations in metastatic breast cancer (mBC) in plasma is critical after progression on aromatase inhibitor therapy and is in alignment with recent NCCN guideline updates. The decision to switch to elacestrant, a second line therapeutic, hinges upon the presence of ESR1 resistance mutations, highlighting the importance of early detection in an easily accessible sample type. We report the performance of an assay that detects 11 ESR1 acquired resistance mutations associated with HR+/HER2- mBC from plasma liquid biopsies that utilizes RT-qPCR technology combined with a novel isolation method that captures exosomal RNA in addition to cfDNA in order to improve mutation detection sensitivity.
Methods: Samples were processed using a novel isolation method included with the kit, which is optimized to enrich for exosomal RNA in addition to cell-free DNA from as little as 2 mL starting plasma volume. The assay workflow includes a single reverse transcription step followed by a preamplification enrichment step and a three-tube multiplex qPCR. The accompanying software applies automated quality controls and summarizes allele calls for both the controls included in the kit and test samples. We characterized the assay for key performance metrics such as precision, sensitivity, and specificity using multiple sample panels comprising a combination of plasma from a cohort of mBC subjects and surrogate samples. All mutant-positive samples were verified against internal reference methods.
Results: Based on an equivalent of 5 mutant copies per 1 mL plasma (utilizing 2 mL plasma total), analytical sensitivity exhibited a percent positive agreement ≥90%. Analytical specificity results were ≥90% negative percent agreement in mutation-negative samples. Single-site precision revealed no significant variability contribution across experiment days, operators, or instruments. The entire workflow from sample to answer was completed within a single workday, including sample isolation and software analysis.
Conclusions: The multiplex RT-qPCR assay exhibited robust performance for 11 ESR1 variants following commonly utilized workflow techniques that enable sensitive and accurate single day sample-to-results. Achieving high specificity and sensitivity levels on qPCR instruments that are broadly accessible will facilitate quick, reliable, early detection from a minimally invasive liquid biopsy in breast cancer patients. This approach demonstrates the potential to improve outcomes by monitoring for the presence of ESR1 mutations to aid in selecting the most appropriate therapy to quickly respond to endocrine therapy resistance.

P4-07-26: CDK 4/6 inhibitor switching and associated dosing patterns in Swedish HR+/HER2- MBC patients

Daniel Nyqvist, Antonios Valachis, Henrik Lindman, Mate Szilcz, Maria Jakobsson

Background: The combination of CDK4/6 inhibitors (CDK4/6i) and endocrine therapy is a first-line treatment standard in patients with hormone receptor-positive (HR+), human

epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC). Switching between CDK4/6i may be used to manage side-effects prior to progression, and the postMONARCH study recently showed evidence on improving efficacy when sequencing CDK4/6i post progression. Limited evidence on real-world switching and associated dosing patterns within this class of drugs exist. This study investigated the frequency and timing of CDK4/6i switching and dosing before and after switch in a real-world setting using a nationwide Swedish cohort of MBC patients.
Methods: This was a retrospective analysis utilizing the population-based Swedish Prescription Registry. The overall cohort included all patients with ≥ 1 dispensation of >1 of the available CDK4/6i (palbociclib, ribociclib and abemaciclib) from January 2017 – May 2024. Dosing before and after switch, overall frequency of CDK4/6i switching as well as time from the start of the first CDK4/6i to the subsequent were investigated. Only the first switch was considered. Information on treatment line of therapy and reason for switching was not available. Patient baseline characteristics and demographics were not available.
Results: Out of 5781 patients with ≥ 1 dispensation of a CDK4/6i, 606 patients (11%) receiving >1 CDK 4/6i were analyzed. The most common switch was from ribociclib; 18% of 1756 patients who started with ribociclib changed to another CDK4/6i: 75% to palbociclib and 25% to abemaciclib. The second most common switch was from palbociclib; 8% of 2905 patients who started with palbociclib changed to another CDK4/6i: 55% to abemaciclib and 45% to ribociclib. There were 58 patients who switched from abemaciclib to another CDK4/6i, representing 5% of 1120 patients. Notably, this may also include patients in the adjuvant setting; 64% changed to palbociclib and 36% to ribociclib.

Within 3 months of initiating CDK4/6i treatment, 201 patients out of the total 606 patients (33%) switched, with most changing from ribociclib; ribociclib-palbociclib (57%) and ribociclib-abemaciclib (15% patients). The remaining switches occurred 4-6 (27%), 7-9 (11%), or 10-12 (7%) months after treatment initiation. After more than a year on treatment, 136 patients (22%) switched CDK4/6i, with the majority changing from palbociclib; palbociclib-abemaciclib (37%) and palbociclib-ribociclib (35%).

Prior to the switch, 343 patients (57%) were on full dose of the initial CDK4/6i treatment, and this share was highest for patients who switched within 0-3 months (71%), and lowest for patients who changed CDK4/6i after more than a year (40%). Half of the patients began the subsequent CDK4/6i treatment on the label dose, and this proportion was highest for patients with a change after more than a year (57%) and varied between 51% for patients switching between 0-3 months to 35% for patients switching between 9-12 months. Overall, 80% of patients started their initial CDK4/6i treatment on the full dose.

Conclusion: Among Swedish patients who started treatment with a CDK4/6i, one in ten have switched to another CDK4/6i. The majority of patients switched to a subsequent CDK4/6i within 6 months of initiating their first CDK 4/6i. Most of these early switchers remained on full dose before the switch. The large proportion of early switchers may be related to tolerability issues. However, further investigation is needed to assess the clinical

reasons and outcomes for such treatment changes. Despite the limitations of this real-world data analysis, these findings provide a new perspective around the trends related to switching and associated dosing in patients treated with CDK 4/6i.

P4-07-27: Real-world observational study of patients with endocrine-resistant, hormone receptor+, HER2- metastatic breast cancer in the first-line setting: Patient characteristics, PIK3CA mutation prevalence, treatments, and clinical outcomes

Peter Lambert, Eirini Thanopoulou, Preet Dhillon

Background: Patients (pts) with endocrine therapy (ET)-resistant, hormone receptor+ (HR+), HER2– metastatic breast cancer (mBC) have a poor prognosis and may derive less benefit when treated with ET + a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) in the first-line (1L) setting. PIK3CA mutations occur in 35–40% of pts with HR+, HER2– mBC and are associated with poor prognosis. In the INAVO120 (NCT03006172) study, the addition of inavolisib, a PI3Kα inhibitor and mutant degrader, to fulvestrant plus palbociclib (a CDK4/6i) conferred a substantially longer progression-free survival (PFS) improvement in pts with PIK3CA-mutated (PIK3CAmut), HR+, HER2– mBC in the 1L, ET-resistant setting. This analysis aimed to evaluate baseline characteristics, PIK3CA mutation prevalence, and treatment outcomes in pts with HR+, HER2– mBC treated in the 1L, real-world (RW) setting, including those pts who met further INAVO120 criteria.
Methods: This is a retrospective, observational study of de-identified, electronic health record-derived data from the United States Flatiron Health Network (thus is not human subjects research, which would have required institutional review board assessment/approval).
Pts selected for inclusion in the study had recurrent HR+, HER2– mBC diagnosed between 2015 and 2023, and started 1L treatment within 90 days of mBC diagnosis. A cohort of pts with recurrent disease, prior ET, and any 1L treatment for mBC was defined ('broad cohort'), as well as 'INAVO120-like' populations (subdivided based on receipt of fulvestrant + palbociclib, fulvestrant + CDK4/6i, or ET + CDK4/6i) that included further criteria such as ET resistance, Eastern Cooperative Oncology Group Performance Status 0–2, no bone-only disease, and no elevated HbA1c or glucose levels at baseline.
Results: The broad cohort included 7096 pts, of whom, 922 met the further INAVO120 criteria (overall INAVO120-like population). All pts in the overall INAVO120-like population had received 1L CDK4/6i + ET; 514/922 pts received CDK4/6i + fulvestrant, of whom 339/514 received palbociclib as the CDK4/6i partner. 39–41% of the INAVO120-like populations (212/922, 120/514, and 82/339) tested positive for PIK3CA mutations. Fast progressors (relapse within ≤6 months [mo] of 1L treatment start) were more frequent in the INAVO120-like populations (35–38%) vs the broad cohort (25%).
Race/ethnicity distribution, body mass index at mBC diagnosis, duration of adjuvant treatment and use of different CDK4/6is were similar between the 'INAVO120-like' populations and the broad cohort.

Compared with the broad cohort, INAVO120-like pts were more likely to have visceral metastases (75–78% vs 48%), stage 3 disease at initial diagnosis (32–37% vs 29%) and a shorter time to mBC diagnosis (3.9–4.8 years vs 5.7 years).
The INAVO120-like populations also had shorter RW median PFS (8.2–8.5 vs 13.0 mo), shorter RW median time to chemotherapy (16.2–21.7 vs 33.0 mo), and shorter RW median overall survival (27.0–29.7 vs 36.8 mo) compared with the broad cohort.
PIK3CA mutation testing at any point was more frequent in pts in the INAVO120-like populations compared with the broad cohort (59–61% vs 45%); however, the proportion of pts tested for mutations prior to 1L treatment was numerically lower, but generally similar across cohorts: 9.5–11.8% (INAVO120-like) vs 12.4% (broad cohort). The PIK3CA mutation rates were similar across cohorts (39–41% vs 41%).
Conclusions: These RW data from a large US, community-based oncology network suggest that pts meeting the INAVO120 criteria have poor outcomes with 1L ET+ CDK4/6i treatment, regardless of the type of ET and CDK4/6i partner. Pts with PIK3CAmut, HR+, HER2– mBC may derive more benefit from therapies targeting the PI3K pathway (since PIK3CA mutations are a predictive biomarker of response), as demonstrated in the INAVO120 study.

P4-07-29: Analytical Validity of the Digistain Test in the Face of Variable Fixation Times: A Study from Charing Cross Hospital

Hemmel Amrania, Arnav Gautam, Zamzam Al-Khalili, Manveer Sroya, William Matthieson, Darius Francescatti, Chris Phillips, Charles Coombes

Background: In the setting of adjuvant therapy for breast cancer, the accuracy of quantitative real-time PCR-based risk profiling tests can be compromised by variable formalin fixation times, affecting the fidelity of genetic material. The Digistain test, using mid-infrared spectroscopy, potentially offers immunity to such pre-analytical variables. This study assesses the robustness of Digistain in maintaining consistent performance across a wide range of fixation times in breast cancer surgery samples.
Methods: We analyzed 233 breast cancer tissue samples collected post-surgery at Charing Cross Hospital, with fixation times documented between 5 to 144 hours. The primary objective was to investigate the consistency of the Digistain Index (DI) across varied fixation durations.
Results: The samples were stratified into three groups based on fixation time: 0-24 hours, 24-48 hours, and 48+ hours. An Analysis of Variance (ANOVA) was performed to compare Digistain Index (DI) values across these groups. The analysis revealed that DI values remained consistent across all groups, with no significant variation in mean DI values attributable to differences in fixation time ($p = 0.84$). This robust consistency of Digistain's results, irrespective of fixation duration, suggests potential advantages in analytical reliability, particularly in contexts where the fidelity of PCR-based tests may be influenced by pre-analytical variables.
Conclusions: These results validate the analytical robustness of the Digistain test,

confirming its suitability for use in clinical settings where fixation times can vary. This attribute positions Digistain as a dependable tool for breast cancer risk stratification in the adjuvant therapy context, enhancing its applicability in routine clinical practice.
Keywords: Breast cancer, Digistain, fixation time, analytical validity, adjuvant therapy, mid-infrared spectroscopy.

P4-07-30: The prognostic and predictive value of Oncotype DX® in ER+/HER2-/pT2N0, cM0 Breast Cancer Patients

Ioannis Natsiopoulos, Venizelos Vasileios, Gregory Xepapadakis, Christos Markopoulos, Rodoniki Iosifidou, Nikolaos Tsoulos, Spiridon Giannoulakis, Georgios Kapetsis, Amanta Psyrri, Zacharenia Saridaki, Adamantia Nikolaidi, Aikaterini Savvidou, Anastasios Mpoutis, Ioannis Mpoukovinas, Athanasios Kotsakis, Athina Christopoulou, Emmanouil Saloustros, Dimitrios Mavroudis, Sofia Aggelaki, Avraam Assi, Dimitrios Tzanninis, Dimitrios Grosomanidis, Elena Fountzila, Efthalia Lala, Eleftheria Ignatiadou, Maria Skondra, Flora Zagouri, Anna Koumarianou, Paris Kosmidis, Stergios Douvetzemis, Konstantinos Papazisis, Kornilia Anastasakou, Foteini Pavlidou, Eleftherios Kampletsas, Fiorita Poulakaki, Georgios Simpilidis, Sofia Triantafillidou, Maroulio Stathoulopoulou

Background: The Oncotype DX® assay is a 21-gene assay used to predict the likelihood of breast cancer recurrence and benefit from chemotherapy in early-stage, estrogen receptor-positive (ER+), HER2-negative (HER2-) breast cancer patients. Based on AJCC Anatomic Stage Groups, breast cancer patients with ER+/HER2-/pT2N0, cM0 tumors are categorized as stage IIA. If the Oncotype Dx® test is performed in such cases and the Recurrence Score (RS) is less than 11, the case should be assigned Pathological Prognostic Stage Group IA. This study aims to evaluate the utility of Oncotype DX® in providing a better prognosis and predicting the benefit of chemotherapy in pT2N0, cM0 breast cancer patients.
Methods: We conducted a retrospective analysis of data from a Greek cohort of ER+/HER2-/pT2N0, cM0 breast cancer patients who underwent Oncotype DX® testing between 2008 and 2020. Patients were categorized based on their Oncotype DX® RS according to AJCC Prognostic stage guidelines into RS<11 and RS ≥11. Additionally, subgroup analysis for patients ≤50 years old was performed in reference to their Oncotype DX® RS and clinical risk status.
Results: A total of 524 ER+/HER2-/pT2N0, cM0 patients were included in the analysis. The mean RS was 17.3. RS 0-10 was reported in 105 (20%) of these cases. In the above cohort, 200 patients were ≤50 years old. RS 0-10 was reported in 39 (19,5%) and RS<16 in 99 (49,5%) of these cases. Further stratification of patients ≤50 years old according to their clinical risk status, identified 163 (81,5%) of them as high clinical risk (T2/G2, G3). RS 0-10 was reported in 25 (15%) and RS<16 in 74 (45,4%) of these cases.
Conclusion: Among breast cancer patients with pT2N0, cM0 ER+/HER2- tumors, 20% had a RS<11. All these patients based on the AJCC 8th Edition Cancer Staging Manual are assigned Pathological Prognostic Stage Group IA. These patients based on TAILORx data have 0,7% distant recurrence risk at 5 years, 3% distant recurrence risk at 9 years and no

chemotherapy benefit. Among younger patients (≤50 years) with pT2N0, cM0 ER+/HER2- tumors, the same percentage (19,5%) had a RS<11 (Pathological Prognostic Stage Group IA). Also, 49,5% out of them had a RS 0-15 and should be treated with only endocrine therapy based on NCCN Guidelines.Additionally, taking into consideration the clinical risk status of the younger patients (≤50 years), 45,4% of those with high clinical risk had a RS<16 and could safely forego chemotherapy.These findings highlight the critical role of Oncotype DX in enhancing risk stratification, predicting recurrence, and guiding treatment decisions for patients with ER+/HER2-/pT2N0, cM0 breast cancer.

P4-08-01: pionERA Breast Cancer: Phase 3 study of first-line giredestrant vs fulvestrant, + a CDK4/6 inhibitor, in patients with estrogen receptor+, HER2- locally advanced/metastatic breast cancer with resistance to prior adjuvant endocrine therapy

Kevin Kalinsky, Rinath Jeselsohn, Meritxell Bellet, Peter Fasching, Gonzalo Gomez-Abuin, Kyung Hae Jung, Sandrine Lavallé, Vanesa Lopez Valverde, Yen-Shen Lu, Richard Schwab, Nicholas Turner, Vanessa Breton, Alberto Zambelli, Fabrice André

Background: Patients (pts) with estrogen receptor-positive, HER2-negative, locally advanced/metastatic breast cancer (ER+, HER2– LA/mBC) who relapse on/after adjuvant endocrine therapy (adj ET) and have endocrine resistance have a high unmet need. For pts who relapse on/or <12 months after adj ET, fulvestrant plus a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is first-line (1L) standard of care. However, fulvestrant has limited efficacy in pts with ESR1-mutated tumors and requires monthly intramuscular injections that negatively impact quality of life (QoL). New treatment options, such as combinations of an oral selective ER degrader (SERD) plus a CDK4/6i (beyond palbociclib) are needed to improve survival, QoL, tolerability, and adherence.
Giredestrant is a highly potent, nonsteroidal, oral SERD that achieves robust ER occupancy and is active regardless of ESR1 mutation status. Giredestrant was well tolerated with promising activity as monotherapy and in combination with any approved CDK4/6i in Phase I/II studies in ER+, HER2– BC. pionERA BC is the first study to investigate an oral SERD (giredestrant) plus investigator's choice of CDK4/6i in pts with 1L ET-resistant ER+, HER2– LA/mBC.
Methods: pionERA BC (NCT06065784) is a Phase III, global, randomized, open-label, multicenter study in pts with ER+, HER2– LA/mBC with resistance to prior adj ET. Pts will be randomized 1:1 to receive giredestrant (30 mg orally, once daily) or fulvestrant (500 mg intramuscularly on Days 1 and 15 of Cycle 1 [28-day cycles], then on Day 1 of subsequent cycles), in combination with investigator's choice of CDK4/6i (palbociclib, abemaciclib, or ribociclib administered per local prescribing information), stratified by: prior adj CDK4/6i (yes vs. no); choice of CDK4/6i; ESR1 mutation status by central testing (ESR1 mutated vs. ESR1 no mutation detected [ESR1nmd]); disease site (visceral vs. non-visceral). Pts will receive treatment until disease progression, unacceptable toxicity, death, or withdrawal of consent.

Eligibility: female/male pts with ER+, HER2– LA/mBC; relapse on prior standard adj ET on treatment after ≥12 months or off treatment within 12 months of completion (prior neoadj/adj CDK4/6i allowed); no prior systemic treatment for LA/mBC; documented ESR1 mutation status by circulating tumor DNA. Enrollment of pts with ESR1nmd tumors will be capped at 60% of the total study population.
Dual primary endpoints (EPs): investigator assessed progression-free survival (PFS) in the ESR1 mutated population and in the full analysis set (per RECIST v1.1). Secondary EPs: PFS (ESR1nmd population); overall survival (OS); investigator assessed confirmed overall response rate; duration of response; clinical benefit rate (per RECIST v1.1); time to chemotherapy; safety; pt-reported outcomes (time to confirmed deterioration in pain, physical and role functioning, global health status/QoL).
The dual primary EPs will be compared between treatment arms using a stratified log-rank test at an overall 0.05 significance level (two-sided). PFS will be assessed using a hierarchical fixed-sequence testing approach. An interim OS analysis is planned at the time of the primary PFS analysis; an independent data monitoring committee review the safety data.
Target enrollment: 1050 pts; recruitment ongoing.

P4-08-02: Identifying unique transcriptomes associated with HER2+ breast cancer recurrence at the single-cell level.

Paola A. Marignani, Jinhong Kim

Precision medicine aims to provide more effective treatments, detect disease earlier and improve patient outcomes. The development of more targeted therapies relies on advanced technologies like transcriptomics and machine learning to identify new and unique markers of a person's cancer. Breast cancer remains one of the leading causes of cancer-deaths amongst women world-wide, with 670,000 deaths world-wide in 2022, thus breast cancer is ranked as the second most common cancer globally, and the number one cancer amongst women. HER2 positive (HER2+) breast cancer accounts for 20-30% of all breast cancer cases and is highly aggressive. The mortality rates for HER2+ are higher than other breast cancer subtypes. When treated with Herceptin, survival rates are good, however approximately 20-30% of cases experience recurrence and metastasis. Our question is whether HER2+ breast cancers express transcriptomic signatures that are distinguishable between non-recurrence and recurrence.
Objective: The objective of our research is to interrogate breast cancers at the single cell level to identify new predictive biomarkers associated with HER2+ breast cancer recurrence using a single-cell microfluidics platform coupled with DNA barcoding genome-wide single-cell RNA-sequencing (scRNA-seq) and machine learning. Specifically, scRNA-seq allows one to study the heterogeneity of breast cancer cells to better understand molecular

mechanisms that support tumorigenesis and recurrence. Herein, we detail the analysis of scRNAseq analysis of resected primary HER2+ breast cancers from patients that received Herceptin adjuvant therapy.
Methods: Single-cell transcriptomes (10X Genomics) were characterized from 8 patients identified with HER2+ breast tumors that were treated with Herceptin adjuvant therapy. From these patients, four did not experience recurrence, while four did experience recurrence within 5 years of Herceptin treatment. Tumors were prepared for scRNAseq analysis, followed by computational analysis of data.
Results: From the 80,000 single nuclei analyzed, we obtained 5.9 billion reads and detected a total of 27,303 genes following quality processing and read mapping. We performed dimension reduction and clustering analysis at pseudo-bulk level merging normal (8 samples), recurred tumor (4 samples) and non-recurred (4 samples) data. We annotated individual cells in each of the three merged data with 14 different cell types. We found 5,147 DEGs (Avg. 514) are common between the recurred and non-recurred samples, while 62.8% (8,691; avg. 869) DEGs and 66.8% (10,344; avg. 1,034) DEGs were specific to recurred and non-recurred data, respectively. Next, we applied GSEA for transcriptomic characterization using multiple reference databases such as transcription factor (TF) collection, biological pathways, hallmark gene sets and gene ontology (GO) terms. We identified 683 (203 unique) and 1,025 (379 unique) TFs were enriched in recurred and non-recurred tumors, respectively. The number of enriched biological pathways revealed that 50 of 62 pathways were activated in non-recurred tumor cells compared with recurred tumor cells where 38 of 62 pathways were activated.
Summary: The outcome of our study reveals significant molecular distinction between recurrent and non-recurrent HER2+ breast cancers, suggesting potential biomarkers for predicting recurrence. Specifically, the identified DEGs and enriched pathways could serve as targets for developing new therapies aimed at preventing recurrence. Future studies will include the integration of scRNAseq data with other omics technologies for a comprehensive understanding of recurrence mechanisms.
PM is supported by Breast Cancer Canada.

P4-08-04: Selective activity of rogaratinib in PIK3CA- and ESR1-wild-type, FGFR1/2-amplified hormone receptor-positive breast cancer (HR+/HER2- BC): a co-clinical trial

Silvana Mouron, María J. Bueno, Silvia Calabuig, Laura Muinelo, Noelia Martínez-Jañez, Sonia Pernas, José Ángel García Saenz, Serafín Morales, Begoña Bermejo, Juan Antonio Guerra, Rodrigo Sánchez-Bayona, Pablo Tolosa, Manuel Alva, Eva Ciruelos, Miguel Quintela-Fandino

Introduction: FGFR1/2 amplification is associated with poor outcomes and treatment resistance in HR+/HER2- BC. However, FGFR inhibitors have shown limited activity in this disease. Recently, we demonstrated that complete cell cycle arrest was only achieved if FGFR inhibitors were combined with CDK4/6i and endocrine treatment (ET) in FGFR-

amplified breast cancer models (PMID33579347). Co-clinical trials (different study designs involving concurrent patient treatment and model testing) aim to expedite and enhance the translation of laboratory discoveries to clinical practice. Thus, we conducted a co-clinical trial with patient-derived tumor organoids (PDTOs) resistant to CDK4/6i and ET and a phase-I clinical trial of fulvestrant, palbociclib and the pan-FGFR inhibitor rogaratinib in women progressing to first-line CDK4/6i combined aromatase inhibitor (AI).
Methods: PDTOs: 4 PDTOs, 3 FGFR1-amplified and 1 FGFR1-non-amplified. Among the amplified, one (H12-5) was PIK3CA mutant (H1047R); one (H12-31) was ESR1 mutant (Y537S); and one (H12-7) was wild-type for both genes; the FGFR1-non-amplified (H12-28) was double wild-type as well. PDTOs viability was explored in response to rogaratinib, fulvestrant, palbociclib, camizestrant, and alpelisib in monotherapy or in combinations. Trial: dose-escalation, multi-centric clinical trial. Women >18 years old with metastatic HR+/HER2- BC progressing to a combination of CDK4/6i plus AI in the first-line, candidates for second-line therapy. Patients were pre-screened for FGFR1/2 amplification (FISH) or overexpression (RNAScope) in a recent tumor sample. Treatment consisted on 28-day cycles of fulvestrant 500 ug in day 1 (and day 15 on cycle 1), palbociclib 100 mg in days 1-21, and rogaratinib bid in days 1-28. Rogaratinib started at 400 mg/bid and was escalated in 200 mg intervals; palbociclib could be escalated to 125 on cycle 2.
Results: PDTOs: the 4 PDTOs were refractory to fulvestrant, palbociclib, and the combination. Rogaratinib monotherapy only displayed modest activity in H12-31. The triple-combination of fulvestrant, palbociclib (1uM each) and increasing rogaratinib was highly effective in H12-7, but lacked activity in H12-5, H12-31 and H12-28 (an FGFR-amplified variant of the latter turned sensitive to the combination). PDTOs H12-5 and H12-31 were re-sensitized by replacing palbociclib for alpelisib and fulvestrant for camizestrant, respectively. Trial: 67 patients were screened; 29 (43%) were positive for FGFR1/2 amplification and/or overexpression. The RP2D was established at 500 ug fulvestrant, 100 mg palbociclib (days 1-21) and rogaratinib 600 mg/bid. Nine patients were treated. The most frequent grade 1/2 toxicity were hyperphosphatemia (77% of patients) and diarrhea (33%). Grade 3 neutropenia occurred in 66.7% of the patients; grade 3 asthenia, diarrhea and hyperphosphatemia were observed in 11.1% of the patients each. Median PFS was 3.5 months.
Five patients displayed PIK3CA and/or ESR1 mutations in the tumor or plasma sample, and 4 were wild-type for both. All double wild-type patients remained PFS for longer than 6-months (185-330 days), and the PFS time comparison between double wild-type against PIK3CA/ESR1-mutant patients favored the former by an almost 5-fold advantage: 274 vs 58 days; P=0.005.
Conclusion: A high percentage (43%) of second-line HR+/HER2- BC displays FGFR1/2 overexpression or amplification, of which approximately half are wild-type for ESR1 and PIK3CA. FGFR1/2 inhibition with rogaratinib in combination with palbociclib and fulvestrant is active in second-line, FGFR1/2-amplified/overexpressed HR+/HER2- BC, but the activity is restricted to wild-type PIK3CA/ESR1 patients. These results frame the population in which the development of this combination should be focused.

P4-08-05: A Phase Ib/II trial of Lenvatinib plus Pembrolizumab plus Fulvestrant in ER+/HER2- Metastatic Breast Cancer (MBC)

Sherry Shen, Stephanie Downs-Canner, Fresia Pareja, Yuan Chen, Karen Suarez, Meagan Ramirez, Sonya Chew, Elaine M. Walsh, Komal Jhaveri

Background: The prognosis for endocrine-resistant ER+/HER2- MBC remains poor and novel therapeutic strategies are urgently needed. Immunotherapy is FDA-approved in triple negative breast cancer but has not shown significant efficacy in ER+ BC. This is likely due to differences in immunogenicity, as ER+ tumors are characterized by low levels of tumor-infiltrating lymphocytes, lower mutational load, and lower PDL1 expression; furthermore, driver alterations associated with ER+ BC can contribute to suppressing immunity. Single-agent immunotherapy has yielded low overall response rates (ORR) in this subtype; priming strategies that improve immunogenicity are needed. Lenvatinib is a multitargeted tyrosine kinase inhibitor that inhibits VEGF, FGFR, PDGFRa, RET, and KIT, leading to modulation of the tumor microenvironment by decreasing regulatory T cells and tumor-associated macrophages. The combination of lenvatinib + pembrolizumab is superior to standard therapies in renal cell carcinoma and endometrial cancer and is FDA-approved in these settings.
Methods: This is a single-center, open-label, phase Ib/II trial of lenvatinib + pembrolizumab + fulvestrant for ER+/HER2- MBC. The objective of this study is to test the efficacy of this triplet combination. Enrolled patients undergo a pre-treatment biopsy and initiate a 2-week lead-in of lenvatinib 20mg PO daily + fulvestrant 500mg IM, after which they undergo an on-treatment biopsy and pembrolizumab 400mg IV q6 weeks is added. Key eligibility criteria include progression on at least 1 prior endocrine therapy combined with a CDK4/6 inhibitor, ≤2 lines of chemotherapy in the metastatic setting, measurable disease per RECIST v1.1, ECOG performance status 0-1, adequately controlled blood pressure of ≤150/90 mmHg with or without anti-hypertensive medications, and adequate organ function. Prior fulvestrant is allowed. Patients with autoimmune disease, prior immunotherapy exposure, or baseline proteinuria are excluded. During the phase Ib safety lead-in portion, a maximum of 6 patients will be enrolled to assess the safety/tolerability of the triplet combination at each dose level, with three dose levels of lenvatinib tested under a dose de-escalation design. Once the maximum tolerated dose (MTD)/ recommended phase II dose (RP2D) of lenvatinib is confirmed, the study will proceed to phase II using a Simon's optimal two-stage design. The primary endpoint of phase II is best ORR by week 24 using RECIST 1.1. Additional secondary endpoints include clinical benefit rate, progression-free survival, duration of response, and safety/tolerability of the triplet combination. With 43 patients, we will have 80% power to compare an estimated ORR of 25% to a historical control ORR of 10% under a Type I error of 5%. This trial opened to accrual January 2024. Clinical trial registry number: NCT06110793]

P4-08-06: Onvansertib enhances the anti-tumor efficacy of trastuzumab deruxtecan in CDK4/6 inhibitor-resistant HR+/HER2- breast cancer patient-derived xenograft models

Sreeja Sreekumar, Elodie Montaudon, Heloise Derrien, Ahmed Dahmani, Tod Smeal, Elisabetta Marangoni, Maya Ridinger

Background: The preferred first-line treatments for hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer is the combination of endocrine therapy and CDK4/6 inhibitors like abemaciclib or palbociclib. Although these regimens are effective, most patients eventually develop resistance leading to disease progression. At this stage, patients typically receive endocrine therapy with or without targeted therapy, followed by chemotherapy. Trastuzumab deruxtecan (T-DXd, Enhertu) is a HER2-directed antibody-drug conjugate with a topoisomerase I (Top1) inhibitor payload. T-DXd is approved for metastatic HER2-low (IHC 1+ or 2+/ISH-) breast cancer patients who have received prior chemotherapy in the metastatic setting or developed disease recurrence within six months of completing adjuvant chemotherapy. Combination therapeutic strategies may be able to extend the clinical benefit of T-DXd. Onvansertib is a highly potent, and selective polo-like kinase 1 (PLK1) inhibitor in clinical development. The combination of onvansertib and irinotecan, a Top1 inhibitor, has shown efficacy in colorectal cancer preclinical models and is currently under clinical evaluation. Here, we investigated the potential of onvansertib to increase the activity of T-DXd in HR+/HER2- breast cancer patient-derived xenograft (PDX) models resistant to CDK4/6 inhibitors and endocrine therapy.
Methods: Four PDX models were established from primary breast tumor (HBCx-3), metastatic bone biopsies (HBCx-180, HBCx-139palbo+fulvR5) and metastatic breast tumor (HBCx-246). The HBCx-246 PDX was resistant to the combination of fulvestrant and abemaciclib, while the other models were resistant to fulvestrant plus palbociclib. PDX tumors were engrafted in nude mice, and were treated with vehicle, onvansertib (oral, 45 mg/kg, 5 days a week), T-DXd (IV, 4 or 10 mg/kg, once every three weeks), or the combination. Tumor growth inhibition (TGI) was calculated as 100% x (Vcontrol-Vtreated)/Vcontrol).
Results: The combination of onvansertib and T-DXd was well tolerated and showed robust antitumor activity in three out of the four PDX models tested. In the HBCx-3 PDX model, the combination therapy caused tumor regression in all mice, whereas onvansertib treatment resulted in tumor progression and T-DXd monotherapy led to tumor stasis. In the metastasis-derived HBCx-139palbo+fulvR5 PDX model, the combination effectively inhibited tumor growth (TGI = 88%) compared to onvansertib (TGI = 54%) and T-DXd (TGI = 68%) monotherapies. Similarly, in the HBCx-246 model, the combination therapy induced profound anti-tumor activity, achieving an 89% TGI compared to 74% TGI with onvansertib and 54% TGI with T-DXd. The effect of the combination in the three responsive models was durable, with significant improvement in event-free survival compared to the monotherapies.
Conclusions: Our preclinical findings strongly support the rationale for combining T-DXd

with the PLK1 inhibitor onvansertib. The combination represents a promising therapeutic strategy for HR+/HER2- breast cancer patients resistant to first-line therapies and merits clinical evaluation.

P4-08-07: Survival outcome in patients with metastatic breast cancer with low hormonal receptor expression

Ahrong Ham, Sewon Lee, Jungmin Jo, Soo Ji Hong, Ji Eun Lee, Haena Lee, Sungchan Gwark, Jeongshin An, Hyun Goo Kim, Jun Woo Lee, Joohyun Woo, Woosung Lim, Byung-In Moon, Sei Hyun Ahn, Hye Ah Lee

Purpose: In the treatment of hormonal receptor positive(HR+) metastatic breast cancer(MBC), various guidelines recommend endocrine therapy as the first-line drug for quality of life if there is no visceral crisis, and recommend an endocrine approach for subsequent therapy as well. However, cases with low hormonal expression have poor endocrine responses even if they are HR+ metastatic breast cancer by definition. In this study, we aimed to compare the survival outcomes of such low HR+ metastatic breast cancer patients.
Method: This study included the patients with metastatic/recurrent breast cancer who has been diagnosed from January 2000 to December 2022 in our institution. Patients were classified according to the level or percentage of estrogen receptor (ER) and progesterone receptor(PR) expression in tumor tissue using immunohistochemistry. Low HR+ was defined with Allred score 3~4 or 1%~10% of ER and PR expression. We classified HER2 negative patients into HR negative, HR low, and HR high groups and retrospectively analyzed their clinical characteristics and survival outcomes. Patient characteristics were compared among the patient groups using Pearson's chi-square test and Kruskall-Wallis tests. The statistical analysis was performed using Kaplan-Meier survival analysis.
Result: A total of 679 MBC patients were enrolled during the period, of which HER2- patients were 455 (67.0%), and of whom HR-, HR low, HR high and unknown were 134 (29.5%), 27 (5.9%), 274 (60.2%) and 20(4.4%), respectively. Median age of HER2-/confirmed HR status 435 patients was 47 years-old (40-55), 430 patients (98.9%) were female and 280 patients (64.4%) showed pre-menopausal status. There were 130 patients (29.9%) with visceral metastasis, 79 (20.3%) were overweight, and 132 (33.8%) were obese. During a median follow-up of 45.7 months, the median overall survival (OS) of the HR low subgroup was 47.9 (95% CI 2.5-93.4), which was lower than that of the HR high group (71.3 months, 95% CI 57.2-85.5), (Log rank p=0.134), and higher than that of the HR- group 28.9 (95% CI 15.7-42.0), (Log rank p=0.390). Median progression-free survival (PFS) for first-line endocrine therapy in the metastatic setting was lower in the HR low group than in the HR high group, but there was no statistical significance (6.0 vs. 16.5 months, Log rank p=0.234).
Conclusion: Endocrine therapy is an important means in HR positive MBC, but oncologic outcomes may be worse for HR low patients than for HR high patients. Therefore, it is

necessary to identify clinical and biologic factors that can guide endocrine therapy and subsequent therapies in HR low MBC patients.

P4-08-08: Real-world data on cyclin-dependent kinase 4/6 inhibitor switching in patients with first-line hormone receptor-positive, HER2-negative metastatic breast cancer

Lu Chen, Matthew H. Secrest, Vanesa López Valverde, Pablo Diego Pérez-Moreno, Alberto Zambelli, Kevin Kalinsky

Background: Standard-of-care first-line (1L) treatment for hormone receptor-positive, HER2-negative metastatic breast cancer (HR+, HER2– mBC) is endocrine therapy + a cyclin-dependent kinase 4/6 inhibitor (ET + CDK4/6i). There are limited data on switching between CDK4/6is in HR+, HER2– mBC after discontinuing a CDK4/6i due to toxicity, with a recent European real-world data (RWD) study suggesting that CDK4/6i switching is rare. We present RWD from a large US population to evaluate CDK4/6i switching frequency and patterns in a broad cohort of patients treated for HR+, HER2– mBC in the 1L, and in a sub-cohort of patients with ET resistance (ETR), to assess whether switching differs in the ETR population. We also assess whether choice of backbone ET impacts CDK4/6i switching patterns.

Methods: This retrospective cohort study used nationwide (US-based) de-identified electronic health record-derived data from the Flatiron Health database. Selection criteria included adult patients with HR+, HER2– mBC who started 1L ET + CDK4/6i treatment between March 1, 2018 and June 1, 2023, with no adjuvant abemaciclib (abema) ≤1 year prior to mBC diagnosis. Switching was defined as receipt of a new CDK4/6i after the 1L start date and before the earliest occurrence of any of the following: disease progression, start of new anti-cancer therapy that was not a replacement CDK4/6i, data cutoff, or death. In patients with recorded adjuvant ET information, ETR was defined as having a duration of adjuvant ET of 12 months or longer and developing metastatic relapses while on ET or within 12 months of ET completion.

Result: Baseline characteristics were similar across CDK4/6is in the overall cohort (N = 4,320); 70% of patients received 1L treatment with an aromatase inhibitor (AI) versus 30% with fulvestrant (FUL). In the ETR sub-cohort (n = 1,080), 39% of patients had 1L AI versus 61% who had FUL. 1L CDK4/6i segmentation was similar between the overall cohort/ETR sub-cohort: palbociclib (palbo) 74%/75%; abema 15%/15%; ribociclib (ribo) 12%/10%. CDK4/6i switching occurred in 3%, 11%, and 10% of 1L palbo-, abema-, and ribo-treated patients, respectively, in the overall cohort and in patients with ETR. The proportion of patients who switched was similar in FUL-treated patients (4%, 13%, and 13% switched from palbo, abema, and ribo, respectively) versus AI-treated patients (3%, 10%, and 10%). Switching prevalence remained similar throughout the 2018–2023 period. In patients who switched from 1L palbo, the majority (69%) received abema as the replacement CDK4/6i. In

patients who switched from 1L abema or ribo, palbo was the most used replacement (in 84% and 74% of patients, respectively). In the ETR sub-cohort, all patients in the 1L abema subgroup who switched CDK4/6is replaced it with palbo, versus 83% of the patients who switched in the 1L ribo subgroup. Median time from start of 1L treatment to switching was 3.3–5.0 months in the overall cohort and 1.5–4.7 months in the ETR sub-cohort.

Conclusions: These RWD show that CDK4/6i switching frequency is generally uncommon, with the frequency being higher in patients who received 1L abema or ribo versus palbo, consistent with discontinuation rates reported in the respective trials. Palbo was the most used option when switching CDK4/6is, and switching patterns were not impacted by the choice of backbone ET or by ETR. Limitations include the use of data from a single country only, the lack of available data on the use of dose reductions prior to CDK4/6i switching, and the emergence of newer data that may impact physicians' preferred choice of CDK4/6i.

P4-08-09: Phase 3, Randomized, Open-label TroFuse-010 Study of Sacituzumab Tirumotecan (sac-TMT) Alone & W/ Pembrolizumab vs. Treatment of Physician's Choice Chemotherapy in Patients With HR+/HER2- Unresectable Locally Advanced or Metastatic Breast Cancer

Sara M. Tolaney, Paolo D'Amico, Liyi Jia, Kim M. Hirshfield, Fatima Cardoso

Background: Additional therapies are needed to improve outcomes in patients with HR+/HER2- breast cancer that progressed on endocrine therapy (ET) plus CDK4/6 inhibitors (CDK4/6i). Trophoblast cell surface antigen 2 (TROP2) is commonly overexpressed in patients with HR+/HER2- metastatic breast cancer (mBC) and is associated with poor prognosis. Sac-TMT (also known as MK-2870/SKB264) is a novel anti-TROP2 antibody-drug conjugate composed of an anti-TROP2 antibody coupled to a cytotoxic belotecan derivative via a novel linker (average drug/antibody ratio, 7.4). In a phase 1/2 study, intravenous (IV) sac-TMT alone had antitumor activity in patients with previously treated HR+/HER2- mBC (ORR, 36.8%). TroFuse-010 evaluates sac-TMT alone or with pembrolizumab vs treatment of physician's choice chemotherapy (TPC) in patients with HR+/HER2- unresectable locally advanced or mBC who have not previously received chemotherapy.
Methods: This phase 3, randomized, open-label study (NCT06312176) is enrolling patients ≥18 y with HR+/HER2- unresectable locally advanced or mBC, ECOG PS ≤1, and a tumor sample for central assessment of TROP2 expression and HR, HER2, and PD-L1 status. Patients are candidates for chemotherapy and had either (a) PD after ≥1 line of ET, 1 of which was with a CDK4/6i, (b) PD ≤6 mo after starting 1L ET plus CDK4/6i where the CDK4/6i was discontinued before the PD, (c) PD >6 mo after starting 1L ET plus CDK4/6i (where the CDK4/6i was discontinued before the PD) and PD on an additional ET (either as monotherapy or combined with a PI3K or mTOR inhibitor), or (d) relapse during or ≤12 mo after completing CDK4/6i given as adjuvant therapy together with ET. Key exclusion criteria are prior treatment with chemotherapy in the metastatic setting and, if treated with prior

(neo)adjuvant chemotherapy, recurrence ≤6 mo after completion of chemotherapy. Patients are randomized 3:3:2 to receive IV sac-TMT 4 mg/kg Q2W, IV sac-TMT 4 mg/kg Q2W plus pembrolizumab 400 mg Q6W, or TPC (paclitaxel, nab-paclitaxel, capecitabine, or liposomal doxorubicin) until radiographic PD, unacceptable toxicity, patient withdrawal, or discontinuation criteria are met. Randomization is stratified by PD-L1 combined positive score (<1 vs 1-9 vs ≥10), TROP2 expression (low/medium vs high), and region (Western Europe vs North America vs Rest of World). Primary endpoints are PFS per RECIST v1.1 by blinded independent central review (BICR) with sac-TMT vs TPC and sac-TMT plus pembrolizumab vs TPC. Secondary endpoints include OS, PFS per RECIST v1.1 by BICR with sac-TMT plus pembrolizumab vs sac-TMT, ORR, duration of response, patient-reported outcomes, and safety. Tumor imaging occurs at baseline, Q9W through week 54, and Q12W thereafter. Recruitment began in April 2024.

P4-08-10: Correlation between prior treatments on CDK4/6 Inhibitors Survival in Hormone receptor-positive metastatic breast cancer

Elina Rodriguez-Melendez, Evelyn Valencia, Katherine García Matamoros, Mayra Santacruz, Felipe Campoverde, Ruth Engracia Vivanco

Background: Breast cancer (BC) is the second most common type of neoplasm wordwide. According to GLOBOCAN 2022, the incidence of breast cancer in Ecuador is 39.5 per 100,000 people/year, with a mortality rate of 11.2 per 100,000 people/year, and represents 12,6% of new cases.
Our health system provides coverage to approximately 60& of the population by th Ministry of Public Health (MSP), 30% by The Ecuatorian Social Security Institute (IESS), 5% by other entities (ISSFA, ISSPOL), and <3% of the population have private medical coverage. Medical care attentions for BC covered by the MSP was 7,134 consults in 2013, with an increase to 8,767 in 2018.
SOLCA Guayaquil, as a national reference center, provides 24,425 oncologic consults per year, 38% correspond to BC. The proportion of clinical stage IV BC varies from 5-10% with and average of 6% in urban areas, reaching up to the 50% in rural areas, so metastatic BC is a public health challenge, especially for countries with emerging economies like ours.
Methods: We conducted an observational, retrospective, case control single center study. All patients with Hormone receptor positive (HR+)/Her 2 negative metastatic BC who had been treated at SOLCA Guayaquil, in the period from 2016 to 2020 were included in the analysis. The clinical and pathological characteristics were recorded, and Pearson linear correlations were determined.
Results: A total of 1,113 patients with BC attended in the period 2016-2020 were included, of which 84 had de novo metastatic BC (7,6%). Of these patients, 37,1% (31 patients) were HR+/HER2 negative BC subtype, which were treated with various chemotherapy protocols. It was evidenced that 19 patients with luminal metastatic BC received cyclin inhibitors in some line of treatment. The average age of the patients in the iCDK4/6 group was 54 years vs. 52 years in the chemotherapy arm. The origen of the patients was mostly from Guayas,

with 61,9% in the iCDK4/6 arm vs 73,3% in the chemotherapy arm. The coverage of the patients in the iCDK4/6 arm was 76,2% by IESS, 19% MSP, and 4,8% institutional, unlike the chemotherapy arm which the coverage was 60% institutional, 26,7% IESS, and 10% MSP. Patients who received CDK4/6 inhibitors has a median indication in the third line of treatment, ranging from first to seventh line of treatment; with a DFS (disease free survival) of 9,05months, and Overal Survival 18,68 months. A Pearson linear correlation between line of CDK4/6 treatment vs. DFS was determined at -0.519, tralating to a moderate negative correlation. Similarly, the waiting time to start iCDK4/6 treatment vs. DFS reported a weak negative correlation of -0.181.
Conclusions: In our population metastatic BC occurs in 7,6%, similar to the reported worldwide. Among the subgroup of luminal metastatic patients, only 19 of them could access CDK4/6 inhibitors in some line of treatment, with an average indication in the third line. It was evidenced that the vast mayority of these patients had some type of health coverage, either IESS or MSP, unlike the chemotherapy arm, where 60% had no health coverage; implying that the patient self-financed the treatment, which could have limited access to iCDK4/6 treatment due to the high cost of medication. Pearson`s correlation analysis evidenced an inversely proportional relationship between the line of treatment and DFS, meaning the later the indication of iCDK4/6 reatment, the shorter the progression time of the disease, and consequently, the shorter OS. The results of the main studies of cyclin inhibitors such as PALOMA 3 TRIAL shows DFS of 9,2 monts vs 3,8 monts in placebo arm, OS 34,9 monts, vs 28 months; and MONALEESA 3 TRIAL shows DFS 20,6 months vs. 12,8 months with placebo, OS 67,6 months vs. 51,8 months, which drastically differ from our reality.
Our results differ from main trials, probably due to the lack of access to target medicine and difficulties in accessing health caer. Thus, better strategies for early access to adequate systemic treatment protocols should be developed.

P4-08-11: Linc01588-V4 is UPR-downregulated lncRNA in a PERK-dependent manner and estrogen-responsive gene mediated cell proliferation and migration of ER+ breast cancer cells

Wen Liu, Sanjeev Gupta, Ananya Gupta, Wenyuan Zhao, Qian Xu

Background: Physiological or pathological processes that disturb protein folding in the endoplasmic reticulum cause a state known as endoplasmic reticulum stress (ER stress) and then activate a set of signalling pathways termed the Unfolded Protein Response (UPR). This concerted and complex cellular response is mediated by three molecular sensors, PKR-like ER kinase (PERK), activated transcription factor 6 (ATF6), and inositol-requiring enzyme 1 (IRE1). UPR is mostly associated with adaptive signalling, allowing cancer cells to cope with adverse environmental conditions and conferring therapy resistance. Long noncoding RNA (lncRNA) belongs to a class of non-protein coding transcripts longer than 200 nucleotides. However, not much is known about UPR-regulated lncRNA and the causative effect of lncRNA in affecting ER stress responses and cancer development. Recent

studies have highlighted the role of interaction between the UPR and the estrogen signaling pathway in contributing to endocrine resistance. Here we have evaluated the role of UPR-regulated and estrogen-responsive lncRNA in breast cancer.
Method: Gene Expression Profiling Interactive Analysis, an interactive web server developed to analyze the RNA sequencing expression data, was used to analyze the Linc01588 expression across all cancers and overall survival in breast cancer patients. Expression of all Linc01588 variants V1-V5 in breast cancer cell lines was verified by conventional PCR. Additionally, UPR-induced and estrogen-responsive Linc01588 was assessed using RT-qPCR in ER+ breast cancer cell lines treated with UPR inducers Brefeldin A and Thapsigargin or estrogen (E2) and estrogen receptors-targeted Tamoxifen and Fulvestrant. Furthermore, sub-clones of MCF7 cells deficient in downstream UPR signalling were utilized to further validate the regulatory mechanisms of Linc01588 in response to UPR stimulation. Linc01588 knockdown clones in MCF7 and T47D generated by the lentivirus strategy were used to investigate the functional mechanism of cell proliferation and migration.
Results: Linc01588 expression is increased in primary and metastatic breast cancer as compared with normal breast tissue. Increased Linc01588 expression was associated with poor overall survival in ER+ and HER2-amplified breast cancer patients but not in TNBC. There are 5 isoforms of Linc01588 and variant 4 (Linc01588-V4) and variant 5 (Linc01588-V5) were two main predominantly expressed variants in breast cancer cell lines. Linc01588-V4 expression was downregulated upon treatment with UPR inducers in ER+ breast cancer cell lines in a PERK-dependent manner. Furthermore, the expression of Linc01588-V4 was markedly elevated in ER+ breast cancer cell lines upon E2-stimulation and 293T cells transiently transfected with estrogen receptors (ERα). Tamoxifen treatment increased Linc01588-V4 expression in MCF7 cells but not in T47D cells. The Linc01588-V5 was downregulated by UPR inducers but not affected by E2, ERα, Tamoxifen, and Fulvestrant. Knockdown of Linc01588-V4 in MCF7 and T47D cells reduced cell proliferation and migration but had no effect on the expression of ERα protein and induction of E2-responsive genes.
Conclusion: We have identified Linc01588-V4 as an estrogen-responsive lncRNA which can regulate cell proliferation and migration of ER+ breast cancer cells.

P4-08-12: Second-line, post-CDKi treatment of metastatic ER+ HER2-negative breast cancer (ER+mBC): The impact of a 25-minute CME video on treatment choices of community-based general medical oncologists (GMOs)

Kathryn Ziel, Taylor Wallace, Komal Jhaveri, Trenton Cruse, Leijah Petelka, Doug Paley, Kirsten Miller, Neil Love

Background: The recent introduction of oral selective estrogen receptor degraders (SERDs) and PIK3CA/AKT/PTEN inhibitors into clinical practice has added complexity to the rapidly evolving biomarker-based management of ER+mBC in patients with disease progression on

a CDKi and endocrine therapy (ET). For almost 40 years our CME group has utilized and evaluated practical, efficient mechanisms to inform GMOs. An important focus has been the use of audio content (cassettes > CDs > podcasts), which allows multitasking (exercise, commuting). Another valuable media tool is video which has evolved from a clumsy, costly analog base to a digital and online platform with profound potential impact. More recently videos are increasingly distributed by email and social media. Since the COVID-19 pandemic along with the widespread availability of telerecording and teleconferencing, our group has increasingly turned to short- and intermediate-form video to deliver oncology education content. For this project, we investigated the impact of a concisely produced video featuring a prominent clinical investigator (KJ) discussing her preferred treatment approach for ER+mBC as well as results of a related survey of the practice patterns of 20 US-based breast cancer clinical investigators. Key survey variables included age, biomarker profile, disease location and time on prior CDKi.

Methods: We recruited 24 US-based GMOs from geographically diverse locations who have presented cases in 1 or more of our CME programs. Participants filled out an online survey that included common clinical scenarios and then viewed a 25-minute highly edited video discussing second-line, post-CDKi treatment decisions specifically with respect to preferred choice of therapy, based on biomarker profile, disease burden and duration of prior CDKi/endocrine treatment (ET). After viewing the video, participants repeated the online survey.

Results: 19 of 24 GMOs stated that they planned to make significant changes to their practices after viewing the program. Overall, in 8 basic scenarios (4 featured in the table), the 24 GMOs answered 192 treatment-based questions and in 67 instances (35%) treatment changed after viewing the video.

Patient subsets of particular interest (see Table) included:

1. ESR1+; PIK3CA WT: For a patient with relapse at 18 months (4/24 GMOs switched to a SERD). For a patient with relapse at 6 months (12/24 switched choices).
2. ESR1+ and PIK3CA+: The split between Capi and E relates to preferred tolerability of a SERD but questions about benefits related to optimal sequencing. Again, for relapse within 6 months on a CDKi 13/24 (54%) changed their treatment decisions.

Additional data: For patients with PIK3CA mutations only, Capi was preferred to alpelisib 19/24 (79%). Of an additional 96 treatment-decision questions 30 GMOs changed their clinical approach after viewing the video (31%).

Conclusions: For this project, we specifically recruited informed GMOs who have been confident enough to present cases on our webinars. However, after being presented with 25 minutes of highly concise video content, almost a third of these very important decisions changed.

While many appreciate the rapid advances in endocrine therapy for breast cancers, the findings here support a quieter revolution not widely appreciated: the simultaneous technologic advances in digital media production and the instant post-pandemic cultural adaption of teleconferencing and recording. In coming months, we will evaluate social media platforms and other methods to reach other audiences, including patients.

P4-08-13: Evaluating CYP3A4-Mediated Drug Interaction Risks for Vepdegestrant, a PROteolysis TArgeting Chimera (PROTAC) Estrogen Receptor (ER) Degrader, in Combination With Cyclin-Dependent Kinase (CDK)4/6 Inhibitors and Everolimus

Stefanie Drescher, Weiwei Tan, Yuanyuan Zhang, Julia Perkins Smith

Background: Vepdegestrant (ARV-471) is an oral PROTAC ER degrader that has shown a manageable safety profile and signals of clinical efficacy as a single agent and in combination with the CDK4/6 inhibitor palbociclib in a phase 1/2 study in patients with ER+/human epidermal growth factor receptor 2 (HER2)- advanced breast cancer who had received prior treatments (NCT04072952). Ongoing studies are evaluating vepdegestrant in combination with other anticancer therapies in patients with ER+/HER2- advanced breast cancer, including with abemaciclib (NCT05548127) or ribociclib (NCT05573555) in the phase 1b/2 TACTIVE-U umbrella study and with everolimus in the phase 1b TACTIVE-E study (NCT05501769). We performed a clinical study in healthy female adults to evaluate the effect of multiple doses of vepdegestrant on the pharmacokinetics (PK) of midazolam, a sensitive index substrate of CYP3A4. Based on the clinical study results, we assessed the potential risk of CYP3A4-mediated drug interactions with anticancer agents currently being tested in combination with vepdegestrant.
Method: A phase 1, open-label, 2-period, fixed-sequence study was conducted in 15 healthy female adults of non-childbearing potential (NCT06256510). In period 1, participants received a single oral dose of midazolam 2 mg alone, followed by a ≥1 day washout period. In period 2, participants received vepdegestrant 200 mg orally once daily (QD) under fed condition on days 1-15, and a single oral dose of midazolam 2 mg on days 1 and 15 ≈1 hour after vepdegestrant dosing. Serial plasma samples were analyzed to estimate the effect of vepdegestrant on midazolam PK. Static mechanistic models1,2,3, incorporating findings of this clinical study and drug interaction mechanisms as victim of CYP3A4-mediated metabolism for each combination partner, were used to calculate the predicted effect of vepdegestrant 200 mg QD administration on the PK of palbociclib, abemaciclib, ribociclib, and everolimus, represented as the ratio of area under the concentration-time curve (AUC) in the presence and absence of vepdegestrant (AUCr).
Results: A total of 14 participants were eligible for evaluation of the effect of vepdegestrant 200 mg QD on the plasma AUC from time 0 extrapolated to infinite time (AUCinf) of midazolam. Midazolam AUCinf was approximately 74% higher when midazolam was given after multiple doses of vepdegestrant compared to when midazolam was given alone. Multiple doses of vepdegestrant were generally well tolerated by all participants; no serious or severe adverse events, and no discontinuations or dose reductions due to adverse events were reported. Based on the observed changes in midazolam AUC, the predicted effect of vepdegestrant on combination partners, expressed as AUCr, ranged from 1.13–1.29 for palbociclib, 1.37–1.55 for abemaciclib, 1.00–1.04 for ribociclib, and 1.38–1.63 for everolimus. These predicted effects based on CYP3A4 metabolism are considered negligible or minor and unlikely to have major impact in clinical combinations.

Conclusions: Vepdegestrant shows a weak inhibitory effect on CYP3A4-mediated metabolism in the clinical study with midazolam. The study results, combined with mathematical modeling, suggest low potential of meaningful drug interactions for vepdegestrant in combination with CDK4/6 inhibitors and everolimus. Clinical data are anticipated from ongoing studies of vepdegestrant in combination with other anticancer therapies in patients with ER+/HER2- advanced breast cancer.

P4-08-14: ALISertib in combination with endocrine therapy in patients with hormone receptor-positive, HER2-negative recurrent or metastatic breast CAncer: the phase 2 ALISCA-Breast1 study

Tufia C. Haddad, Sofia Braga, Adam M. Brufsky, Karthik V. Giridhar, Erica L. Mayer, Ruth M. O'Regan, Cristina Saura, Seth A. Wander, Georg F. Bischof, Judith D. Bebchuk, Lisa D. Eli, Brian G. Barnett, Joyce A. O'Shaughnessy

Background: Despite the wide range of available treatment options for patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) recurrent or metastatic breast cancer (MBC), optimal treatment after progression on CDK4/6 inhibitors (CDK4/6i) remains unclear. Several mechanisms of resistance to CDK4/6i have been postulated, including increased expression of Aurora kinase A (AURKA), a key regulator of mitosis associated with poor prognosis in multiple tumor types. Further implicated in CDK 4/6i resistance, high c-Myc or RB1 loss of function (LOF) have been associated with transcriptional co-regulation or synthetic lethality, respectively, with AURKA.
Alisertib is a highly selective, reversible, ATP-competitive, orally administered, small-molecule AURKA inhibitor with antiproliferative activity in HR+ BC-derived cell lines and BC xenograft models. Greater alisertib sensitivity has been reported in models with elevated AURKA or c-Myc expression, or RB1 LOF. Clinically, alisertib showed efficacy in phase 1 and 2 trials, including objective response rates (ORRs) of 19.6–20% and median progression-free survival (PFS) of 5.4–5.6 months alone or with fulvestrant in pts with HR+/HER2-, endocrine-resistant MBC. The most common treatment-related grade ≥3 adverse events (AEs) were neutropenia, anemia, and leukopenia.
Methods: ALISCA-Breast1 (NCT06369285) is a randomized phase 2 study. Primary objective: to determine the optimal alisertib dose level administered with selected endocrine therapy (ET) for use in future studies based on observed safety (AEs, serious AEs per CTCAE v5.0) and efficacy (ORR, duration of response, disease-control rate, PFS, overall survival). Secondary objectives: to identify biomarkers correlating with efficacy; to evaluate alisertib pharmacokinetics (PK). Key inclusion criteria: age ≥18 years; ECOG performance status 0 or 1; confirmed HR+, HER2–, recurrent or metastatic breast adenocarcinoma not

amenable to curative therapy; available tumor tissue for biomarker analyses; progression on or after ≥2 prior ET lines in recurrent or metastatic setting; prior CDK4/6i with ET in recurrent or metastatic setting; ≥1 measurable target lesion per RECIST v1.1. Pre-menopausal pts are eligible if amenable to treatment with a luteinizing hormone-releasing hormone agonist. Key exclusion criteria: prior chemotherapy in recurrent or metastatic setting; bone-only disease not meeting the measurability definition per RECIST v1.1; prior AURKA-specific or pan-Aurora-targeted agents; active infection; immunocompromised pts; unstable brain metastases; uncontrolled symptomatic visceral disease. Eligible pts will be randomized 1:1:1 to alisertib 30mg, 40mg, or 50mg orally twice daily on days 1–3, 8–10, and 15–17 every 28 days and combined with physician's choice of anastrozole, letrozole, exemestane, fulvestrant, or tamoxifen not previously used in the recurrent or metastatic setting or progressed upon in the adjuvant setting. Up to 50 pts will be enrolled per arm at multiple centers in the USA and Europe. Treatment will continue until disease progression, unacceptable toxicity, or consent withdrawal. Stratification factors: time to recurrence/progression after initiating CDK4/6i therapy (<12 mo or ≥12 mo); presence of visceral disease (yes/no). All pts will undergo sparse PK sampling. Tumor tissue will be centrally assessed for biomarkers, including but not limited to RB1, MYC, TP53, ESR1, PI3K/AKT pathway, HER2 and AURKA genomic alterations and/or expression levels. The study is expected to determine the optimal alisertib dose to combine with ET and may identify biomarker(s) that define pts deriving the greatest benefit from alisertib-containing therapy.

P4-08-15: Levels of Circulating Tumor DNA as a Predictive Marker for Early Switch in Treatment for Patients with Metastatic Breast Cancer: A Phase 2 Randomized, Open-Label Study

Frances Valdes, Carmen Calfa, Mauricio Escobar, Lawrence Negret, Aleksei Efremov, Dmitry Tabakov, Egor Savin, Kelley Lauziere, Alexander Bagaev, Elisa Krill, Alejandra Perez

The efficacy of a CDK4/6 inhibitor (i) with an aromatase inhibitor (AI) or fulvestrant (ful) as frontline therapy for hormone receptor positive (HR+) human epidermal growth factor receptor 2- (HER2-) metastatic breast cancer (MBC) is limited by the onset of resistance mutations. For breast cancer, the prognostic value of ctDNA has been validated; however, the clinical utility of serial ctDNA monitoring remains unclear. Results from PADA-1 support the utility of serial ctDNA monitoring to guide an early switch in frontline therapy based on molecular progression (MP) in patients (pts) with HR+HER2- MBC. This strategy led to improvements in median progression free survival (mPFS) of 7 months and time to second progression (PFS2) of 15.4 months.
This is a randomized phase 2 study conducted in pts receiving an AI or ful and a CDK4/6i as first-line therapy for HR+HER2- MBC evaluating the efficacy of switching a frontline regimen upon detection of a molecular signal, rise in ctDNA, suggesting MP prior to clinical progression (CP). Compared to PADA-1, this study is utilizing a more comprehensive biomarker, ctDNA ratio>1. The calculated ctDNA ratio (ctDNA value at time of assessment

over baseline value) corresponds to mutant allele abundance (mutant copies/ml of plasma) at a given timepoint relative to baseline quantification. Use of this ratio as a dynamic marker of response has been validated by O'Leary et al and Darrigues et al. This study design also includes pts with de novo HR+HER2- MBC, a prior history of breast cancer and those who progressed on adjuvant endocrine therapy. In Step 1, enrolled pts will receive frontline therapy with a CDK4/6i and AI or ful. ctDNA will be serially monitored. When a ctDNA ratio >1 is detected and there is no synchronous CP, pts will be randomized in Step 2 to continue the same therapy until CP, which is the current standard of care (SOC), or switch to an alternative second-line regimen. The primary endpoint is PFS in Step 2. Secondary endpoints include the number and percentage of pts with events of MP and no CP and the median time from enrollment to this event, overall response rate, clinical benefit rate, PFS2, overall survival and patient-reported outcomes.
Study feasibility will be evaluated based on the number of pts with MP events (ctDNA ratio>1 and no synchronous CP). Trial accrual will be suspended if <15% of the first 25-30 pts have MP without synchronous CP. To date, 24 pts have enrolled, with follow up < 12 months in all pts. Seventeen pts are in Step 1 and two are in Step 2. Two had CP prior to MP and are off study. Two had MP without CP and proceeded to Step 2 and were randomized to an early switch in therapy or maintenance of frontline therapy. Another 3 have been censored and are off study not related to progressive disease. Plasma samples (n=43) were ctDNA-positive (detectable somatic events), with actionable findings (BRCA2, PIK3CA, ESR1, PTEN variants) and biologically relevant findings (ARID1A, NOTCH3, MSH3, FANCM, NOTCH1, MAP3K1 variants) detected by the BostonGene Liquid Biopsy test in 7 and 6 samples, respectively. At screening/baseline, 20/29 pts (70%) had detectable levels of ctDNA. As expected for pts in Step 1 responding to frontline therapy, ctDNA abundance and cfDNA yield decreased during treatment, with a median pre-treatment and median on-treatment ctDNA abundance of 17.8 mutant copies/ml and 3.3 mutant copies/ml (P<0.01), respectively, for cases with ctDNA-positive baseline timepoints.
This pilot serves to document the feasibility of serial ctDNA monitoring and the early switch approach to then expand to phase II. The overall aim is to validate the utility of serial ctDNA monitoring as a predictive biomarker, and identify a strategy to extend duration of disease control and prolong survival in pts with MBC.

P4-08-16: Modulating Gut Microbiota to enhance the efficacy of Immunotherapy in Triple Negative Breast Cancer (TNBC)

Samarpan Majumder, Manisha Poudel, Fokhrul Hossain, Giulia Monticone, Kristina Larter, Zhi Huang, Justin Brown, Sonali Ghosh

Background: Triple-negative breast cancer (TNBC) is the most aggressive form of breast cancer affecting the African American (AA) population disproportionately and is diagnosed more frequently in younger, premenopausal women. Obesity is a known risk factor for increased TNBC incidence, and the association of gut dysbiosis with obesity is now established. Immune checkpoint blockade anti-PD-1 therapy (pembrolizumab) is currently

the standard of care for early TNBC. Evidence suggests modulating the gut microbiome enhances cancer immunotherapy efficacy in melanoma and lung cancer patients. However, there are no studies on early TNBC.

Overarching Challenge

The number of patients with early TNBC who benefit from anti-PD-1 therapy remains suboptimal.

Objective: Our study aims to enhance the efficacy of anti-PD-1 therapy by modulating the gut microbiota in a mouse model of obesity and TNBC. We hypothesize that a probiotic supplement will enhance the efficacy of anti-PD-1 therapy. We will then test the hypothesis that women with early TNBC who respond to anti-PD-1 therapy have distinct gut microbiota profiles compared to non-responders.

Results: We determined the efficacy and safety of two weeks of probiotic supplementation before anti-PD-1 therapy (pembrolizumab) on objective response rates in an obese mouse model of triple-negative breast cancer. This was evaluated by measuring the objective response rate (tumor burden as a read out) after two weeks of anti-PD-1 treatment. The underlying mechanism of microbiota mediated potentiation of anti-PD-1 therapy was further evaluated by a) 16s and metagenomics sequencing; b) total transcriptomic profiling of tumors from control and experimental groups and c) Short Chain Fatty Acids (SCFAs) and cytokine profiling of corresponding harvested plasmas as secondary endpoint. To test the hypothesis that two week of probiotic supplementation before tumor engraftment and anti-PD-1 therapy would cause an increased objective response rate (reduced tumor burden) when compared to groups that received anti-PD-1 therapy alone or isotype control, we conducted a permutation-based extension of multivariate analysis of variance and a two-sample test of independent means. For this, FVB female mice were used and at five weeks of age, mice were switched to a diet that mimics the “Western diet” (ENVIGO, Cat # TD.88137, Indianapolis, IN, USA). This diet reliably induces obesity. After 16 weeks of obesity induction mice were randomized in a 1:1 ratio to a probiotic dietary supplement or usual care for two weeks. We used a probiotic formulation from Creative Enzyme which is a blend of 13 human probiotic strains (Cat # PRBT-035, NY; ~3.38X1010 (Figure 5). It contains most of the species of Lactobacillus and Bifidobacterium that traditionally constitute commensal bacteria that colonize the gut. Authenticated TNBC C0321 claudin low mouse tumor cells (In Vitro Technologies) were injected into the 4th mammary fat pad of all the mice with a 1:1 ratio with Matrigel. Once tumor was engrafted, mice were divided into three groups- probiotics+ anti-PD1, anti-PD1 only, and serotype control and treatment was subsequtly administered. A two-tailed t-test comparing the anti-PD1 group with the probiotics + anti-PD1 group produced a statistically significant ($P<0.0001$) outcome confirming our prediction that probiotics supplementation positively affect anti-PD1 therapy in FVB obese mouse model. A Kaplan-Meier survival plot based on our record of mouse survival over the course of the treatment demonstrates that only probiotics supplement plus Anti-PD1 therapy and not Anti-PD1 therapy alone could provoke statis tically significant survival benefit over isotype control ($p=0.046$) in our study. Furthermore, 16s sequencing profiling on fecal samples illustrates that anti-PD1 therapy alone could induce a significant increase in Akkermensia at genus level consistent with significant

correlation between clinical responses to anti-PD1 therapy in a few other cancer types. We also identified probiotic treated mice showing abundance of Faecalibaculum at genus level. Faecalibaculum blocks tumor progression in mouse model of colorectal cancer. However, detailed metagenomics profiling is imperative to understand species level characterization to illustrate the difference in gene/pathway modulation pertaining to different cohorts subjected to different treatment conditions. Analysis of cytokine profile from collected blood revealed elevated levels of proinflammatory cytokines viz., IL-1b, IL-6, TNF-α, MCP-1 and VEGF in untreated plasma from mice when compared to plasmas from mice treated with probiotics. For feasibility study in human subjects, we already have our pilot study recruiting volunteers to confirm whether the fecal microbiome differs between patients with and without obesity and early TNBC who achieve a pathologic complete response from preoperative anti-PD-1 therapy (NCT06318507). We are recruiting subjects from the Pennington Cancer Center at Baton Rouge General Hospital and the Mary Bird Perkins Cancer Center at this time.

Impact

TNBC is the most aggressive form of breast cancer, with a high risk of early recurrence and death. This study will provide translational insight into a biological mechanism that explains patient outcome heterogeneity in response to anti-PD-1 therapy. The study provides critical experimental data to demonstrate causality and feasibility to justify larger-scale interrogations to modulate the gut microbiome in women with early TNBC who plan to begin anti-PD-1 therapy.

Innovation

This study is the first to determine how a probiotic supplement can enhance anti-PD-1 efficacy in early TNBC.

P4-08-17: First-in-human Phase 1 study of BTX-9341, a first-in-class, CDK4/6 bifunctional degrader, as a monotherapy and in combination with fulvestrant in patients with advanced and/or metastatic HR+/HER2- breast cancer.

Amita Patnaik, Danette Powell, Aparajita H. Chourasia, Massimo Cristofanilli, Ewelina Morawa, Jeremy Barton, Rachel M. Layman, Matthew Goetz

Background: BTX-9341 is a first-in-class, oral bifunctional degrader of cyclin-dependent kinase 4 (CDK4) and cyclin-dependent kinase 6 (CDK6), both clinically validated cell cycle targets in hormone receptor (HR)-positive (+)/human epidermal growth factor receptor 2 (HER2)-negative (-) breast cancer. Preclinical data highlight the superiority of BTX-9341compared to CDK4/6 inhibitors in terms of robust inhibition of retinoblastoma (RB) phosphorylation and CDK2 and Cyclin E transcription, cell cycle arrest, in vivo efficacy in breast cancer xenografts and, ultimately, in the ability to overcome key resistance mechanisms that limit the impact of CDK4/6 inhibitors in second-line (2L) HR+/HER2- breast cancer.

Methods: This first-in-human (FIH), Phase 1 trial of BTX-9341 (BTX-9341-101) will be a

multicenter, nonrandomized, open-label trial to evaluate the safety, tolerability, pharmacokinetics (PK), and preliminary efficacy of BTX-9341 in patients with advanced and/or metastatic HR+/HER2- breast cancer who received prior CDK4/6 inhibitor therapy and have no mutations in RB.
The trial will consist of initial dose escalation using accelerated titration and a Bayesian Optimal Interval (BOIN) design (Part A) of BTX-9341, both as monotherapy and in combination with fulvestrant. The dose expansion (Part B) of BTX-9341 in combination with fulvestrant will use a Bayesian Optimal Phase 2 (BOP2) design. The primary objective of Part A is to determine the maximum tolerated dose (MTD)/maximum evaluable dose (MED) of BTX-9341 monotherapy and/or combination therapy. The primary objectives of Part B are to obtain preliminary evidence of BTX-9341 efficacy and to confirm the recommended phase 2 dose (RP2D) of BTX-9341 combination therapy. Secondary objectives include characterization of the plasma PK profile of BTX-9341 following single and multiple doses of the drug administered as a single agent and/or in combination with fulvestrant and exploratory objectives will assess pharmacodynamic (PD) effects and PK/PD correlations. Approximately 82 patients will be enrolled and non-randomly assigned initially to Part A (dose escalation; ~36 participants) and later to Part B (dose expansion; ~46 participants). BTX-9341 will be evaluated as an oral therapeutic administered once a day (QD) in 28-day treatment cycles.
Note: Dr. Rachel M. Layman and Dr. Matthew Goetz have contributed equally to this abstract.

P4-08-18: M6 metabolite enhances the efficacy of the Rac/Cdc42 inhibitor MBQ-167 in metastatic advanced breast cancer

Nilmary Grafals-Ruiz, Julia Medina, Jessica Colon, Jorge Duconge, Cornelis Vlaar, Jose F. Rodriguez-Orengo, Suranganie Dharmawardhane

MBQ-167 is a Rac/Cdc42 specific inhibitor effective in the nM range. In mouse models of spontaneous and pre-existing metastasis, MBQ-167 significantly inhibits triple-negative breast cancer (TNBC) and HER2+ breast cancer tumor growth and metastasis. MBQ-167 shows no toxicity up to 1000 mg/kg in rodents and dogs, thus received IND status from the USFDA, and is currently in Phase 1 clinical trials. Several MBQ-167 metabolites were detected through a mammalian liver microsome assay, and the compound M6 was identified as the most abundant metabolite. In addition, M6 was detected as the major metabolite from dog plasma following oral dosing with 200 or 400 mg MBQ-167 BID. M6 demonstrated parallel pharmacokinetics as MBQ-167, at 10X less concentration than MBQ-167, in plasma during the first 24 hours. In the ongoing clinical trial, “Open-Label, First-in-Human Trial of Oral MBQ-167, as Single Agent in Subjects with Therapy Resistant Advanced Breast Cancer (NCT06075810)”, 20 mg MBQ-167 BID demonstrated a Tmax of 3-4hrs, for both MBQ-167 and M6 (N=4). M6 paralleled the MBQ-167 pharmacokinetics, where MBQ-167 showed a Cmax of 1.9 microM while M6 had a Cmax of 0.014 microM. The Cmax of both compounds was sustained for up to 24 hours. To determine whether M6 is effective as an

anti-breast cancer compound, pre-clinical studies were performed using human TNBC and HER2+ breast cancer cell lines. Rac/Cdc42 activation assays were conducted using pulldowns for GTP-bound Rac or Cdc42 and western blotting for the active phosphorylation status of the Rac/Cdc42 downstream effector P21-activated kinase (PAK). M6 at a similar concentration as MBQ-167 (250nM) significantly inhibited Rac/Cdc42/PAK activation. Wound healing assays for cell migration, MTT assays for viability, and caspase 3/7 assays for apoptosis demonstrated that M6 (250nM) significantly inhibited breast cancer cell motility without affecting viability or apoptosis. Immunocompromised mice bearing green fluorescent protein (GFP)-tagged human HER2+ tumors were treated with 10 mg/kg BW MBQ-167 or M6 by I.P. 5X a week for ten weeks. Tumor growth and metastasis were quantified by GFP fluorescence through in vivo digital whole-body imaging and ex vivo stereoscopy of excised organs following necropsy. M6 was similarly effective as MBQ-167, with a statistically significant 90% reduction in tumor growth and metastasis compared to the vehicle. Therefore, M6 is expected to significantly contribute to the duration and intensity of MBQ-167 efficacy in metastatic advanced breast cancer. This study was supported by the US Army Breast Cancer Research Program (BCRP) W81XWH2010041 and HT9425-23-1-0166 (to SD) and HT9425-23-1-0381 (to JFRO).

P4-08-19: Phase I Safety and Efficacy Study of Autophagy Inhibition to Augment the Antiproliferative and Biological Effects of Low Dose Palbociclib plus Letrozole in Estrogen Receptor-Positive, HER2-negative Metastatic Breast Cancer (MBC)

Akshara Singareeka Raghavendra, Nicole M. Kettner, Danielle Kwiatkowski, Senthil Damodaran, Yan Wang, David Ramirez, Dan S. Gombos, Kelly K. Hunt, Yu Shen, Khandan Keyomarsi, Debu Tripathy

Purpose: Endocrine therapy with a CDK4/6 inhibitor is standard therapy for estrogen receptor-positive, HER2-negative metastatic breast cancer (ER+/HER2- MBC), yet clinical resistance develops. Previously, we showed that low doses of palbociclib activate autophagy, reversing initial G1 cell cycle arrest. High concentrations induced off-target senescence. The autophagy inhibitor hydroxychloroquine (HCQ) induced on-target senescence at lower palbociclib doses in preclinical models.
Patients and Methods: We conducted a phase I trial (NCT03774472) of HCQ (400, 600, 800mg/day) with palbociclib and letrozole, using a 3+3 design. Eligible patients were age ≥ 18 years with a histologically confirmed diagnosis of ER+/HER2- MBC and were candidates for treatment with CDK4/6 inhibitor and endocrine therapy. Primary objective included safety, tolerability, and HCQ recommended phase 2 dose (RP2D). Secondary objectives included tumor response and biomarker analysis.
Results: Fourteen postmenopausal women with ER+/HER2- MBC were evaluable [400mg (n=4), 600mg (n=4), 800mg (n=6)]. Grade 3 adverse events (AEs) included hematological (3 at 800mg), skin rash (2 at 600mg), and anorexia (1 at 400mg), with no serious AEs. Best responses were partial (2), stable (11), and progression (1). Tumor decreases ranged from

11% to 30%, with one 55% increase. Biomarker showed drops in Ki67, Rb, and nuclear cyclin E in responders. The combination therapy demonstrated significant overall survival (OS) benefit, with the median OS not reached, significantly exceeding the typical 53.9 months for palbociclib and letrozole alone.
Conclusions: This phase I study demonstrated acceptable safety for HCQ. The RP2D of HCQ was 800mg/day with continuous palbociclib (75mg/day) and letrozole (2.5mg/day). These findings suggest that adding HCQ can enhance the efficacy of standard therapy, potentially offering significant survival advantages in ER+/HER2- MBC patients.These results support further investigation into HCQ as a valuable addition to CDK4/6 inhibitor regimens, offering a promising strategy to improve long-term outcomes and quality of life for patients with ER+/HER2- MBC. This approach could lead to a paradigm shift in managing resistance and enhancing the therapeutic arsenal against this challenging cancer subtype.

P4-08-20: Trial in progress: A first-in-human phase 1a/b, dose-escalation/expansion study of BG-68501/ETX-197 (CDK2 inhibitor) as monotherapy or in combination with fulvestrant for patients with HR+/HER2- breast cancer and other advanced solid tumors

Jennifer Man, Bruno Fang, Alexander Philipovskiy, Brian A. Van Tine, Rohit Joshi, Marion Carrigan, Alejandra Ragone, Hao Zheng, Yang Liu, Sally Baron Hay

Background: Cyclin-dependent kinase (CDK) 2 can regulate the cell cycle through the interaction with cyclin E or cyclin A during the G1/S and S/G2 transitions, respectively. Elevated CDK2 activity is a key resistance mechanism to CDK4/6 inhibition in HR+/HER2− breast cancer (BC). Other genomic alterations, eg, loss of RB1, can cause resistance in additional solid tumors, including high-grade serous ovarian cancer, gastric cancer, small cell lung cancer (SCLC), and endometrial cancers. CCNE1 amplification or cyclin E overexpression may confer sensitivity to CDK2 inhibition. BG-68501/ETX-197 is a potent, selective inhibitor of CDK2, with preclinical evidence showing potent activity in biochemical and cellular assays, marked antitumor activity in cancer xenograft models, and superior selectivity for CDK2 over other CDK family members.
Methods: This study is a first-in-human, phase 1a/b, open-label, multicenter study to evaluate the safety, tolerability, PK, pharmacodynamics, and preliminary antitumor activity of BG-68501/ETX-197 in pts with advanced, nonresectable, or metastatic solid tumors, including HR+/HER2− BC. In the dose-escalation phase (phase 1a), sequential cohorts will receive increasing doses of BG-68501/ETX-197 as monotherapy, or in combination with fulvestrant; additionally, safety expansion cohorts will receive BG-68501/ETX-197 at doses recommended for further evaluation. In the dose-expansion phase (phase 1b), pts with HR+/HER2− BC, platinum-refractory or -resistant serous ovarian, fallopian tube, primary peritoneal cancer (PROC), extensive-stage SCLC (ES-SCLC), or CCNE1-amplified advanced solid tumors will receive BG-68501/ETX-197 orally as monotherapy or combined with fulvestrant. Eligibility criteria include pts ≥18 years with histologically or cytologically confirmed advanced or metastatic solid tumors potentially associated with CDK2

dependency who have received ≥1 line of treatment for locally advanced or metastatic disease and prior endocrine therapy and a CDK4/6 inhibitor in either the adjuvant or locally advanced or metastatic setting for HR+/HER2− BC or prior standard of care for all other advanced solid tumors.
For the dose-escalation phase (phase 1a), the primary objectives are to assess the safety and tolerability of BG-68501/ETX-197 monotherapy or in combination with fulvestrant, and to determine the maximum tolerated dose, maximum administered dose, and recommended dose for expansion (RDFE); secondary objectives are to assess preliminary antitumor activity (ORR, duration of response [DoR], time to response [TTR], disease control rate [DCR] and clinical benefit rate [CBR]) as assessed by investigator per RECIST v1.1, and PK.
For the dose-expansion phase (phase 1b), the primary objectives are to assess the antitumor activity (ORR) of BG-68501/ETX-197 in combination with fulvestrant in pts with HR+/HER2− advanced or metastatic BC, and BG-68501/ETX-197 as monotherapy in pts with PROC, ES-SCLC, and other advanced or metastatic solid tumors with CCNE1 amplification; secondary objectives are to further assess the antitumor activity (DoR, TTR, DCR and CBR) of BG-68501/ETX-197 alone in the previously mentioned advanced solid tumors or in combination with fulvestrant in HR+/HER2− metastatic BC, and to assess the safety and tolerability and PK of BG-68501/ETX-197 at the RDFE (NCT06257264).
The study is currently recruiting pts, with 14 sites open across two countries and 6 pts enrolled. Enrollment is complete for 1 cohort and cohort 2A is currently enrolling pts.

P4-08-21: Chlorogenic acid and cinnamaldehyde in combination demonstrate antimetastatic capabilities and induce apoptosis in MCF7 and MDA-MB-231 breast cancer cell lines via downregulation of the Akt pathway

Yusuff Olayiwola, Lauren S. Gollahon

The majority of reported breast cancer-associated deaths are directly correlated with metastatic disease. Furthermore, the nature of current metastatic cancer treatments detrimentally impacts other organ systems. Thus, there remains the need for more effective and safer strategies to treat metastatic breast cancer at a systemic level. Recently, more attention has been given to Natural Products as candidate anticancer approaches. This study is aimed at investigating the synergistic impact of two such natural compounds, chlorogenic acid and cinnamaldehyde (CGA:CA). We hypothesized that CGA:CA in combination, would decrease the metastatic potential of breast cancer cells by suppressing their invasive and migratory abilities induced through AKT pathway activation. We also hypothesized that apoptotic cell death would occur as a result of downregulation of Akt activation. To test this hypothesis, suppression of migration and invasion after treatment was analyzed by wound healing and Transwell Matrigel assays. FACSsort was performed to determine expression of the migration and invasion associated biomarkers fibronectin, vimentin, and EpCAM. Western blotting was used to determine the effect of the natural

products on expression of phospho-AKT, E- and N-cadherin, as well as the apoptotic marker and caspase 3 and BCL2-α. Annexin V/propidium iodide fluorescence microscopy and growth curves were conducted to analyze apoptosis induction. Results showed decreased phosphorylated Akt expression upon treatment with CGA:CA. the anticancer effect of the compounds on Akt activation resulted in inhibition of metastasis, evidenced by restoration of epithelial characteristics such as increased expression of E-cadherin and EpCAM, downregulation of N-cadherin, fibronectin, vimentin and MMP-9 expression and lack of cell migration. Annexin V and Western results showed that CGA:CA significantly inhibited cancer cell growth and induced apoptosis via increased expression of caspase 3 and downregulation of Bcl2-α. Overall, the present study demonstrated that CGA:CA combination downregulated the Akt pathway, induced apoptosis, and arrested the migration and invasion of both triple-positive and triple-negative breast cancer cell lines.

P4-08-22: Overcoming Olaparib Resistance in BRCA-Mutated Triple-Negative Breast Cancer: Synergistic Potential of DNA Repair Pathway Inhibitors

Diana Hawkins-Westergard, Anya Dimitrijevic, Clinton Yam, Rachel M. Layman, Naoto T. Ueno, Banu Arun, Jangsoon Lee

Background: Triple-negative breast cancer (TNBC) requires new treatment options due to its aggressive nature, high recurrence rates with standard-of-care treatment, and heterogeneous therapeutic effectiveness of existing treatments for metastatic TNBC. Poly(ADP-ribose) polymerase (PARP) inhibitors are approved treatments for HER2-negative breast cancer with germline BRCA (gBRCA) mutation, and they are of particular interest for patients with gBRCA-mutated TNBC due to their role in exploiting DNA repair deficiencies. Two PARP inhibitors (olaparib and talazoparib) are FDA-approved for patients with metastatic gBRCA mutated breast cancer. Although PARP inhibitor treatment has high response rate and improved progression-free survival, resistance to PARP inhibitors poses an emerging and significant challenge, necessitating the identification of novel therapeutic targets to overcome this resistance and improve patient outcomes with gBRCA mutated TNBC. This study aims to identify novel therapeutic targets whose inhibition could enhance the efficacy of PARP inhibitors in TNBC and olaparib-refractory TNBC.
Methods: We conducted a preclinical experiment to achieve our aim. We generated olaparib-resistant (OPR) cell lines using BRCA-mutated TNBC cell lines (SUM149, HCC1937, and MDA-MB-436). These cell lines were treated with olaparib until they achieved at least a 10-fold higher concentration of IC50 than their parent cell lines. To identify potential synergistic kinase targets, we performed a non-biased high-throughput 709 Kinome-Library RNA interference assay using SUM149-OPR cells. Target candidates were selected using the Sensitivity Index (SI > 0.12) and STRING interactome analysis. We then conducted a series of assays, including a sulforhodamine B viability assay, a soft-agar assay, and a Bliss Synergy Score analysis, to determine the combination effect of selected kinase inhibitors and olaparib using SUM149-OPR, HCC1937-OPR, and MDA-MB-436-OPR cell lines. Finally, we

conducted a soft-agar assay to evaluate in vitro tumorigenicity.
Results: Kinome-Library RNA interference screening revealed that the DNA damage pathway (ATR, CDK12, etc.) and phosphoinositide 3-kinases pathway (PIK3CG, PIK3R3, PIK3R4, etc.) as potential canonical pathways targets for synergizing with olaparib efficacy. PLK4 was selected as non-canonical target. Based on target identification, we selected inhibitors of ATR (elimusertib, gartisertib), ATM (AZD1390), PLK4 (CFI-400945), CDK12 (SR-4835), PI3KCA (copanlisib), and AKT (capivasertib) for proliferation assays. We found that targeting the DNA damage repair pathway was the most effective in enhancing the efficacy of olaparib in both parent and olaparib-resistant TNBC cell lines. Bliss score ranges are 5.509 to 48.763 for elimusertib (ATR inhibitor), 7.872 to 71.406 for gartisertib (ATR inhibitor), and 4.660 to 45.836 for AZD1390 (ATM inhibitor). Further, we observed a significantly enhanced in vitro antitumor effect of the olaparib and elimusertib combination ($P<0.05$).
Conclusions: Our preclinical study identified DNA repair pathways as potential targets to enhance the efficacy of olaparib in both parent and olaparib-refractory gBRCA mutated TNBC cell lines. Future in vivo studies, including patient-derived xenografts and additional mechanistic analyses to further understand dual DNA targeting synergy, are warranted to validate this therapeutic approach for TNBC with gBRCA mutation.

P4-08-23: Preclinical characterization of DF1001, a first-in-class dual NK and T cell engager targeting HER2-high or HER2-low tumors

Laurens Lambert, Gregory Chang, Mitchell Bigelow, Tanmay Dichwalkar, Daniel Fallon, Patrick Kirby, Stuart Hicks, Nicolai Wagtmann, Ann Cheung

Background: DF1001 is a first-in-class TriNKET® immune engager, designed to activate both innate and adaptive immune effector cells, including NK, CD8+ T, NKT, and gd T cells, through engagement of the activation receptors CD16a and/or NKG2D. DF1001 targets immune cell effectors against tumor cells by anchoring to HER2, a clinically validated target that is widely expressed across breast, gastric, esophageal, lung, bladder, and other oncologic indications. DF1001 is uniquely differentiated from HER2-targeted therapeutics due to its distinct immune-engaging mechanism of action (MOA) which is active against HER2-low expressing cancers, where HER2 mAbs such as trastuzumab are clinically ineffective. In addition to DF1001's ability to target a range of HER2 expressing tumors, its favorable safety profile enables therapeutic combination with standard of care agents, including the TROP2-targeted ADC sacituzumab govitecan-hziy (Trodelvy®) for treatment of HR-positive metastatic breast cancer (MBC). Sacituzumab govitecan-hziy has been reported to enhance NK cell lysis and deplete immunosuppressive cells in the tumor microenvironment, suggesting potential synergy with DF1001 to drive a more potent therapeutic response against tumor cells expressing HER2 and/or TROP2. Here we present the preclinical characterization of the mechanism of action of DF1001 and the safety profile of DF1001 in non-human primates as well as the potential of combining with sacituzumab govitecan-hziy.

Methods: DF1001 affinity measurements were conducted with recombinant protein reagents using surface plasmon resonance. DF1001 cell binding and HER2 signal inhibition assays were performed in HER2-high and HER2-low cell lines. DF1001 cytolysis, cytokine release, and combination with sacituzumab govitecan-hziy was assessed in primary immune effector: tumor cell co-culture assays. The safety profile of DF1001 was assessed in a repeat-dose 28-Day GLP intravenous study in cynomolgus monkeys and a human in vitro cytokine release assay.
Results: DF1001 bound HER2 with high affinity and NKG2D with low affinity, while retaining native IgG1-like binding to CD16a through the Fc domain. On cell lines with a range of HER2 levels, DF1001 consistently exhibited higher maximal binding compared to trastuzumab. DF1001 led to HER2 signal inhibition as measured by reduced AKT phosphorylation and arrested the growth of HER2-high cells. DF1001 elicited robust CD8+ T cell and NK cell-mediated lysis of HER2-expressing cell lines, including cells expressing HER2 at low levels. In addition to direct tumor cell killing, DF1001 triggered potent NK cell activation when bound to HER2 and elevated secretion of proinflammatory cytokines and chemokines, including IFN-gamma, TNF-alpha, CCL5/RANTES and CXCL10, a known T cell chemoattractant. In long-term immune: tumor co-culture assays with HER2- and TROP2-expressing cell lines, sacituzumab govitecan-hziy enhanced DF1001 NK cell-mediated tumor lysis, while preserving immune cell effector viability. DF1001 was well tolerated in a repeat-dose GLP intravenous NHP study, and the top dose of 120 mg/kg was the no observed adverse effect level (NOAEL). There was no evidence of cytokine release syndrome (CRS) in monkeys or the human in vitro cytokine release assay.
Conclusions: The DF1001 TriNKET® targets robust immune-mediated activities, which enhances cytolytic responses directed at both HER2-high and HER2-low tumors and elevates local release of inflammatory cytokines/chemokines without causing CRS. DF1001 TriNKET's favorable drug safety profile and distinct immune-engaging MOA positions it to complement and synergize with SOC agents such as sacituzumab govitecan-hziy in the HER2-low solid tumor setting. DF1001 is currently under evaluation in patients with locally advanced or metastatic solid tumors in PhI/II trials (NCT04143711).

P4-08-24: AKTive-001: A Phase 1/1b Multiple Cohort Trial of ALTA2618 in Patients with Advanced Solid Tumors with AKT1 E17K Mutation (Trial in Progress)

Anthony Tolcher, Andreas Varkaris, Jordi Rodón, Alexander I. Spira, Kari Wisinski, Vivek Subbiah, Gerald Falchook, Judy Wang, Sarah Sammons, Marla D. Lipsyc-Sharf, Rebecca Shatsky, Nancy Chan, Cynthia X. Ma, Andrew Chi, Eric Murphy, Dana Peters, Vicky Kang, Kevin M. Kalinsky

Background: AKT1 E17K is an activating driver mutation with a prevalence of 4-8% in breast cancer, with the vast majority found in HR+/HER2-negative breast cancer. Approximately 90% of AKT driver mutations are AKT1 E17K, and half of AKT1 E17K-mutant breast and gynecologic cancers are homozygous for the AKT1 E17K oncogene with

concurrent loss of the wildtype (WT) AKT1 allele. These genomic features suggest AKT1 E17K exhibits uniquely potent oncogene addiction in these tumor types.

Non mutant-selective AKT inhibitors have demonstrated clinical activity in patients with AKT1 E17K-mutant cancers, however their clinical benefit is hindered by significant on-target WT AKT-related toxicity, including diarrhea, fatigue, hyperglycemia and rash. Selective inhibition of the AKT1 E17K variant is predicted to limit or avoid on-target WT AKT toxicities, including hyperglycemia mediated by AKT2 inhibition. Furthermore, potent and sustained suppression of AKT1 E17K enabled by a mutant-selective approach is anticipated to enhance ORR and DOR relative to WT AKT inhibitors.

ALTA2618 is an oral allosteric AKT1 E17K mutation-selective inhibitor that selectively, covalently, and potently inhibits the AKT1 E17K variant. ALTA2618 exhibits approximately 24-fold and at least 236-fold greater selectivity for AKT1 E17K over AKT1 (with WT E17) and AKT2 E17K, respectively. ALTA2618 has demonstrated potent, dose-dependent, and prolonged anti-tumor activity, including complete regressions, in AKT1 E17K-mutant HR+/HER2-negative breast, triple-negative breast, and uterine endometrial patient-derived xenograft models implanted in mice at dose levels that did not induce body weight loss or hyperglycemia.

The AKTive-001 Phase 1/1b study is evaluating ALTA2618 in patients with previously treated, locally advanced, unresectable or metastatic solid tumors with AKT1 E17K mutation.

Trial Design: ALTA2618 is a Phase 1/1b first-in-human (FIH) clinical trial of ALTA2618 in patients with advanced solid tumor malignancies with AKT1 E17K mutation. Patients will be administered ALTA2618 orally once daily (QD). Patients will be enrolled in 2 segments: a Phase 1 dose escalation segment and a Phase 1b dose expansion segment. The Phase 1 dose escalation segment will use the modified Toxicity Probability Interval methodology (mTPI-2). Three cohorts will be evaluated during the Phase 1b segment, including patients with HR+/HER2-negative breast cancer (Cohort A), gynecological cancers (Cohort B), and all other solid tumor types (Cohort C). Disease assessments per RECIST 1.1 are every 6 weeks for the first 48 weeks, then every 12 weeks.

Patients must be ≥18 years old; have an ECOG PS of ≤1; have adequate organ function; and have had no prior PI3K/mTOR inhibitors. A limited number of patients may have received prior AKT inhibitors during dose escalation. Patients should have received, are ineligible for, or declined treatment with a known overall survival benefit for their specific cancer type. For eligibility of Phase 1b Cohort A (HR+/HER2-negative breast cancer), tumors must express ER with or without co-expression of PR; HER2-negative is defined as 0/1+ on IHC, or 2+ on IHC and ISH-negative. Patients with non-HR+/HER2-negative breast cancer subtypes will be enrolled into Cohort C. Patients will be treated with ALTA2618 orally, QD, until disease progression, unacceptable adverse events, patient refusal, or death.

The main study objectives are to characterize the safety and tolerability, to evaluate the pharmacokinetics and clinical activity, and to identify the recommended doses of ALTA2618 for dose expansion.

Sites will be opened in the US, EU, Asia and Australia. Enrollment will begin in September 2024.

P4-08-25: Overall survival in patients with HR+/HER2- advanced breast cancer treated in a phase 1b trial evaluating gedatolisib in combination with palbociclib and endocrine therapy

Rachel Layman, Hope S. Rugo, Robert Wesolowski, Hyo Han, Jennifer M. Specht, E. Claire Dees, Erica M. Stringer-Reasor, Peter Kabos, Vandana Abramson, Anthony Shields, Charlotte Moser, Igor Gorbatchevsky, Pratima Nayak, Samuel Suzuki, Sarah Mutka

Background: Gedatolisib is a pan PI3K/mTOR inhibitor and was evaluated in a multicenter, open-label, phase 1b dose-escalation and dose-expansion trial in combination with palbociclib and endocrine therapy in patients with hormone receptor-positive/HER-2 negative (HR+/HER2-) breast cancer with varying categories of prior therapy (ClinicalTrials.gov NCT02684032). The primary objective of the dose-escalation cohorts was safety while the primary endpoint of the dose-expansion cohorts was investigator-assessed objective response. Median progression-free survival at 12 months was 72.1%, 54.5%, 23.6%, and 53.2% for Arms A, B, C, and D, respectively, as defined in the methods. In the dose-expansion cohorts gedatolisib triplet therapy achieved overall response rates (ORR) of 85%, 77%, 36% and 63% in Arms A, B, C and D respectively. Based on the promising ORR of the phase 1b trial, further follow-up was warranted to analyze survival outcomes. Here we report survival results of patients who received gedatolisib combined with palbociclib plus letrozole or fulvestrant.

Methods: Female patients aged at least 18 years from 17 sites across the USA with HR+/HER2- advanced breast cancer and an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1 were enrolled in the phase 1b trial. There were 2 dose-escalation arms that assessed safety of gedatolisib 180 mg/week plus standard doses of palbociclib with endocrine therapy of letrozole or fulvestrant. The dose expansion portion had 4 patient cohorts based on prior treatment history, with Arm A comprising patients with no prior systemic treatment for breast cancer, Arm B with patients with 1-2 prior endocrine therapies but no history of CDK4/6 inhibitor, and Arms C and D with patients with one or more prior lines of therapy, including a CDK4/6 inhibitor. Gedatolisib 180 mg was administered intravenously weekly in 28-day treatment cycles for Arms A-C, and on days 1, 8, and 15 for Arm D. Endocrine therapy with letrozole or fulvestrant and CDK4/6 inhibition with palbociclib were administered at standard dose. Participating sites were asked to collect patient outcome for survival analysis.

Results: As of the phase 1b study data lock on June 29, 2022, the median overall survival was not reached in any group. The sponsor has initiated overall survival follow up for all patients that will be presented at the conference which provides at least 2 years of additional follow-up time.

Conclusions: Gedatolisib in combination with palbociclib and letrozole demonstrated promising overall response rates and progression-free survival in patients with HR+/HER2-advanced breast cancer that warrants further evaluation of overall survival outcomes.\

P4-08-26:Trial in progress: First-in-human phase 1a/1b, dose-escalation/expansion study of BGB-43395 (CDK4 selective inhibitor) as monotherapy or combination therapy in Chinese patients with metastatic HR+/HER2- breast cancer & other advanced solid tumors

Jian Zhang, Zhanmin Zhang, Yuping Sun, Tao Qin, Gilbert Y. Wong, Ping Zhou, Yiran He, Zhimin Shao

Background: Dysregulation of cyclin-dependent kinase (CDK) 4 is observed in various solid tumors. CDK4/6 inhibitors provide substantial clinical benefit; however, pts with advanced or metastatic HR+/HER2− breast cancer (BC) eventually develop resistance and may experience toxicities associated with current treatments. BGB-43395 is a potent, selective, orally bioavailable CDK4 inhibitor, with preclinical evidence showing antitumor activity and substantial selectivity for CDK4 over CDK6, thus minimizing off-target toxicity and potentially toxicity-related dose reduction/discontinuations, and therefore supporting further evaluation in pts.

Methods: This phase 1a/1b, open-label, multicenter study is evaluating the safety, tolerability, PK, pharmacodynamics (PD), and preliminary antitumor activity of BGB-43395 given orally as monotherapy or in combination with fulvestrant, letrozole, or other combination partners in Chinese pts with advanced or metastatic solid tumors, including HR+/HER2− BC (NCT06253195). In the dose-escalation phase (phase 1a), sequential cohorts of pts with advanced solid tumors will receive increasing dose levels of BGB-43395 given orally as monotherapy (Part A) and cohorts of pts with 2L+ HR+/HER2− BC will receive increasing dose levels of BGB-43395 in combination with either fulvestrant (Part B) or letrozole (Part C). In the dose-expansion phase (phase 1b), pts with advanced or metastatic HR+/HER2− BC will receive the recommended dose for expansion (RDFE) of BGB-43395 in combination with fulvestrant.

Eligible pts are ≥18 years of age with histologically or cytologically confirmed locally advanced or metastatic solid tumors associated with CDK4 dependency who have received prior standard-of-care therapy, including ≥1 line of treatment for locally advanced or metastatic disease and prior endocrine therapy and a CDK4/6 inhibitor in either the adjuvant or locally advanced or metastatic setting for HR+/HER2− BC, or ≥2 lines of HER2-targeted therapy for pts with HR+/HER2+ BC (phase 1a); locally advanced or metastatic HR+/HER2− BC in pts who have received ≥1 line of treatment for locally advanced or metastatic disease and prior endocrine therapy and a CDK4/6 inhibitor (phase 1b); and ECOG PS ≤1.

For phase 1a, the primary objectives are to assess the safety and tolerability of BGB-43395 monotherapy or as part of combination therapy, and to determine the maximum tolerated dose, maximum administered dose and RDFE; secondary objectives are to assess preliminary antitumor activity (ORR, duration of response [DoR] and time to response [TTR] as assessed by the investigator per RECIST v1.1) and the PK of BGB-43395. Exploratory endpoints are PFS as assessed per investigator, disease control rate (DCR) and clinical benefit rate (CBR) per RECIST v1.1, PD, and assessment of biomarkers associated

with response. For phase 1b, the primary objective is to assess the antitumor activity of BGB-43395 (ORR assessed by the investigator); secondary objectives are to further assess the antitumor activity (DoR, TTR, DCR, CBR, and PFS assessed by the investigator), safety and tolerability, and PK of BGB-43395. Exploratory endpoints are overall survival and potential biomarkers associated with response. As of May 28, 2024, the study is currently enrolling pts, with five pts currently dosed in the dose-escalation phase across 12 sites in China.

P4-08-27: PMD-026, a First-in-Class RSK Inhibitor, Overcomes Acquired Resistance to CDK4/6 Inhibitors or Aromatase Inhibitors in HR+/HER2- Breast Cancer Preclinical Models

Sandra Dunn, Aarthi Jayanthan, Jangsoon Lee, Toshiaki Iwase, Nanae Ogata, Nicholas Sharp, Sandra E. Dunn, Brian Barnett, Naoto T. Ueno

Background: RSK2 (90 kDa ribosomal S6 kinase 2) is a kinase implicated in developing hormone receptor positive (HR+) breast cancer. Additionally, RSK1, RSK3, and RSK4 promote breast cancer metastases and resistance. Upon activation, RSKs translocate from the cytoplasm to the nucleus, directly binding to the estrogen receptor (ER) and Y-box binding protein 1 (YB-1), subsequently promoting tumor growth. Specifically, nuclear RSK2 leads to the development of ER+ breast cancer in mice. RSK2 binding occurs outside the common ER mutational hotspots on the activation function 2 (AF-2) ligand binding domain, triggering a conformation change in ER to promote transcription uniquely. Thus, we hypothesize that targeting RSK2 alongside endocrine therapy improves patient outcomes independent of ER mutations. Its emerging role in resistance is underscored by a study showing that RSK2 is the most highly induced protein in the MAPK pathway following the development of acquired resistance to the aromatase inhibitor letrozole. Invariably, patients will progress on CDK4/6 inhibitors (CDK4/6i) combined with aromatase inhibitors in the first-line setting. In the second-line setting, fulvestrant as a single agent only delivers a median progression-free survival (PFS) of 2.35 months and an overall response rate of 5.9% in patients. Notably, PMD-026, our first-in-class, oral small molecule pan-RSK inhibitor, provided 4.8 months of PFS as a single agent in RSK2+ patients who received five prior lines of therapy, including CDK4/6i and endocrine therapy, in our exploratory Phase 1/1b clinical trial. This study addresses the potential of co-targeting RSK and ER as a novel strategy to overcome resistance to CDK4/6i and/or aromatase inhibitors.
Results: By querying the METABRIC database, we show RSK2 and YB-1 are strongly correlated in primary HR+ ($p < 0.0001$, $n = 1356$ patients), as well as triple negative ($p = 0.03$, $n = 253$ patients) breast cancers. Given that RSK/YB-1 regulates the G2/M phase of the cancer cell cycle, PMD-026 could potentially overcome CDK4/6i- resistance mechanisms that mount at G1/S. In patient-derived xenografts (PDx) that progressed on CDK4/6i or endocrine therapies, RSK2 was highly expressed in 69% (11/16) of the models. Therefore, we evaluated PMD-026 in the CDK4/6 resistant cell lines, T47D-IBR and MCF-7-IBR, both of which are ESR1 WT. PMD-026 blocked RSK signaling and suppressed pYB-1S102 in

parental T47D and T47D-IBR cells, leading to tumor cell death. In the MCF-7-IBR model, PMD-026 combined with fulvestrant or oral selective estrogen receptor degraders (SERDs) consistently demonstrated a high degree of synergy, indicating a class effect. These models had elevated pERK and Cyclin E expression, commonly elevated in CDK4/6i resistance, suggesting dysregulation of the G1/S cell cycle checkpoint can be blocked by PMD-026. Next, we addressed the opportunity to overcome aromatase resistance using PMD-026 in PDx models. Gene expression analysis of primary breast cancer PDx models indicated high expression of RSK2 mRNA in 63% (65/104) of the models screened. The high RSK2 expressing HR+/HER2- BR9469 PDx model was selected from a patient who had progressed on an aromatase inhibitor. This model, which has ESR1 (Y537S), p53, BRCA1/2, and PIK3CA mutations, was inhibited by PMD-026 in a dose-dependent manner.
Conclusion: Inhibiting the RSK pathway with PMD-026 in combination with endocrine therapies shows promising potential in overcoming resistance to CDK4/6 inhibitors. The synergistic effect observed with PMD-026 and fulvestrant supports Dauntless-1, our newly launched Phase 2 clinical trial (NCT04115306) for second-line patients with RSK2+ tumors. This trial is for patients who have progressed on one prior line of CDK4/6i and aromatase inhibitors.

P4-08-28: Results of the Dose-Escalation Cohort of a Phase 1 Trial of Intratumoral HER2- and HER3-Primed Dendritic Cells Injections for the Treatment of Early-Stage TNBC and HR Low Positive Breast Cancer. DecipHER trial

Ricardo Costa, Aixa E. Soyano, Avan Armaghani, Jennifer Childress, Loretta Loftus, Edith Abraham, Junmin Whiting, Qianxing Mo, Zena Jameel, Tracey O'Connor, Kimberley Lee, Susan Hoover, John Kiluk, Catherine Lee, Christine Laronga, Nazanin Khakpour, Hyo S. Han, Hatem H Soliman, Brian J. Czerniecki

Background: Patients (pts) with breast cancer (BC) harboring low expression of hormone receptors (HR) and human epidermal growth factor receptor-2 (HER2) have poorer outcomes compored to other subsets of BC. Results from the KEYNOTE-522 trial showed that activation of the immune system using a PD1/PD-L1 approach leads clinically meaningful improvement in the outcomes of patients with these high-risk tumors. Dendritic cells (DCs) are antigen presenting cells which are pivotal for robust cytotoxic responses via broader activation of the adaptive immune system.
Methods: DecipHER is a dose-escalation, dose-expansion phase 1 trial designed to assess the safety and preliminary effiacy of autologous HER2- and HER3-primed DCs in combination with KEYNOTE-522 regimen in a maximum of 30 pts. Pts with clinical stage cT1-cN1/2 or cT2-4cN0/2, HR < 20, HER2-negative BCs are eligible. Pts with inflammatory BC and uncontrolled immune-mediated diseases are excluded. After collection through apheresis, autologous DCs are primed against 6 HER2 and 8 HER3 immunogenic peptides. Pts receive alternating US-guided intratumoral HER2 and HER3 DCs injections administered twice a week for 8 doses starting 2 weeks prior to neoadjuvant KEYNOTE-522 regimen. The

dose-escalation phase of the study had a classic 3+3 design (ie DL1-3 [10-20, 30-50, 80-100 million], maximum n=18). Additionally, 12 pts will be treated at the maximum tolerated dose (MTD) in the dose-expansion cohort. Dose-limiting toxicities (DLT) were defined as grade 3 or higher non-hematologic or hematologic adserve events (AEs) thought to be at least possibly related to DCs; any grade 4 nausea, vomiting or diarrhea [or grade 3 if duration > 3 days]) during the 5 weeks following treatment initiation. Secondary endpoints include absolute risk of AEs, pathological complete response (PCR) and recurrence-free survival. Tumor tissue, blood and stool samples are being collected for correlative analyses.
Results: A total of 12 pts (6 on DL3) were enrolled between 08/2022 and 01/2024. The median age was 51.5 (35-71) and 25% of pts were black; 91% had grade 3, 41.7% had T3 and 75% had N1 BCs. One patient received only 2 HER2- and 4 HER3-primed DCs due to low cell yeild. Grade 1 and 2 AEs that were at least possibiliy related to DCs (>10%) were headache (66.7%) chills (50%), fatigue (33.3%), flue-like symptoms (33.5%), fever (25%), nausea (16.7%) and pain (16.7%). No DC-associated grade 3 or higher AEs were observed. None of the toxicities met the definition of DLT. For DL1, 2 out of 3 pts had an SAE (i. cholelithiasis complicated by sepsis and ii. pneumonitis and syncope; 5 and 14 weeks after last DC injection; respectively). No SAEs were observed on dose levels 2 or 3. Immune-related AEs were pneumonitis (1pt), hypothyrodism and adrenal insuficiency (1 pt), hyperthyroidism (1pt). pCR was observed in 5 out of 10 evaluation pts. Base on thees findings, DL3 (80-100 million) was selected for the dose-expansion cohort.
Conclusion: Intratumoral DCs in combination with standard neoadjuvant chemotherapy and pembrolizumab were well tolerated in pts with high-risk HR <20, HER2-negative BCs. The dose-expansion cohort portion of this trial is ongoing; correlative analyses will follow. The study is open at H. Lee Moffitt Cancer Center. Clinical trial information NCT05504707.
Funding: Shulas' foundation.

P4-08-29: Efficacy and safety of larotrectinib in patients with TRK fusion breast cancer: an updated analysis

Cristiano Souza, Ezra Y. Rosen, Antoine Italiano, Felipe Cruz, Biswajit Dubashi, Mahmut Gumus, Jessica Lin, Maria de Miguel Luken, Daniel Orbach, Sun Young Rha, Domnita-Ileana Burcoveanu, Natascha Neu, Chiara E. Mussi, Lin Shen, Alexander Drilon

Background: Larotrectinib is the first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in patients with TRK fusion cancer; approval was based on a robust and durable objective response rate in both adult and pediatric patients with various cancers. Here, we report long-term efficacy and safety data in patients with TRK fusion breast cancer (BC).
Methods: Patients with TRK fusion BC treated with larotrectinib were identified from 2 clinical trials (NCT02576431 [NAVIGATE] and NCT02637687 [SCOUT]). Most patients received larotrectinib 100 mg twice daily. Responses were assessed by an independent review committee (IRC) per Response Evaluation Criteria in Solid Tumours v1.1. The data cutoff date was July 20, 2023.

Results: At data cutoff, 16 patients were identified, 15 of whom were eligible for IRC assessment. Median age was 54 years (range 10–70). At enrollment, 2 (13%) patients had locally advanced disease and 14 (88%) had metastatic disease. Six (38%) patients had secretory carcinoma, 2 of whom were male; 10 (63%) patients had non-secretory carcinoma. NTRK gene fusions were identified by next-generation sequencing (NGS), fluorescence in situ hybridization, and an unknown method in 13 (81%), 2 (13%), and 1 (6%) patients, respectively. Of the 6 patients with secretory carcinoma, 4 had triple-negative BC (TNBC) and 2 had estrogen receptor-positive (ER+) / human epidermal growth factor receptor 2 (HER2) negative tumors. Of the 10 patients with non-secretory carcinoma, 4 had TNBC, 2 had ER+/HER2-equivocal (eq) BC, 2 had ER+/HER2 negative BC, 1 had ER–/HER2eq BC and 1 had ER+/HER2+ BC.
Three patients with non-secretory carcinoma had known CNS metastases at baseline. Overall, 4, 2, and 10 patients had 0, 1, or ≥2 lines of prior systemic therapy, respectively; 3 of the patients with secretory carcinoma were treatment-naïve.
The overall response rate (ORR) for the IRC-eligible patients (n=15) was 53% (95% confidence interval [CI] 27–79): 4 (27%) patients had complete responses (CRs; including 1 pathological CR [pCR]), 4 (27%) had partial responses (PRs), 3 (20%) had stable disease (SD), and 3 (20%) had progressive disease (PD); response in 1 patient (7%) was not evaluable. ORR for patients with secretory carcinoma (n=6) was 83% (95% CI 36–100): 3 (50%) patients had CRs (including 1 pCR), 2 (33%) had PRs, and 1 (17%) had SD. ORR for patients with non-secretory carcinoma (n=9) was 33% (95% CI 7–70): 1 (11%) patient had a CR, 2 (22%) had PRs, 2 (22%) had SD, and 3 (33%) had PD; response in 1 patient (11%) was not evaluable. In all patients, median time to response was 1.7 months (range 0.9–5.6). Median duration of response (DoR) was not reached (95% CI 7–not estimable [NE]); median follow-up was 43 months. Median progression-free survival (PFS) was 9 months (95% CI 2–NE); median follow-up was 44 months. Median overall survival (OS) was 21 months (95% CI 8–NE); median follow-up was 47 months. The 4-year rates for DoR, PFS, and OS were 73% (95% CI 41–100), 38% (95% CI 13–63), and 38% (95% CI 11–65), respectively. Treatment duration was 0–60+ months. Treatment-related adverse events (TRAEs) were mostly Grade 1/2. Grade 3/4 TRAEs occurred in 3 (19%) patients: hepatic cytolysis and hepatitis, both in 1 patient; paresthesia and thrombocytopenia in 1 patient each. There were no treatment discontinuations due to TRAEs.
Conclusions: Larotrectinib demonstrates rapid and durable responses and a favorable safety profile in patients with TRK fusion secretory or non-secretory BC. These results support the wider adoption of NGS panels that include NTRK gene fusions to identify patients who might benefit from TRK inhibitor therapy.

P4-08-30: Preclinical Characterization and Safety of First-in-Class, brain penetrant ALC1 Inhibitor EIS-12656 in HRD cancers

Adrian Schomburg, William Menzer, Markus Lechner, Gunnar Knobloch, Katharina Sahiri, Xin Zhang, Andreas Ladurner

EIS-12656, a first-in-class ALC1 inhibitor, has shown promising antitumor activity in preclinical studies, aimed at effective cancer management. Our inhibitor specifically targets ALC1, a crucial chromatin remodeler activated by PARP within the DNA damage response (DDR) context. This study focuses on the comprehensive preclinical characterization and safety evaluation of EIS-12656, currently in a Phase I/II clinical trial. Biochemically, EIS-12656 is an allosteric, activation dependent inhibitor of ALC1. Its inhibition results in the trapping of ALC1 alongside PARP1 and PARP2 at sites of DNA damage.
EIS-12656 demonstrated selective cytotoxicity against multiple human cancer cell lines deficient in homologous recombination, with IC50 values in the nanomolar range. This selective targeting of PARP1, PARP2, and ALC1 at sites of DNA damage resulted in G2/M arrest. In vivo studies indicated that EIS-12656 has monotherapy efficacy outcompeting best in class PARP inhibitors. EIS-12656 is well-tolerated at doses up to 1.000mg/kg in both rodent and non-rodent species and displays no significant adverse effects on body weight, food consumption, or clinical observations. Hematological and clinical chemistry analyses revealed no deviations from normal ranges. Histopathological examinations showed no drug-related toxicities. EIS-12656 is well absorbed, distributed, brain penetrant and accumulates in the tumor. Pharmacokinetic analysis indicated dose-proportional exposure and a half-life suitable for once-daily oral administration, providing a strong rationale for the currently recruiting Phase I/II clinical trial to further assess EIS-12656's safety and efficacy in biomarker selected oncology patients.

P4-09-01: Contrast-enhanced ultrasound traced secondary sentinel lymph nodes in early-stage breast cancer to streamline sentinel lymph node biopsy----a preliminary study

Xiaoling Liu, Jicheng Li, Meiyang Huang, Siyang Cao, Aishi Deng, Xia Liu, Jieyu Zhong, Wei Wei

Background: Sentinel lymph node biopsy(SLNB) has replaced axillary lymph node dissection (ALND) as the standard method for axillary staging in clinically node-negative patients. It avoids the complications associated with ALND and allows assessment of nodal status in patients with clinically node-negative breast cancer. Dual agent tracing method of SLNs using methylene blue dye and radioactive sulphur colloid showed excellent detection rates, however the SLNs picked out were not only the first stop, they were included both the first stop(SLNs) and stops thereafter(secondary SLNs, SSLNs). In this study, we conducted contrast-enhanced ultrasound (CEUS) sentinel lymphnode mapping method, to detect a more accurate and visuallizable method of tracing the very first stop of lymphnode. SLNs and SSLNs were labeled preoperatively with a hook wire and skin surface marking, aiming to streamline sentinel lymph node biopsy (SLNB).
Methods: From December 2019 to June 2024, we prospectively collected data of 66 patients with early breast cancer scheduled for surgery in our hospital. Dual tracing method was conducted to detect SLNs on the all patients. In addition, we also conducted CEUS preoperatively, to trace SLNs, SSLNs, and lymphatic draining vessels. All tracing data were

recorded by sketches and marked on patient's skin. Selected patients were labeled with a novel hook wire for SLN. CEUS mapping for SLNs/SSLNs and SLNB surgery were performed by a fixed ultrasound and surgical team. All lymph nodes marked were picked out and recorded with clinical data, such as blue dye result, radioactive counting, et al. Pathological examination on all lymph nodes were made to determine metastatic state. Statistical analysis were made using SPSS 26.0. Non-parametric paired sample wilcoxon test was performed for SLN during and before operation, and the count data rate (%) was indicated by $\chi 2$ test. $P < 0.05$ was considered statistically significant.

Results: 66 patients underwent dual tracing SLNB identified a total of 290 SLNs, among which, 15 SLNs were found positive by pathological biopsy. CEUS method detected a total of 87 SLNs, which was fewer than the numbers detected by the dual tracing method ($Z=-3.076$, $P<0.05$). The detection rate of positive SLNs was 13.80%, higher than that of the dual tracing method (positive SLN rate as 5.17%) ($\chi 2=7.480$, $P<0.05$). The concordance rate between the two methods was 98.48%, on the first lymph node detected, which were the actual SLN. Following the SLNs, all SSLNs displayed by CEUS were found within the markings of dual tracing method, with a concordance rate of 100%. CEUS cumulatively detected 110 SSLNs, with a detection rate of 90.90%, and a positive SSLN detection rate of 2.73%. The concordance rate between all lymph nodes marked by CEUS and those marked by the combined method was 99.49%, and in all cases, there were no instances of positive SSLNs identified by CEUS while the SLNs were negative, indicating by our study population, no skip metastasis occurred.

Conclusions: Preoperative CEUS mapping of SLNs shows a high concordance with SLNs traced by dual tracing method using methylene blue dye and radioactive sulphur colloid. It can differentiate SSLNs from SLNs, and provide a possibility of deescalating axillary SLNB by avoiding SSLN dissection.

P4-09-02: Multiparametric MRI and Transfer Learning for Predicting Positive Margins in Breast-Conserving Surgery: A Multi-Center Study

Xue Zhao, Jing-Wen Bai, Sen Jiang, Zhen-Hui Li, Jie-Zhou He, Zhi-Cheng Du, Xue-Qi Fan, Shao-Zi Li, Guo-Jun Zhang

Background: Breast-conserving surgery (BCS) maintains high appearance satisfaction while minimizing postoperative complications. However, positive surgical margin is the most important risk factor to cause local recurrence or recurrence in breast and increase the reoperation rate, even following by additional treatments such as radiotherapy during BCS. Preoperative predictive tools are urgently needed to optimize surgical decisions in BCS. In this study, we developed a series of Base- and Transfer-MMRMs based on multiparameter magnetic resonance imaging (mpMRI) and Radiomics for the preoperative prediction of positive surgical margins in BCS across multiple centers.

Methods: This retrospective study enrolled 444 patients who received BCS in three hospitals from January 2019 to April 2024 in China. The patients were divided into four

cohorts: SUMCCH-1 (from Cancer Hospital of Shantou University Medical College, n = 158), SUMCCH-2 (from Cancer Hospital of Shantou University Medical College, n = 60), XAH (from Xiang'an Hospital of Xiamen University, n = 52), and YNCH (from Yunnan Cancer Hospital, n = 174). All patients had preoperative breast MRI scans before BCS, and surgical margin status was determined through pathological examination. During the model construction stage, clinicopathological and Radiomics features of breast MRI (including DCE, T2WI, and DWI sequences) were extracted and selected via t-test and least absolute shrinkage and selection operator (LASSO) logistic regression. Eight machine learning classifiers were used for model development, and transfer learning (TL) was performed to improve the model's generalization ability. The performance of the Base- and Transfer-MMRMs were assessed using metrics such as area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity.
RESULTS: The rates of positive surgical margins in BCS varied significantly: 26.6% in SUMCCH-1, 20.0% in SUMCCH-2, 34.6% in XAH, and 9.8% in YNCH. The Base-MMRM achieved an AUC of 0.889 in the internal test cohort and 0.771 in the validation cohort after being trained on SUMCCH-1 and validated on SUMCCH-2 but performed poorly in external centers. TL approach significantly improved AUC in both XAH (from 0.533 to 0.902) and YNCH (from 0.359 to 0.855) cohorts compared with the Base-MMRM. Furthermore, the Shapley additive explanation (SHAP) method, along with subgroup analysis, enhanced the interpretability of this model.
Conclusion: This multi-center study developed a precise preoperative model for predicting the risk of positive surgical margins in BCS by utilizing MRI and clinicopathological data. The TL could enhance the predictive accuracy across external centers, making it easier to implement the model in different hospitals.

P4-09-03: Reoperation Rates Following Breast-Conserving Surgery in a Brazilian Cohort

Anne Dominique Nascimento Lima, Eduardo Camargo Millen, Andre Mattar, Alan Felipe Oliveira de Alencar, Carlos Frederico Freitas de Lima, Daniele Pitanga Torres, Eduarda Goulart, Fabrício Palermo Brenelli, Felipe Pereira Zerwes, Francisco Pimentel Cavalcante, Isabela Avila Small, Jose Bines, Marcelo Antonini, Maria Beatriz de Paula Leite Kraft, Martina Lichtenfels, Renato Zocchio Torresan, Antonio Luiz Frasson

Introduction: In early breast cancer, Breast-conserving surgery (BCS) should be performed as the first option whenever is suitable, as it provides the same overall survival than mastectomy with favorable aesthetics results. However, the risks of a positive margin will demand a further surgery, that may affect the cosmesis and add financial and emotional distress. These risks underscore the importance of effective strategies to reduce the rate of reoperation. There is a knowledge gap about the reoperation rate after breast-conserving surgery and adjuvant radiotherapy in Brazil.Objective: Analyze the reoperation rate after BCS in Brazil, aiming to identify predictive factors.Methods: This retrospective multicenter cohort study included breast cancer patients from public and private hospitals in Brazil. The

study focused on patients who underwent breast-conserving surgery and adjuvant radiotherapy between January 2016 and December 2022, with cancer stages ranging from I to III. Patients aged under 65 who underwent conservative surgery without radiotherapy were excluded from the study. Statistical analyses were performed using the R application for Windows, version 4.4.1. The association between independent variables and the outcome was assessed using logistic regression to evaluate the relationship between each potential risk factor (independent variable) and the outcome "Reoperation." Odds ratios (OR) and respective 95% Confidence Intervals (CI) for each variable were presented, along with the p-value obtained from the Wald test. Given the small number of reoperations, multiple logistic regression was not performed due to low statistical power. Values of $p<0.05$ were considered statistically significant. This study was approved by the Research Ethics Committee (n°.6,907,736) in accordance with the ethical principles established by the National Health Council.Results: Of the 705 patients included in the study, 40 (5.7%) underwent reoperation. This included 10 out of 72 patients (13.9%) from public hospitals and 30 out of 631 patients (4.8%) from the private sector. Among these patients, 557 (79.6%) underwent Wide Local excision (WLE) and 141 (20.4%) underwent therapeutic mammoplasty (oncoplastic surgery). Of the 40 patients who required reoperation, 32 (80%) had positive margins, 26 (65%) underwent frozen section and/or margin shaving, while 12 (30%) did not undergo frozen section or margin shaving. Additionally, 25 (62.5%) showed the presence of tumor cells in the surgical specimen. Regarding the type of reoperation performed, there were 24 re-excision, 10 nipple-sparing mastectomies, 2 skin-sparing mastectomies, and 1 modified radical mastectomy. In the univariate analysis, the risk of reoperation was higher in patients with positive margins (OR 23.53; 95% CI 9.79-69.94; $p<0.001$), those treated in public hospitals (OR 3.23; 95% CI 1.44-6.72; $p<0.003$), and those with multifocal tumors (OR 2.92; 95% CI 1.11-6.79; $p<0.019$).Conclusion: This contemporary Brazilian study demonstrated low reoperation rates after breast-conserving surgery (BCS) at 5.7%, regardless of the use of strategies such as frozen section, margin shaving, or therapeutic mammoplasty. Further studies with larger cohorts are needed to better understand this scenario.

P4-09-04: Vacuum-assisted biopsy (VAB) versus standard breast surgery among patients with pCR after neoadjuvant therapy.

Nikolay Amirov, Petr Krivorotko, Alexander Emelyanov, Viktoriia Mortada, Roman Pesotsky, Tengiz Tabagua, Anna Artemyeva, Sergey Yereschenko, Elena Zhiltsova, Yana Bondarchuk, Diana Enaldieva, Daria Ulrikh, Sergey Novikov, Zhanna Bryantseva, Irina Akulova, Ekaterina Busko, Tatiana Semiglazova, Vladimir Semiglazov

Introduction. Nowadays, in patients with breast cancer (BC) and complete pathological response (pCR) after neoadjuvant systemic therapy (NST) role of surgery is uncertain. Vacuum-assisted biopsy (VAB) of the tumor bed in breast cancer has shown promising results as a minimally invasive method for diagnosing pCR. In a NCT04293796 clinical trial we are investigating refusion of standard breast cancer surgery among patients with pCR,

which was confirmed using VAB. This paper presents a retrospective analysis of treatment of patients with triple-negative (TNBC) and HER2-positive breast cancer who achieved pCR after NST, depending on different types of invasive breast surgery, including data from patients who underwent VAB alone without subsequent breast surgery.
Materials and Methods. We retrospectively analyzed 3247 patients who underwent surgery in the department of breast tumors at the National Medical Research Center of Oncology named after. N.N. Petrov from January 01, 2021 until July 01, 2023. Patients were included if they had unifocal invasive HER2+ and TNBC (cT1–2N0–1M0), who had histologically confirmed pathological complete response (ypT0N0) after NST. Patients with TNBC received 4 cycles of AC q21d followed by 12 cycles of weekly paclitaxel and carboplatin AUC 2.0. HER2+ patients received dual anti-HER2 blockade with chemotherapy (TCHP or AC-DHP regimen). Patients were not included in the analysis if an intraductal component was identified by core-biopsy, as well as if they carried germline mutations in the BRCA1/2 genes. All patients were divided into three groups: breast-conserving surgery (BCS) group, the mastectomy (ME) group, and the VAB group. Primary endpoint was 2-year ipsilateral breast tumor recurrence-free survival (IBTR-FS). Secondary endpoint was 2-year disease-free survival (DFS).
Results. Of the 3247 patients analyzed, 81 patients who met the inclusion criteria were included in the final analysis. There were 39 patients in the BCS group, 19 patients in the ME group, and 23 patients in the VAB group. Median follow-up was 24 months. Median survival was not reached for any endpoint. 2-year IBTR-FS was 100% in the BCS group vs. 100% in the ME group vs. 91.3% in the VAB group [p=.159]. 2-year disease-free survival (DFS) was 97.4% in the BCS group vs 94.7% in the ME group vs 87.0% in the VAB group [p=.396]. The hazard ratio (HR) for recurrence did not differ depending on the surgical procedure performed. When measuring HR adjusted for lymph node status (cN) and disease stage, there was a statistically significantly higher risk in the VAB group [HR adjusted for cN: 12.236, (95% CI, 1.163 - 128.773), p = 0.037; HR adjusted for stage: 17.071, (95% CI, 1.255 – 232.173), p=0.033].
Conclusion. We need further observational studies and large randomized prospective trials to determine the safety of VAB as a method for de-escalation of breast cancer surgery.

P4-09-05: Trends in mastectomy for non-metastatic breast cancer patients in an institution with limited resources

Francisco Pimentel Cavalcante, Tallita Moniele Gomes Pinheiro, Felipe Pereira Zerwes, Eduardo Camargo Millen, Andre Mattar, Marcelo Antonini, Fabrício Palermo Brenelli, Guilherme Garcia Novita, Antonio Luiz Frasson, Ruffo Freitas-Junior

Introduction: Breast-conserving surgery (BCS) is the preferred surgical treatment for early-stage breast cancer. In recent years, however, an increase in mastectomies has been observed in developed countries. The advent of genetic knowledge, the possibility of immediate reconstruction, and the false impression of greater safety have been associated with the increase in mastectomies. This trend, however, has not yet been adequately

evaluated among breast healthcare in low- and middle-income countries.
Method: This is a retrospective study of patients undergoing surgery for non-metastatic breast cancer between 2012 and 2019 at the General Hospital of Fortaleza (HGF), an institution that exclusively treats patients from the public health system in Brazil (SUS). In Brazil, 80% of the population's healthcare is provided through the SUS. The main objective of the study was to evaluate the rates of mastectomy during the period, with immediate reconstruction or without reconstruction, as well as BCS. The chi-square test, with Bonferroni adjustment, was applied to the relative frequency of procedures performed to test the statistical significance in the evolution of surgery frequencies over the years. The research was initiated after approval by the Research Ethics Committee of the institution (CAAE 29325720.7.0000.5040).
Results: After applying the study's inclusion criteria, 805 patients undergoing surgical treatment for non-metastatic breast cancer were included for analysis, with an average of 100 surgeries per year (range 85-118) during the study period. Mastectomy was performed in 552 cases (68.57%), while 253 patients underwent BCS (31.42%). Among patients undergoing mastectomy, 181 (32.78%) had immediate reconstruction, with the highest proportion using implants (92.26%). Evaluating the proportions of each type of surgery during the study period, a statistically significant change was found only for breast-conserving surgery (p=0.001; Bonferroni adjustment: p=0.003), compared to mastectomy without reconstruction (p=0.623; Bonferroni adjustment: p=0.299) and mastectomy with reconstruction (p=0.591; Bonferroni adjustment: p=0.663).
Conclusion: There was no increase in mastectomy rates, with and without immediate reconstruction, over the years, but a trend of increasing BCS. More studies are needed for a better understanding of this trend in locations with limited access to healthcare.

P4-09-06: Oncologic Outcomes of Breast-Conserving Surgery versus Mastectomy after Neoadjuvant Chemotherapy: Results from a Contemporary Multicenter Cohort

Francisco Pimentel Cavalcante, Felipe Pereira Zerwes, Ryane Alcantara, Eduardo Camargo Millen, Andre Mattar, Marcelo Antonini, Anne Dominique Nascimento Lima, José Bines, Fabrício Palermo Brenelli, Guilherme Garcia Novita, Anastacio Berretini Junior, Rafael Henrique Szymanski Machado, Alessandra Borba Anton Souza, Danielle Calheiros Campelo, René Aloisio da Costa Vieira, Antonio Luiz Frasson

Introduction: Previous studies have shown a higher rate of local recurrence (LR) in breast-conserving surgery (BCS) after neoadjuvant chemotherapy (NAC) without impacting survival. However, currently, the use of more effective systemic treatment, understanding of disease biology, and improved imaging methods, with lesion marking before NAC, may impact local control.
Material and Methods: The main objective of this study was to evaluate oncologic outcomes: local recurrence (LR), distant recurrence (DR), and death in patients with non-metastatic breast cancer, undergoing BCS compared to mastectomy after NAC, through a contemporary

multicenter retrospective cohort study in Brazil involving public institutions in two different Brazilian regions with limited access to resources. Between 2013 and 2023, at the General Hospital of Fortaleza (Northeast region, HDI 0.754) and the Pontifical Catholic University of Rio Grande do Sul (South region, HDI 0.867) were evaluated. Disease-free survival (DFS) curves, DFS by tumor stage (T1, T2, T3, T4), distant recurrence-free survival (DRFS), as well as overall survival (OS), were developed using the Kaplan-Meier method and Cox proportional hazards model. Finally, multivariate logistic regression was performed to assess the association of clinical-demographic and treatment characteristics with LR. The significance level adopted was 5%.
Results: Patients undergoing NAC (n=365), between 2013 and 2023, at the General Hospital of Fortaleza and the Pontifical Catholic University of Rio Grande do Sul (PUC/RS) were evaluated, with 165 women undergoing mastectomy and 200 undergoing BCS, constituting the analysis groups. In the mastectomy group, there were more cases aged over 70 years (12.7% versus 7%; p=0.02) and T4b tumors (16.4% versus 4.5%; p=0.0003), while in the BCS group, there were more patients with negative axilla (42% versus 31.5%; p=0.02). After a mean follow-up of 65 months (4-124), 18 LR were observed, with 8 cases (4.8%) in the mastectomy group and 10 events in the BCS group (5.0%), with no significant difference (p=0.95), as there were no differences in DR (mastectomy 10.9% [18/165] versus BCS 9% [18/200]; p=0.58). On the other hand, more deaths were observed in the mastectomy group (8.5% [14/165] versus 3% [6/200]; p=0.03). DRFS showed no significant differences between the groups (91% BCS versus 89% HR: 1.25, 0.65-2.42; p=0.4). However, when OS was evaluated, patients undergoing BCS had better outcomes compared to mastectomy (97% versus 91.5%; HR: 2.62; 1.06-6.69; p=0.03). The estimated 10-year DFS stratified by tumor stage showed no significant difference, except in T4 disease which showed a higher risk for the mastectomy group (81.8% versus 94.5% HR: 2.86, 1.54-5.30; p=0.0008). In multivariate analysis, T3/T4 staging (OR: 4.37, 1.03-21.91; p= 0.04) and axillary dissection (OR: 5.11, 1.14-35.52; p= 0.04) were associated with LR in BCS.
Conclusion: In this contemporary cohort of patients undergoing NAC, that received treatment in public institutions with limited access to resources, BCS did not present worse oncologic outcomes compared to mastectomy. Further studies are needed to confirm these findings.

P4-09-07: Clinical Outcomes of Reverse-Sequence Endoscopic Nipple-Sparing Mastectomy with Direct-to-Implant Breast Reconstruction in Breast Cancer Patients with Large or Severe Ptotic Breast: A Single-center Prospective Cohort Study

Hui Dai, Xiaoman Cao, Faqing Liang, Yanyan Xie, Kawun Chung, Qing Zhang, Mengxue Qiu, Huanzuo Yang, Jiao Zhou, Yu Feng, Zhenggui Du

Background: Nipple Sparing Mastectomy (NSM) with direct-to-implant breast reconstruction (DIBR) is not recommended or even considered contraindicated in breast cancer patients with large or severe ptotic breasts (LSPB). The commonly used NSM

methods for the patients are often based on the Wise-pattern skin-reducing technique, which have some shortcomings in surgical safety and breast aesthetics. The reverse-sequence endoscopic NSM (R-E-NSM) with DIBR has shown promising clinical outcomes for patients with LSPB, and aesthetic outcomes can be enhanced by the combination of the air inflation adjustment technique (AIAT). This study aimed to evaluate the safety and aesthetic outcomes of the R-E-NSM with DIBR and AIAT in breast cancer patients with LSPB and to investigate the feasibility of NSM with DIBR in the patients.
Methods: The prospective study enrolled breast cancer patients who underwent R-E-NSM with DIBR from September 2020 to August 2024 at a single institution. According to whether or not the suprasternal notch-to-nipple distance was over 25 cm, all patients were categorized into the LSPB group and the non-LSPB (NLSBP) group. The propensity score matching (PSM) was used to balance the baseline characteristics between the two groups. Then, the surgical safety, aesthetic outcomes, and oncologic safety were compared between the two groups.
Results: A total of 562 breast cancer patients were eligible for the study, including 98 patients in the LSPB group and 464 in the NLSPB group. After PSM, 343 patients were retained, with 87 patients in the LSPB group (mean [SD] age: 42.2[9.3] years, median [IQR] follow-up time: 20.9 [13.6, 32.9] months) and 256 in the NLSPB group (mean [SD] age: 42.4[8.9] years, median [IQR] follow-up time: 22.3 [10.3, 31.9] months). The mastectomy weight of patients in the LSPB group was significantly higher than that in the NLSPB group (573.1±146.2g vs. 337.3±105.5g, $P < 0.001$). After PSM, there were no significant differences in any complications (27.6% vs. 21.9%, P = 0.276), major complications (4.6% vs. 2.7%, P = 0.617), minor complications (24.1% vs. 20.3%, P = 0.451) and implant complications (20.7% vs. 25.0%, P=0.415) between the LSPB and NLSPB groups. The Ueda scores and Breast-Q were insignificantly different between the two groups after PSM(all $P > 0.05$). Without AIAT, patients in the LSPB group had relatively inferior Ueda scores to those in the NLSPB group (proportions of “excellent” 37.9% vs. 56.1%), while with AIAT, the difference decreased (proportions of “excellent” 72.4% vs. 78.1%), through both of them have no significant difference. In the LSPB group, the Ueda scores in patients undergoing AIAT were significantly better than those without AIAT (proportions of “excellent” 72.4% vs. 37.9%, P=0.002). The local recurrence-free survival (P = 0.205), distant metastasis-free survival (P = 0.903), and disease-free survival (P = 0.532) were not significantly different between the two groups.
Conclusions: R-E-NSM with DIBR can bring favorable surgical safety, aesthetic outcomes, and oncologic safety for patients with LSPB, similar to patients with NLSPB. AIAT helps improve breast aesthetics for patients with LSPB. We suggest that LSPB is not a contraindication to endoscopic breast reconstruction, which is worthy of clinical promotion and offers a new or even superior option for breast cancer patients with LSPB beyond the NSM with Wise-pattern skin-reducing technique.
Keywords: Breast cancer, Large breast, Severe Breast Ptosis, Reverse-sequence endoscopic nipple-sparing mastectomy, Direct-to-implant breast reconstruction， air inflation adjustment technique.

P4-09-08: Outcomes after Autologous Breast Reconstruction for Triple-Negative Breast Cancer among Black and White Patients

Mattia Mahmoud, Dustin Crystal, Sarah Barnett, Stephany Perez-Rojas, Payal D Shah, Neil K. Taunk, Robyn Broach, Said C. Azoury, Oluwadamilola "Lola" Fayanju

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype disproportionately diagnosed among Black women as compared to White women and for which multidisciplinary treatment and coordination among surgeons, medical oncologists, and radiation oncologists is especially important. Autologous breast reconstruction after mastectomy, an increasingly sought surgical option for patients with TNBC, is associated with significant aesthetic and psychological benefits. However, autologous breast reconstruction is technically challenging and while rare, postoperative complications can potentially confer significant morbidity, delay next steps in treatment, and even result in death. It is unclear, however, whether receipt of autologous reconstruction is associated with adverse oncologic outcomes for patients with TNBC and whether previously observed racial disparities in receipt of and outcomes after post-mastectomy reconstruction are also observed among patients with TNBC. We sought to examine and compare overall survival and recurrence rates after autologous breast reconstruction among Black and White patients with TNBC.
Methods: We identified females ≥18 yo diagnosed with invasive triple-negative carcinoma at our institution between 2007 and 2017 and who underwent autologous reconstruction. We collected data on demographics, medical and surgical history, breast tumor data, systemic and radiation treatment composition and sequence, intraoperative details, reconstruction complication and revision information, recurrence, and mortality. Cox proportional models were used to estimate hazard ratios and 95% confidence intervals of the potential recurrence and mortality differences by race. Survival times were measured from the date of surgery to date of death or date of last contact.
Results: There were 135 patients included in the analysis: 34 Black, 89 White, 4 Asian/Pacific Islander, and 8 with unknown race/ethnicity. A majority of patients had Stage II disease: clinical stages 1 (42, 32%), 2 (65, 51%), 3 (15, 11%), and 4 (3, 2%). There were 47 (35%) patients with nodal involvement. More patients received neoadjuvant therapy first (59, 56%) compared to those who received surgery first (46, 44%). Median time to cancer recurrence and mortality was 5.97 and 6.45 years, respectively. Mean age at diagnosis was 48.53 years while mean body mass index (BMI) was 29.78 kg/m2. There were 87 (64%) patients who never smoked, 6 (4%) who currently smoked and 42 (31%) who smoked prior to surgery. Transverse rectus abdominis myocutaneous flap (TRAM) (61% for left breast and 58% for right breast) and deep inferior epigastric perforator (DIEP) flaps (21% for left breast and 26% for right breast) were the most common autologous reconstruction procedures. Of the 135 patients, 38 (28%) patients had their breast cancer recur and 34 (25%) patients died. There were no differences in mortality (p=0.29) or recurrence (p=0.47) by race/ethnicity, and neither smoking nor obesity status significantly affected risk of mortality or recurrence.
Conclusion: There were no significant differences in recurrence or mortality by race after

mastectomy and autologous reconstruction for TNBC patients. Further investigation with larger patient samples could identify risk factors that better predict adverse outcomes post mastectomy and reconstruction.

P4-09-09: Prepectoral Implant-Based Breast Reconstruction: A New Standard of Care. Experience of a Chilean Breast Oncoplastic Surgery Group

Jaime Letzkus, José Manuel Lagos, María José Del Rio, Jorge Gamboa, Daniela Hidalgo, Guillermo Belmar

Introduction: Prepectoral breast reconstruction (PPBR) has gained popularity among breast surgeons due to its preservation of chest wall anatomy, maintenance of normal pectoral muscle function, minimal morbidity, reduction of breast pain, and avoidance of animated breast deformity. Implant-based breast reconstruction (IBR) remains the most widely utilized technique globally, facilitated by advancements in modern implants and synthetic adjunctive materials, alongside significant improvements in mastectomy and reconstruction methods. Historically, IBR was primarily performed using a sub-pectoral two-stage technique, often in conjunction with post-mastectomy radiotherapy (PMRT). However, IBR can be associated with complications such as capsular contracture, secondary breast elevation, breast pain, and animated deformity.
The aim of this study is to report preliminary outcomes of patients undergoing IBR using the prepectoral technique, delineating specific indications and complication rates.
Method: This is a retrospective analysis from a prospective database of reconstructive patients who underwent PPBR from July 2019 to June 2024 at both public university hospitals and private practice centers in Santiago, Chile. Oncological and immediate reconstructive procedures were performed by a team of breast surgeons with Level 3 oncoplastic and reconstructive training. Patients were preoperatively assessed by a multidisciplinary oncological committee. Surgical feasibility for conservative mastectomy and prepectoral reconstruction was evaluated on an individual basis, with specific informed consent obtained. The study analyzed general demographic data, comorbidities, genetic mutation status, histopathological information, adjuvant therapies (chemotherapy and radiotherapy), and technical details of the mastectomy and reconstruction procedures, including complications.
Results: A total of 119 patients (132 PPBR procedures) were included. The average patient age was 47 years (range 27-70), with an average BMI of 27.2. Seventeen patients had pathogenic mutations, and 18 underwent bilateral reconstruction. Definitive implants were used in 116 (88%) patients, with 95 cases being nipple-sparing mastectomies (NSM). Inframammary fold incision was used in 73 cases, and mesh was utilized in 33 cases. PMRT was administered to 43 patients. Mild to moderate complications occurred in 51 patients and there was an implant loss rate of 6% (8 out of 132 implants).
Conclusion
PPBR demonstrated a low complication rate and minimal implant loss. In well-selected

patients, it is a safe and efficient reconstructive technique offering excellent aesthetic outcomes, often without the need of mesh. PPBR avoids animated breast deformity and is associated with reduced chronic breast pain, making it suitable for both therapeutic and risk-reduction purposes.

P4-09-10: Evaluation of Axillary Treatment in Patients with Early Breast Cancer According to Study Z0011 in a Public Tertiary Hospital in the Federal District, Brazil

Thais Vivan, Mauro Passos Pinto, Vinicius Santos Xavier, Fernanda Cristina Salum, Carolina de Miranda Fuschino, Angelica de Figueiredo Resende Esterl, Rodrigo Costa Pepe

Introduction: The radical mastectomy technique described by Halsted in 1894 was based on the concept that more extensive surgical resection increased the likelihood of patient cure. Over more than 120 years, medical knowledge about breast cancer has expanded, enabling less mutilating treatments with equal or better survival rates, especially following studies on tumor biology. Axillary surgical treatment has been a significant milestone, changing medical management and reducing the rates of axillary lymph node dissection after the publication of the American College of Surgeons Oncology Group Z0011 clinical trial, that demonstrated that patients with initial cT1-T2 tumors without palpable axillary adenopathy, undergoing breast-conserving surgery, systemic adjuvant treatment, and radiotherapy, maintained overall survival and distant recurrence-free survival rates, even with 1 or 2 metastatic axillary lymph nodes, compared to those who underwent axillary dissection.
Objectives: To evaluate the applicability of the Z0011 protocol in the axillary treatment of early invasive breast cancer and its impact on reducing axillary lymph node dissection by omitting this surgical treatment.
Method: This is an observational, descriptive, retrospective study based on data collected from the medical records of patients who underwent surgical treatment at a public hospital, Hospital de Base, in the Federal District, Brazil.
Results: A total of 119 patients from the mastology service at Hospital de Base met the Z0011 eligibility criteria. Nine patients were excluded due to failure in patent blue migration, resulting in 110 patients included in the study. The average age of patients was 58 years (ranging from 35 to 83 years). The predominant immunohistochemical profile was luminal B (55%), followed by luminal A (30%), HER2 positive (9%), and triple-negative (6%). Among the HER2 positive patients, 80% also had positive hormone receptors (HR), while 20% were HR negative. Among the 110 patients, 27% had sentinel lymph node (SLN) metastasis. Specifically, 19% had metastasis in 1 SLN, 3% had metastasis in 2 SLNs, and 5% had metastasis in 3 or more SLNs. Consequently, 83% of patients with 1 or 2 metastatic SLNs did not undergo lymphadenectomy, representing a significant omission of axillary surgical treatment.
Conclusion: The successful replication of the Z0011 protocol in our study demonstrates the significant potential for reducing axillary lymphadenectomy in patients treated at our

hospital, with an observed 83% reduction in axillary dissection among patients with axillary lymph node metastasis. These findings are particularly important as they underscore the feasibility of implementing the Z0011 protocol in a public hospital setting, providing evidence that even in resource-constrained environments, it is possible to achieve substantial improvements in patient care.

P4-09-11: The use of indocyanine green instead of blue dye for dual-tracer sentinel lymph node biopsy in breast cancer

Madison Kolbow, Qianyun Luo, Schelomo Marmor, Jennifer Witt, Sydne Muratore, Todd M. Tuttle, Jane Y.C. Hui

Introduction: Dual-tracer sentinel lymph node biopsy (SLNB) with technetium-99m sulfur colloid (Tc99) and blue dye has been the standard method utilized in breast cancer surgery. The use of blue dye can be associated with skin tattooing, skin necrosis (methylene blue), and allergic reactions (isosulfan blue). The aim of this study was to determine if indocyanine green (ICG) is a suitable replacement for blue dye for dual-tracer SLNB.
Methods: We performed a single-center retrospective study of female breast cancer patients age ≥18 years who underwent SLNB with Tc99 and ICG from November 2022 to April 2024. ICG mapping was performed by injecting a total of 0.1 ml of ICG intradermally into the areolar skin of the right breast at the 12 and 9 o'clock positions or of the left breast at 12 and 3 o'clock positions preoperatively. Tc99 mapping was performed by injecting Tc99 into the retroareolar breast preoperatively. Intraoperatively, the SPY Portable Handheld Imager was utilized to visualize fluorescent SLNs and a gamma detector was utilized to identify SLNs with Tc99 uptake. Operative reports were reviewed to determine sentinel lymph node (SLN) identification rate with ICG (fluorescent) and Tc99 (radioactive). Pathology reports were reviewed to determine the pathology of excised SLN.
Results: One hundred and nineteen SLNBs were performed on 117 patients. The median age at time of surgery was 59.0 years and the median BMI was 26.9. Most patients had invasive ductal carcinoma (76%) and a primary tumor located in the upper outer quadrant (50%). The proportions of patients receiving mastectomy (47%) and breast-conserving surgery (53%) were similar. Thirty-two patients (27%) received neoadjuvant chemotherapy. The mean number of SLNs retrieved per SLNB was 1.6 (fluorescent, 1.50; radioactive, 1.48). Overall, at least one radioactive or fluorescent SLN was identified in 93.2% of all patients. Of all excised SLNs, 89.4% were fluorescent, 88.4% were radioactive, and 81.9% were both fluorescent and radioactive. Overall, 26 patients (22.2%) had SLN metastases; of SLNs identified with metastases on pathologic examination, 87.2% were fluorescent and 74.6% were radioactive. Three patients (2.6%) experienced skin flap necrosis and one patient (0.85%) experienced prolonged skin discoloration. No patients experienced allergic reactions.
Conclusion: This study demonstrates that SLN identification rates using ICG and Tc99 are comparable to those using blue dye and Tc99. Thus, ICG is a suitable alternative for blue dye in times of tracer shortage and may avoid complications specific to blue dye. Future work

should assess if ICG is a suitable tracer for SLNB in low-resource settings where Tc99 is not available.

P4-09-12: Factors influencing axillary node clearance in early breast cancer care in the UK in 2023

Stuart A McIntosh, Helen Flint, Julie Douglas, Philipp A. Dietrich, Victoria Bush, Richard Simcock

Early breast cancer (EBC) treatment is multimodal; as more effective systemic therapies become available, decision-making and personalised treatment selection become more complex, although factors such as tumour size, grade and nodal status remain important. Advances in treatment are driving an evolution in care. This study sought to understand the UK breast cancer management landscape and challenges facing healthcare professionals (HCPs) in relation to decision-making around axillary surgery in patients with ER+ HER2- disease.
HCPs involved in EBC patient management (n=70; 29 medical oncologists, 13 clinical oncologists, 10 surgeons, 13 pharmacist prescribers and 5 nurses) were surveyed August to December 2023.
NICE guidance states that patients with radiologically detected node-positive (N+) disease should be offered axillary node clearance (ANC). However, only 21% of HCPs stated their multidisciplinary teams would perform ANC with 1 involved node identified pre-operatively and 30% where 2 nodes were seen. Approximately 40% stated the decision to carry out ANC would depend on other factors such as tumour size, comorbidities and age. However, of those citing other factors, 56% said this decision would be to inform further treatment. Similarly, following a positive sentinel lymph node biopsy (SLNB), only 11% would perform ANC for a single positive node, and 30% for 2 involved nodes. Again, almost 40% said the ANC decision would depend on other factors, but here 81% of those said that the decision for ANC would be to inform further treatment. For greater burdens of nodal disease, ANC was much more likely in both radiologically detected and SLNB detected nodal disease.
These findings show that for patients with a low burden of radiologically detected axillary nodal disease, only a small proportion routinely undergoes ANC, in contrast to NICE recommendations. However, this proportion is higher in those with a positive SLNB. It appears that some patients may undergo ANC to inform further treatment decisions. Given that more extensive axillary surgery does not improve outcomes, but is associated with significant morbidity, it is clear that improved methods to inform decisions about further adjuvant treatment are required.

P4-09-13: Intraoperative assessment of margins in breast conserving therapy: Comparison of intraoperative specimen mammography and intraoperative pathologic evaluation

Susanne Briest, Alma Luise Bayer, Laura Weydandt, Mireille Martin, Anne Kathrin Höhn, Ivonne Nel, Bahriye Aktas

Background: Breast-conserving therapy is a long-standing standard surgical procedure for treating breast cancer. The aim is the complete resection of the tumor with free margins to avoid additional surgery and possible relapse. The optimal way to document tumor-free margins intraoperatively is still unclear.
Methods: In a retrospective study, we analyzed patients who underwent breast-conserving surgery for the treatment of early breast cancer in our institution. Patients with ductal carcinoma in situ (DCIS), locoregional relapse and those after neoadjuvant chemotherapy were excluded. We investigated the value of intraoperative pathologic evaluation compared with intraoperative specimen mammography for the assessment of tumor-free margins in breast conserving surgery.
Results: Between 2009-2022, 465 patients underwent breast conserving surgery and received both intraoperative pathologic evaluation by frozen section and specimen mammography at our institution. The median age of the patients was 62 years. We found 59.1 % of the patients to have an invasive tumor not otherwise specified (NOS), 14.2% to present with an invasive lobular cancer and 18.1% with a mixture of both types, while 8.6% of our patients had another type of tumor, e.g. medullar. Most of the patients, 76.3 %, were node negative and had a tumor stage pT1c. The highest accordance between the results for frozen section and specimen mammography was seen in patients older than 70 years (77.7%), having an invasive breast cancer of no special type (73.8%) and a pT2 tumor stage according to the TNM classification (73.1%). Patients with a hormone-receptor negative tumor had higher accordance rates as well as those with a HER2 positive breast cancer. The difference between the accordance of the two methods was statistically significant only for patients younger than 50 years and those having a G3 tumor. To evaluate the value of the two methods for determining the margin during surgery we calculated the sensitivity, the specificity and the positive predictive value for the specimen radiography as compared to the frozen section resulting in 52.6%, 76.7% and 31.3%, respectively.
Conclusion: The intraoperative specimen mammography is not a reliable method to assure tumor free margin for patients undergoing breast conserving surgery. The pathological evaluation of tumor specimen in addition to the specimen mammography resulted in a very low re-excision rate. Only 2.4% of the patients in our cohort had positive margins after complete pathological evaluation postoperatively. While the intraoperative frozen section seems to be the best way to avoid a second surgery, this method is costly and requires the presence of a pathologist. Thus, an improvement of the specimen mammography and the development of new imaging methods are needed.

P4-09-14: Results of combined breast cancer treatment depending on various types of reconstruction after mastectomy and radiation therapy

Daria Ulrikh, Petr Krivorotko, Zhanna Bryantseva, Sergey Novikov, Viktoria Mortada, Roman Pesotskiy, Yana Bondarchuk, Nikolay Amirov, Alexander Emelyanov, Diana Enaldieva, Valerii Levchenko, Elena Zhiltsova, Tengiz Tabagua, Konstantin Zernov, Irina Akulova, Larisa Gigolaeva, Kirill Nikolaev, Aleksandr Komyakhov, Sergey Yerechshenko, Vladimir Semiglazov

Background. Implant-based breast reconstruction, in contrast to autologous reconstruction, often requires revision surgery and ultimately leads to reconstructive failure, especially in the context of adjuvant radiation therapy. Reconstructive failure and capsular contracture (CC) remain the most common complications leading to unsatisfactory aesthetic results. To date, there is no therapeutic target for the direct treatment of CC, which emphasizes the importance of its prevention. Also the consensus is lacking regarding the optimal reconstruction plan for patients requiring adjuvant radiation therapy.
Objective. To determine the impact of risk factors on the development complications of breast reconstruction and the incidence of capsular contracture and reconstructive failure in the era of multidisciplinary breast cancer treatment using modern surgical and therapeutic approaches.
Materials and methods. This retrospective study included 466 patients diagnosed with breast cancer who received combined treatment from 2016 to 2021 at the FSBI “N.N. Petrov NMRC of Oncology” of the Russian Ministry of Health. The patients were divided into 3 groups: immediate reconstruction (N=158), immediate-delayed (N=210) and delayed (N=98). Features of the surgical intervention, neoadjuvant and/or adjuvant systemic therapy were analyzed to determine the association with the risk of developing capsular contracture.
Results. Every fourth patient (24.0%, 112/466) may encounter a complication after mastectomy with reconstruction and adjuvant radiation therapy. There was no correlation between potential risk factors depending on the general status of patients (age, obesity, diabetes mellitus, hypertension, history of smoking) and the occurrence of complications after combination treatment. Capsular contracture during alloplastic reconstructive plastic surgery with adjuvant radiation therapy, according to the literature, is a common complication with a complex and multifactorial pathogenesis. Despite the low incidence of CC III-IV Baker scale in the present study (6.9%, 32/466), the majority of patients required revision surgery (90.6%, 29/32). There was no correlation between risk of CC depending on the systemic treatment of patients ($z < 1,96$).
Conclusion. The analysis of complications and reconstructive failures showed that immediate breast reconstruction at the FSBI "N.N. Petrov NMRC of Oncology" of the Ministry of Health of Russia is the safest method of reconstruction in the combined treatment of breast cancer with the lowest incidence of severe complications (9.5%, 15/158, $z>1.96$), which plays a key role in the development of reconstructive failures (Pearson Correlation=0.861, $p<0.001$). However, these surgeries are associated with a

significant number of capsular contractures (15.2%, 24/158, z>1.96, Pearson Correlation=0.230, p<0.001) and statistically depend on the subpectoral location of the endoprosthesis (22.1%, 21/95; z = 2.79), the choice of textured implants (20.8%, 22/106; z = 2.02) and periareolar access during surgery (31.4%, 11/35; z > 1,96). That's why these complications require finding ways to minimize risks to optimize treatment in each individual case in short and long term.
Key words: breast cancer, mastectomy, adjuvant radiation therapy, reconstructive plastic surgery, complications, capsular contracture, reconstructive failure, risk factors.

P4-09-15: The Role of Axillary Reverse Mapping during Sentinel Lymph Node Biopsy in Breast Cancer Patients

Nikolay Amirov, Tengiz Tabagua, Nikolay Amirov, Valerii Levchenko, Viktoriia Mortada, Roman Pesotsky, Alexander Emelyanov, Pavel Krzhivitsky, Vladimir Semiglazov

Introduction. The incidence of lymphedema after axillary lymphadenectomy varies widely, ranging from 14.1% to 33.4%, with the highest rates seen in patients receiving adjuvant radiation therapy. The routine use of sentinel lymph node biopsy (SLNB) instead of lymphatic axillary dissection (LAD) resulted in a lower incidence of lymphedema, ranging from 3.5% to 11%. Therefore, even when we perform an SLNB procedure, we cannot always offset the risk of complications. This is because the lymph nodes responsible for lymph drainage in the upper limb may be among the removed sentinel lymph nodes.
Aim. To evaluate the relationship between sentinel lymph nodes and lymph nodes responsible for the lymph drainage from the upper limb in BC patients when performing SLNB by radioactive isotope (RI) method and with visualization of the lymph collector of the upper limb using indocyanine green (ICG), an axillary reverse mapping (ARM) technique.
Materials and Methods. The retrospective analysis was carried out in the FSBI N.N. Petrov NMRC of Oncology. Thirty-five patients diagnosed with breast cancer during the surgical stage of treatment, including SLNB and the method of ARM using ICG was applied to visualize lymph nodes and vessels responsible for lymph drainage of upper limb tissues.
Results. In 6 (17.14%) cases, the sentinel lymph node turned out to be the lymph node responsible for the lymphatic collector of the upper limb. Standard histology showed tumor cells in only 1 in 6 cases. In the remaining 29 cases (82.86 %) it was possible to preserve the lymphatic collector (lymph nodes and lymphatic vessels) from the tissues of the upper limb.
Conclusion. Performed analysis showed that the marking of lymphatic vessels in the upper limb allows the differentiation of the zones responsible for lymphatic drainage, which in turn determines a selective approach to lymph node removal. Also, if the lymph node responsible for draining lymph from the upper limb is removed, preventive measures can be taken to prevent lymphedema.

P4-09-16: Progesterone Receptor Expression Significantly Correlates with Recurrence Score Regardless of Menopausal Status in HR+/HER2- BC Patients

Federica Martorana, Gianmarco Motta, Maria Vita Sanò, Carlo Carnaghi, Maria Luisa Puglisi, Claudia Gelsomino, Giuseppe Corsaro, Martina La Terra, Stefano Marletta, Giada Maria Vecchio, Gaetano Magro, Giuseppe Catanuto, Gaetano Castiglione, Francesco Caruso, Antonio Rizzo, Michele Caruso, Paolo Vigneri

Background: Clinical and pathological (CP) features have been historically considered the most reliable parameters to define breast cancer (BC) prognosis and select adjuvant therapy accordingly. In the last decade, the OncotypeDX genetic test has entered clinical practice as it refines risk stratification and anticipates chemotherapy benefit for HR+/HER2- BC after surgery. To date, several retrospective series have correlated classical histopathological parameters with the recurrence score (RS) with heterogenous results. Moreover, most of these reports did not take into account patient menopausal status.
Material and Methods: We retrospectively collected data on consecutive patients with HR+/HER2- early BC who underwent OncotypeDX testing between September 2021 and March 2024, followed at a single Institution. CP characteristics were retrieved. Continuous variables were reported as median and interquartile ranges (IQR), while binomial and categorical variables were classified as rates. Linear regression analysis was performed considering RS as a continuous outcome, while logistic regression analysis was performed separately for pre- and post-menopausal patients, dichotomizing the RS with 16 and 25 as high-risk thresholds for each group. Statistical analyses were carried out with the STATA v18.0 software.
Results: Of the 187 identified patients, 180 had complete CP data and were included in the analysis. 63 (35.0%) were pre-menopausal and 117 (65.0%) were post-menopausal. Median age in our patient cohort was 57 years (IQR 49-67.5). Most patients had pT1 pN0 (111, 61.7%), moderately differentiated (G2=119, 66.1%) disease with high ER expression (median 95%, IQR 90-95%) and a median Ki67 proliferation index of 25% (IQR 15.30%). Median PgR expression was 80% (40-90%) in the overall population, 90% (IQR 55-90%) in pre-menopausal women and 70% (IQR 30-90%) in post-menopausal patients. Median recurrence scores were 16 (IQR 12-22), 15 (IQR 11-18) and 17 (IQR 12-22) in the overall, pre- and post-menopausal cohorts.
The RS displayed a direct correlation with G3 disease (p 0.01), HER2 2+ status (p 0.02) and Ki67% (p<0.0001), and an inverse correlation with ER% (p 0.03) and PgR% (p<0.0001). Among pre-menopausal patients, only Ki67% (0.02), ER% (0.01) and PgR% (<0.0001) retained statically significant correlations with the RS, while in the post-menopausal population significance persisted for G3 (p 0.03), HER2 2+ status (p 0.003), Ki67% (p 0.001) and PgR% (p <0.0001).
Using logistic regression analysis, in pre-menopausal patients PgR% was the only variable predicting an RS>16, with an odds ratio (OR) of 0.95 [95% confidence interval (CI) 0.93-0.98, p 0.001]. The area under the ROC curve for PgR% to predict RS was 0.75. In post-menopausal patients, HER2 2+ status (OR 5.53; 95% CI, 1.29-23.68; p 0.021), Ki67% (OR

1.08; 95% CI, 1.01-1.16, p 0.031) and PgR% (OR 0.95; 95% CI 0.93-0.98, p<0.0001) significantly correlated with an RS>25. In this subset of patients, the area under the ROC curve for PgR% to predict RS was 0.87.
Conclusion: In our cohort of HR+/HER2- early BC patients, patient menopausal status influenced the correlation between the RS and classical histopathological features. The rate of PgR expression was the only variable consistently correlating with the RS, regardless of menopausal status. Hence, the prognostic and predictive role of this, often overlooked, parameter deserves further investigation in larger and multicentric cohorts, along with a prospective validation.

P4-09-17: Oncotype DX® breast cancer assay in older patients: a real-life cohort

Clement Grosnon, Djamel Ghebriou, Anne Sabaila, David Buob, Mariana Nedelcu, Lauren Seknazi, Marjolaine Legac, Mathieu Jamelot, Coralie Prebet, Emile Darai, Cyril Touboul, Jean-Pierre Lotz, Joseph Gligorov, Marc-Antoine Benderra

Introduction: The 21-gene Oncotype DX® Breast Recurrence Score test was designed for HR+, HER2- early-stage breast cancer (eBC) to aid in the decision-making process regarding adjuvant chemotherapy. Its validity and utility have been demonstrated prospectively across multiple studies, though data on older patients remain limited.Methods: This retrospective cohort study included all consecutive patients over 70 with eBC treated between January 2018 and December 2023 at Tenon Hospital, Paris, France.Results: Of the 365 patients included, the mean age was 77.6 years (range 70-96). Among these, 84,4% had HR+/HER2- eBC. Most patients had invasive ductal carcinomas (75%), N0/Nmic node involvement (75%), grade 2 tumors (60%), and tumor sizes <5 cm (65%). Axillary lymph node dissection was performed in 20% of the patients, while 66% underwent sentinel lymph node biopsy. Oncotype DX® testing was requested for 86 patients, 27,9% of HR+/HER2- eBCs. A Recurrence Score (RS) >25 was found in 13 patients (15%), including those with N+ (15%), grade 3 (69%) and Ki67 >20% (62%). Three patients had a RS >25 with T2, grade 2 breast cancer. Chemotherapy was not initiated in 6 out of the 13 patients with a high RS: 2 were deemed unfit according to geriatric evaluation, 2 refused chemotherapy, and 2 for unknown reasons.Conclusion: This observational study provides valuable insights into the management of HR+ eBC in older patients, emphasizing the importance of considering Oncotype DX® to optimize treatment strategies in these patients.

P4-09-18: Adjuvant abemaciclib use and outcomes in patients with high-risk hormone receptor-positive, HER2-negative breast cancer: a real-world analysis.

Monique Tavares, Carolina Pereora Dos Santos, Pedro Henrique Benfatti Gomes, Carolina Campanholo Marques, Leonardo Gil Santana, Andre Luiz Cicilini, Lucas Pivetta Genovez,

Fernanda Alves Sobrinho, Solange Moraes Sanches, Luciana De Moura Leite, Marcelle Goldner Cesca, Felicia Peterson Cavalher, Vladmir Claudio Cordeiro De Lima

Background: More than 90% of patients with breast cancer are diagnosed with early-stage disease, of whom approximately 70% have tumors that are hormone receptor-positive (HR+) and human epidermal growth factor receptor 2 negative (HER2 -). Standard treatment varies depending on the risk of recurrence but includes combinations of surgery, radiotherapy, adjuvant/neoadjuvant chemotherapy, and endocrine therapy (ET). Patients with HR+/HER2-, node-positive early breast cancer (EBC) are at high risk of recurrence (up to 30% at five years) and need intensification of treatment. The MONARChE study demonstrated the efficacy of abemaciclib combined with endocrine therapy as an adjuvant treatment for patients with high-risk early breast cancer. This study evaluated the real-world applicability of these findings in a cohort of Brazilian patients, highlighting patient characteristics, treatment regimens, adverse events, and outcomes.
Methods: We collected data from patients diagnosed with high-risk (MONARChE criteria) RH+/HER2-, early breast cancer, who received and treated at A. C. Camargo Cancer Center, Brazil, from January 2021 to May 2024. Data collected included patient demographics, menopausal status, body mass index (BMI), germline BRCA1/2 mutation status, receptor status, chemotherapy and surgery details, histological grade, KI67 levels, pathological staging, and treatment outcomes.
Results: We 89 HR+/HER2-, high-risk early breast cancer patients who received adjuvant abemaciclib following the MONARChE study protocol. The median follow-up was 33 months. Among the 89 patients, 87 (98%) were female, with a median age of 50 years (range 26-85). Of these, 54 patients (62%) were pre-menopausal, and 32 (37%) were post-menopausal. Sixteen percent were older than 65, and 84% were 65 or younger. The median BMI was 27, with 58% having a BMI >25. Approximately 5.62% had a germline BRCA1/2 mutation. Most patients had tumors with histological grade (HG) 2 (55%) and ≥ 20% (N=71, 81.6%). Estrogen receptor (ER) > 20% was observed in 86 tumors (97%), progesterone receptor (PR)> 20% in 72 patients (81%), and HER2-low in 79% of patients. Thirty-six patients (40%) received neoadjuvant chemotherapy, 46 (51%) received adjuvant chemotherapy, and 7 (7.87%) did not receive chemotherapy. Chemotherapy regimens included AC-T in 70 patients (79%), TC x 4 cycles in 2 patients (2%), and TC x 6 cycles in 9 patients (10%). Regarding surgery, 39 patients (43%) underwent segmental resection, and 50 patients (56%) underwent mastectomy. T stage was T1 in 37%, T2 in 42%, T3 in 17%, and T4 in 2.27%, while N stage was N1 in 43%, N2 in 25% , and N3 in 22% . Grouped staging was II in 54% and III in 46%. The response rate among the 36 patients who received neoadjuvant chemotherapy was RCB-0 in 4.6%, RCB-1 in 1%, RCB-2 in 12%, and RCB-3 in 18% . Ninety-two percent of patients received adjuvant radiotherapy. Adjuvant endocrine therapy consisted of tamoxifen in 6% of patients, goserelin + tamoxifen in 2%, aromatase inhibitors (AI) in 39%, and AI + goserelin in 31%. Programed duration of endocrine therapy was for seven years in 13% of patients, ten years in 29%, and five years in 26%. The most commonly reported adverse events were diarrhea in 49% of patients, fatigue in 12%, neutropenia in 9%, elevated transaminases in 13%, nausea in 5%, and no toxicity in 14%. Dose adjustments were necessary in 26 patients (29%) (20% reduced to 200mg/day

and 9% to 100mg/day). Suspension of treatment with abemaciclib occurred in 16 (16%) patients due to limiting toxicity. During the follow-up, only one patient experienced disease recurrence during adjuvant therapy.
Conclusion: This cohort was composed of younger premenopausal patients with a high prevalence of overweight and low frequency of germline BRCA1/2 mutations. Tumors were predominantly HG2, T2, N, and stage II. Most received adjuvant chemotherapy with anthracyclines and taxanes, adjuvant radiotherapy, and double hormonal blockade with AI. Diarrhea was the most common toxicity and the leading cause of dose reduction or discontinuation of therapy. Until the last follow-up, most were still using adjuvant abemaciclib without evidence of disease.

P4-09-19: Exploring cellular heterogeneity of localised breast cancers

Beata Kiedik, Daniel L. Roden, Kate Harvey, Ghamdan Al-Eryani, Sunny Z. Wu, Mun N. Hui, Sandra O'Toole, Elgene Lim, Charles M. Perou, Alexander Swarbrick

Breast cancer exhibits heterogeneity at various levels, from subtype differences between patients (inter-patient heterogeneity) to diverse malignant cell compositions, variability in hormone receptor (HR) expression, and cellular makeup within single breast cancer samples (intra-tumour heterogeneity). Despite the availability of numerous effective therapies, many patients still experience incomplete treatment responses and subsequent relapse. These adverse outcomes are often due to the critical but frequently overlooked factor of cellular heterogeneity.
To gain deeper insights into intra-tumour heterogeneity, we applied single-cell technologies to a cohort of 250 primary, untreated breast cancers. We optimized tissue cryopreservation methods, eliminating the need for fresh sample processing, and developed multiplex tissue profiling techniques. These cost-efficient processes improve handling of small tissue sizes, such as biopsies, and reduce batch effects. To ensure accurate and reliable data processing, we created a scalable computational workflow that includes benchmarked methods for sample SNP-demultiplexing, doublet detection, high-resolution cell annotation, and cellular integration. Additionally, we extended our existing methods to study the cellular heterogeneity of breast cancers.
Our method, scSubtyper, examines the phenotypic differences between malignant cells within tumours by comparing each single cell to features associated with different molecular subtypes and assigning each cell to one of these subtypes. Our previous study and preliminary results from this project revealed that over 90% of samples exhibit a mix of malignant cells of different subtypes, and 50% of samples contain cells with characteristics of all subtypes, demonstrating that cellular heterogeneity exists not only between malignant cells but also within malignant cells of a tumour. Our second approach, known as ecotyping, assesses patterns of cell type frequencies across samples and groups them based on the similarity of these co-occurrences. Preliminary results have revealed the existence of five ecotypes that lack significant associations with clinical subtypes. Application of the same approach exclusively within the HR-positive samples identified four ecotypes characterized by distinct abundances of immune and stromal cells. This analysis revealed that ecotypes

are not simple surrogates for clinical and molecular subtypes, but their presence could influence different responses to treatment.
Together, our high-throughput tissue processing and computational approaches to study intra-tumour heterogeneity are now being applied to our large, well-annotated clinical cohort. Supported by preliminary results, we hypothesize that this study will play a vital role in optimizing breast cancer patient stratification to improve treatment management and outcomes.

P4-09-20: Extended Endocrine Adjuvant therapy for Early HR+ Breast Cancer, Comparisons Between Molecular Expression Profiles

Lowell Hart, Stacey Garofalo, William Amick

Molecular gene expression profiles are commonly used now in early stage HR+ breast cancer to determine adjuvant systemic therapy and can prognosticate recurrence risk in years 0-5, although predictive and prognostic use for prevention of late relapse in years 5-10 with extended hormonal therapy remains controversial and direct comparisons of the available assays are few. Breast Cancer Index (BCI) is a genomic assay that analyzes 11 genes using qRT-PCR expression profiling to interrogate multiple cell-signalling pathways associated with breast cancer recurrence risk. These genes do not overlap with the other commonly used early breast cancer genomic assays.
We reviewed retrospective data from 75 patients in Florida and North Carolina in both a private practice and an academic practice who had early stage HR+ breast cancer and had a commonly used 30 gene or 70 gene genomic assay sent, as well as a later BCI assay. We sought to determine if patients classified as low or intermediate risk on the standard early assays had a higher risk BCI profile or a potential benefit from longer term hormonal therapy, and also if high risk patients might show a potential lack of benefit from longer term hormonal therapy and therefore avoid possible adverse effects such as bone loss and menopausal symptoms.
Results- We did find that a significant number of patients with low or intermediate risk on 30 or 70 gene assays had a higher than expected late relapse risk on the BCI assay, approximately 25-30%. Data will be presented in the poster, along with outcomes. In addition we found that some patients with high risk 30 or 70 gene assays had a low risk of late relapse on the BCI assay, suggesting lack of benefit from extended hormonal adjuvant therapy.
Conclusions- We were able to confirm in this contemporary group the comparison findings of the 2016 TransATAC analysis that there can be a significant disparity between early recurrence risk as determined by the standard 30 or 70 gene expression profiles, and the BCI risk of late recurrence, as well as the potential benefit of longer term hormonal therapy in these patients. This suggests that the 11 gene BCI assay may be able to help patients decrease risk of late recurrences and avoid also unnecessary treatment related toxicity.

P4-09-21: Metastatic disease in patients with early breast cancer and a low Oncotype DX® Recurrence Score: A review of clinicopathological features

Javid Alibhai, Anita Maria Huws, Saira Khawaja, Asma Munir, Yousef Sharaiha, Sohail Khan, Nida Javed

Background: Prognostication and prediction in the adjuvant setting in early breast cancer has been evolving since the introdcution of gene expression profiling, with a move away from traditional clinical parameters such as tumour size, histological grade and lymph node status toward mutligene panel testing. However, it has become increasingly evident that both approaches are needed to provide personalised risk prediction. Although these tools have helped inform adjuvant therapy decisions and prognostication in early breast cancer, the aspiration of personalised prediction is still awaited as these tests may not reflect tumour heterogeneity. A retrospective analysis exploring the clinicopathological features of patients with genomic scores who developed metastatic disease within ten years of diagnosis was undertaken to investigate potential risk factors for recurrence.
Methods: A retrospective review was conducted to identify patients with node negative early breast cancer who had undergone Oncotype DX RS testing between 2007 and 2018. Exclusions included preeinvasive disease, and patients with no follow up data or outcomes measures. Clinicopathological details of patients with recurrent disease and low genomic risk, defined as a Recurrence Score less than 26, were evaluated. NPI was calculated. Chemotherapy regimes, use and duration of endocrine therapy was noted. The date of recurrence, metastatic site, and the date of death was recorded.
Results: The cohort consisted of 121 caucasian female patients with a mean age of 68.36 years (range 35 to 84). Histological subtypes included 79.34% (96/121) ductal cancers, 16.53% (20/121) lobular cancers, 2.48% (3/121) mucinous carcinomas, 0.83% (1/121) micropapillary cancers, and 0.83% (1/121) mixed ductal lobular cancers. mean tumour size of whole cohort was 23.75mm. Percentage of recurrence scores <11 was 27.27% (33/121), 11-17 was 46.28% (56/121) and 18-25 was 26.45% (32/121). Mean recurrence score of cohort was 13.80. Mean NPI 3.4. Of the 121 patients, seven developed recurrence (5.79%), and five patients (4.13%) developed a new/second breast primary. The cases with metastatic disease were all grade 2 ductal cancers. Most recurrences were diagnosed greater than 5 years following diagnosis (range 2 to 10 years). Metatastic sites were lung 100% (7/7), liver 28.57% (2/7), bone 28.57% (2/7) and local recurrence noted in 28.57% (2/7). The overall mortality rate was 6.61% (8/121 - two non-cancer deaths). Of the patients who developed metastatic disease (n=7), all tuours were PR positive, and 6 of the 7 were ER8, PR8 suggesting luminal A subtype.The mean NPI of the metastatic group was 3.54. The percentage of patients with metastatic disease with a recurrence score of 0-10, 11-15, 16-20 and 21-25 was 42.86% (3/7), 42.86% (3/7), 0%, and 14.28% (1/7), respectively. 57.14% (4/7) received adjuvant Letrozole for a minimum of 5 years. The patient with a recurrence score of 24 received adjuvant chemotherapy and developed metastatic 4 years post diagnosis while on Tamoxifen.
Discussion: The mortality rate of the cohort is consistent with the literature, with a 5 to 10

year disease free survival of 94.21%. There was no statistically significant difference in the recurrence scores, NPI and clinicopathological findings in the two groups. The incidence of pulmonary metastases in this cohort warrants further investigation. Primary breast tumour site was in the inner quadrant in two patients and one patient had a positive intramammary nodes with negative sentinle nodes. The cohort investigated is from a homogeneous population. Records suggest that compliance with adjuvant endocrine therapy was good, although this is difficult to verify. Studies suggest that noncompliance can be a factor in recurrence in these cohorts.
Conclusion: The quest for personalised prediction and prognostication in early breast cancer is ongoing. Genomic tests have resulted in a significant reduction in the number of patients receiving adjuvant chemotherapy. However, a more multifacted approach may be required to tailor treatment decisions incorporating genomic testing, clinicopathological features and individual characteristics with the aim of improving outcomes for patients with hormone receptor positive early breast cancer.

P4-09-22: Distant disease-free survival (DDFS) across key subgroups from the phase 3 NATALEE trial of ribociclib (RIB) plus a nonsteroidal aromatase inhibitor (NSAI) in patients with HR+/HER2− early breast cancer (EBC)

Sara Hurvitz, Michal Jarzab, Montserrat Munoz Mateu, Erin Cobain, Jin Zhang, Arielle Medford, Alistair Ring, Priyanka Sharma, Christian Schem, Ionut Temciuc, Zheng Li, Murat Akdere, Juan Pablo Zarate, Denise A. Yardley

Background: In the NATALEE trial, RIB + NSAI has demonstrated invasive disease-free survival and DDFS benefits in patients with stage II and III HR+/HER2− EBC. In an analysis with all patients off RIB, RIB + NSAI reduced the risk of distant disease recurrence vs NSAI alone. Understanding the impact of adjuvant treatments on distant disease recurrences across patient subgroups is critical for clinical decision-making. We present DDFS data from the 4-y landmark analysis of NATALEE across clinically relevant subgroups.
Methods: In NATALEE, patients were randomized 1:1 to receive either RIB (400 mg/d, 3 wk on/1 wk off for 3 y) + NSAI (anastrozole 1 mg/d or letrozole 2.5 mg/d for 5 y) or NSAI alone, with men and premenopausal women also receiving goserelin. NATALEE included patients with anatomic stage IIA (either node-negative [N0] with additional risk factors or N1 [1-3 axillary lymph nodes]), IIB, or III disease per AJCC (8th edition). DDFS was a secondary endpoint and was defined as the time from randomization to the first event of distant recurrence, second primary non-breast invasive cancer (except for basal and squamous cell skin carcinomas), or death from any cause. DDFS was assessed across patient subgroups, including anatomic stage and nodal status, using Kaplan–Meier analysis and a Cox proportional hazards model.
Results: At the data cutoff of April 29, 2024, with a median duration of follow-up for DDFS of 44.2 months and all patients off RIB, RIB + NSAI demonstrated both a DDFS benefit (HR, 0.715 [95% CI, 0.604-0.847]; nominal P value <.0001) and a distant recurrence-free survival

benefit (HR, 0.705 [95% CI, 0.589-0.844]; nominal P value <.0001) in the intent-to-treat population. The DDFS benefit was consistent regardless of anatomic stage (stage IIA [n=1001]: HR, 0.396 [95% CI, 0.218-0.720]; stage IIB [n=1045]: HR, 0.806 [95% CI, 0.524-1.238]; stage IIIA [n=1832]: HR, 0.697 [95% CI, 0.524-0.926]; stage IIIB [n=317]: HR, 0.569 [95% CI, 0.326-0.994]; stage IIIC [n=890]: HR, 0.878 [95% CI, 0.649-1.188]). The absolute DDFS benefit with RIB + NSAI vs NSAI alone increased from 3 y to 4 y for all stage subgroups (stage IIA, 2.3% to 5.1%; IIB, 0.8% to 2.6%; IIIA, 3.1% to 4.6%; IIIB, 6.8% to 11.4%; IIIC, 2.4% to 4.5%). Similarly, a consistent improvement in DDFS was observed regardless of nodal status (N0 [n=613]: HR, 0.696 [95% CI, 0.403-1.204]; node-positive [N+] [n=4480]: HR, 0.726 [95% CI, 0.608-0.867]), and the absolute DDFS benefit increased from 3 y to 4 y across nodal subgroups (N0, 2.7% to 4.2%; N+, 2.4% to 4.6%). The DDFS benefit with RIB + NSAI vs NSAI alone, with increasing benefit up to 4 y, was consistent across other clinically relevant subgroups, including those based on menopausal status and Ki-67 status. Conclusions: With all patients off RIB, RIB + NSAI consistently reduced the risk of distant recurrence across clinically relevant subgroups, including in patients with N0 disease. The DDFS benefit was sustained after the 3-y RIB treatment duration, with increasing absolute benefit up to 4 y. These findings further support adding RIB to adjuvant NSAI in a broad population of patients with HR+/HER2− EBC.

P4-09-23: Challenges and opportunities for CDK4/6i therapy in adjuvant early breast cancer

Richard Simcock, Helen Flint, Julie Douglas, Philipp A. Dietrich, Victoria Bush, Melanie Hovey, Stuart A McIntosh

CDK4/6 inhibitors (CDK4/6i) are a class of medicines that have been studied and introduced in early Breast Cancer (EBC) in the UK since June 2022. Currently, abemaciclib is the only licensed and reimbursed CDK4/6i for use in hormone receptor positive, human epidermal growth factor receptor 2 negative (HR+/HER2-) EBC in the UK. Prognosis in HR+/HER2- EBC has improved significantly over recent decades. However, despite these advances, the risk of recurrence remains high for many patients. To reduce the risk, the arrival of CDK4/6i therapy in combination with endocrine therapy in EBC occurs at time when there are multiple other therapeutic advances in the neoadjuvant, adjuvant and metastatic Breast Cancer treatment landscape, which can pose challenges for adoption. This study sought to understand the UK Breast Cancer treatment landscape and challenges facing Healthcare Professionals (HCPs), focusing on the impact of the introduction of current and future CDK4/6is.
HCPs involved in EBC patient management who were not necessarily prescribers were surveyed between August to December 2023 (n=70, oncologists, surgeons, pharmacists and nurses). The aim of the survey was to better understand the early breast cancer patient pathway in the UK from diagnosis, through risk stratification and finally treatment decisions and to explore key challenges faced by clinicians and how these differ around the country. 72% of respondents had treated between 5-30 patients with a CDK4/6i in this

setting. The majority of HCPs (89%) have experience of adjuvant CDK4/6i prescribing in routine clinical practice, while 23% of HCPs have used adjuvant CDK4/6i in clinical trials. Staff shortages and clinic capacity are the most significant challenges for breast cancer services when delivering adjuvant therapy. Most HCPs (91%) cite the introduction of CDK4/6is to have impacted on time spent educating patients. In line with this, digital patient education, patient apps and psychological support were common suggestions from survey respondents to help manage EBC patients on new therapies.
Survey respondents reported that on average 10% patients decline adjuvant CDK4/6i, mainly due to additional hospital visits, toxicity from previous treatment and side effect concerns. Poor performance status and prohibitive comorbidities were the most likely factors to prevent CDK4/6i therapy initiation in EBC.
Patient reviews were reported to be typically monthly with a medical oncologist for up to 3 months after initiation of adjuvant CDK4/6i treatment. After this period, follow-up was commonly quarterly and predominantly maintained by Medical Oncologists, however there was no consistent standard of follow-up.
If permitted through commissioning, 70% of HCPs would consider rechallenging a patient with a CDK4/6i if their disease progressed. 78% of respondents highlighting they would use a different CDK4/6i and different endocrine therapy backbone following a 12-month treatment-free interval.
The introduction of CDK4/6is in EBC offers improved outcome for patients, but comes with additional strain on service delivery, particularly staff shortages, capacity constraints and additional patient follow up by HCPs. These findings suggest further need to streamline EBC care. UK service providers may need to evaluate and adjust healthcare infrastructure in order to deliver optimal care for EBC patients.

P4-09-24: Revealing the connection: Clinicopathological characteristics and Oncotype DX Scores in Invasive Lobular Breast Cancer

Zaida Morante, Yomali Ferreyra, Iris Otoya, Norma Huarcaya, Natalia Valdiviezo, Tatiana Vidaurre, Carlos Castañeda, Guillermo Valencia, Mariano Lopez-Pereyra, Martin Falla, Jose Galarreta, Silvia Neciosup, Henry Gómez

Background: Oncotype DX™ (ODX) score estimates prognosis of cancer recurrence and predicts benefit of chemotherapy. It also individualizes the patient's adjuvant chemotherapy prescription for BC. Invasive lobular carcinoma (ILC) ranked second as the most common type of breast carcinoma, accounting for approximately 15% of tumors of breast origin. In this analysis, we aimed to explore the association between OncotypeDX Recurrence Score (RS) and clinical characteristics of ILC patients.
METHODS: We retrospectively reviewed clinical data from 55 ILC patients diagnosed at Instituto Nacional de Enfermedades Neoplásicas (INEN, Lima-Peru) and Oncosalud with available ODX reports. We evaluated the linear relationship between the Recurrence Score (RS) and continuous variables like age, tumor size, ER, PR, and Ki 67 using scatter plots with confidence intervals and Pearson correlation coefficients. Boxplots were also generated to

compare RS across categorical variables, using statistical tests such as Kruskal-Wallis and Mann-Whitney U. P-values less than 0.05 were considered significant.
RESULTS: In our cohort, 96.4% (n=53) were classified as low-risk (RS=0-25), and only two cases with high-risk (RS=26-100). Progesterone Receptor (PR) status was negative in 18.2% (n=10), and 31.6% had Ki67 levels <20%. We found that only Ki67 expression was positively correlated with RS (p=0.0089). Patients stratified according to Ki67%<=14% (p=0.03) or Ki67%<=20% (p=0.02) also showed significant differences in RS. Regarding the histologic grade, G3 seems to have a higher mean RS (u=19.40) compared to G1/G3 (u=14.36), the significance of this variable remains unclear in our cohort (p=0.07).
CONCLUSIONS: Stratifying patients according to Ki67 levels (% <= 14% and % <= 20%) revealed significant differences in RS (p=0.03 and p=0.02, respectively). This underscores the importance of Ki67 as a potential biomarker for predicting recurrence scores and, consequently, the risk of recurrence in ILC.

P4-09-25: Estrogen Receptor Expression and Clinical Outcomes in Breast Cancer: Insights from a Single-Center Study

Enrique José Zamudio Lozoya, Luisa Fernanda González-González, Victor Baylon-Valdez, Patricio Ochoa Elizondo, Regina Martínez-García-Lascurain, Paolo Mendoza-Muraira, Rafael Martínez-Sanciprián, Beatriz De León-Jiménez, Alma Andrea Elizaldi-San Miguel, Gustavo Gil Reza Bravo, América Susana Mares García, René Lázaro González-Mendoza

Breast cancer presents a diverse clinical spectrum characterized by distinct subtypes that significantly influence treatment strategies and prognostic outcomes. Hormone-sensitive breast cancers, defined by estrogen receptor (ER) and/or progesterone receptor (PR) expression, play a crucial role in guiding therapeutic decisions. Understanding the complexities of ER-positive tumors is paramount due to their diverse biological behaviors and varied responses to treatment.
This retrospective, single-center study conducted at Chihuahua's State Cancer Center reviewed the medical records of 1224 breast cancer patients diagnosed with positive estrogen receptor status, aged ≥ 18 years, between January 2012 and June 2023. The study specifically focused on categorizing patients into two groups based on their ER levels: those with levels greater than 10% (high ER) and those with 10% or less (low ER). Clinicopathologic characteristics and recurrence rates were meticulously evaluated using Pearson's chi-square test to establish comparisons and determine statistical significance. Among the estrogen receptor-positive patients, 420 (34.31%) exhibited low ER expression, while 804 (65.69%) had high ER expression. Significant differences were observed in tumor size (T) between the groups (p=0.00). In the low ER group, 56.54% had T1 and T2 tumors, whereas 43.46% had T3 and T4 tumors. Conversely, the high ER group predominantly also presented with T1 and T2 tumors (71.32%) but compared to T3 and T4 tumors (28.68%). Regarding lymph node involvement, 67.41% of the low ER group had positive lymph nodes, compared to 60.36% in the high ER group, showing a statistically significant difference (p=0.010). Tumor grade analysis revealed that 59.52% of low ER patients were in grade 3,

while only 30.05% of high ER patients were in grade 3 (p=0.00). Finally, concerning recurrence rates, the high ER group exhibited an 11.44% recurrence rate, whereas the low ER group exhibited nearly double the rate at 21.43% (p=0.00).
In conclusion, our findings highlight that low estrogen receptor expression is significantly associated with more aggressive tumor biology, characterized by larger tumor sizes, higher grades, and a substantially increased recurrence rate. These results underscore the critical importance of integrating estrogen receptor levels into treatment planning and management strategies for breast cancer patients, advocating for tailored therapeutic approaches particularly in cases of low ER expression.

P4-09-26: Impact of NCCN/ASCO Guidelines and Epic Software Enhancement on Utilization of the Breast Cancer Index Test and its Role in the Quality of Cancer Care at Community Centers

Cindy Chau Tran, Abhijeet Deshmukh, Sharonlin Bhardwaj, Thanh Nga Doan, Irene Kang, Nikhila Kethireddy, Joanne Mortimer

Background: The Breast Cancer Index® or BCI™ test is a gene-based test that analyzes two key aspects of early-stage, hormone receptor-positive breast cancer. In a first aspect, the HOXB13:IL17BR ratio (H/I) assesses how well the cancer is likely to respond to continued hormone therapy. In a second aspect, the molecular grade index (MGI) predicts the likelihood of recurrence. This combination of features helps inform the appropriate duration of endocrine therapy beyond traditional tests. Importantly, the BCI test is effective for both lymph node-negative and lymph node-positive patients. The BCI test was incorporated into the NCCN Clinical Practice Guidelines in Oncology (NCCN® Guidelines) in January 2021 and the ASCO® Clinical Practice Guideline (ASCO Guideline) in April 2022. Additionally, Epic® medical record software was recently updated to allow users to order the BCI test. We examined the frequency of BCI test orders as a quality improvement metric, both at the main campus of the City of Hope Cancer Center and our community network.
Methods: Data was obtained from Biotheranostics, Inc., for the period January 2020 to mid-2024. We analyzed the data for testing rates with the BCI test over four time periods: pre-NCCN Guidelines (Jan 2020-Jan 2021), post-NCCN Guidelines (Jan 2021- April 2022), post-ASCO Guideline (April 2022-May 2024) and post-Epic medical record software integration (May 2024 - current).
Results: A total of 822 women with early-stage breast cancer underwent testing with the BCI test during the study period. Following the NCCN Guidelines update in January 2021, there was a notable increase in adoption of testing with the BCI test, with utilization increasing by 83% (p=0.026). Following endorsement of the BCI test by the ASCO Guideline update in April 2022, there was a further increase in test ordering by 30% (p=0.22). Increased utilization of the BCI test was comparable at the main campus and our community network. The test was ordered comparably for all age groups, LN- and LN+ disease, HER2- and HER2+ patients, and pre- and post-menopausal status. The Epic

software enhancement has been in place for one month with early evidence of increased test ordering.
Conclusion: The updates to the NCCN and ASCO Guidelines led to a significant increase in utilization of the BCI test at all City of Hope sites of practice. We anticipate that the Epic software enhancement will lead to further utilization of the BCI test.

P4-09-27: The clinical benefits of CDK 4/6 inhibitors and biomarker interactions on HR+/HER2- advanced breast cancer patients: an updated pairwise meta-analysis of randomized controlled trials and network meta-analysis

Sheng-Fan Wang, Chian-Ying Chou, Yi-Wen Chao, Tzu-Kuan Chan, Wan-Yu Yeh, Chern-En Chiang, Chen-Huan Chen, Hsin-Chen Lee, Ling-Ming Tseng, Yuh-Lih Chang, Hao-Min Cheng, Chun-Yu Liu

Background: The combination of cyclin-dependent kinase (CDK) 4/6 inhibitors with endocrine therapy has significantly improved the outcome of advanced hormone receptor-positive (HR+) and human epidermal growth factor receptor-2 negative (HER2-) breast cancer. However, challenges persist in identifying biomarkers of response or resistance to CDK4/6 inhibitors in the context of primary or secondary endocrine resistance and in determining their impact on overall survival (OS). A comprehensive pooled investigation and the identification of biomarker interactions may lead to a better understanding of the clinical benefits of CDK4/6 inhibitors.
Methods: To address these issues, we conducted a systematic review and a pairwise meta-analysis of randomized controlled trials of oral CDK4/6 inhibitors, including palbociclib, ribociclib, abemaciclib, dalpiciclib, and lerociclib. We examined the clinical benefits and biomarker (such as PIK3CA, TP53, and ESR1) interactions of CDK4/6 inhibitors in HR+ and HER2- advanced breast cancer. The analysis involved calculating the hazard ratio (HR) and exploring the efficacy of different CDK4/6 inhibitors in specific patient populations using network meta-analysis. The P-score was utilized to rank the effectiveness of various treatments by calculating their probabilities, facilitating comparisons in the network meta-analysis.
Results: The findings indicated that CDK4/6 inhibitors consistently confer clinical advantages to patients with HR+/HER2- advanced breast cancer, showing significant improvements in progression-free survival (PFS, HR 0.55, 95% CI 0.52-0.59) and OS (HR 0.80, 95% CI 0.74-0.86). Sensitivity analysis confirmed the robustness of these results. Subgroup and meta-regression analyses demonstrated that the clinical benefits of CDK4/6 inhibitors are consistent across various subgroups (lines of therapy and category of endocrine therapy), covariates (follow-up duration and patient characteristics), and biomarkers, with the exception of the PIK3CA mutation status (p=0.03). Specifically, we found that the interaction of PIK3CA mutation status might be essential to endocrine-therapy naive patients (First-line treatment: PIK3CA wild-type vs. mutation, HR 0.41 vs. 0.58, p for interaction = 0.03; second-line or subsequent treatments: PIK3CA wild-type vs.

mutation, HR 0.49 vs. 0.54, p for interaction = 0.68). Furthermore, the network meta-analysis revealed that all approved CDK4/6 inhibitors are equally effective for HR+/HER2- advanced breast cancer patients, providing confidence in the current treatment options. However, the clinical benefits and ranking probabilities varied for different outcomes in specific individual populations.
Conclusions: In conclusion, the PIK3CA mutation status emerges as a promising biomarker for the use of CDK4/6 inhibitors in HR+ and HER2-advanced breast cancer patients with endocrine therapy-naive breast cancer. This finding suggests the potential for future targeted and effective treatments. Moreover, the similar efficacy of currently approved CDK4/6 inhibitors for patients with HR+/HER2- advanced breast tumors provides a strong foundation for further research and development in this field.

P4-09-28: Perioperative treatment regimens and efficacy outcome measures in early-stage HR+/HER2- breast cancer: A systematic literature review of randomized controlled trials

Peter Schmid, Jagadeswara Rao Earla, Astha Jain, Duygu Bozkaya, Rahul Kamath, Kim M Hirschfield, Prabhakar Pandey, Amin Haiderali

Background: Hormone receptor positive and human epidermal growth factor receptor 2 negative (HR+/HER2-) breast cancer (BC) accounts for ~70% of early-stage cases. A systematic literature review was conducted to summarize the perioperative (neoadjuvant therapy and/or adjuvant therapy) treatment regimens and the efficacy outcomes in this setting.
Methods: Embase, Medline and Cochrane were searched from database inception to May 19th 2023; relevant conferences were also searched from 2021 to 2023 (inclusive). English language publications of randomized control trials (RCTs) including adult patients with early-stage HR+/HER2- BC receiving neoadjuvant therapy and/or adjuvant therapy (excluding endocrine [ET] only neoadjuvant therapy) were included.
Results: Of 3,490 records identified, 71 RCTs (window of opportunity: n=2 [3%], Phase II: n=39 [55%], Phase III: n=27 [38%], not reported: n=3 [4%]) were included. The cumulative sample size was 78,457, which ranged from 21 to 9,719 across the trials. The HR status among the included populations of these trials were reported as follows: HER2-/HR+ (n=57 trials) and HER2-/ER+ (n=14). Mean/median age of the patients varied from 46.9 to 65.6/46 to 76 years, respectively across the 26 trials where age was reported. Anatomical stage varied across studies (Stage I [Range]: 0.1% to 59%, Stage II: 25.3% to 100%, Stage III: 5% to 74.1%). Among studies which reported histological grade, the proportion of patients with grade 3 disease ranged from 3% to 55%. Where reported, nodal status varied among patient cohorts (N0: 5.1% to 98.1%, N1: 33.1% to 67.4%, N2: 2% to 37.0%, N3: 1.6% to 13.6%). Treatment interventions varied across the RCTs. Chemotherapy (CT) with or without ET was included in 33 studies overall; as neoadjuvant treatment in 21 RCTs (30%), adjuvant treatment in 9 RCTs (13%) and both neoadjuvant and adjuvant in 3 RCTs (4%). Targeted therapies (including CDK4/6, PARP, PI3K and AKT inhibitors) with or

without CT or ET was included as neoadjuvant treatment in 19 RCTs (27%) and as adjuvant treatment in 6 RCTs (8%). Immunotherapies with or without CT or targeted therapies were included as neoadjuvant treatment in 12 RCTs (17%). Antibody drug conjugates (SGN-LIV1A) were included in 1 RCT (1%). Primary endpoints included pathologic complete response (pCR: n=32; 45%), invasive disease-free survival (IDFS: n=8; 11%), disease free survival (DFS: n=5; 7%), objective response rates (ORR: n=5; 7%) and change in Ki67 expression (n=3; 4%). Event free survival (EFS) was not reported as a primary endpoint in any included trials. Median duration of follow-up ranged between 0.5 to 14.4 years across the included trials.
Conclusions: Heterogeneity was observed in terms of patient characteristics, treatment regimens, and outcome measures among clinical trials in perioperative setting. EFS, a relevant efficacy outcome measure for perioperative interventions, was not reported as a primary endpoint in the existing literature; to date clinical trials evaluating perioperative neoadjuvant plus adjuvant regimens in HR+/HER2- BC have been limited. An emerging trend for clinical trials investigating immunotherapy-based perioperative neoadjuvant plus adjuvant interventions was observed, reflective of the unmet need for innovative therapies among patients with early-stage high-risk HR+/HER2- BC.

P4-09-29: PR status cannot predict Oncotype DX Recurrence Score®: a study in a Greek cohort of N0M0/ER+/PR-/HER2- breast cancer patients tested with Oncotype DX

Vasileios Venizelos, Rodoniki Iosifidou, Christos Markopoulos, Gregory Xepadakis, Nikolaos Tsoulos, Spiridon Giannoulakis, Georgios Kapetsis, Amanta Psyrri, Zacharenia Saridaki, Ioannis Natsiopoulos, Adamantia Nikolaidi, Aikaterini Savvidou, Anastasios Mpoutis, Ioannis Mpoukovinas, Athanasios Kotsakis, Athina Christopoulou, Emmanouil Saloustros, Dimitrios Mavroudis, Sofia Aggelaki, Avraam Assi, Dimitrios Tzanninis, Dimitrios Grosomanidis, Elena Fountzila, Efthalia Lala, Eeleftheria Ignatiadou, Maria Skondra, Flora Zagouri, Anna Koumarianou, Paris Kosmidis, Stergios Douvetzemis, Konstantinos Papazisis, Kornilia Anastasakou, Foteini Pavlidou, Eleftherios Kampletsas, Fiorita Poulakaki, Georgios Simpilidis, Sofia Triantafillidou, Maroulio Stathoulopoulou

Background: The Oncotype DX assay is a widely utilized genomic test that helps predicting the risk of breast cancer recurrence and the potential benefit of chemotherapy in early-stage, hormone receptor-positive (HR+) breast cancer patients. Low/absent expression of PR in ER-positive breast tumors is associated with more proliferative and aggressive disease, poorer prognosis and recurrence. However, the predictive value of progesterone receptor (PR) status in determining chemotherapy benefit remains unclear. This study focuses exclusively on PR-negative breast cancer patients to assess whether PR status can predict chemotherapy benefit using Oncotype DX scores.
Methods: We retrospectively analyzed data from a Greek cohort of pT1-3N0, cM0/ER+/PR-/HER2- breast cancer patients who underwent Oncotype DX testing between 2008 and 2020. Patients were categorized based on their Oncotype DX recurrence scores (RS) into

low (0-25) and high (>25) risk groups.
Results: A total of 268 PR-negative, ER+/HER2- patients were included in the analysis. The mean RS was 20.3. (Mean RS reported in TailorX study regardless of PR status was 18.2). RS 0-25 was reported in 130 (48,5%) of them, while 138 (51,5%) had a RS >25.
Conclusion: In PR-negative, pT1-3N0, cM0/ER+/HER2- breast cancer patients, PR status alone does not predict the RS and hence, the benefit of chemotherapy. The Oncotype DX assay effectively stratifies these patients, highlighting those with high RS (>25) who will benefit from chemotherapy. These findings underscore the importance of using Oncotype DX scores rather than PR status alone to guide chemotherapy decisions in PR-negative breast cancer patients.

P4-09-30: The Impact Of Online Education On Clinician Knowledge, Competence, And Confidence In Understanding the Latest Clinical Trial Data for HR+/HER2- Early Breast Cancer With a High Risk of Recurrence

Urvi Patel, Nabil Dorkham, Victoria Phoenix

Background: The treatment landscape in HR-positive, HER2-negative early breast cancer with a high risk of recurrence is constantly evolving with new data being regularly released at different congresses. Clinicians need to be updated regarding this data and its implications for clinical practice. Two global educational activities were developed that consisted of a 30-minute panel discussion between 2 experts and a 30-minute online enduring activity of a live symposium. We assessed the educational impact of the online educational activities.

Methods: A repeated-pairs pre-/post-assessment study design of knowledge, competence and confidence was used to assess impact, in which everyone served as their own control. A paired samples t-test assessed mean differences in the average number of correct responses to the matched pre-/post-assessment questions, and a McNemar's test assessed significance of improvement in single questions (and learning objectives) from pre- to post-assessment. P values <.05 are statistically significant. The first activity launched in January 2023 and the second activity in December 2023 and data was collected till January 2024.

Results: The analysis included 266 oncologists from the US and outside of the US who answered all the pre-/post-assessment questions. Each assessment question was mapped to an activity learning objective., which were grouped into three core topics. All core topics showed a significant improvement in education. The core topic knowledge of the latest data group had an n of 266, there was a relative change of 35% from pre-correct/confidence of 51% to post-correct/confidence of 69% ($p < 0.001$). For the core topic competence in applying the latest clinical trial data, the group had an n of 55, there was a relative change of 15% from pre-correct/confidence of 48% to 55% post-correct/confidence ($p < 0.05$). Lastly, the core topic confidence in interpreting the clinical implications of the latest data group had an n of 266, there was a relative change of 44% from pre-correct/confidence of

32% to post-correct/confidence of 46% ($p < 0.001$)
Conclusions: There was a significant improvement of oncologists' knowledge, competence and confidence related to clinical trial data. As new data is continuously being released at different congresses, regular educational activities to update clinicians are important to apply this knowledge in clinical practice.

P4-10-01: Testosterone & Tamoxifen (T&T) trial: adding Testosterone to Tamoxifen in male breast cancer patients

Jasmine Moustaquim, Jasper van Geel, Michel van Kruchten, Erik de Vries, Marcel Stokkel, Andor Glaudemans, Geke Hospers, Carolien Schröder

Background: Male breast cancer (MBC) is very rare and has worse outcome compared to BC in women. MBC specific interventions are lacking. Non-adherence to mainstay tamoxifen treatment is common, due to feminizing side effects and reduced quality of life, and related to worse survival. Thus, well-tolerated endocrine treatment is an unmet need in MBC. MBC expresses both estrogen- and androgen receptors (ER and AR) in 97% of cases. As the AR functions as tumor suppressor in ER+ BC, adding testosterone to tamoxifen may improve both tumor response and tolerability in MBC. Therefore, we assessed the safety profile of tamoxifen plus testosterone in patients with metastatic MBC.
Methods: In this single-arm pilot study, patients received tamoxifen 20mg plus testosterone 25mg once a day, increased to 50mg after 3 weeks in case of good tolerance. Primary endpoint was safety (assessed as grade 3-4 adverse events (AEs) according to Common Terminology Criteria of Adverse Events (CTCAE) v5.0). Secondary endpoint was tumor response and duration (according to RECIST1.1) assessed after 8 weeks, thereafter every 12 weeks.
Results: Five MBC patients were enrolled with median age of 63 years, and mean two (1-3) previous endocrine treatment lines for metastatic MBC. All patients had received prior tamoxifen monotherapy, in either adjuvant or metastatic setting. No grade 3-4 AEs were observed. Two out of 19 grade 1-2 AEs were possibly related to the treatment: grade 1 anxiety and nausea, both spontaneously resolved. Other low grade AEs were probably related to (progressive) disease (n=7) or from another cause not likely related to the treatment (n=10). Regarding responses, 3/5 patients showed clinical benefit with in one patient a partial response duration of 10 months and in two patients ongoing stable disease at the time of analysis (resp. 12 and 15 months), 2/5 patients had progressive disease at 8 weeks. All patients spontaneously reported improved well-being.
Conclusions: In this unique MBC intervention trial, tamoxifen plus testosterone showed good safety, tolerability as well as long-term responses in the majority of patients. Therefore, this could be a promising new endocrine approach in this rare MBC population.

P4-10-02: RYZ101 (225Ac-DOTATATE) ± pembrolizumab in estrogen receptor-positive, human epidermal growth factor receptor 2-negative, locally advanced and unresectable or metastatic breast cancer progressing after prior therapy: the phase 1b/2 TRACY-1 study

Erica Mayer, Kathy Miller, Komal Jhaveri, Randy Yeh, Elizabeth Sakach, Vikas Prasad, Denis Ferreira, Paul Herszdorfer, Lucy Gong, Joanne Li, Kim Ma, Susan Moran, Lisa Bodei, Gary Ulaner

Background: RYZ101 (actinium-225 [225Ac]-DOTATATE) is a radiolabeled somatostatin analog (SSA) for the treatment of patients with solid tumors expressing somatostatin receptor-type 2 (SSTR2). RYZ101 is composed of the alpha-emitting radioisotope 225Ac, the chemical chelator DOTA (tetraxetan), and SSA octreotate (TATE). RYZ101 binds with high affinity to SSTR2 on the cell surface and is internalized, where the alpha-particle emission of 225Ac results in lethal double-strand DNA breaks. Although SSTR-directed therapy is widely used in well-differentiated gastroenteropancreatic neuroendocrine tumors (GEP-NETs), its use in non-GEP-NET SSTR-expressing neoplasms is still emerging. Clinical positron emission tomography (PET) imaging has reported SSTR expression in breast cancers and a correlation between tracer uptake and estrogen receptor (ER) expression. Available data support investigating the efficacy of RYZ101 in patients with ER+, HER2-negative, locally advanced and unresectable or metastatic breast cancer who are endocrine-refractory and have received prior chemotherapy and/or antibody–drug conjugates (ADCs). As preclinical evidence suggests that alpha-particle emitter radiopharmaceutical therapy (RPT) has immunostimulatory effects that may enhance anti-tumor activity of immunotherapy, the combination of RYZ101 and pembrolizumab will also be investigated.
Methods: TRACY-1 (IND#170007) is a global, multicenter, open-label, 3-part (dose escalation, randomization, expansion) phase 1b/2 study. Key inclusion criteria are: age ≥18 years; histologically confirmed, ER+, HER2-negative locally advanced and unresectable or metastatic breast cancer not amenable to treatment with curative intent; endocrine-refractory disease; documented progression (per RECIST v1.1) after ≥2 and ≤4 prior lines of chemotherapy or ADC (≥1 must be ADC); ≥1 RECIST-measurable SSTR–PET-positive lesion with ≥80% of RECIST-measurable lesions being SSTR–PET-positive on screening scan. Key exclusion criteria are: prior RPT, anti-PD-1/L1/L2 therapy or a prior agent directed to another stimulatory or co-inhibitory T-cell receptor; prior anticancer therapy in past 4 weeks or external beam radiotherapy in past 6 weeks. Primary objectives are to determine the recommended phase 2 dose (R2PD) of RYZ101 (dose escalation; anticipated n=6–18), the optimal treatment regimen of RYZ101 alone or in combination with pembrolizumab (randomization; n=30 per arm), and the efficacy of RYZ101 at the optimal treatment dose and regimen (expansion; n=100). During dose escalation, patients will receive RYZ101 by IV infusion every 6 weeks for up to 6 cycles at a starting dose of 6.5 MBq (Dose Level [DL] 1), with escalation to DL 2 (8.3 MBq) and DL 3 (10.2 MBq), or dose de-escalation to 4.6 MBq if DL 1 is not tolerated, based on dose-limiting toxicity rates. In randomization, RYZ101 will

be administered at the RP2D every 6 weeks for a total of 6 infusions; patients receiving combination therapy will also receive pembrolizumab 400 mg IV every 6 weeks for up to 2 years or until progression. In expansion, patients will receive RYZ101 alone or in combination with pembrolizumab as determined in randomization step. Concomitant amino acid IV infusions (containing L-arginine and L-lysine) will be co-infused with RYZ101 for renal protection. The study is expected to begin enrolment in July 2024.

P4-10-03: Potential risk factors for health-related quality of life (HRQoL) in palbociclib (PAL) plus endocrine therapy (ET) and ET alone patients with HR+/HER2- advanced breast cancer (ABC): exploratory analysis from 6-month longitudinal study (JBCRG-26)

Shigehira Saji, Mari Oba, Aya Ueda, Kaori Terata, Mihoko Doi, Shigenori Nagai, Masaya Hattori, Kenichi Watanabe, Nobuko Tamura, Manabu Futamura, Kei Koizumi, Naoki Niikura, Tempei Miyaji, Yasuaki Muramatsu, Linghua Xu, Asuka Matsui, Norikazu Masuda, Hiroko Bando

Background: PAL is a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) for the treatment of HR+/HER2- ABC. In phase 3 clinical trials, HRQoL was generally maintained and/or improved in patients (pts) treated with PAL+ET compared with placebo+ET. Previously, we reported that PAL+ET and ET monotherapy did not impact on HRQoL or physical activity (SABCS2023, PO1-05-06). Here, we explored potential risk factors related to HRQoL changes in the pts treated with PAL+ET or ET alone evaluated with a mobile application.
Methods: This prospective, observational, multicenter study was conducted in Japanese women with HR+/HER2- ABC initiating PAL+ET (Group 1) or ET alone (Group 2) in 1L/2L setting. HRQoL was assessed using EORTC-QLQ-C30 at baseline and Day 15 of each cycle via a smartphone-based app for 6 cycles (24 weeks). Patient data, including baseline characteristics, treatment, and adverse events, were collected via electronic case report forms. A multivariate mixed effects model was conducted to explore risk factors for HRQoL changes, including treatment group, cycle, baseline HRQoL, line of therapy, education, employment, menopausal status, ECOG-PS, TMN stage, BMI, visceral metastases, and dose reduction as fixed effects. This was exploratory analysis and a trend of GHS change and related risk factors were evaluated. Positive score of estimated mean change represents improvement of global health status (GHS), and negative score represents deterioration of GHS.
Results: Ninety-nine pts were enrolled (Group 1: 78, Group 2: 21). Pts had a median age of 56/52 years (Group 1/2); 51%/33% had visceral metastases; 59%/43% were stage IV at initial diagnosis; 36%/33% were fully employed. In each group, 95% (78 pts and 20 pts, respectively) completed the 6-cycle observation period. In the overall population for each group, GHS was maintained across the observation period. Based on the analysis, treatment cycle demonstrated an association with GHS change from baseline score in early cycles (Cycle 2: mean change=4.79, 95%CI 0.93-8.65,; Cycle 3: mean change=6.53, 95%CI 2.75-10.31, p=0.001). Later cycles 4-6 continued to show a trend toward improvement in QOL;

however these were less prominent. Additional trends included that CDK4/6i combination treatment (mean change=3.02, 95%CI -4.04- 10.07), first-line treatment (f mean change=2.87, 95%CI -4.18-9.93), and part-time employment (mean change=3.82, 95%CI -3.68- 11.32), which all showed improvement towards GHS from baseline; whereas, stage IV/other (mean change=-2.45, 95%CI -8.58- 3.65) and dose modification (mean change=-2.06, 95%CI -6.02-1.90) trended towards GHS decrease from baseline. Notably, by cycle 4, 91 pts remained on study (Group 1: 73, Group 2: 18).
Conclusion: In this Japanese cohort, a gradual improvement in HRQoL was observed in the initial cycles of PAL+ET and ET alone. Although this is a small cohort of pts, our exploratory data provide an initial hypothesis around which pts may experience a benefit/detriment in HRQoL. Further investigation is warranted. (NCT04736576)

P4-10-04: Utility of genomic testing and targeted treatment for patients with hormone receptor-positive metastatic breast cancer

Himil Mahadevia, Ibrahim Khamees, Simran Chandra, Kensey Gosch, Parth Sharma, Kelly Gast, Timothy Pluard, Whitney Hensing

Background: Optimal sequencing of subsequent treatments after progression on initial hormone therapy plus CDK4/6 inhibitor (HT + CDK4/6i) in patients with hormone receptor-positive (HR+), HER2-negative metastatic breast cancer (MBC) has not been well established; however, we prefer to continue hormone-based therapy for as long as possible before switching to chemotherapy, due to its favorable toxicity profile. Next-generation sequencing (NGS) of tumor tissue or circulating tumor DNA (ctDNA) can reveal actionable alterations for targeted therapy. Several targeted agents have been approved for genes commonly mutated in MBC, including ESR1, PIK3CA, AKT, PTEN, ERBB2, and BRCA1/2, and many newer agents are under investigation in clinical trials. Consequently, we aimed to evaluate the use of genomic testing and the adoption of targeted therapies in patients with HR+, HER2-negative MBC and hereby present updated results.
Methods: Our retrospective cohort included patients with HR+, HER2-negative MBC who experienced progression after initial treatment with HT + CDK4/6i and received treatment at the Koontz Center for Advanced Breast Cancer (KCABC) at St. Luke's Cancer Institute. KCABC is a specialized clinic dedicated to the care of MBC patients. MBC patients underwent genomic testing using commercially available NGS assays. Clinically actionable alterations were defined as those with targeted treatment available as standard of care or as part of a clinical trial: PIK3CA, PTEN, AKT, ESR1, ERBB2, BRCA1, BRCA2, PALB2 mutations, and high TMB (≥10). A subgroup of patients received alteration-targeted therapy (ATT), and a comparison was made with those who did not. Baseline clinical characteristics and genomic testing results were described using summary statistics. Time to initiation of chemotherapy and overall survival (OS) were compared between groups using Kaplan-Meier analysis and the log-rank test.
Results: In the study, 136 HR+, HER2 negative MBC patients received treatment following initial HT + CDK4/6i treatment. Of these, 110 patients (80.8%) underwent genomic testing,

with 54 (39.7%) being tested before starting the second line of treatment. Of those tested, 95 (86.8%) were found to have a targetable alteration. Alteration-targeted therapy (ATT) was administered to 39 patients, and 17 patients received ATT as second-line therapy after HT + CDK4/6i. The most common targetable alterations identified were ESR1 (39.0%) and PIK3CA mutations (33.8%), followed by PTEN alterations (11.8%), BRCA1/2 (7.4%) and ERBB2 (5.1%) mutations. The most utilized ATT was alpelisib in 21 patients (53.8%), followed by neratinib in 6 (15.4%), elacestrant in 5 (12.8%), talazoparib in 3 (7.7%), olaparib in 2 (5.1%) and capivasertib in 2 (5.1%) patients. No significant difference was observed in time to initiation of chemotherapy or OS for patients who received ATT compared to those who did not.
Conclusions: A significant proportion of patients with HR+, HER2-negative MBC in our cohort underwent genomic testing after progression on initial treatment with HT + CDK4/6i, and the vast majority (86.6%) of these individuals were discovered to have at least one alteration that could be acted upon. We found no significant improvement in OS or time to initiation of chemotherapy for those who received ATT compared to those who did not. However, it is worth noting that the proportion of participants who received ATT was small. Only 39 patients (28.7%) received ATT, with alpelisib being the most common treatment. Since the approval of alpelisib in 2019, many new targeted agents have been in development. This includes two new agents approved in the past two years. These new treatments are poised to have better tolerability and potentially greater efficacy, which could lead to broader acceptance and more significant benefits of ATT in HR+ HER2-negative MBC.

P4-10-05: LITESPARK-029: A Phase 2, Randomized, Open-label Study of Belzutifan Plus Fulvestrant in Patients W/ Estrogen Receptor Pos, HER2-Negative Unresectable Locally Advanced or Metastatic Breast Cancer After Progression on Previous Endocrine Therapy

Bora Lim, Liyi Jia, Preeti K. Sudheendra, Kim M. Hirshfield

Background: Endocrine-based therapy (ET), either alone or in combination with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors, prolongs progression-free survival (PFS) and overall survival (OS) in patients with metastatic hormone receptor positive (HR+) and human epidermal growth factor receptor 2 negative (HER2–) breast cancer. After progression on first-line therapy, next line therapy options provide limited gains in PFS owing in part to resistance mechanisms (e.g., hyperactive FOXA1). The transcription factor hypoxia-inducible factor 2α (HIF-2α), a major target of FOXA1, regulates key components of angiogenesis and subsequent development of metastasis. Preclinical studies show the ability of a HIF-2α antagonist to significantly suppress tumor growth, particularly when combined with fulvestrant. Belzutifan, a HIF-2α inhibitor, is approved for the treatment of patients with advanced renal cell carcinoma following a PD-(L)1 inhibitor and vascular endothelial growth factor tyrosine kinase inhibitor. LITESPARK-029 (NCT06428396) evaluates the efficacy and safety of belzutifan plus fulvestrant versus everolimus plus

fulvestrant or exemestane in patients with estrogen receptor positive (ER+)/HER2– unresectable locally advanced or metastatic breast cancer.
Methods: This phase 2, randomized, active-controlled, open-label, multicenter study is enrolling patients aged ≥18 years with centrally confirmed ER+/HER2– unresectable, locally advanced or metastatic disease. Eligible patients must have had radiographic disease progression on ≥12 months of ET plus CDK4/6 inhibitor therapy in the noncurative setting or received ≥2 lines of ET in the noncurative setting including CDK4/6 inhibitor where the CDK4/6 inhibitor was discontinued due to intolerance (not due to progression). Patients must also be eligible for additional ET with everolimus in combination with either fulvestrant or exemestane per local investigator assessment, have an Eastern Cooperative Oncology Group performance status of 0 or 1, have adequate organ function, and provide a new or recent core biopsy for central determination of ER and HER2 status. Previous treatment with chemotherapy, antibody-drug conjugates, or PARP inhibitors in the noncurative setting is prohibited. Patients are randomized 1:1 to receive belzutifan 120 mg orally once daily plus fulvestrant 500 mg on days 1 and 15 of cycle 1 and on day 1 of all subsequent 28-day cycles or everolimus 10 mg orally once daily plus fulvestrant (as above) or exemestane 25 mg orally once daily until disease progression or unacceptable toxicity. Randomization is stratified based on treatment with previous ET plus CDK4/6 inhibitor therapy (<18 months duration prior to progression vs ≥18 months duration prior to progression or no progression). Tumor imaging is performed at screening, every 8 weeks from randomization through week 56, and every 12 weeks thereafter. The primary endpoint is PFS per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 by blinded independent central review (BICR). Secondary endpoints include PFS rate per RECIST version 1.1 by BICR at 6 and 12 months, OS, objective response (complete response [CR] or partial response [PR]) per RECIST version 1.1 by BICR, clinical benefit (CR, PR, or stable disease for ≥24 weeks), and safety. The study start date was July 2024.

P4-10-06: Preclinical characterization of BGB-43395, a potential best-in-class CDK4 selective inhibitor with potent pharmacodynamic and anti-tumor activity in HR+HER2- breast cancer models

Hengrui Zhu, Hanzi Sun, Wenqing Xu, Jing Li, Xiaoxin Liu, Tingting Zhang, Xudong Luan, Jing Wang, Ying Ma, Mingchao Kang, Shuran Li, Yilu Zhang, Chi Guan, Xin Li, Jingjing Meng, Jiyuan Zhang, Yao Yao, Zhirong Shen, Xiaomin Song, Fan Wang, Sean Lin, Yu Shen, Zhiwei Wang, Xuesong Liu, Lai Wang, Ye Liu

Cyclin-dependent kinase (CDK) 4/6 inhibitors (palbociclib, ribociclib and abemaciclib) in combination with endocrine therapies have become the standard of care for patients with metastatic hormone receptor-positive, HER2-negative breast cancer (HR+HER2- BC). However, HR+HER2- BC is primarily dependent on CDK4, while CDK6 inhibition by dual CDK4/6 inhibitors often leads to dose-limiting neutropenia, which requires treatment holidays or dose reductions, thus limiting sustained CDK4 inhibition. Therefore, BGB-43395, a CDK4 selective inhibitor, was developed to reduce neutropenia by sparing CDK6,

thereby maximizing CDK4 inhibition to further improve clinical benefit.
BGB-43395 is a highly potent CDK4 kinase inhibitor with high selectivity over CDK6 and other CDK family kinases at biochemical level. In addition, BGB-43395 also demonstrated great selectivity against a panel of other kinases. These properties translated into a desirable toxicity profile in nonclinical toxicity studies, where BGB-43395 was well tolerated without concerning of neutropenia and gastrointestinal toxicity issues.
In the biochemical assay, BGB-43395 exhibits superior kinase inhibition against CDK4 compared to approved CDK4/(6) inhibitors (palbociclib, ribociclib and abemaciclib) and investigational CDK4 inhibitor PF-07220060. The potency of BGB-43395 was further determined by RB1 phosphorylation inhibition in human breast cancer cell lines. Compared to PF-07220060 and approved CDK4/6 inhibitors, BGB-43395 demonstrated more potent inhibition of RB1 phosphorylation (pRB1-S780) in CDK4-dependent HR+HER2- BC cell lines. As a result, BGB-43395 showed greater anti-proliferative activity in HR+HER2- BC cell lines as well as other cancer cell lines including prostate, ovarian, endometrial and lung cancer.
The in-vivo pharmacodynamic and anti-tumor activity of BGB-43395 were further evaluated in CDK4-dependent tumor models. BGB-43395 monotherapy demonstrated significant inhibition of RB1 phosphorylation in a dose-dependent manner in MCL Jeko1 and HR+HER2- MCF7 mouse xenograft tumors. BGB-43395 monotherapy treatment resulted in a greater tumor growth inhibition than palbociclib at clinically relevant dose in Jeko1 xenograft models. BGB-43395 in combination with fulvestrant also demonstrated a greater tumor growth inhibition compared to palbociclib in combination with fulvestrant in HR+HER2- MCF7 xenograft models.
In summary, BGB-43395 is a potential best-in-class CDK4 inhibitor with high potency and selectivity over CDK6 and other kinases, providing an opportunity to achieve high exposure and thus maximum on-target CDK4 inhibition for the treatment of HR+HER2- breast cancer and other CDK4 dependent cancers. BGB-43395 is currently undergoing clinical investigation as monotherapy or in combination with endocrine therapies in patients with metastatic HR+HER2- BC and other advanced solid tumors (NCT06120283).

P4-10-07: Evaluation of pharmacokinetics and safety of imlunestrant in participants with hepatic impairment

Stephanie White, Elaine Shanks, Eunice Yuen, Stephen David Hall, Vivian Rodriguez Cruz, Xuejing Wang

Background: Imlunestrant is a next-generation, oral selective estrogen receptor (ER) degrader designed to deliver continuous ER-target inhibition. Imlunestrant is under study for the treatment of ER+ advanced breast and endometrial cancers. Hepatic impairment (HI) is a common condition, particularly in cancer patients, and it can alter the pharmacokinetics (PK) of anticancer drugs, impacting their safety. Given that the intended patient population for imlunestrant may include cancer patients with HI, it is crucial to determine whether HI can impact the imlunestrant PK and safety profile. Here we present

PK and safety data of imlunestrant in postmenopausal females of nonchildbearing potential (FONCBP) with and without HI following a single oral dose in a fasted state.
Methods: This phase 1, open-label, 3-site study was conducted between July 2022 and February 2024 in FONCBP with normal hepatic function or HI. Participants (pts) were assigned to 4 different treatment arms, according to the Child-Pugh (CP) score: Group (G) 1 - normal hepatic function; G2: mild HI; G3: moderate HI, and G4 - severe HI. Pts were screened 28 days prior to enrollment, admitted to a clinical research unit (CRU) on Day -1, where they remained resident for PK and safety assessment following drug administration. In G 1, 2 and 3, pts received a single dose of 400 mg of imlunestrant, whereas pts in G4 received a single dose of 200 mg, while fasted. Plasma samples were collected for PK analyses. Key endpoints included PK parameters (AUC(0-tlast), AUC(0-∞), and Cmax) and safety.
Results: Twenty-seven females (G1: n=9; G2: n=6; G3: n=6; G4: n=6) were included in the study (age: 45-71 years). Compared to pts with normal hepatic function, the AUC(0-tlast) geometric least square mean (GLSM) ratios for pts with mild or moderate HI by the CP scores were 1.2 (90% confidence interval (CI); 0.82, 1.8) and 2.2 (1.5, 3.3), respectively. Compared to pts with normal hepatic function, the dose-normalized (DN)-AUC(0-tlast) in pts with severe HI by the CP scores was 2.9 (90% CI;1.8, 4.7). The AUC (0-∞) GLSM ratios were 1.2 (90% CI; 0.8, 1.8) and 2.2 (90% CI; 1.5, 3.3) for the mild and moderate HI groups, respectively. The AUC(0-∞) normalized ratio of the severe HI group was 3.1 (90% CI; 1.9, 4.9). The imlunestrant Cmax GLSM ratio was similar between pts with normal hepatic function and those with mild (1.3 (90% CI; 0.8, 2.0)), moderate (1.5 (90% CI; 1, 2.4)) and severe (1.6 (90% CI; 1, 2.7)) HI. The median elimination half-life was 33.1 hours in pts with normal hepatic function, 42.8, 46.3 and 67.0 hours in pts with mild, moderate and severe HI, respectively. Additional exploratory analysis of PK parameters based on the National Cancer Institute (NCI) classification of HI, showed there were significant differences in imlunestrant PK when administered to pts with mild and moderate HI compared to pts with normal hepatic function. Only 1 pt was categorized with severe HI by NCI classification as such, this group was excluded from NCI based analyses. The average fraction unbound in plasma was similar across groups. Most TEAEs were mild or moderate in severity. TEAEs were reported by 2 pts with moderate HI and severe HI, respectively. Nausea and headache were the only TEAEs reported by more than 1 pt.
Conclusions:
Imlunestrant administered as a single oral dose in the fasted state was well tolerated in healthy FONCBP, as well as pts with mild, moderate and severe HI determined by the CP classification. There were no significant differences in the exposure profiles of imlunestrant in pts with mild HI in comparison to pts with normal hepatic function. However, in pts with moderate and severe HI, statistically significant increases in imlunestrant AUC (but not Cmax) were observed when compared with normal hepatic function. This data will inform the recommendations for dosing patients with HI under treatment with imlunestrant.

P4-10-08: Impact of an Online Educational Activity on Oncologists' Knowledge and Confidence Regarding the Management of HR-Positive/HER2-Negative Metastatic Breast Cancer

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Eloise Ballard, Jamie Habib, Peter Schmid

Background: The management of HR+/HER2− metastatic breast cancer (mBC) is evolving with the introduction of novel therapies, particularly in the post-CDK 4/6 inhibitor setting. The objective of this study was to assess if an online continuing medical education (CME) activity could improve oncologists' knowledge of the latest evidence regarding novel and emerging therapies for HR+/HER2− mBC.
Methods: This educational activity consisted of a 30-minute video presentation with synchronized slides, including a whiteboard animation illustrating the mode of action of novel agents. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A chi-squared test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 25th of August 2023, with data collected through 11th December 2023 being reported in the current study.
Results: The analysis set consisted of responses from oncologists (n=59) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in oncologists' overall knowledge (P< .01). Overall correct responses increased from 57% pre- to 75% post-CME. Specific areas of improvement include:

- Knowledge of the latest clinical data of emerging therapies for HR+/HER2− mBC (pre 65%, post 80%; P < .01)
- Knowledge of the mode of action of novel agents for HR+/HER2− mBC (pre 41%, post 64%; P < .01)

After education, 44% of oncologists had a measurable increase in confidence in their ability to identify patients suitable for participation in clinical trials investigating novel treatment, and that increase was, on average, 64%.
Conclusions: This study demonstrates the success of an online, 30-minute CME activity on improving the knowledge and confidence of oncologists regarding the evolving treatment landscape of HR+/HER2− mBC, including in areas where many clinicians appeared to have relatively high knowledge levels at baseline. However, as new data continue to emerge, it will be important to provide ongoing education to clinicians so that they feel confident in interpreting the clinical evidence and translating it into practice.

P4-10-09: Genomic Profiles of Early Progressors vs Exceptional Responders on CDK4/6i in ER+ HER2- Advanced Breast Cancer

Tim Kong, Shana Thomas, Andrew Davis, Emily Podany, Jing Xi, Cynthia Ma, Katherine Clifton

Background: CDK4/6 inhibitors (CDK4/6i) paired with endocrine therapy (ET) remain first-line (1L) therapy for patients (pts) with hormone receptor positive (HR+) HER2 negative (HER2-) advanced breast cancer (aBC). A subset of pts will demonstrate primary resistance to CDK4/6i, as characterized by early progression, while other patients will remain on CDK4/6i for an extended duration prior to progression. We sought to examine clinical and genomic differences between a cohort of early progressors and exceptional responders.
Methods: Pts with HR+ HER2- aBC from a phase II trial of an alternative schedule of palbociclib (palbo alt dosing trial NCT 3007979) and from a retrospective CDK4/6i study were included in this analysis. Pts in the retrospective CDK4/6i study included pts receiving CDK4/6i as part of standard of care (SOC) first-line therapy for HR+ HER2- aBC at Washington University in Saint Louis from 2016 to 2024. Clinical information, including treatment start and stop dates, was collected from the electronic medical record. Progression-free survival (PFS) was estimated by the treatment duration on a specified treatment regimen. Early progression (EP) on CDK4/6i was defined as PFS < 6 months (mo) and late progression (LP) was defined as PFS > 48 mo. Overall survival (OS) was defined as time to death from the initiation of CDK4/6i. NGS testing was performed using the Guardant360 or Tempus platforms per SOC at time points per the treating physician's discretion in the retrospective CDK4/6i study patients and Whole Exome Sequencing (WES) of circulating tumor DNA was performed on the palbo alt dosing trial patients at baseline and progression.
Results: Of the 54 pts enrolled on the palbo alt dosing trial, 10 experienced EP and had WES available. The median age of EP pts with WES was 64 years at time of metastatic diagnosis and the majority (6/10) had recurrent [AD1] disease with visceral involvement (8/10). The median PFS of EP pts with WES was 3.1 mo and OS was 14.5 mo. Of retrospective study pts, 20 patients had EP on CDK4/6i, 10 of which had SOC NGS testing during at least one time point. The median age of EP pts with SOC NGS testing was 61 years at time of metastatic diagnosis and the majority (8/10) had recurrent [AD2] disease with visceral involvement (6/10). The majority of these pts received palbo (9/10) paired with letrozole (9/10) and did not have recurrence on adjuvant endocrine therapy (6/10). The median PFS of EP pts with SOC NGS was 3.9 mo and OS was 22.3 mo. Of the 38 pts on the retrospective study with LP on CDK4/6i[EP3], 17 were excluded as they were still receiving therapy. 10 pts with LP had NGS testing available. The median age these pts was 64 at time of metastatic diagnosis and the majority (7/10) of the LP pts had recurrent disease with bone only involvement (6/10). The majority of these pts received palbo (10/10) paired with letrozole (8/10) and did not have recurrence on adjuvant endocrine therapy (8/10). The median PFS was 65.7 mo and most patients (6/10) were alive at data analysis. When analyzing genomic differences between the EP and LP pts, there was no significant difference in rates of PIK3CA, ESR1, TP53, and ATM mutations. More patients in the EP cohort had amplification

(amp) of AR or AR mutations of uncertain significance (4/14 samples), CCND1 amps (2/14) and GATA3 mutations (2/14) at any time point. More patients in the LP cohort had RB1 (3/15 samples), GNAS (3/15), KRAS (2/15), EGFR (2/15) mutations and FGFR1 amps (2/15) at any time point.Frequencies of ESR1 alterations were similar in WES baseline (5/10), SOC EP (5/11), and SOC LP (5/9) samples, but less frequent in WES progression samples (1/10).
Conclusions: Early progression on CDK4/6i is associated with a particularly poor prognosis; however, there are patients with exceptional response to CDK4/6i who may remain on therapy for an extended time. There were variations in the mutation profiles between the two cohorts, though this data set was limited in size. Additional analysis of genomic variants is needed to identify profiles of patients who may significantly benefit from CDK4/6i.

P4-10-10: Changing treatment paradigms and unmet needs in patients with hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2-) metastatic breast cancer (mBC): Results from health records data

Alberto Montero, Di He, Miguel Miranda, Luis Berrocal-Almanza, Timothy Pham, Sam Hillman, Clara Chen

Background: Despite treatment advances for patients with HR+, HER2− mBC, most tumors acquire resistance, leading to disease progression. Outcomes worsen with subsequent treatment, underscoring a need for novel treatments that prolong disease control with earlier lines of therapy. We aim to describe treatment paradigms and real-world clinical outcomes in patients with HR+, HER2− mBC.
Methods: This retrospective cohort study included US adult patients from the Flatiron Health oncology database who were diagnosed with HR+, HER2− mBC between January 2017 and March 2023 and received any systemic oncologic therapy. Eligible patients were grouped into 3 cohorts according to the year of mBC diagnosis: 2017–2018, 2019–2020, or 2021–2023. Patients were followed through September 2023. Baseline characteristics at mBC diagnosis and treatment patterns were summarized using descriptive statistics. The unadjusted Kaplan–Meier method was used to estimate time to treatment discontinuation (TTD) and overall survival (OS). A Cox regression analysis was used to determine hazard ratios for OS. Inverse propensity weighting was used to eliminate confounding factors (age, sex, race, region, practice type, payer type, de novo vs recurrent disease, and ECOG performance score).
Results: Of 6,838 eligible patients (median age, 65 y; 99% female), 38% were initially diagnosed with de novo mBC, and 81% were treated at a community practice. The most prescribed first-line (1L) treatments overall were CDK4/6 inhibitor (CDK4/6i)-containing regimens (57%), single-agent endocrine therapy (ET; 28%), and chemotherapy (CT; 14%). From 2017–2018 to 2021–2023, CDK4/6i-containing regimen use in the 1L increased from 49% to 62% of patients. Median TTD for 1L CDK4/6i plus an aromatase inhibitor was 12.7 mo (95% CI: 12.0–13.4), with 28% and 48% of patients discontinuing therapy by 6 mo and

12 mo, respectively. In the second-line (2L; n=3,841), the main treatments overall were CDK4/6i-containing regimens (49%), CT (25%), and single-agent ET (16%). CDK4/6i-containing regimen use in the 2L increased from 45% in 2017–2018 to 56% in 2021–2023. Of patients who received 2L CDK4/6i-containing regimens, 54% were new to CDK4/6i, and 46% were rechallenged with CDK4/6i (i.e., switched to another CDK4/6i and/or changed ET). In the third-line (3L; n=2,050), treatments overall included CT (35%), CDK4/6i-containing regimens (32%), single-agent ET (16%), mTOR inhibitor–containing regimens (8%), and PI3Kα-specific inhibitor–containing regimens (5%). CDK4/6i-containing regimen use in the 3L increased from 31% in 2017–2018 to 36% in 2021–2023. Of patients who received 3L CDK4/6i-containing regimens, 33% were new to CDK4/6i, and 67% were rechallenged with CDK4/6i. Across treatment lines, median OS was similar in 2017–2018, 2019–2020, and 2021–2023 (41.4 mo, 42.0 mo, and not reached, respectively; p=0.9956). Relative to 2017–2018, mortality risk was comparable in 2019–2020 (HR 1.00; 95% CI: 0.92–1.09) and 2021–2023 (HR 1.01; 95% CI: 0.90–1.14).
ConclusionsCLUSIONS: CDK4/6i-containing regimens were the most used 1L treatment for patients with HR+, HER2– mBC; however, about half of patients discontinued CDK4/6i treatment within 1 year, suggesting the need for novel therapies that extend 1L treatment time and improve outcomes. There was no predominant treatment used in the 2L or beyond; CDK4/6i reuse was consistently observed. CT use increased when patients progressed to subsequent lines, suggesting that the percentage of patients who no longer responded to current standard of care increased. Despite increased use of CDK4/6i beyond the 1L, mortality has not improved in real-world practice since 2017, highlighting the need for novel therapies to improve outcomes.

P4-10-11: The Impact of Live and Online Education on Clinical Knowledge, Competence, and Confidence in the Use of Novel Antibody–Drug Conjugate Therapy for HR-Positive Breast Cancer

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Jamie Habib, Javier Cortés

Background: Antibody–drug conjugates (ADCs) are rapidly changing the treatment landscape for advanced breast cancer and are now being explored in earlier disease setting. The objective of this study was to assess the effect of an online continuing medical education (CME) activity on clinicians' knowledge in the clinical data on novel ADCs for the treatment of HR-positive breast cancer, competence in managing patients on treatment with an ADC, and confidence in their ability to integrate novel ADC therapy into clinical practice for patients with HR-positive advanced breast cancer.
Methods: This educational activity consisted of a 90-minute live symposium and video enduring activity with a downloadable slide deck. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to

post-assessment. P values < .05 are statistically significant. The live symposium took place on 20th of October, 2023 and the enduring activity launched on 20th of November, 2023, with data collected through 12th April, 2024 being reported in the current study.
Results: 50 oncologists and 20 surgeons who answered all the assessment questions were included in this analysis. Both physician groups demonstrated an improvement in knowledge and competence across all 3 learning themes:

- Knowledge of the latest clinical trial data: correct responses from oncologists increased from 44% pre-CME to 58% post-CME, P < .05; correct responses from surgeons increased from 30% pre-CME to 44% post-CME, P < .05
- Knowledge of ongoing clinical studies: correct responses from oncologists increased from 32% pre-CME to 44% post-CME, P < .05; correct responses from surgeons increased from 16% pre-CME to 40% post-CME, P < .01
- Competence related to managing patients receiving ADC therapy: correct responses from oncologists increased from 26% pre-CME to 55% post-CME, P < .001; correct responses from surgeons increased from 18% pre-CME to 26% post-CME, P < .248

All increases are statistically significant expect Surgeons' competence related to managing patients on ADC therapy.
Additionally, 36% of oncologists and 36% of surgeons reported increased confidence in integrating ADC therapy into clinical practice for patients with HR-positive advanced breast cancer, and that increase was, on average, 89% and 86% among the two physician groups, respectively.
Conclusions: This analysis demonstrates the positive educational impact of a live and subsequent online CME activity on clinicians' knowledge, competence and confidence regarding ADC therapy for breast cancer. As the treatment landscape continues to evolve in this field, it is important to provide ongoing education to clinicians so that they feel confident and competent when applying novel therapies in clinical practice.

P4-10-12: Abemaciclib monotherapy after disease progression on prior CDK4/6 inhibitors in patients with metastatic hormone-receptor positive breast cancer

Sahar Shahamatdar, Katherine Clifton, Julianna Wu, Annika Putur, Irene Kuter, Aditya Bardia, Dejan Juric, Laura Spring, Katherine Harris, Beverly Moy, Jennifer Shin, Neelima Vidula, Cynthia Ma, Seth A. Wander

Introduction: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) in conjunction with endocrine therapies have transformed the treatment landscape for patients with metastatic hormone-receptor positive (HR+)/HER2- breast cancer. Studies exploring the clinical utility of CDK4/6i re-introduction after disease progression on prior CDK4/6i-based therapy have yielded mixed results, including the recent phase III postMONARCH trial (which interrogated the combination of fulvestrant and abemaciclib in the second-line metastatic setting). Here, we explore the clinical outcomes of abemaciclib monotherapy after disease progression on prior combined CDK4/6i and endocrine therapy.

Methods: We collected retrospective clinical data at two academic institutions (Massachusetts General Hospital and Barnes-Jewish Hospital) according to site-specific IRB-approved protocols from patients with metastatic HR+/HER2- breast cancer who had received abemaciclib monotherapy after disease progression on another CDK4/6i-based therapy in the metastatic setting. We summarized patient and treatment characteristics and conducted time-to-event analyses.
Results: In this preliminary analysis, a total of 16 patients received abemaciclib monotherapy after disease progression on prior CDK4/6i-based therapy. All 16 received prior palbociclib-based therapies. Eleven of these patients continued abemaciclib until disease progression or death, while five patients stopped therapy due to toxicity (three due to gastrointestinal side effects, one due to fatigue, and one due to atrial fibrillation). Patients received palbociclib-based therapy for a median of 16.2 months and abemaciclib for a median of 3.8 months (95% confidence interval, 2.0-7.5 months). Five patients received abemaciclib for >180 days prior to disease progression/death. Conversely, only two patients discontinued abemaciclib prior to 90 days after initiation due to disease progression. Four out of the 16 patients received abemaciclib as the subsequent line of treatment immediately following progression on palbociclib. The median time from progression on palbociclib-based therapies to starting abemaciclib was 10.7 months, with a median number of two intervening lines of therapy. Efforts are underway to combine this cohort with additional patients receiving abemaciclib monotherapy in this setting at other institutions to enhance clinical sample size. Planned analyses will include retrospective review of radiographic images to estimate overall response rate and exploration of genomic sequencing to identify molecular mediators of response and resistance to abemaciclib monotherapy. These ongoing efforts will be presented at the meeting.
Conclusions: A subset of patients tolerated abemaciclib monotherapy for > 180 days before progression/death despite progression on prior combination palbociclib and endocrine therapies. This is the first effort to interrogate the utility of abemaciclib monotherapy in this setting and will provide additional insights related to serial CDK4/6-directed therapy in this patient population. These results demonstrate clinical promise in continued CDK4/6 inhibition and raise questions about mechanisms of resistance and the identification of patients that would benefit from abemaciclib monotherapy.

P4-10-14: Real-world palbociclib dose adjustment and outcomes in HR+/HER2- metastatic breast cancer: Flatiron database analysis

Rachel Layman, Xianchen Liu, Benjamin Li, Lynn McRoy, Connie Chen, Gabrielle B Rocque, Adam Brufsky

Background: A cyclin dependent kinase 4/6 inhibitor (CDK4/6i) in combination with endocrine therapy has become standard of care for HR+/HER2- advanced/metastatic breast cancer (MBC). CDK4/6i dose adjustment is recommended based on individual safety and tolerability during the treatment of MBC. Clinical trial data demonstrated that Palbociclib (PAL) dose adjustment had no significant impact on progression-free survival (PFS). Small

real-world studies have not demonstrated consistent outcomes associated with PAL dose adjustment, including real-world PFS (rwPFS) and overall survival (OS). Large real-world studies with longer follow-up are needed to understand patient characteristics and clinical outcomes associated with CDK4/6i dose adjustment. This study examined PAL dose adjustment and outcomes in HR+/HER2- MBC in routine clinical practice.
Methods: Using Flatiron Health longitudinal database, we conducted a retrospective analysis of HR+/HER2- MBC patients who started PAL plus an aromatase inhibitor (AI) as first-line therapy between February 2015 and March 2020 (index period). Patients were assessed from start of PAL+AI to September 30, 2020 (data cutoff), death, or last medical activity, whichever came first. Dose adjustment was defined as a change of PAL daily dose compared to initial/previous prescription dose. Treatment duration was defined as months from start of PAL+AI to end of the treatment. OS was defined as months from start of PAL+AI to death. rwPFS was defined as months from start of PAL+AI to death or disease progression, evaluated based on clinical assessment or radiographic scan/tissue biopsy. Kaplan-Meier analysis was used to estimate treatment duration, rwPFS, and OS. Multivariable Cox proportional hazard regression models were performed to adjust for baseline characteristics: age, sex, race/ethnicity, healthcare practice type, initial diagnosis, Eastern Cooperative Oncology Group Performance Status, National Cancer Institute-Comorbidity Index, disease free interval from initial breast cancer to MBC diagnosis, bone only disease, lung/liver involvement, and number of metastatic sites.
Results: A total of 1,324 patients received PAL+AI during the index period. Mean age was 67.1 years (SD=9.6), 99.2% were female, and 68.0% were white. Of these patients, 1,110 (83.8%) initiated PAL at 125 mg/day, 144 (10.9%) at 100 mg/day, 48 (3.6%) at 75 mg/day, and 22 (1.7%) did not have information about initial dose. Among 1,302 patients who had initial dose documented, 524 (40.3%) experienced dose adjustment. Comparted with patients without dose adjustment, those with dose adjustment were more likely to be white (71.8% vs 65.8%) and had a higher proportion of lung/liver involvement (35.5% vs 32.4%). Median follow-up was 28.5 and 22.6 months in patients with and without dose adjustment, respectively. Median treatment duration was longer in patients with dose adjustment than in those without dose adjustment (27.4, 95%CI = 24.5–30.6 vs 21.4, 95%CI = 19.7–26.5 months). Patients with and without dose adjustment showed similar median rwPFS (20.5, 95%CI=17.8–25.9 vs 19.6, 95%CI=16.9–21.7 months; unadjusted HR = 0.90, 95%CI = 0.77–1.04, p=0.162; adjusted HR = 0.89, 95%CI = 0.76–1.04, p=0.133). Median OS was significantly prolonged in patients with dose adjustment than in those without dose adjustment (57.8, 95%CI=49.0–NA vs 51.4, 95%CI=45.3-58.7 months; unadjusted HR = 0.72, 95%CI = 0.59–0.88, p=0.001; adjusted HR = 0.73, 95%CI = 0.59–0.89, p=0.002).
Conclusions: Similar to other CDK4/6is, PAL dose adjustment is common in the treatment of HR+/HER2- MBC. PAL dose adjustment did not have significant effect on rwPFS but was associated with prolonged treatment duration and OS. Further research is needed to confirm these findings and understand the reasons for PAL dose adjustment in real-world settings.

P4-10-15: Evaluating the APIS ESR1 Mutations Kit: Performance and LoD Testing in Varied Wildtype Backgrounds

Anna Gasior, Joanna Gorniak, Andreas Voss, Ryan Nana, Ava Read, Luke Matthews, Kimberly Howard, Leanne Gough, Christine Hoy, Colette Whitfield

Introduction: Mutations in the estrogen receptor 1 (ESR1) gene are crucial for understanding and predicting resistance to endocrine therapy in ER-positive breast cancer. The APIS ESR1 Mutations Kit (APIS Assay Technologies, Manchester, UK) offers a cost-effective, rapid, and highly sensitive qPCR assay designed to detect eleven ESR1 mutations (E380Q, S463P, P535H, L536R/Q/H/P, Y537C/S/N, and D538G). The kit is optimized for use with DNA from plasma (cfDNA) or FFPE tissue. This study evaluates the performance of the APIS ESR1 Mutations Kit, particularly its sensitivity in detecting ESR1 mutations in varied wildtype backgrounds.
Methods: DNA fragments encoding all ESR1 mutations detected by the APIS kit, were spiked into wildtype (WT) DNA background. The Limit of Blank (LoB) and Limit of Detection (LoD) for each mutation were determined using approximately 5,000 copies WT background DNA. To evaluate the effect of higher WT backgrounds on LoD and LoB, samples with a 0.5% mutant allele frequency (MAF) were prepared with higher WT DNA backgrounds (approximately 10,000 and 50,000 copies). This approach aimed to highlight the importance of assessing sensitivity based on the copy number rather than %MAF. A dilution series of DNA fragments, ranging from 5 to 10,000 copies per reaction, was analyzed to determine linearity. The kit's performance was further assessed using the SensID ESR1 Reference Set 1% AF cfDNA (SensID GmbH, Rostock, Germany). All PCR runs were conducted using a QuantStudio™5 Dx Real-Time PCR System.
Results: The APIS kit successfully detected all mutations at ≤ 1.0% MAF in WT background of approximately 5,000 copies, detecting the most prevalent mutations, D538G and Y537S, at 0.4% and 0.1% MAF, respectively. In higher WT backgrounds, mutations D538G, Y537S/C/N, L536H/Q and P535H were detected in 0.5% MAF samples with approximately 10,000 copies background. In approximately 50,000 copies background, mutations D538G, Y537S/C/N, E380Q and P535H were detected in 0.5% MAF samples. No false positive calls were observed for any mutations, regardless of the WT background. Linearity was maintained within 90-110% across a range of 50 to 10,000 copies per reaction. When tested with the SensID ESR1 Reference Set, the APIS kit accurately detected all ESR1 mutations, with no false positives calls.
Conclusions: The APIS ESR1 Mutations Kit exhibited high sensitivity and specificity as a qualitative qPCR assay for detecting ESR1 mutations in varying wildtype backgrounds. Additionally, testing with the SensID ESR1 Reference Set 1% AF cfDNA confirmed the kit's performance and LoD at ≤ 1% MAF with external material. The APIS kit is a valuable tool for assessing ESR1 mutations in both clinical and research settings, offering a more accessible alternative to traditional NGS and dPCR assays.

P4-10-16: INX-315, an oral, potent and selective CDK2 inhibitor in patients with CDK4/6 inhibitor resistant ER+/HER2- breast cancer or CCNE1 amplified solid tumors: phase 1 monotherapy dose escalation

Antoinette Tan, Antonio Giordano, Catherine Shannon, Carey Anders, Nashat Gabrail, Kevin Kalinsky, Patrick Roberts, George Au-Yeung

Background: Cyclin-dependent kinases (CDK) are a family of serine/threonine kinases that heterodimerize with regulatory subunits called cyclins to drive cell cycle progression, cell division, and associated biological processes. CDK2 plays a crucial role in promoting G1/S transition and S phase progression. Dysregulated CDK2 activity commonly occurs through amplification of CCNE1 (gene that encodes cyclin E1 protein) and/or overexpression of cyclin E1, and mutations that inactivate CDK2 endogenous inhibitors (e.g., p27), respectively. INX-315 is an oral, potent, and selective small molecule CDK2 inhibitor in early clinical development with best-in-class potential.
Methods: NCT05735080 is a first-in-human study designed to evaluate the safety, tolerability, pharmacokinetics (PK) and preliminary antitumor activity of INX-315 in patients with recurrent advanced/metastatic cancer, including estrogen receptor positive (ER+)/Human Epidermal Growth Factor Receptor 2 Negative (HER2-) breast cancer who progressed on a prior CDK4/6 inhibitor (CDK4/6i) regimen and patients with CCNE1 amplified solid tumors (defined by next generation sequencing), including high grade serous ovarian cancer (HGSOC), who progressed on prior standard of care treatment. This study is evaluating dose levels of INX-315 QD in 28-day cycles in Part A, with dose escalation utilizing a Bayesian Optimal Interval Design (BOIN) to select dose levels for the Expansion Phase. Blood samples for PK and circulating biomarker analyses were collected.
Results: By June 27, 2024, 27 patients were enrolled in 5 dose cohorts with increased dose levels (100 mg to 600 mg) and are included in the safety analysis. Median age was 60 years old (range 29-78), 78% were female, and 78% white. Tumor types studied include ER+/HER2- Breast Cancer (n=8), HGSOC (n=10), and other solid tumors (n=9). Median prior lines of therapy were 5 with a range of 2-10. At the time of data cut, 11 patients were receiving treatment, of which 2 are ER+/HER2- breast cancer, 13 discontinued treatment due to progression of disease (PD), 2 withdrew consent, and 1 physician decision. No discontinuations due to adverse events (AEs) were observed. The most frequent treatment-related adverse events occurring in ≥15% of cases, included decreased platelet count (48%), nausea (37%), decreased neutrophil count (29%), anemia (26%), diarrhea (26%), vomiting (22%) and decreased white blood cells (15%). Treatment-related Grade 3 AEs included fatigue (7%) and decreased white blood cell count (7%), as well as diarrhea, anemia, and decreased neutrophil count (4% each). Two treatment-related grade 4 AEs were decreased neutrophil count and decreased platelet count (4%). At the time of the data cut off, two patients (ER+/HER2- breast cancer and CCNE1 amplified HGSOC) have confirmed partial responses. Additionally, 14 pts (63.6%) had a best response of stable disease, with 4 patients (2 ER+/HER-) achieving at least a 20% tumor reduction. INX-315 plasma concentrations increased with dose and achieved 24-hour trough concentrations ≥ the predicted effective concentrations (Ceff) starting at the first dose level (100 mg QD).

Pharmacodynamic studies are ongoing.
Conclusions: INX-315 monotherapy at increasing QD dose levels was generally well tolerated and demonstrated monotherapy antitumor activity in heavily pretreated patients with ER+/HER2- breast cancer and CCNE1amplified solid tumors. Dose escalation and optimization is ongoing to determine the dose levels to be further evaluated in monotherapy (CCNE1 amplified HGSOC) and combination (ER+/HER2- breast cancer) expansion parts of the study.
Clinical trial information: NCT05735080.

P4-10-17: An Analysis of the Breast Cancer Vaccine Landscape

Michelle Tregear, Michele Rakoff, Elle Dellsy, Debbie Laxague

Background: Cancer vaccines and the idea of using the immune system to improve cancer treatment has a long history, and until recently, has been met with limited success. However, advances in technology and improved understanding of the immune system have led to promising vaccine approaches to both treating and preventing cancer. This analysis explores the evolution of breast cancer (BC) vaccines.
Methods: We conducted a systematic search of clinicaltrials.gov (CT.gov) for BC vaccine trials registered through Feb 29, 2024, yielding 220 studies that were downloaded into a Microsoft Excel file. Manual searches of published BC vaccine review articles identified 13 additional BC vaccine trials not retrieved in our CT.gov search. A total of 233 studies were screened by two of the authors for relevance. Eligibility criteria included that all studies be clinical studies, including randomized, non-randomized, and cohort trials that evaluated a tumor vaccine in patients with BC. Trials of multiple tumor types were included if BC was among the cancer studied. Non-cancer vaccine trials were excluded, as were studies with a withdrawn status yielding 186 trials for review and classification according to a pre-defined taxonomy that included: BC subtype; cancer stage; primary purpose of the vaccine; vaccine platform; antigen targets; drug combinations; trial phase; trial design; primary and secondary endpoints; key sponsors, collaborators, and funders; trial status; start/completion year, and results. Four BC patient advocates (all graduates of Project LEAD®) systematically reviewed and abstracted each trial according to the taxonomy. Coding was reviewed by two individuals. Disagreements were adjudicated by team review. Following detailed abstraction, 11 additional studies were excluded yielding 175 registered trials for analysis. Additional searches of PubMed and Google Scholar were done to identify published findings for all included clinical trials.
Results: Of the included trials, 101 were Phase 1, 33 Phase 1-2, 37 Phase 2, and four Phase 3. A total of 75 trials did not restrict participation to a specific BC subtype whereas 40, 46, and 14 focused on HER2+, TNBC, and HR+ BC, respectively. Five trials included patients with DCIS. For disease stage, 96, 63, 11, and 7 involved patients with advanced/metastatic stage, early stage, early stage/metastatic-no evidence of disease, and no BC (i.e., DCIS or high risk), respectively. Vaccine trials focused in early-stage disease have increased in recent years whereas vaccines targeting advanced disease have remained relatively stable over time. Peptide-based vaccine platforms were the most common (n=80), followed by 50

cell-based, 26 viral vector-based, and 26 DNA-based vaccines, including numerous examples of mixed platforms. HER2 was the most common target antigen (N=50 studies), followed by CEA (N=29), MUC1 (N=11), hTERT (N=7), and Brachyury (n=7). Most vaccines targeted a single antigen, with an increasing trend toward vaccines with multiple antigen targets. All but 45 trials included some form of combination therapy, including 27 with immune checkpoint inhibitors, 45 chemotherapy, and 21 with HER2 targeted agents. A total of 28 of 108 completed trials had results posted on CT.gov. Twenty-nine had results published elsewhere while 30% had completion dates beyond 2023.
Conclusions: This analysis provides a wealth of information on the evolution of the BC vaccine landscape, including key trends in antigen targets, vaccine platforms, and immune modulatory adjuvants. While most BC vaccines have had therapeutic purposes, largely in the advanced/metastatic setting, there has been an increased focused in recent years on secondary and primary prevention.

P4-10-18: Potential predictive biomarkers for a fibroblast growth factor receptor (FGFR) inhibitor: Phase 1b trial of tasurgratinib (E7090) with endocrine therapies (ET) for ER+, HER2+ recurrent/metastatic breast cancer (BC) resistant to CDK4/6 inhibitors

Takahiro Kogawa, Takanori Ishida, Kan Yonemori, Ayumi Kataoka, Akihiko Shimomura, Kenjiro Aogi, Ken Takai, Toru Mukohara, Takahiro Nakayama, Hitomi Sakai, Shigehisa Kitano, Shingo Kobayashi, Taisuke Uehara, Shuyu Li, Tingting Song, Yohei Otake, Junji Tsurutani

Background: CDK4/6 inhibitors (CDK4/6i) combined with ET are standard first-line treatment for people with ER+, HER2− recurrent/metastatic BC. Previous studies suggest that FGFR gene alterations or overexpressions may contribute to resistance to CDK4/6i + ET. Here, we investigated the relationship between gene alterations or expression and sensitivity to the FGFR inhibitor, E7090.
Methods: We evaluated E7090 with or without ET in patients with ER+, HER2− recurrent/metastatic BC after CDK4/6i exposure (NCT04572295). Part 1 included treatment with fulvestrant (FUL) 500 mg + E7090 (105 or 140 mg) or exemestane (EXE) 25 mg + E7090 (105 or 140 mg). In part 2, patients with high FGFR1–2 protein expression by IHC received E7090 140 mg monotherapy. In part 3, patients received the recommended regimen (FUL + E7090 105 mg) to evaluate preliminary efficacy and safety. Tumor samples were collected at baseline (BL) and on cycle 3 day 1 (C3D1). Gene abnormalities were evaluated using FoundationOne®CDx (F1CDx) or whole-exome sequencing (WES), while mRNA expression was assessed using nCounter® PanCancer Pathways Panel. DNA sequencing analyzed FGFR-related gene abnormalities, ESR1 gene mutations, and PI3K/AKT pathway genetic mutations. Leveraging mRNA expression data from this study and the TCGA database, we established 3 gene-signature scores related to FGF/FGFR signaling—Signature Score 1, 2, and 3 (based on the TCGA database, BL gene expression in this study, and expression changes on pre/post samples from this study, respectively)—to

predict the clinical outcome of E7090 in BC. We explored potential correlations between gene alterations or gene-signature scores at BL and clinical outcomes (objective response rate [ORR] and progression-free survival [PFS]).
Results: Fifty-one patients received E7090 (E7090 105 mg + FUL, n=35 [3 from part 1 and 32 from part 3]; E7090 140 mg + FUL, n=3; E7090 105 mg + EXE, n=3; E7090 140 mg + EXE, n=9; E7090 140 mg monotherapy, n=1). Gene alterations in 42 patients were assessed by F1CDx (n=14) or WES (n=28) and gene expression was related to FGF/FGFR signaling assessed in 48 patients (BL only, n=40; paired BL and C3D1, n=8). The most frequently altered genes (> 20%) were: TP53 (38%); PIK3CA (33%); CCND1 (26%); ESR1 (26%); FGF19 (26%); FGF4 (26%); FGF3 (24%); and FGFR1 (24%). In the groups with or without FGF/FGFR pathway gene alterations, the ORRs were 15.0% (n=3/20) and 27.3% (n=6/22), and the PFS medians (mPFS) were 3.5 and 3.7 mos (altered vs unaltered: HR=1.100 for PFS), respectively. Among patients with or without ESR1 mutations, the ORRs were 9.1% (n=1/11) and 25.8% (n=8/31), and the mPFS were 3.5 and 3.7 mos (HR=1.631), respectively. Among patients with or without AKT pathway gene alterations, the ORRs were 15.8% (n=3/19) and 26.1% (n=6/23), and the mPFS were 3.5 and 5.4 mos, respectively (HR=1.513). For the gene-expression biomarker analyses, the Signature Score 1 high-score group had an ORR of 42.1% (n=8/19) and mPFS of 16.6 mos, whereas the low-score group had an ORR of 10.3% (n=3/29) and mPFS of 3.6 mos (high vs low: HR=0.524). For Signature Score 2, ORRs and mPFS in the high-score (n=19) and low-score (n=29) groups were the same as for Signature Score 1 (HR=0.506). For Signature Score 3, the high-score group had an ORR of 39.1% (n=9/23) and mPFS of 16.6 mos, whereas the low-score group had an ORR of 8.0% (n=2/25) and mPFS of 3.6 mos (HR=0.484).
Conclusions: These results emphasize that FGFR pathway activation evaluated with mRNA expression of selected genes at BL—rather than FGFR gene abnormalities—is a key molecular determinant for sensitivity to E7090, an FGFR inhibitor. Future validation of these biomarkers is necessary in a larger population of people with ER+/HER2− BC.

P4-10-20: First-in-human phase 1a, dose-escalation study of BGB-43395 (CDK4-selective inhibitor) as monotherapy and in combination with fulvestrant or letrozole in patients with metastatic HR+/HER2+ breast cancer and other advanced solid tumors

Timothy Yap, Gerald Falchook, Jennifer Man, Dhanusha Sabanathan, Robert Wesolowski, Ildefonso Rodriguez-Rivera, Hui Gan, Gilbert Y. Wong, Yaxi Chen, Shiyang Wang, Hao Zheng, Shom Goel

Background: Despite the approval of cyclin-dependent kinase (CDK) 4/6 inhibitors (CDK4/6i) in HR+/HER2− breast cancer (BC), pts may develop resistance and experience toxicities with current treatments. BGB-43395 is a potent and selective CDK4i, showing preclinical antitumor activity with improved CDK4 coverage and greater selectivity for CDK4 over CDK6, thus minimizing off-target toxicity and potentially toxicity-related dose reduction/discontinuations. Here, we present the preliminary results of an ongoing first-in-

human, phase 1a dose escalation, open-label, multicenter trial of BGB-43395 given orally as monotherapy in pts with advanced solid tumors (Part A) or as part of combination therapy in pts with fulvestrant (Part B) or letrozole (Part C) in pts with 2L+ HR+/HER2− BC (NCT06120283).
Methods: Eligible pts were ≥18 years of age with histologically or cytologically confirmed advanced, metastatic, or unresectable solid tumors associated with CDK4 dependency. Permitted prior therapies included ≥2 lines of treatment including endocrine therapy (ET) and CDK4/6i in either the adjuvant or advanced metastatic setting for pts with HR+/HER2− BC, ≥2 lines of HER2 targeted therapy for pts with HR+/HER2+ BC, and standard of care for pts with other advanced solid tumors. Primary objectives were to assess the safety and tolerability of BGB-43395 as monotherapy or combined with fulvestrant or letrozole, and to determine the maximum tolerated dose or maximum administered dose and the recommended dose for expansion. Secondary endpoints were to evaluate pharmacokinetics and preliminary antitumor activity assessed per RECIST v1.1 by investigator.
Results: As of May 20, 2024, 23 pts (17 in Part A [including 6 with HR+/HER2− BC], 3 in Part B, and 3 in Part C) were enrolled in the ongoing dose escalation portion of the study. In all, there were 7 dose cohorts (5 in Part A, 1 in Part B and 1 in Part C). In Parts A, B and C, respectively, 14/17 (82.4%), 2/3 (66.7%) and 3/3 (100%) pts had metastatic disease. The median (range) number of lines of prior therapy was 3.0 (1–10) in all pts in Part A (3.5 [2–10] in the 6 HR+/HER2− pts in Part A), 4.0 (2–8) in Part B, and 4.0 (1–5) in Part C. All of the 12 HR+/HER2− BC pts in Parts A, B, and C, received prior CDK4/6i, ET, and chemotherapy (CT), except 1 pt in Part C who did not receive CT. TEAEs occurred in 15/17 (88.2%), 1/3 (33.3%) and 0 pts in Parts A, B, and C, respectively, and were primarily grades 1 and 2. For all 23 patients, the most common TEAEs were diarrhea (12/23; 52.2%; 1 pt grade 3), nausea (7/23; 30.4%; all grades 1 and 2), anemia (3/23; 13.0%; 1 pt grade 3), fatigue (3/23; 13.0%; all grades 1 and 2), and vomiting (3/23; 13.0%; all grades 1 and 2). Treatment-related AEs occurred in 14/23 (60.9%) pts (13 in Part A, 1 in Part B and 0 in Part C) and were primarily grade 1 and 2 except for 3 pts with grade 3. There were no DLTs or TEAEs leading to treatment discontinuation or death. Updated clinical data will be presented.
Conclusion: BGB-43395 is a novel CDK4-selective inhibitor and a promising agent for tumors with high CDK4 dependency with the potential to minimize off-target toxicity. To date, BGB-43395 has been safe and tolerable, supporting continued development. The dose-escalation phase is currently ongoing.

P4-10-21: Enhanced anti-tumor activity of zelenectide pevedotin in triple negative breast cancer (TNBC) patients (pts) with NECTIN4 gene amplification (amp)

Niklas Klümper, Viktor Grünwald, Johannes Brägelmann, Meredith McKean, Elisa Fontana, Antoine Italiano, Loic Verlingue, Capucine Baldini, Valentina Boni, Alberto J Montero, Thibault de la Motte, Bernard Doger, Jordi Rodón Ahnert, Cecile Vicier, Carly Campbell, Tara Gelb, Sean Santos, Kate Josephs, Cong Xu, Nicholas Keen, Kevin Lee, Santiago Arroyo, Markus Eckstein

Background: Zelenectide pevedotin (zele, formerly BT8009) is a highly selective Bicycle® Toxin Conjugate (BTC) comprised of a bicyclic peptide targeting Nectin-4 conjugated to monomethyl auristatin E. BTC® molecules have lower molecular weight and shorter plasma half-life than antibody-drug conjugates, with distinct pharmacokinetics/dynamics, i.e., potential for rapid tumor penetration and minimal healthy tissue exposure. NECTIN4 amp has been shown to be a predictive biomarker for response to Nectin-4 targeted therapy in metastatic urothelial cancer (Klümper et al., 2024). An analysis of NECTIN4 amp in a large, independent sample of 245 breast cancer (BC) pts indicates that amp is common, seen in 19% (30/161), 14% (5/36) and 23% (11/48) of HR+/HER2-, HER2+ and TNBC, respectively (Klümper et al., unpublished data). This initial post-hoc analysis assesses the utility of NECTIN4 amp as a predictor of zele response in heavily pretreated BC pts.
Methods: Zele is being evaluated in the ongoing Phase 1/2 study BT8009-100/Duravelo-1 (NCT04561362) for safety and efficacy in pts with advanced solid tumors associated with Nectin-4 expression including BC pts. This analysis focuses on TNBC study pts who had baseline tissue sample available, had consented to optional future research, and tested for NECTIN4 amp by fluorescence in-situ hybridization. NECTIN4 amp positivity was defined as a ratio of NECTIN4: centromere 1 (CEN1) of 2.0 or higher. Assessment of anti-tumor activity was per RECIST v1.1 by investigator. Objective response rate (ORR) is based on the efficacy evaluable population.
Results: As of 29 August 2024, 32 heavily pretreated pts with TNBC enrolled in the monotherapy dose escalation and expansion cohorts of BT8009-100. Thirty-one TNBC pts were treated with the zele recommended Phase 2 dose of 5 mg/m2 weekly. At baseline, TNBC pts had a median age of 52 (30-76), median prior lines of therapy of 6 (2-13), and ECOG of 0 or 1 (50.0% each). Of 32 enrolled TNBC pts treated with zele, 30 were efficacy evaluable. Four pts achieved partial response (PR) resulting in an ORR of 13.3% (95% CI: 3.8, 30.7).
Nineteen pts were tested for NECTIN4 amp, 6 of whom were positive (31.6%). Of these, 3 achieved a PR with an ORR of 50.0% (95% CI: 11.8, 88.2), and the remaining 3 had stable disease (SD; disease control rate 100.0%). All 3 NECTIN4 amp responders were previously treated with sacituzumab govitecan. Of the NECTIN4 non-amp pts, 1/13 had a PR: ORR of 7.7% (95% CI: 0.2, 36.0). Of note, the non-amp responder pt harbored a polysomy, with NECTIN4 and CEN1 copy number >6 (NECTIN4:CEN1 ratio <2.0). Four HR+ BC pts were tested for NECTIN4 amp. One responder (1/ 4) was also the only one harboring a NECTIN4 amp.
Safety and tolerability of zele in the TNBC population was similar to a previously reported cohort of bladder cancer pts (Reig et al., 2024). Grade 3 or higher zele-related adverse events (AEs) occurred in 34.4% of all TNBC pts, and Grade 3 or higher zele-related serious adverse events (SAEs) occurred in 12.5% of all TNBC pts. Zele-related AE frequencies were similar in the NECTIN4 amp pts; however, no NECTIN4 amp pts had a zele-related SAE.
Conclusions: NECTIN4 amplification appears to show predictive clinical utility in identifying pretreated TNBC pts with enhanced response to zelenectide pevedotin, with an ORR of 57.1% in NECTIN4 gene amp positive pts including polysomy versus an ORR of 13.3% in biomarker unselected TNBC. Despite the limited sample size, this post-hoc analysis

underscores the promising anti-tumor activity of zelenectide pevedotin in pts with NECTIN4 amp TNBC, who continue to have significant unmet medical need for effective, well-tolerated therapy. These findings support further exploration of zele and NECTIN4 amp stratification strategies in BC pts, particularly TNBC.

P4-10-22: Eflapegrastim, a long-acting GCSF, administered the same day as chemotherapy in patients with early-stage breast cancer: Results from a multicenter, open-label, study

Manuel Modiano, Omkar Marathe, Shanta Chawla, Jeffrey L. Vacirca, Kenneth Crist, Howard Franklin, Lee Schwartzberg

Introduction: Patients (pts) with early-stage breast cancer (ESBC) receiving docetaxel and cyclophosphamide (TC) chemotherapy have a high risk of severe neutropenia (SN) and febrile neutropenia (FN) that can increase the risk of life-threatening infections and lead to chemotherapy dose reductions or treatment delays. The National Comprehensive Cancer Network recommends prophylactic treatment with granulocyte colony stimulating factor (GCSF) to reduce the risk of FN. Eflapegrastim is a novel long-acting GCSF consisting of recombinant human GCSF covalently linked to human IgG4 Fc fragment via a short polyethylene glycol linker. Eflapegrastim, via transcytosis and recycling, demonstrates increased bone marrow residence compared with pegfilgrastim, potentially improving its bioavailability following chemotherapy and allowing same-day dosing. Same day dosing has the potential to improve pt convenience by reducing multiple office visits. In the phase 3 pivotal trials ADVANCE (NCT02643420) and RECOVER (NCT02953340), eflapegrastim was administered ~24 hours post TC administration. Both studies showed non-inferiority of eflapegrastim to pegfilgrastim in reducing the duration and incidence of neutropenia in pts with ESBC receiving TC. In this study, we evaluated the safety of same-day dosing of eflapegrastim in the same disease setting.
Methods: This multicenter, open-label study (NCT04187898) enrolled pts with confirmed ESBC (stage I to IIIA), aged ≥ 18 years who were candidates for neoadjuvant or adjuvant TC. Pts received subcutaneous eflapegrastim (single, fixed dose of 13.2 mg [3.6 mg GCSF]) 0.5 h ± 5 min post TC (intravenous docetaxel 75 mg/m2 + cyclophosphamide 600 mg/m2) The primary endpoint was the time to recovery of absolute neutrophil counts (ANC) from nadir to ≥ 1.5×109/L in C1. Secondary endpoints included incidence of SN (ANC < 0.5×109/L) and FN (ANC < 1.0×109/L and temperature of > 38.3 oC or 2 consecutive readings ≥ 38.0 oC over 2 hours), duration of SN (DSN), and incidence of neutropenic complications, including use of antibiotics and/or hospitalizations. Blood samples for complete blood counts with differential were collected pretreatment and on day 1 and daily on days 4–10 of C1. Safety assessments began with the first dose of TC and lasted until 35 ± 5 days after the last dose of eflapegrastim. Here, we report the treatment-emergent adverse events (TEAEs) of interest. All results reported are descriptive.
Results: A total of 53 pts (mean [SD] age: 62.7 [11.9] years; female: 100%) from 13 sites

across the US, were enrolled (White: 62.3%; Black or African American: 9.4%; others: 28.3%). Pts were relatively healthy (ECOG 0, 52.8% [n = 28] patients; ECOG 1, 47.2% [n = 25] patients). Efficacy in C1 was evaluable in 49 patients. Mean (SD) time to ANC recovery was 1.8 (1.1) days. Incidence of SN was 46.9% (n = 23) and mean (SD) DSN was 0.8 (1.0) days. Incidence of FN was 2% (n = 1). No neutropenic complications were observed during the study. Safety was assessed in all 53 patients who received at least 1 dose of eflapegrastim. Overall, 43 patients (81.1%) experienced any TEAE of musculoskeletal pain. Common musculoskeletal-related TEAEs experienced by ≥ 10% of patients were bone pain (52.8%; n = 28); back pain (26.4%; n = 14), arthralgia or pain in extremity (17.0%; n = 9 for each); and myalgia (13.2%; n = 7). No deaths were reported during the study.
Conclusions: These findings suggest that administration of eflapegrastim on the same day as TC chemotherapy may be advantageous in reducing the time to ANC recovery and related complications in pts with ESBC. The AEs observed in this study were consistent with those generally observed in pts receiving TC and other GCSF products.

P4-10-23: Preclinical anti-tumor activity of BB-1701, a HER2-targeting eribulin conjugated ADC, in HER2-low breast cancer PDx models.

Shogo Yamaguchi, Keiji Furuuchi, Toshimitsu Uenaka, Taro Semba

Background: HER2-low breast cancer (BC) is the diagnosis in approximately 60~65% of HER2 "negative" breast cancer patients. Recently, the clinical landscape of HER2-low BC has changed with the approval of a HER2 targeting antibody-drug conjugate (ADC), trastuzumab-deruxtecan (T-DXd). Suitable drug candidates for next-line therapy in HER2-low BC after T-DXd are in need of investigation. BB-1701 is an ADC consisting of a trastuzumab and eribulin payload. When BB-1701 targets HER2-expressing cancer cells and is internalized, free eribulin is cleaved from the ADC by cathepsin B and causes cytotoxicity. Neighboring cells are also affected with bystander cytotoxicity as well as non-cytotoxic effects on the microenvironment. We evaluated the anti-tumor activity of BB-1701 using clinically relevant BC patient-derived xenograft (PDx) models to identify the potential clinical usefulness of BB-1701 in HER2-low BC.
Method: We established 32 human BC PDx models. These models were characterized using gene expression with RNA-seq and by HER2 immunohistochemistry (IHC). We basically grouped these 32 models into 3 classes: 1) HER2-negative (TPM<90), 2) HER2-low (TPM=90~400) and 3) HER2-high (TPM>1000) with HER2 mRNA expression and confirmed with HER2 IHC analysis. We selected 6 HER2-low PDx models, characterized

them by stroma composition, and tested the anti-tumor activity of T-DXd at clinically relevant doses. The anti-tumor activity of BB-1701 was also evaluated in these models at single or double administration doses of 3, 10, and 30 mg/kg (Q3W). Tumor samples were collected before treatment, at the tumor regression phase, and at the tumor re-growth phase. These samples were then evaluated for mode-of-action investigations.
Result: 32 PDx models were classified into 5, 23, and 4 models with HER2 negative, low, and high respectively by HER2 expression levels based on RNA-seq analysis. To investigate the anti-tumor activities of BB-1701 against HER2-low models, we selected 2 groups of models: 3 HER2 lower models (TPM=90-130) and 3 HER2 higher models (TPM=180~400) from 23 HER2-low PDx models. While T-DXd exhibited significant anti-tumor activity in all 6 models, we found one (IM-BRE-029) to be the least sensitive to T-DXd. In this model, tumors progressed approximately 21 days after the administration of 10 mg/kg T-DXd and a shorter duration of tumor regression than was observed in other PDx models. IM-BRE-029 PDx tumors are characterized by a rich stromal component in histopathological analyses. BB-1701 also showed anti-tumor activities with tumor regression in all models in both with the HER2 lower and HER2 higher groups. And in IM-BRE-029 model, BB-1701 exhibited a clear anti-tumor activity at 3 mg/kg and long-term tumor regression was achieved with 2 shot administrations at 10 or 30 mg/kg. In this symposium, we will describe model characterization results of these 6 PDx models, focusing on IM-BRE-029, and present the anti-tumor activities of BB-1701.
Conclusion: These results indicate that BB-1701 has the potential to provide clinical benefit to HER2-low BC patients. A phase 2 clinical trial in patients with HER2 positive or HER2-low unresectable or metastatic BC is ongoing (NCT06188559).

P4-10-24: Extracellular matrix remodelling is a targetable feature of invasive lobular carcinoma (ILC)

Renee Flaherty, Flavia Hughes, George Sflomos, Carlos Ronchi, Hazel Quinn, Solene Pezot, Samuel Jouny, Harveena Padda, Theo Roumeliotis, Giovanna Ambrosini, Beatrice Howard, Cathrin Brisken

Background: Invasive lobular carcinoma (ILC) has previously been identified as overexpressing collagens and elastin as well as LOXL1, a collagen cross-linking enzyme belonging to the lysly oxidase (LOX) family. Abberant LOX activity can promote breast cancer invasion and metastasis through remodelling of the extracellular matrix (ECM). The clinical stage pan-LOX inhibitor PXS-5505 has demonstrated anti-tumour potential through the disruption of the collagen matrix in models of pancreatic and myeloid cancer, and exhibits an excellent safety profile. Given that ILCs are enriched for ECM remodelling, we propose that inhibition of LOX be investigated as a therapeutic strategy in the treatment of ILC.
Methods: We xenograft ILC cells into the milk ducts of mice (MIND) to faithfully recapitulate ILC disease progression including ECM remodelling processes. We used cell line and PDX MIND models of ILC to examine their response to LOX inhibition (LOXi) alone and

combination with ovariectomy (OVX) to mimic aromatase inhibition (AI).
Results: Treatment with LOXi alone significantly decreased primary tumour growth compared to vehicle in cell line and patient derived xenograft models of ILC. This was accompanied by changes in the “matrix structure” and downmodulation of proliferative markers, and a transcriptional level MYC and ER signalling pathways. The magnitude of response to LOXi differed across ER+ ILC models, either being sufficient to reduce primary tumour growth alone (SUM44, p=0.000410), or in combination with OVX (MM134, p=0.032). In the metastatic ER- IPH-926 model LOXi significantly reduced metastatic dissemination to the lungs (p=0.013). Histologically, combination treatment decreased collagen matrix density and alignment as well as the Ki67 index. Proteomic profiling revealed LOXi alone and in combination with OVX downmodulated matrix-associated proteins, as well as MYC transcription factor targets. Functional pathway and keyword enrichment analysis identified down modulation of cell adhesion, cell cycle and apoptosis-related pathways.
Conclusion: These data demonstrate that ECM remodelling is a targetable feature of ILC and suggest that the LOXi PXS-5505, a well tolerated drug provides additional benefit to standard of care endocrine therapy. Changes in fibrillar collagen and matrix-associated proteins result in decreased MYC activity, which may serve as an endpoint in a prospective window trial.

P4-10-26: PRISM high-throughput screening to elucidate how tumor microenvironments modulate drug responses of breast cancer cells

Blanche C. Ip, Jillian N. Eskra, Tenzin Sangpo, Ashish Bino George, Melissa Ronan, Matthew G. Rees, Jennifer A. Roth

Cancer treatment options including small molecules, antibody-drug conjugates (ADCs), CAR T-cells, and combination therapies are rapidly expanding to improve cancer patient survival. However, efficacy of targeted therapies is limited by interpatient and intratumoral heterogeneity in breast cancer, and may be further exacerbated by dysregulated tumor microenvironments. For example, studies suggested that changes in tumor and breast tissue microenvironment in obesity (e.g. inflammation, increased growth factors) could lead to worsened prognosis that could be related to therapy resistance. Systematic characterization of the cellular effects of emerging drug candidates, particularly across different tumor microenvironments, is challenging, as it needs to be surveyed in diverse cancer contexts beyond just a handful of cancer cell lines.
To overcome this challenge, we created PRISM (Profiling Relative Inhibition Simultaneously in Mixtures), an effective drug discovery screening platform with over 900 genetically distinct cancer cell lines of diverse lineages, to rapidly test therapeutics in a high-throughput manner. These cell lines, including 33 different breast cancer cell lines covering diverse cell types and subgroups, carry a specific 24 nucleotide “barcode” tag and have rich baseline genomic and functional characterization. They are first pooled into 20-25 cell pools of different lineages with similar growth rates, then subsequently cultured together with or

without drugs. The relative barcode quantity read out by NextGen sequencing determines cell line responses to drugs. This pooled approach significantly reduces the time and the resources required for drug screening. Importantly, utilizing the rich cell line characterization to interpret viability profiles enables the identification of drivers of differential sensitivity and potential biomarkers of compound response. Furthermore, we created a breast cancer cell specific pool to investigate how media conditions mirroring different tumor microenvironments [e.g. media filtration, addition of insulin (0.01 mg/mL) or EGF (0.01 ug/mL)] can impact drug effects on breast cancer cells.
In the PRISM 900+ cell panel treated with ADCs conjugated to different payloads that target HER2, there was a clear association between cell line sensitivity and ERBB2 (encoding HER2) gene expression, with the strongest effects on viability observed in a subset of cell lines overexpressing ERBB2. Upon further comparison of biomarker profiles across different ADCs, we established relationships between payload resistance and ABCB1 efflux pumps emerged for a subset of ADC payloads.
Using the breast cancer cell specific pool, our data showed that estrogen receptor (ER) degraders fulvestrant and vepdegestrant (ARV-471) had significantly greater effects in reducing viability of ER+ versus ER- breast cancer cell lines. Media filtering reduced the drug effects of fulvestrant but not ARV-471, suggesting that ARV-471 efficacy may be less sensitive to the tumor microenvironment than fulvestrant. Lapatinib (HER2/neu and EGF receptor inhibitor) was more effective in killing HER2+ than HER2- negative breast cancer cells, with cells cultured in EGF-spiked media being more sensitive to lapatinib, whereas media filtration diminished its effects. We did not observe breast cancer subgroup specific killing by alpelisib (PI3K inhibitor) or olaparib (PARP inhibitor), but breast cancer cells became less sensitive to alpelisib when cultured in either insulin- or EGF-spiked media, and less sensitive to olaparib in EGF-spiked media.
Overall, our study highlights how the PRISM 900+ cell panel can provide insights into drug specificity, cancer subtype selectivity, and to uncover clinically relevant targets. The breast cancer specific pool can further increase the throughput of understanding how drug responses may be altered in different tumor microenvironments in breast cancer.

P4-10-27: Epigenetic Drug Profiling for Breast Cancer Therapy: A Focus on Receptor Modulation and Heterogeneity

Rahat Alam, Igor Bado

Breast cancer is the second leading cause of cancer death in women. The primary cause of mortality is associated with the metastasis process of cancer cells to other organs. It has become obvious that epigenetic alteration plays a crucial role in breast cancer progression through the modulation of various signaling pathways. Additionally, the plastic nature of cancer cells is essential to their adaption in different metastatic sites. However, implementing epigenetic therapies in the clinic has been challenging due to the ubiquitous expression of many epigenetic factors. Here, we evaluate a library of epigenetic drugs to

determine their impact on receptors commonly targeted in breast cancer. These include estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). We coupled an immuno-fluorescence imaging approach to bioluminescence imaging to capture receptor heterogeneity and the proliferation index of each epigenetic drug. So far, we have assessed 460 drugs that target various factors, including Epigenetics, JAK/STAT, DNA Damage, Angiogenesis, Cell Cycle, PI3K/Akt/mTOR and Cytoskeletal Signaling targeting and histone deacetylases (HDACs), DNA methyltransferases (DNMTs), histone methyltransferases (HMTs), aurora kinase PARP, Sirtiin, EGFR, JAK, Plm pathways. We also analyzed the expression of key epigenetic markers (e.g., EZH2) and stemness-associated factors (e.g., SOX9). As a result, we found BIO, an inhibitor of GSK-3 and JAK, increases ER expression. Similarly, Curcumin, an inhibitor of p300 histone acetyl-transferase and Histone deacetylase (HDAC) promotes a broader range of factors, including Her2, Sox9, and ER. Interestingly, (+)-JQ1(BET bromodomain inhibitor), I-BRD9 (BRD9 inhibitor) and CUDC-101 (HDAC inhibitor) drastically reduced Ki67 level. Overall, these findings suggest a potential for combination therapy. While further investigation of these promising candidates is needed (3D, ex vivo, and in vivo testing), this investigation reveals new possibilities to overcome therapeutic resistance in breast cancer.
Keywords: Breast cancer, epigenetics, drug screening.

P4-10-28: Efficacy, safety and biomarker results of AC699, a chimeric estrogen receptor degrader, in patients with advanced or metastatic breast cancer

Erika Hamilton, Rachel Layman, Michael Danso, Wei He, Joy Nolte Fong, Katherine C. Pehlivan, Manish R. Patel

Background: Endocrine therapy is the mainstay of therapy for patients with estrogen receptor positive (ER+) advanced or metastatic breast cancer. The combination of endocrine therapy along with cyclin dependent kinase 4/6 (CDK) inhibitors has improved progression free survival (PFS) in the frontline metastatic setting to over 24 months. However, in later lines of therapy, monotherapy treatment with selective estrogen receptor degraders (SERDs) result in PFS of <4 months and limited objective response rates (ORR) of <15%, demonstrating high unmet medical need. AC699 is a chimeric degrader that functions by binding to ERα, bringing it into proximity with the E3 ligase cereblon, resulting in ubiquitination and degradation of ERα. Safety, efficacy and biomarker data from an ongoing phase 1 dose escalation trial of AC699 is presented here (NCT05654532).
Methods: Patients with ER+/HER2- locally advanced or metastatic breast cancer who had received at least two prior lines of endocrine therapy or at least one prior line if combined with a CDK4/6 inhibitor were enrolled in this study, which followed a standard 3+3 dose escalation design. Additional patients were backfilled at selected cleared dose levels. Patients were treated with AC699 dosed orally, once a day, in 28-day cycles, and followed for response with imaging assessments performed every 2 cycles. The relationship between ESR1 mutational status and anti-tumor activity was investigated as an

exploratory analysis. Changes in circulating tumor cell (CTC) count and circulating tumor DNA (ctDNA) were also assessed.
Results: Thirty-five female patients with a median age of 60 year received AC699 at five dose levels ranging from 100 to 600 mg. The population was heavily pre-treated with a median of 5 (range 1-10) prior lines therapy, including 3 (range 1-8) in the metastatic setting. All patients had received a prior CDK4/6 inhibitor. Twenty-eight (80%) patients had measurable disease while 7 (20%) had non-target evaluable bone lesions only. Twenty-two patients with measurable disease had a follow up imaging assessment and were evaluable for response. The ORR was 23% (5/22) with 4 confirmed partial response and 1 unconfirmed partial response. The clinical benefit rate (CBR), defined as patients who achieved complete response, partial response, or stable disease ≥24 weeks was 30% (8/27). In the subgroup of evaluable patients with a confirmed ESR1 mutation (defined as a variant allele frequency [VAF] of >1% assessed in their baseline ctDNA sample), the ORR was 56% (5/9), the CBR was 55% (6/11) with 1 patient still receiving AC699. In patients who had an ESR1 mutation at baseline, 10 had a ctDNA sample at the end of cycle 1, and all 10 had a decrease in the VAF of the predominant ESR1 variant. In the entire population, 70% (19/27) of patients had a decrease in CTC count following initiation of study treatment.
Adverse events (AE) occurred in 77% (27/35) of patients with nausea (17%), dehydration (14%), fatigue (14%), hot flush (14%), and neutrophil count decreased (14%) being the most common. Treatment related AEs occurred in 37% (13/35) of patients, all of which were Grade 1 or 2, including hot flush (14%), nausea (11%) and neutrophil count decreased (9%). No dose limiting toxicities, dose reductions or discontinuations occurred due to treatment related AEs, and the maximum tolerated dose was not reached.
Conclusions: AC699 monotherapy given orally once daily was tolerable in this ongoing trial. Preliminary results demonstrated the highest objective response rates to our knowledge in a post-CDK4/6 population compared to previously reported phase 1 trials. In addition, a vast majority of patients had an initial response to therapy as demonstrated by a decrease in CTC count, even in those who progressed shortly thereafter. A phase 2 study will begin enrolling in early 2025.

P4-10-29: Repurposing hypertensive drugs for breast cancer therapies

Maninder Khosla, Shengli Dong, Suresh K. Alahari

Background: Triple-negative breast cancer (TNBC) is a challenging disease to treat in patients due to a lack of well-defined molecular targets and the highly proliferative and invasive nature of these tumors. There exist several targeted therapies, but only a fraction of patients responds to these therapies and these patients typically develop resistance and relapse. The development of a new therapeutic strategy for the treatment of TNBC is desperately needed. Work in our lab has previously identified Nischarin as a potential tumor suppressor of breast cancer. The binding of Nischarin to imidazoline receptors leads to inhibition of tumor cell migration, invasion, tumor growth and metastasis. Moxonidine is

a clinically approved centrally acting drug used to treat hypertension and is believed to function through imidazoline receptors. In addition, rilmenidine, a moxonidine like compound behaves the same way, and here we repurpose these drugs for breast cancer therapies. Our data for the first time show that moxonidine upregulates Nischarin expression as well as decrease tumor cell growth in vitro. In addition, rilmenidine, has also been shown to downregulate TNBC growth with a lower IC50 as compared to moxonidine.
Results: Our data reveal that a dose dependent increase in Nischarin protein expression in TNBC cell line MDAMB231 treated with moxonidine as well as rilmenidine. Additionally, analysis of cell viability through MTT assays suggested that increased treatment of moxonidine or rilmenidine leads to reduced mitochondrial activity in multiple TNBC cell lines. Nischarin positive BC patients have increased overall survival (OS). We downloaded mRNA expression (level 3RNAseq v2) and survival information for 921 patients with breast invasive carcinoma from TCGA portal. In addition, publicly available RNAseq data from TCGA suggests decreased Nischarin expression in TNBC as compared to other breast cancer subsets (LumA, LumB and normal tissue). These data suggest that Nischarin expression is low in TNBC, and it is important to induce the expression in TNBC.
Conclusions: Triple-negative breast cancer is an incredibly deadly subset of a highly heterogenous disease. These tumors are highly refractory to clinically approved therapies due in part to their highly proliferative and metastatic capabilities. Nischarin has been shown to downregulate the proliferation of cancer cells as well as inhibit their metastatic potential. Using clinically approved hypertensive drugs moxonidine and rilmenidine as drugs to regulate TNBC tumor development by increased Nischarin expression can serve as a fundamental basis for a novel new therapeutic strategy.

P4-10-30: Injectable novel hydrogel formulation for bacterial encapsulation

Makpal Akishova, Ansal Diassova, Arailym Myrzagaliyeva, Yernur Kenzhegazin, Irshad Kammakakam

Background information: Nowadays, temperature-sensitive hydrogels are widely used for the targeted delivery of drugs to solid tumor sites, as they can become solid at body temperature and retain drugs only at the tumor site. They are biodegradable, biocompatible, and have pores for the sustained release of drugs, which makes them perfect scaffolds for trapping bacterial cells. Mesoporous hydrogel with genetically engineered bacteria that synthesizes anticancer drugs inside can be injected into subcutaneous levels of the human body to kill rapidly differentiating cancer cells.
We synthesized a chitosan-β-glycerophosphate-hyaluronic acid hydrogel, which was then encapsulated with genetically engineered E. coli bacteria. The main goal of this study was to create a scaffold for genetically engineered bacteria and assess its effectiveness regarding pore size, release behavior, and cytotoxic activity.
Methods: Chitosan-β-glycerophosphate-HA hydrogel was synthesized via physical crosslinking and sol-gel transition was examined using rheometer. SEM imaging showed

correlation between pore size and concentration of hyaluronic acid. MTT assay assessed cytotoxicity levels towards E.coli cells and release was monitored via Bacterial Release Test.
Results: Sol-gel transition appeared in 8 min and the rheometer identified solidification temperature as 36.62 °C. With increasing concentrations of hyaluronic acid from 0.5% to 2%, the pore size decreases from 56 um to 3.94 um. Viability of E.coli cells reduced to 20.9045% which indicates that hydrogel does not have significant adverse effects on bacterial cells. Release in 72 hours showed sustained release bacteria, which confirmed that hydrogel can be used as a drug delivery system.
Conclusion: Novel temperature sensitive drug delivery systems for bacterial encapsulation can be time and resource saving for drugs released by bacterial strains, chitosan-β-glycerophosphate-hyaluronic acid hydrogel characterizations showed stronger ability to be used as scaffold and further in-vivo studies are needed.

P4-11-01: Retrospective analysis of outcomes of HR-positive/HER2-negative early-stage breast cancer patients from adjuvant GEICAM studies and El Álamo IV registry

Sonia Servitja, Raquel Andrés, Álvaro Rodríguez-Lescure, Miguel Martín, Manuel Ruíz-Borrego, Ángel Guerrero-Zotano, Begoña Bermejo, Antonio Antón, Montserrat Muñoz, Mireia Margeli, Isabel Álvarez, Luis Antonio Fernández, José Ponce, Josefina Cruz-Jurado, Purificación Martínez, Sara López Tarruella, Margarita Amenedo, Andrea Blasco, Óscar Polonio, MIguel Gil-Gil

Background: Endocrine therapy (ET) with or without abemaciclib is the current standard of care for intermediate- and high-risk hormone receptor (HR)-positive/HER2-negative early breast cancer (EBC) patients (pts). The NATALEE study, with 33.3-months follow-up (F-U), showed that the addition of 3 years of ribociclib to ET improves the 3-year (y) invasive Disease-Free Survival (iDFS) by 3.1% compared with ET alone in that population. Obtaining data on the long-term risk of relapse can be of great help in interpreting trial results and making decisions about new adjuvant drugs.
Methods: Retrospective analysis of 8819 HR-positive/HER2-negative EBC pts recruited from El Álamo IV registry (pts diagnosed between 2002 and 2005) and 5 adjuvant GEICAM studies (9805, 9906, 2003-02, 2003-10 & 2006-10) carried out from 1999 to 2010. In order to estimate their long-term outcomes, pts were divided into 3 cohorts (C), 2 of them according to the NATALEE study definition of risk of recurrence: C1 and C2: high- and intermediate-risk and one (C3) of low-risk (stage I and T2N0 plus one of the following features: histological G1 or G2 or GX with Ki-67 <20%).
Results: 20.0% of pts were high-risk, 36.0% intermediate-risk and 44.0% low-risk. Prior chemotherapy in neo/ adjuvant setting was used in 75.5% of patients (88.9%, 88.1% and 59.1% in cohort 1, cohort 2 and cohort 3, respectively). The median exposure time to adjuvant ET was 5 years (range: 0-15 years), similar in all cohorts. Selective Estrogen Receptor Modulator (SERM) were administered in 67.4% of patients, either alone (36.1%)

or with aromatase inhibitors (31.3%) mainly in sequence. With a median F-U of 10.7 years from adjuvant ET start, 10-y iDFS, 10-y distant DFS (dDFS) and 10-y overall survival (OS) were 77.8%, 80.9% and 86.1% in the overall population, respectively. 10-y iDFS were 57.8%, 77.3% and 87.2%, 10-y dDFS were 60.5%, 80.5% and 90.5%, and 10-y OS were 70.1%, 86.6% and 93.0%, in C1, C2 and C3, respectively. In C1, invasive relapse rate (IRR) and distant disease rate (DRR) had a peak in years 2-3 and a second peak in year 7, while in C2 and C3 the rates increased steadily (being higher at all timepoints in C2). In C1, death rate (DR) had a soft peak in years 3-4 and years 7-8 while in C2 and C3 they increased steadily (also being higher at all timepoints in C2).
Conclusions: Intermediate-risk pts have a 10-y iDFS of 77.3%, and 10-y OS of 86.6%. IRR and DRR had a peak in years 2-3 and a second peak at year 7-9 in the 3 cohorts, higher for high-risk pts. Longer F-U of the NATALEE study is needed to see the potential benefit of adjuvant ribociclib in intermediate-risk pts.

P4-11-02: Characterization of BTX-9341, a bifunctional degrader of CDK4 and CDK6 for HR+/HER2- breast cancer.

Hannah Majeski, Kirti Kandhwal Chahal, Angela Pasis, Casey Carlson, Qiao Liu, Arvind Shakya, Akinori Okano, Shenlin Huang, Aparajita Chourasia, Leah Fung

CDK4/6 inhibitors (CDK4/6i) such as palbociclib, abemaciclib and ribociclib are used to treat HR+/HER2- breast cancer, but patients can develop resistance via many mechanisms, several of which converge on upregulation of the cyclin D-CDK4/6 signaling node. This has been shown to limit the effectiveness of CDK4/6i in ER+ breast cancer with up to 20% of patients exhibiting innate resistance and up to 70% of patients developing acquired resistance after 3 years on therapy (Scheidemann, 2021). To address acquired resistance, we sought to apply a degrader approach. We utilized our PRODEGY platform of Cereblon (CRBN) binders to synthesize CRBN mediated CDK4/6 bifunctional degraders and identified BTX-9341 as a development candidate.
Breast cancer cell lines treated with BTX-9341 for 6 hours demonstrated up to 85% degradation of CDK4 and CDK6 with DC50s <1nM. BTX-9341 showed specificity for CDK4/6, with minimal off-target binding or degradation. CDK4/6 phosphorylates retinoblastoma protein (Rb) which releases the transcription factor E2F, inducing the expression of genes including CDK2 and Cyclin E which promote cell cycle progression. To determine the effect of BTX-9341 on downstream signaling, we examined Rb phosphorylation by in-cell western, and E2F target gene expression by qPCR and western. BTX-9341 was potent in all assays, with phospho-Rb IC50s <30nM, and E2F target gene downregulation at concentrations as low as 10nM. These downstream effects were sustained for 72 hours with BTX-9341 treatment, whereas rapid recovery was seen with CDK4/6i treatment. We used a 2D colony formation assay (CFA) to assess inhibition of proliferation. BTX-9341 potently inhibited cell proliferation with CFA IC50s of 20-50nM while CDK4/6i had CFA IC50s of 50-1000nM. This increased activity was due to CRBN mediated target degradation, as demonstrated by a shift in CFA IC50 values in a CRBN

knockout cell line towards the values seen with the inhibitors. Combining BTX-9341 with selective estrogen receptor degraders (SERDs) resulted in a synergistic anti-proliferative effect in HR+ breast cancer cells. In a palbociclib-resistant HR+/HER2- cell line model BTX-9341 maintained a low CFA IC50 (<150nM) while CDK4/6i displayed IC50s > 1μM. [SG1] BTX-9341 showed enhanced inhibition of Rb phosphorylation and a stronger synergistic effect with SERDs in CFA assays than CDK4/6i in this palbociclib resistant model. BTX-9341 displays excellent pharmacokinetic properties which allowed for oral dosing in xenograft studies. In several breast cancer xenograft models, BTX-9341 showed dose-dependent tumor growth inhibition, tumor regression at higher dose levels, and was effective with multiple alternate dosing regimens.
These results demonstrate the excellent activity of BTX-9341 as a single agent and in combination with SERDs, particularly in comparison to CDK4/6i. BTX-9341 mediated downregulation of CDK2 and cyclin E1, which are known to drive resistance to CDK4/6i, was more pronounced and more sustained than that mediated by CDK4/6 inhibitors including approved inhibitors such as palbociclib and inhibitors under clinical development such as PF-07220060. BTX-9341 maintained single agent activity and synergistic activity with SERDs in a CDK4/6i resistant model. These results indicate that utilizing a degrader such as BTX-9341 may be more effective in a post CDK4/6i setting than switching to a new CDK4/6 inhibitor. Based on this data, we have initiated a Phase 1 clinical trial with BTX-9341 as a monotherapy and in combination with fulvestrant, for HR+/HER2- breast cancer patients who have progressed on CDK4/6i therapy.
Reference: Scheidemann, Erin R, and Ayesha N Shajahan-Haq. “Resistance to CDK4/6 Inhibitors in Estrogen Receptor-Positive Breast Cancer.” International journal of molecular sciences vol. 22,22 12292. 14 Nov. 2021, doi:10.3390/ijms222212292

P4-11-03: Prediciting high risk hormone receptor (HR) positive Her-2 negative early breast cancer (BC) by artificial intelligence (AI) algorithms

Gul Basaran, Akif Gunes, Ufuk Kara, Alper Sonkaya, Mehmet Teomete, Alptekin Arıfoglu, Evrim Tezcanlı, Ozge Gumusay, Aykut Soyder

Background: Genomic tests are needed in addition to clinical/pathological factors to optimize adjuvant treatment decisions in most patients with HR positive Her-2 negative early BC. We aimed to develop an AI-based model to predict high risk HR positive Her-2 negative early BC by using clinical/pathological data and Oncotype DX scores. Methods: 234 patients who underwent Oncotype Dx test at our center between 2008 and 2023 were included. Clinical/pathologic characteristics and OncotypeDx scores were analysed by an ensemble of XgBoost, Random Forest, LightGBM, and Decision Tree machine learning algorithms to predict high risk disease. The dataset was split into two subsets: 75% for the training and 25% for the test set. The final model is chosen to maximize the precision of high-risk patients by using the data associated with high risk (HR) Oncotype-Dx scores and also the clinical/pathological data from patients who had distant metastases (DM) with low and intermediate recurrence score (RS). Results: Median follow up was 84 months and

median age was 47. Among 234 patients % 65 had stage I, % 22 had node positive, % 78 had grade 2 disease. Fourteen %, 68% and 18% of patients had HR, intermediate (IR) and low risk (LR) Oncotype Dx scores respectively, % 72 had clinically LR disease. Six %, 21% and 88% of patients with LR, IR and HR RS received adjuvant chemotherapy. There were 25 events: 13 DM, 2 local/regional relapse, 1 second primary, 9 deaths (7 due to BC). Two patients with HR, 8 patients with IR and 3 patients with LR Oncotype Dx scores had DM. The training (n: 175) and test set (n: 59) had similar risk level distributions. There were 6 DM, 2 deaths due to BC in the test set. Among 6 patients with DM, one patient had LR Oncotype Dx and IR AI-based score, another patient had IR Oncotype Dx and HR AI-based score, 4 patients have concordant scores (3 had IR, 1 had HR in both Oncotype Dx and AI-based model). Oncotype Dx and AI-based predicted scores were concordant in 5/11 (45%) patients with HR, 28/39 (%72) patients with IR and 1/9 (11%) patients with LR Oncotype Dx scores in the test set. There were no DMs in the AI-based low risk group vs one patient with DM in the Oncotype DX LR group. Conclusion: Our model might be used to predict high/intermediate risk patients and its performance needs validation with additional new datasets before its clinical implementation.

P4-11-04: Correlative analysis of Breast Cancer Index with Body Mass Index for prediction of extended endocrine therapy benefit in the BCI Registry study

Natalia Siuliukina, Brandon O'Neal, Amanda K.L. Anderson, Yi Zhang, Kai Treuner, Joyce O'Shaughnessy

Background: Hormone receptor-positive (HR+) breast cancer patients derive only modest benefit from extended endocrine therapy (EET) while facing an increased risk of late distant recurrence (DR). The Breast Cancer Index (BCI) is a validated genomic assay for providing individualized risk of overall (0-10y) and late (5-10y) DR and predicts the likelihood of benefit from EET. The predictive component of BCI, the HOXB13/IL17BR ratio [BCI (H/I)] with a high status predicting EET benefit, has been validated in several randomized controlled trials including MA.17, Trans-aTTom, IDEAL, and NSABP B-42.
Previous studies suggest that breast cancer survivors who are overweight or obese based on Body Mass Index (BMI) are at an increased risk of cancer recurrence, and higher all-cause mortality. This analysis aims to investigate the correlation between BCI and BMI in patients enrolled in the BCI Registry study.
Methods: The BCI Registry study is a prospective study to evaluate the long-term clinical outcome, decision impact and medication adherence in early-stage, HR+ breast cancer patients. BMI scores were categorized as underweight/normal (BMI < 25), overweight (25 ≤ BMI < 30), obese (30 ≤ BMI < 40), and severely obese (BMI ≥ 40). BCI score, BCI (H/I) and categorical groups based on default cut-points were calculated as previously described. Spearman's correlation coefficient (R) was used to estimate the correlation between BCI (H/I), BCI risk score, and BMI as continuous variables. Kruskal-Wallis test was used to assess pairwise comparisons between BMI groups and BCI categories.

Results: BCI and BMI results were included from 1664 breast cancer patients (74.8% T1; 53.5% grade II; 79.5% N0). BCI (H/I) classified 1025 patients (61.6%) as BCI (H/I)-Low and 639 (38.4%) as BCI (H/I)-High. BCI scores classified 771 patients (46.3%) as low-risk and 893 (53.7%) as high-risk for late DR. BMI classified 417 patients (25.0%) as underweight/normal, 552 (33.2%) as overweight, 584 (35.1%) as obese and 111 (6.7%) as severely obese. When analyzed as continuous variables, no correlation with BMI was observed for BCI (H/I) (R=-0.04) nor BCI score (R=0.007). In addition, no significant relationship was observed between BMI and BCI (H/I) categories (p = 0.16) as well as between BMI and BCI prognostic groups (p =0.51).
Conclusions: BCI (H/I) and BCI risk scores exhibited no correlation with BMI categories. BCI (H/I) consistently stratified patients into low- and high-likelihood for extended endocrine benefit independent of BMI categories, suggesting that BMI is not a reliable indicator for predicting recurrence risk or benefit from EET.

P4-11-05: Aromatase inhibitors mediate specific gut-bug interactions to shift the microbiome and decrease inflammation during adjuvant treatment in breast cancer patients.

Katherine Cook, Katherine Ansley, Haley Westervelt Mabry, Emily Douglas, Akiko Chiba, Alexandra Thomas

Background: Recent studies implicate the gut microbiome as a potential risk factor for breast cancer and a feature modifying anti-cancer drug therapeutic response. However, whether orally administered endocrine-targeting therapies such as aromatase inhibitors (AI) used post-surgery in the adjuvant setting to reduce estrogen receptor-α (ER+) breast cancer recurrence, modify the gut microbiome is unknown. We measure the shift in the gut microbiome and plasma inflammation marker as part of the ongoing Oral Aromatase Inhibitors Modify the Gut Microbiome Effecting Estrogen Bioavailability clinical trial (NCT05030038).
Methods: Eligibility requirements include women with a breast cancer diagnosis after surgical and radiation treatment before being prescribed adjuvant AI therapies. After consenting for trial, women undergo a baseline fecal collection and blood draw before starting their aromatase inhibitor. Patients provided a 4-weeks and 12-weeks fecal sample, along with a 12-weeks blood sample. Fecal DNA was isolated and 12M read depth metagenomic microbiome sequencing was performed. Inflammatory cytokines and other microbial-derived metabolites were measured in plasma using ELISA and metabolomics approaches.
Results: Samples from 10 women with matching fecal and plasma specimens were analyzed for microbiome and inflammatory cytokines. Administration of AI did not significantly modify α-diversity or β-diversity measurements. However, we did observe that AI therapy resulted in a significant enrichment of Oscillospiraceae_us (0.8% baseline vs. 1.4% 12-weeks), Parabacteroides merdae (0.4% baseline vs. 0.9% 12-weeks), and Ruthenibacterium lactatiformans (0.2% baseline vs. 1.3% 12-weeks) proportional abundance. Furthermore,

oral AI therapy administration significantly reduced the proportional abundance of Faecalibacterium prausnitzii (2.1% baseline vs 0.7% 12-weeks). Administration of AI also resulted in a significant decrease in plasma interferon (IFN)γ, interleukin (IL)-2, IL-5, IL-10, and sCD137.
Conclusions: Increased Oscillospiraceae family members (often considered commensal short-chain fatty acid (SCFA) producers) are observed with AI administration; However, AI therapy is associated with decreased F. prausnitzii (a butyrate-producing bacteria) proportional abundance, suggesting a community shift in SCFA-producing populations to potentially modify gut health. This is further supported by increased R. lactatiformans proportional abundance associated with AI therapy. R. lactatiformans produce lactate and acetate which may influence anti-inflammatory outcomes. Further studies are needed to determine potential drug-microbiome interactions that may mediate efficacy.

P4-11-06: Neoadjuvant anlotinib plus nab-paclitaxel based chemotherapy in patients with HER2-negative breast cancer: A prospective, single-arm, single-center, phase II clinical study

Huimin Meng, Yidi Wang, Songpeng Li, Mengxuan Li, Jing Kong, Jing Fan, Ting Wang

Background: Antiangiogenic agent plus neoadjuvant chemotherapy confers an improvement in pathological complete response (pCR) rate among patients with HER2-negative breast cancer. Anlotinib is a novel multi-target tyrosine kinase inhibitor that effectively inhibit VEGFR, FGFR, c-KIT, c-MET, and RET. This phase II study aims to evaluate the efficacy and safety of anlotinib combined with chemotherapy as neoadjuvant treatment in HER2-negative breast cancer.
Patients and methods: Eligible patients (pts) were women, aged 18-70 years, ECOG status 0-2, previously untreated HER2-negative breast cancer. The HER2-negative was defined as immunohistochemistry of 0, 1+, and 2+/ISH-. Pts were required to have a palpable primary tumor at least 20 mm in diameter in the breast as assessed by physical examination. Pts received 5 cycles of anlotinib (12 mg qd, d1-14; q3w) plus 6 cycles of nab-paclitaxel (200 mg/m2, q3w), anthracycline (pirarubicin 50 mg/m2) and cyclophosphamide at 500 mg/m2, followed by surgery. The primary endpoint is pCR rate (ypT0/Tis ypN0) and the secondary endpoints include objective response rate (ORR), disease-free survival (DFS), overall survival (OS), and safety.
Results: From Aug 2021to Jun 2024, a total of 31 pts were enrolled and 1 pts discontinued the study due to HER2 amplification. The median age was 46 years (range, 31-68) and the ECOG score of all patients was 0. Estrogen receptor status was ≥10% in all 30 pts and progesterone receptor status was ≥20% in 25 pts (25/30, 83%). Lymph node metastasis was observed in 64% (19/30) of the pts. At the data cut off time of 30th Jun 2024, 28 pts received at least one dose of study treatment and 27 pts underwent surgery. The pCR rate (ypT0/Tis ypN0) was 14.8% (4/27). The bpCR rate (ypT0/is) and apCR rate (ypN0) were both 18.5% (5/27). There were more patients with RCB-2 (12/27), and fewer patients with RCB-0 (4/27), RCB-1 (3/27), and RCB-3 (7/27). According to the preoperative evaluation, 4

pts (4/28, 14.3%) achieved complete response (CR) and 22 pts (22/28, 78.6%) achieved partial response (PR). The ORR was 92.9% (26/28, 95% CI, 76.5%-99.1%). The grade 3 AEs were hematological toxicity in 3 cases and headache in 1 cases.

Conclusion: Anlotinib plus nab-paclitaxel based chemotherapy as neo-adjuvant therapy in patients with HER2-negative breast cancer showed favorable objective response rate and manageable toxicity. The enrollment is still ongoing.
Clinical trial information: NCT05558722.

P4-11-07: The Oncotype DX® test to guide adjuvant chemotherapy treatment decisions for early node-negative HR+/HER2- breast cancer patients in Japan: a cost-effectiveness analysis

Kei Koizumi, Tobiasz Lemański, Gebra Cuyún Carter, Sebastien Eymere, Ataru Igarashi, Steve Millen, Mariko Nomoto, Yoshie Onishi, Vladislav Berdunov, Masamitsu Hihara, Aki Kudo, Pieter Drost, Naoki Niikura

Background: For patients with hormone-receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-), axillary lymph node-negative (N0) early-stage breast cancer, adjuvant chemotherapy treatment decisions are traditionally determined by clinico-pathological features. While the use of clinico-pathological features may provide useful prognostic information, it is not able to predict the benefit of adjuvant chemotherapy, which may lead to over- or undertreatment. The Oncotype DX Breast Recurrence Score® test has been reimbursed in Japan since September 2023, and to date, it is the only multigene assay with the ability to predict chemotherapy benefit validated by evidence from randomized clinical trials. The aim of the study was to estimate cost-effectiveness of guiding chemotherapy treatment decisions using the Oncotype DX® test compared to using clinico-pathological risk alone among women with N0 HR+/HER2- early breast cancer from a Japanese healthcare perspective.
Methods: A previously published cost-effectiveness model built in Microsoft Excel estimated the cost-effectiveness of the Oncotype DX test compared to treatment decisions based on clinico-pathological risk alone over a lifetime horizon. This model used a decision tree coupled with a Markov model and was adapted to a Japanese healthcare payer perspective, complying with Japanese cost-effectiveness analysis guidelines. The N0 population was studied as a whole, as well as in subgroups based on age and clinico-pathological risk, defined according to tumour size and histologic grade. The modelled proportions of patients assigned to adjuvant chemotherapy and supportive treatment was informed by eight clinical experts in Japan to reflect current country-specific clinical practice. The Markov part of the model included health states representing recurrence-free, distant recurrence, death, as well as acute myeloid leukaemia (AML) and congestive heart failure (CHF) as latent adverse events of chemotherapy. The probability of distant recurrence of breast cancer conditional on test result category was derived from pivotal trials. Costs of testing,

adjuvant and supportive treatment, disease management, and short-term adverse events were informed using Japanese cost sources. To assess uncertainty, deterministic and probabilistic sensitivity analyses were performed.
Results: Using the Oncotype DX test was a dominant strategy compared to using clinico-pathological risk alone, with lower costs (-¥1,629,239) and additional health benefit (0.163 quality-adjusted life years, QALY) in the overall N0 population. This result was mainly driven by a reduced rate of distant recurrence for patients correctly treated with adjuvant chemotherapy after using the Oncotype DX test, which led to substantial cost savings and QALY gains. Probabilistic sensitivity analysis showed the Oncotype DX test was dominant against clinico-pathological risk alone in 99.4% of 5,000 simulations. Similar results were reported across subgroups; the Oncotype DX test was consistently cost-effective across all age and clinical subgroups considered, and was dominant (cost-saving and more effective) in 3 of 4 subgroups; in the subgroup aged≤50 with high clinical risk, the incremental cost-effectiveness ratio was ¥397,541/QALY.
Conclusion: Using the Oncotype DX test to guide chemotherapy treatment decision for women with early-stage N0 HR+/HER2- breast cancer is expected to be cost saving and a cost-effective strategy in Japan. It is expected to yield substantial net costs savings in most of the subgroups considered while increasing QALYs gained from avoiding chemotherapy adverse events and distant recurrence.

P4-11-08: Comparative analysis of clinician and AI decision making in HR+/HER2- early breast cancer.

Roberto Buonaiuto, Aldo Caltavituro, Rossana Di Rienzo, Angela Grieco, Federica P. Mangiacotti, Alessandra Longobardi, Vincenza Cantile, Pietro De Placido, Erica Pietroluongo, Valeria Forestieri, Giampaolo Bianchini, Carmen Criscitiello, Michelino De Laurentiis, Carmine De Angelis, Grazia Arpino, Mario Giuliano

Background: Growing use of artificial intelligence (AI) has shown potential utility in assist imaging analysis, patient monitoring and treatment planning. Of note, pretrained Chatbots AI such as CHAT-Generative Pretrained Transformer 4o (GPT-4o) are emerging as groundbreaking tools to potentially answer clinically relevant questions and predict treatment decisions in oncology. However, the decision-making capability of these tools may substantially vary among specific clinical areas. Moreover, advantages and limitations of their use in daily clinical practice still appear unclear.
Methods: In this study, we evaluated CHAT GPT-4o performance compared with clinician recommendations for the adjuvant treatment of patients (pts) with hormone receptor-positive, HER2-negative early-stage breast cancer (HR+/HER2- eBC). Specifically, we analyzed the indication for multigene testing, type of test, and pre- and post-test treatment recommendations. Additionally, we evaluated CHAT GPT-4o prediction of multi-gene test results. Clinicians' pre-test and post-test decisions relative to consecutive HR+/HER2- eBC pts who underwent Oncotype DX test as per clinical practice (n=380) at the University of Naples Federico II were collected. GPT-4o and clinicians' decisions were expressed as

treatment strategy [chemotherapy (CT) followed by endocrine (CT-ET) vs ET alone], type of CT, and type of ET. Inter-decisions reliability was expressed as agreement rates and Cohen's kappa coefficient values. GPT-4o genomic testing prediction was expressed as percentage probability that the test would indicate high risk [Recurrence Score (RS)> 25] or low risk (RS≤ 25) in postmenopausal pts, and high risk (RS > 25), intermediate risk (RS 16-25) and low risk (RS≤ 15) in premenopausal pts. Genomic test prediction was evaluated using the Area Under the Curve (AUC) metric to determine accuracy in identifying high-risk and low-risk pts. The statistical association between predicted and observed results was analyzed by Chi Square test.
Results: Genomic testing was proposed by GPT-4o for all pts of our cohort. Among multigene assays, GPT-4o recommended the Oncotype DX for all cases. The agreement between clinician and AI pre-test decision (CT-ET vs ET) was 68% (kappa 0.391, $p < .001$), whereas the agreement in post-test decision was 93% (kappa 0.810, $p < .001$). Notably, the agreement between clinicians' pre-test and post-test treatment recommendations was 55% (kappa 0.198, $p < .001$), whereas concordance between pre-test and post-test treatment recommendations provided by AI was 68% (kappa 0.281, $p< .001$). Before Oncotype DX results, clinician recommended CT for 60.1% of pts, with docetaxel-cyclophosphamide (59.1%) as the preferred chemotherapy regimen. On the contrary, pre-test recommendation by GTP-4o included ET in 60.6% of cases, especially aromatase inhibitors (69.1%). The AI prediction of Oncotype DX RS results was associated with an AUC of 0.746 and 0.805 among postmenopausal and premenopausal pts, respectively. GTP-4o predicted with higher accuracy high genomic risk compared to low genomic risk in postmenopausal pts (89.4 % vs 45.5%, $p< 0.001$). On the contrary, in premenopausal pts AI showed lower accuracy in predicting low and intermediate genomic risk as compared with high genomic risk (55.9% vs 41% vs 66.7%, $p< 0.001$).
Conclusions: Without Oncotype DX results, the agreement in treatment recommendations between GTP-4o and clinicians was modest, and this discordancy deserve deeper investigation. Pre-test indications provided by GPT-4o were less impacted by the multigene assay results, maybe due to the capability of AI to better approximate Oncotype DX results. After Oncotype DX results, the agreement between AI and clinicians was extremely high indicating the key role of multigene testing in guiding treatment decisions.

P4-11-09: Epigenetic Alterations Affecting Cell Morphogenesis and Tumor Plasticity Pathways in Primary Tumors of Breast Cancer Patients with High Nodal Involvement

Sookyung Ahn, Andrés F. Bedoya-López, Miquel Ensenyat-Mendez, Pere Llinàs-Arias, Diego M. Marzese, Maggie L. DiNome

Introduction: Survival rates for patients with breast cancer have improved significantly with widespread screening and effective systemic therapies. However, patients who present with advanced nodal stage at diagnosis have higher rates of distant relapse and require more aggressive therapies than patients with pathologic N1 disease (pN1). Understanding

the molecular alterations that occur in primary breast cancer (BC) that drive progression to a higher nodal stage (>pN1) could uncover potential therapeutic targets for patients with regionally metastatic BC. Given that epigenetic mechanisms represent that crucial layer of dynamic change that regulates genome-wide gene expression, we assessed the DNA methylation profiles of primary BC at various nodal stages.
Methods: We conducted an exploratory study using a well-annotated, retrospective cohort of ER+/HER2- treatment-naive primary BC from patients with clinically positive nodes and complete pathologic nodal data treated at Duke University (n=49, 30 cases pN1 vs. 19 cases >pN1). DNA was extracted from paraffin-embedded samples, and DNA methylation profiling was performed using the Illumina EPIC BeadChip v1 arrays. The ChAMP package was utilized to correct batch effect, and the Wilcoxon test was used to identify Differentially Methylated Sites (DMS). Tumor content purity was assessed using the LUMP algorithm and Gene Ontology enrichment of the DMSs was examined with the GOmeth tool. Data analysis and visualization were performed using the R packages ggplot2 (v. 3.4.4), circlize (v. 0.4.16), and gplots (v. 3.1.3.1), with data management facilitated by the tidyverse (v. 2.0.0) collection.
Results: Tumor purity was similar between the two groups ($p>0.05$). The comparison revealed distinct DNA methylation patterns in 962 genomic regions between pN1 and >pN1 tumors (differential methylation > 15%, $p<0.01$); 683 regions were hypermethylated and 279 were hypomethylated in the >pN1 group. There was a significant enrichment of biological processes associated with morphogenesis among the hypermethylated sites, with 22 of the 43 affected molecular pathways linked to cellular morphogenesis. Additionally, epigenetic alterations were predominantly found in pathways related to the response to bone morphogenic protein (BMP). Expression-methylation Quantitative Trait Loci (emQTLs) were linked to epithelial to mesenchymal transition (EMT) genes in >pN1 tumors. Finally, higher methylation of the protocadherin cluster genes (PCDHGA) and regions encompassing DUSP6 and KRT7 genes were identified in tumors of higher nodal stage. These findings suggest inherent or acquired epigenetic alterations in primary BC associated with higher nodal stage.
Conclusions: Understanding the mechanisms underlying lymph node invasion in breast cancer progression is crucial for improving the clinical management of patients with BC. This study indicates that ER+/HER2- primary tumors from patients with higher nodal involvement have an epigenetic predisposition to activate morphogenic differentiation and EMT more efficiently than patients with lower nodal involvement. Deeper insight into these alterations could contribute to more accurate prognostic tools, the development of novel therapeutic approaches, and potentially help avoid more aggressive axillary procedures.

P4-11-10: Long-term Outcome of Slowly Proliferating Luminal Type ILC versus IDC

Ji Won Yoo, Jai Min Ryu, Se Kyung Lee, Byung Joo Chae, Jonghan Yu, Seok Won Kim, Seok Jin Nam, Jeong Eon Lee

Introduction: Invasive lobular carcinoma (ILC) ranks as the second most common histopathological subtype of breast cancer, following invasive ductal carcinoma (IDC). Prior studies have demonstrated that while ILC patients initially exhibit better survival rates within the first 5 years, their long-term outcomes are comparable to, or worse than, those of IDC patients. However, the lower prevalence of ILC relative to IDC and their distinct clinicopathological characteristics complicate direct comparisons between the two groups. This study aims to evaluate the long-term outcomes of luminal type A IDC versus ILC.
Methods: This retrospective cohort study analyzed data from January 2008 to December 2015 at Samsung Medical Center. The study included patients with patients with primary breast cancer who underwent surgery and were histologically diagnosed with either IDC or ILC, were hormone receptor-positive, HER2-negative, and had a Ki-67 index ≤20. Patients with mixed histopathology, those undergoing palliative surgery, and those treated with neoadjuvant chemotherapy were excluded. Cohort analyses were performed in various subsets: real-world setting, patients receiving more than 2 years of endocrine therapy, and propensity score-matched cohorts.
Results: In the real-world setting, of the 3439 patients, 3156 had IDC and 283 had ILC. With a median follow-up of 110 months (range 0-195 and 1-190 months, respectively), ILC patients exhibited worse long-term outcomes. Although breast cancer-specific survival (BCSS) did not show a significant difference ($p=0.081$), analysis by 5-year periods indicated significantly poorer survival for ILC patients beyond 5 years (5 to 10 years, $p=0.004$; 10 to 15 years, $p=0.014$). Disease-free survival (DFS) and distant metastasis-free survival (DMFS) were significantly worse in the ILC group ($p<0.001$ and $p=0.005$, respectively). In the second analysis, excluding patients with less than 2 years of endocrine therapy, 2919 IDC and 269 ILC patients remained. With median follow-ups of 112 months (range 17-195 months) and 110 months (range 19-190 months) respectively, the ILC group showed poorer long-term DFS and DMFS ($p<0.001$ and $p=0.007$, respectively). However, the ILC group exhibited a significantly higher incidence of synchronous contralateral breast cancer, pathologic T and N stages, and a lower nuclear grade compared to the IDC group ($p<0.001$, $p<0.001$, $p=0.040$, $p<0.001$, respectively). The third analysis used propensity score matching to control for confounding variables, including age, BMI, menopausal status, BRCA status, synchronous contralateral breast cancer, pathologic T and N stages, TNM stage, nuclear grade, histologic grade, adjuvant chemotherapy, and duration of endocrine therapy. In this analysis, long-term survival outcomes did not significantly differ between groups (BCSS $p=0.248$, DFS $p=0.265$, DMFS $p=0.429$).
Conclusion: The study reveals that in the real-world setting, the long-term outcomes of ILC are worse compared to IDC. However, when adjusted for clinicopathological parameters, the long-term outcomes of ILC do not significantly differ from those of IDC.

P4-11-11: Real world data on breast cancer prognostication in India using CanAssist Breast- an indigenous test validated in global studies.

Somashekhar, Rajiv Kumar, D. G. Vijay, Praveen Dadireddy, Shekhar Patil, Rohan Khandelwal, Mandeep Singh, Garima Dagga

Objective: Data on prognostication of Asian HR+/HER2/neu- early stage breast cancer patients using Western prognostic tests is limited and intriguing. Asian patients do get diagnosed almost a decade earlier and typically in Stage II thus the underlying tumor biology could be different. CanAssist Breast (CAB)- an immunohistochemistry and artificial intelligence based prognostic test was developed on Indian patient's tumors and validated in retrospective global studies in India, US, Spain, Germany, Austria, Italy and via prospective-randomized completed TEAM trial in The Netherlands. CAB is included in Asian geriatric Society's guidelines as well. Since mid 2016, CAB is in clinical use in India as well as Sri Lanka, Bangladesh, UAE and Turkey. In this abstract we assess the usefulness of CAB in our day to day treatment planning in India.

Methods: We analysed use of CAB on total 643 consecutive patients in our clinical practice from mid 2016 till December 2023. Specifically, we analyzed how does CAB segregate patients under/over 48 years ie pre/post-menopausal, N0, N1 patients. Patients with varying levels of tumor size, tumor grade and expression of ER and PR.

Results: Over all CAB segregated 66% patients as 'low risk' and 34% as 'high risk' for distant recurrence. Median age of the patient was 58 years and median tumor size was 2.5cm. Majority (75%) of patients were over 48 years of age. The low:high risk segregation in pre and post-menopausal was similar at 68:32 and 65:35. The current data is represented from North, South and West of India and in each of the regions as well the distribution of low:high risk proportions was similar. 33% patients had T1 tumors, 63% had T2 tumors however the low: high risk proportions in T1 versus T2 were significantly different at 84:16 and 59:41 respectively. Majority (75%) of patients had lymph node negative disease (N0) and the low:high risk proportions were 75:25 and 35:65 in N0 and lymph node positive (N1) disease. G1 tumors represented 12% of the total while 64% were G2 and 24% had G3 tumors. Low risk percentage across the three tumor grades was significantly different at 92%, 77% and 24% respectively. 88% of patients had ER and PR positive disease while 5% had ER+/PR- disease and for 7% PR status was unknown. 88% of patients had high ER expression (>70%) while 10% had intermediate (10-70%) and 1% had low ER (1-9%) expression. 46% patients had T2N0, 27% had T1N0, 7% had T1N1 and 17% had T2N1 disease. 99% were HER2/neu negative. CAB was used to plan treatment for all of these patients. We have treatment details for 77% of the patients. 94% of low risk patients did not get chemotherapy and 84% of high risk patients got chemotherapy. For the 6% low-risk patients who got chemotherapy, we believe the potential reasons could be N1 disease, G3 disease, high Ki67 index, Her2+ disease and pre-menopausal patients.

Conclusion: CAB is able to segregate the patients into low or high risk in line with clinical parameters. CAB has helped 94% of low-risk patients to avoid chemotherapy. CAB represents tumor biology of younger patients and coupled with world-wide validation it presents as a cost-effective, ideal alternative to western prognostic tests to patients in Asia.

P4-11-12: CLEAR-B - Adjuvant therapy effectiveness in patients with primary breast cancer: A retrospective registry study

Bahriye Aktas, Hanna Huebner, Andreas Hartkopf, Maggie Banys-Paluchowski, Ingolf Juhasz-Böss, Nadia Harbeck, Hans-Christian Kolberg, Elmar Stickeler, Marcus Schmidt, Marc Thill, Michael Untch, Thorsten Kühn, Nina Ditsch, Lothar Häberle, Manuel Hoerner, Daniel Anetsberger, Kathrin Nicole Truch, Christian Roos, Christian Mann, Erik Belleville, Tanja Fehm, Peter A. Fasching

Objectives: Adjuvant endocrine treatment for premenopausal patients with early hormone receptor positive HER2 negative (HRpos/HER2neg) breast cancer (BC) is supposed to depend on the estimated risk profile. Patients with a high recurrence risk should be offered aromatase inihibtors (AI) and ovarian function suppression (OFS) and patients with a low recurrence risk tamoxifen (TAM) with or without OFS. However utilization of these treatment options is diverse even in high risk patients. Aim of this retrospective study was therefore to assess the treatment patterns and outcomes of endocrine treatment variability in a real world setting.
Methods: CLEAR-B is an anonymized retrospective study that uses prospectively collected data generated in the course of the certification process of breast centers in the period from January 2016 to June 1019 and from January 2022 to December 2023. Eligible were premenopausal patients with early HRpos/HER2neg BC an intermediate high and very high recurrence risk. Patient and disease characteristics are documented along with information about recommended and performed adjvuant treatments as well as information about recurrence and death.
Results: The first patient was documented in February 2023. A total of 3.000 patients will be documented until August 2024 at 75 study sites in Germany. An interim analysis showed that the majority of documented patients is treated with tamoxifen despite an increased recurrence risk. Changes in therapy patterns and patient/disease characteristics will be analyzed according to patient risk profiles and in the two assessment periods (2016-2019 vs. 2022-2023). Additionally the context of healthcare provision (treatment centers vs. de-central healthcare) will be investigated.
Summary: Awareness of treatment standards along with efficacy data and quality of life data is important to make informed therapy decisions about adjuvant endocrine treatment together with the patients. A full analysis of treatment patterns over time and outcomes will be presented at the conference.

P4-11-13: High Progesterone Receptor (PR/PGR) Expression Determined by APIS Breast Cancer Subtyping Kit Correlates with Oncotype Dx Recurrence Score

Anna Gasior, Marcus Vetter, Elena-Diana Chiru, Joanna Gorniak, Sara Rollinson, Andreas Voss, Leanne Gough, Mathew Harrison, Kimberly Howard, Martina Sonderegger-Stalder, Matthias Matter, Simone Muenst, Christian Kurzeder

Introduction: Expression of ER, PR, HER2, and Ki67 serve as valuable prognostic and predictive markers, with PGR expression believed to predict favourable outcomes in ER+ HER2- breast cancer (BC). Traditionally, the expression of these markers is determined by immunohistochemistry (IHC), which is well established for ER, PR and HER2, but for Ki-67 faces challenges in standardization. Several quantitative gene expression tests, like Oncotype Dx, aim to overcome these challenges but are often limited by their costs.
The APIS Breast Cancer Subtyping Kit offers an accurate and cost-efficient method for determining ER/PR, HER2, and Ki67 expression. This study seeks to assess the relationship between Oncotype Dx recurrence score (RS) and PGR expression as determined by the APIS kit.
Methods: Tissue from a cohort (N=153) of ER+/HER- BC patients diagnosed between 2020 and 2022 at Cantonal Hospital Basel-Land and Basel University Hospital was included in this study. Each patient had a valid Oncotype DX RS score on file and received at least one line of adjuvant therapy. PGR expression was determined using the APIS kit, following instructions for use. Spearman correlation tests were applied to the data to examine the association between the tests. The model classification explorer (JMP v 16.0) was used to predict PGR expression cut-offs for RS and plot a receiver operator curve (ROC) for the data.
Results: A moderate Spearman's correlation coefficient of ρ = -0.4876 between the APIS kit and the Oncotype Dx RS was observed. ROC curve for PGR prediction of oncotype score was (0.782 (95% CI 0.717-0.847)). When stratifying RS scores by low (<26) and high risk (>26) a PGR ΔCt of above 3.06 was calculated to identify the low-risk group. The specificity for low-risk RS was 93.5% (95% CI 79.3-98.2%), with a positive predictive value of 0.949.
Conclusions: This study demonstrates that PGR expression, as assessed by APIS Breast Cancer Subtyping Kit, could potentially predict low-risk tumours identified by Oncotype Dx reliably, offering a cost-effective pre-screening tool. Additional validation is necessary to affirm its diagnostic accuracy.

P4-11-14: Prescribing patterns and real-world clinical usage of adjuvant abemaciclib for early-stage, high-risk, hormone receptor positive breast cancer

Sneha Rajendran, Zhexi Lu, Valerie Gao, David Lazris, Faith Seltun, Joshua Wang, Kathryn Demanelis, Julia Foldi

Background: The FDA approved abemaciclib in October 2021 for use in conjunction with hormone therapy for adjuvant treatment of early-stage, high-risk, hormone receptor positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative breast cancer (BC) based on the results of the monarchE trial (NCT03155997), which demonstrated that adding abemaciclib improved invasive disease-free survival. Given its recent FDA approval, the prescribing practices and real-world uptake of abemaciclib have not been extensively reported. The objective of this retrospective study was to determine the rate of adjuvant abemaciclib prescribing for high-risk HR+ patients (pts) and to determine the pt and provider factors that were associated with its prescribing. We also sought to describe the

clinical experience (e.g., dose reductions, toxicities) of pts on adjuvant abemaciclib.

Methods: Data regarding demographics, clinicopathologic characteristics, and adjuvant treatment details were obtained from the University of Pittsburgh Medical Center Cancer Registry on pts with lymph node (LN)-positive, stage I-III HR+/HER2- BC, diagnosed between 1/1/2021-8/31/2023. Pts were included in our analysis if they initiated hormone therapy on or after 7/12/2021. High-risk status was determined by monarchE inclusion criteria for two cohorts: 1) AJCC nodal status N2+, N1 and tumor grade 3, or N1 and T3+ (i.e., cohort 1) or 2) N1 and Ki-67 (%) ≥20 (i.e., cohort 2). Under the 2021 FDA approval guidelines, pts were eligible for abemaciclib if their tumors were N2+ or N1 and Ki-67% ≥20 and either grade 3 or T3+. Additional information regarding abemaciclib was extracted from the electronic health records. We evaluated the relationship between tumor-, provider-, and pt-level factors and receiving prescription for abemaciclib (outcome) using Pearson's χ-square tests and multivariable logistic regression models, adjusted for age at diagnosis, race/ethnicity, nodal status, tumor size, and grade.

Results: The entire high-risk cohort included 469 pts, and 272 (58%) were eligible for abemaciclib under 2021 FDA approval guidelines. Median age was 61 years (range 24-93), the majority of pts were white (93%) and most (61%) were treated at UPMC Hillman Cancer Center community sites. 320 (68%) pts had N1 and 149 (32%) pts had N2+ disease. Overall, 163/469 pts (35%) were prescribed abemaciclib – 120/272 pts (44%) eligible under 2021 FDA guidelines. Of pts that met monarchE inclusion criteria for cohort 2, 20% (29/144) received abemaciclib. Abemaciclib prescriptions significantly increased by year of diagnosis with 28% and 42% of pts diagnosed in 2021 and 2022, respectively, receiving a prescription ($p=0.012$). In multivariable logistic regression analysis, age at diagnosis, nodal status, and tumor size were associated with receiving a prescription for abemaciclib ($p < 0.05$). Among pts in our cohort who were not prescribed adjuvant abemaciclib and had documented reason for not being prescribed (n=80), the most common reason was the pt did not want it (n=44, 55%). Of pts who were prescribed abemaciclib (n=163), 47% (n=77) had dose modified, 81% (n=132) experienced one or more toxicities, and 20% (n=32) discontinued treatment. The most common reason for dose modification and discontinuation was diarrhea. At study cutoff of 4/1/2024, 80% of pts who started abemaciclib either completed the planned two years of treatment or continued on the medication.

Conclusions: In this single institution, retrospective study, adjuvant abemaciclib prescribing was low. Considering the benefit of adjuvant abemaciclib in pts with high-risk HR+/HER2- BC, further research is required to address barriers to its prescribing and to improve our understanding of factors that influence physician and pt decisions.

P4-11-15: Variability in physician treatment decisions for HR+ / HER 2 negative Early Breast Cancer in young patients: a Latin-American survey

Dana P. Narvaez, Federico Waisberg, Victoria Costanzo, Danilo Aguirre, Cynthia Villarreal, Matías Chacón, Sergio Rivero, Alexis Ostinelli, Fernando Namuche Ojeda, Alvaro Encinas Casanave, María Lucila González Donna, Cinthia Gauna, Juana Vazquez, María P. Molina Espinosa, Sara C. Altuna Mujica, Ronald Limón, Kayra K.Sanchez Muñoz, Claudia Martinez, Adrian Nervo, Gonzalo Gomez Abuin, Santiago Bella, Andrea Aguilar, Vanesa Lopez, Pablo Mandó, Valeria Caceres

Introduction: Breast cancer in young people (age ≤ 40), represents 5% of all breast cancer cases. Population outcomes for this group are often derived from subgroup analyses of randomized or retrospective trials. Limited data about physicians' knowledge, attitudes and practices as they relate to this diagnosis. The aim of our study was to evaluate the decision-making process in Latin-American oncologists for the treatment of young women with early breast cancer.
Methods: A survey was designed with 30 items. Principal topics included: use of ovarian suppression, indication for adjuvant chemotherapy, fertility, use of genomic tests and recommendations for management of treatment-associated symptoms.
Content validation was undertaken by Argentinian oncologists of SUMA (Argentinian Group for the treatment and research of breast cancer).
The study was conducted via an online questionnaire, sent by email to professional societies and to oncologists involved in the management of breast cancer patients.
Descriptive analyses were included. Chi square test was performed to evaluate relationships between physician characteristics (country, gender, years of expertise, whether the physician worked in a tumor specific clinic or not) and responses. The level of statistical significance was set at $p < 0.05$, two-tailed.
Results: A total of 329 Latin American oncologists from 17 Latin-American countries participated in the electronic survey.
The responding oncologists included 74.5% who treated patients with any tumor type (ALLT), 14.6% specialized in breast and gynecological tumors (BRGY), and 10.9% focused exclusively on breast tumors (BREX). Working in a tumor-specific clinic was associated with differential utilization of several treatments or diagnostic tests, including ovarian suppression (OFS) for therapeutic purposes during neo/adjuvant chemotherapy (74.7% ALLT, 91.6% BRGY, 86.1% BREX; p=0.031), selective recommendation for OFS with endocrine therapy during the adjuvant setting (51.4% ALLT, 66.6% BRGY, 75% BREX; $p < 0.001$), and routine evaluations of FSH levels during treatment with OFS (70.5% ALLT, 86.8% BRGY, 86.2% BREX; p=0.038). Genetic counseling was always offered in young patients by 47.8%, 72.9% and 69.4% of physicians with ALLT, BRGY and BREX clinics, respectively (p=0.014).
The use of genomic platforms for decision-making also differed: 55.6% of BREX oncologists reported always using these platforms in cases of young women compared to 38.8% of oncologists who treat all types of tumors ($p <0.001$). Specifically, chemotherapy was recommended to patients with recurrence score higher than 20 by 49%, 77.8% and 60.4%

of oncologists with ALLT, BRGY and BREX clinics, respectively (p=0.003)
The reported practices did not differ among professionals from different countries .
Conclusions: According to the results of our survey the approach to managing early HR+ HER2- negative breast cancer in young women differ depending by professional focus. Full results will be presented. Further research is needed to understand the basis for these differences. However, given the heterogeneity of responses, our study highlights the need for specific guidelines for the management of breast cancer in young patients.

P4-11-16: Improvement of Pathologic Complete Response Prediction with Plasma Cytokine Profiles in Hormone Receptor-Positive Early Breast Cancer Treated with Neoadjuvant Chemotherapy

Noel Blaya Boluda, Esmeralda García-Torralba, Esther Navarro Manzano, Miguel Pérez Ramos, Elisa García Garre, Alejandra Ivars, Esperanza Guirao, Pilar de la Morena Barrio, Ana Fernández Sánchez, Alicia de Luna Aguilar, Gema Moreno, Elena García-Martínez, Francisco Ayala de la Peña

Background: Neoadjuvant chemotherapy (NCT) is the standard of care for most cases of HER2-positive early breast cancer (BC) and is also used in selected patients with HER2-negative hormone receptor (HR)-positive BC. Immune biomarkers, especially stromal tumor infiltrating lymphocytes (sTIL), have been shown to be useful for prediction of pathologic complete response (pCR). However, this prediction is less accurate both in HER2+ and HER2- HR-positive BC. The interplay between the peripheral and the tumor microenvironment immune compartments might have implications for the search of new predictive immune biomarkers. Plasma levels of cytokines and growth factors may allow the identification of differential immune and inflammatory activation states in BC patients, potentially contributing to chemotherapy response.The aim of this study was to determine if circulating plasma cytokines might improve prediction of pCR in early HR+ BC treated with NCT.
Methods: Pre-treatment plasma levels of cytokines were determined in a prospective single-center cohort of women with hormone receptor (HR)-positive BC treated with NCT. Bead-based multiplex assays and Luminex technology was used to simultaneously obtain the plasma concentrations of 29 cytokines and growth factors. The outcome variable was pCR. After pre-processing of plasma cytokine values (log transformation, asignment of half the limit of detection to non-detectable values, treatment of outliers and imputation of missing values with an iterated random forest algorithm), cytokine variables were discretized into high vs low concentration using k-means clustering. In order to identify the information that each variable could add to prediction of pCR, a minimum-redundancy maximum-relevance mutual information algorithm was applied to all relevant clinical and pathological variables and to pre-treatment dichotomized cytokine levels. The first four variables in the mutual information relevancy matrix, together with HER2 status, were included in multivariable logistic regression models for pCR. Goodness of fit of the models were compared with the likelihood ratio test (LLRT). AUC (area under cuve) of ROC

(receiver-operating curve) was calculated to evaluate model performance.We used R version 4.2.3 (package varrank) for statistical analysis and data visualization.
Results: We included 63 patients with HR-positive early BC in the study. Median age: 49 (range: 31-76); 39,7% grade III; 33,4% stage III; 39 patients HR+/HER2- (61,9%) and 24 HR+/HER2+ (38,1%). All HER2+ patients received antiHER2 treatment combined with NCT. After NCT, pCR rate was 28.6%; ypN0 rate was 57.1%. Maximal relevance for pCR corresponded to grade 3, CD28 baseline levels, TNFa baseline levels, Ki-67 (continuous variable), negative progesterone receptor (PgR) and HER2 amplification. Higher plasma levels of TNFa and lower levels of CD28 were significantly associated with pCR. A logistic regression model for pCR based only in clinical and pathological variables (Grade 3, odds ratio [OR] 11.1, 95%CI 2.67-61.5; Ki67, OR 1.05, 95%CI 1.01-1.10; HER2+, OR 4.37, 95%CI 0.93-26.70) was improved (LLRT, p=0.005) after inclusion of baseline cytokine levels into the model. In the final multivariate model, OR was 11.0 for TNFa (95%CI, 1.86-120.0, p=0.02) and 0.19 for CD28 (95%CI, 0.02-0.96, p=0.08). The ROC-AUC of the first model was 0.87, while the model including cytokine levels had a ROC-AUC of 0.92.
Conclusions: In HR-positive early BC, circulating cytokine TNFa and CD28 provided predictive value for pathologic complete response after neoadjuvant chemotherapy, beyond the information provided by classic clinical and pathological variables. Validation of these findings in a larger cohort and further research on the relationships between tumor and circulating immune biomarkers of chemotherapy response might improve the current selection approach of HR+ BC patients for primary systemic treatment.

P4-11-17: Prognostic significance of complete cell cycle arrest compared to the CPS + EG scoring system in patients with HR+/HER2- breast cancer receiving neoadjuvant chemotherapy

Sohyun Moon, Sung Gwe Ahn

Background: Pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) is not predictive in HR+/HER2- breast cancer patients. Complete cell cycle arrest (CCCA) is regarded as a biomarker associated with response to endocrine therapy and recurrence-free survival (RFS). The CPS + EG scoring system has been developed and validated to predict a prognosis in patients receiving NAC. We evaluated a prognostic influence of CCCA compared to the CPS+EG score in patients with HR+/HER2- breast cancer who had residual tumors after NAC.
Methods: Between January 2007 and June 2021, we retrospectively identified 1,419 HR+/HER2 breast cancer patients who underwent NAC in two academic institutes in South Korea. Among these, 918 with Ki67 index in surgical specimens with residual cancer were included. We obtained the CCCA value, which is Ki67 less than or equal to 2.7%. The clinicopathologic stage (CPS) + EG scores were obtained, and the cutoff for high risk was defined as ≥3. The primary endpoint of this study is recurrence-free survival (RFS).
Results: In 918 patients, the CCCA rate was 60.1% (552/918) with a 7-year RFS of 75.8% (95% CI, 71.3-80.6%) in the CCCA group compared to 63.9% (95% CI, 58.0-70.4%) in the

non-CCCA group. The group with CCCA showed significantly longer 7-year recurrence-free survival (RFS) rates compared to the non-CCCA group in both CPS + EG score-high patients (75.9% vs. 62.6%) and CPS + EG score-low patients (84.2% vs. 78.9%). In multivariable analyses, achieving CCCA was demonstrated as a prognostic factor for RFS (hazard ratio 0.488, 95% CI, 0.361-0.660) independent of stage, age, grade, and the CPS-EG score. Conclusions: Our findings show that achieving CCCA is associated with improved survival among patients with HR+/HER2- breast cancer who do not attain a pathologic complete response after NAC and suggest that a prognostic significance of CCCA is independent of the CPS-EG score.

P4-11-18: Efficacy of anthracycline- and taxane-containing neoadjuvant chemotherapy for luminal HER2-negative BRCA-mutated breast cancer

Yaroslav Zhulikov, Elena Kovalenko, Maxim Khoroshilov, Ekaterina Evdokimova, Elena Lubennikova, Inna Ganshina, Andrey Novikov, Alexander Petrovskiy, Danila Denchik, Vladimir Sholohov, Elena Artamonova

Introduction: Germline mutations in the BRCA1/2 genes occur in 5-10% of patients with luminal HER2-negative (ER+HER2-) breast cancer (BC) and are associated with a more aggressive course of the disease. Data on the effectiveness of neoadjuvant chemotherapy (NACT) in this group is limited. The aim of the study was to assess the rate of pathological complete response (pCR) in BRCA mutated ER+HER2- BC patients (pts) receiving NACT.
Materials and methods: This retrospective study included pts with ER+ (ER>10%) HER2- stage II-III BC and germline BRCA1/2 mutations (mut) 4th or 5th pathogenicity class. Pts received anthracycline- and taxane-containing NACT (4 cycles AC every (q) 2 or 3 weeks (w) then 4 cycles docetaxel 75 mg/m2 q3w or 12 paclitaxel 80 mg/m2 ± carboplatin AUC2 weekly) in a single center from September 2017 to December 2023. All the pts from the center's database meeting the criteria mentioned above were included in the study.
Results: Thirty one pts were included, 14 (45.2%) with BRCA1 mut, 16 (51.6%) - BRCA2 mut, one (3.2%) had both. Mutations were detected by PCR in 17 (54.8%) pts and by NGS in 14 (45.2%). AC q3w and q2w received 11 (35.5%) and 20 (64.5%) of pts respectively, docetaxel and paclitaxel – 17 (54.8%) and 14 (45.2%), 6 pts (19.4%) received carboplatin. Mean age was 40.5 years (27-58), 29 pts (93.5%) were premenopausal. Most of them (71%) had a locally advanced stage, 58% - cT4 and 83.9% - cN+. More than 2/3 (74.2%) of tumors were G2, 25.8% - G3, 87.1% had ER expression >50%, 67.7% - progesterone receptors >20%. Median ki67 was 49.6% (17-85). Luminal B subtype identified in 29 (93.5%) cases. The pCR rate was 45.2% (N=14), in the subgroup of BRCA1mut pts - 64.3% (N=9), BRCA2mut - 31.3% (N=5) (p=0.07).
Discussion: Anthracycline- and taxane-containing NACT in BRCA mut ER+HER2- BC achieved pCR in 45.2%, which substantially exceeds the rate of pCR in luminal BC - 16-18%. BRCA mutation could be an independent factor in the choice of neoadjuvant/adjuvant therapy due to the high chemosensitivity of these tumors.

P4-11-19: An analysis of sexual dysfunction symptoms in hormone receptor positive breast cancer patients during adjuvant endocrine therapy in a single Brazilian center

Daniela Pereira, Stany de Paula, Isabella Barros, Marcella Winter, Flavia Paes, Daniele Suzuki, Danielle Santos, Romualdo Sousa, Angelica-Nogueira Rodrigues

Background: Hormone receptor positive (RH+), HER 2 negative (HER 2-) early-stage breast cancer (BC) patients undergo adjuvant endocrine therapy (ET) during a period ranging from five to ten years, and the treatment impact on sexual life hasn't been properly addressed as it should. In this study performed in a single Brazilian center we aim to show the impact of prolonged ET on the sex lives of early stage BC patients in ET.
Methodology: 105 women with an early-stage RH+, HER 2 - invasive BC undergoing adjuvant ET for at least 6 months were included. We separated sexually active and inactive patients, with sexually active being defined as having engaged in sexual intercourse at least once in the past four weeks. Those with an active sex life took the Female Sexual Function Index questionnaire (FSFI) and sexual dysfunction was indicated by a score of <=26.55 on the FSFI, while > 26.55 indicated an absence of sexual dysfunction. Data collection was performed using RedCap software. The data analysis was done using the RStudio program.

Results: Patients average age was 58.7 years, 57.8% were married, 58.9% were white and 51.0% had a college degree. Prior to BC diagnoses, 65.4% of the women were sexually active and only 42.3% have engaged in sexual relations in the four weeks before answering the questionnaire. Regarding the stage of the disease, 42.9% and 41% of the patients were in stages I and II, respectively, while only 16.2% were in stage III. The sexual function score indicated sexual dysfunction in 77.3% patients (SD = 21.8), with the main determinant factors being the domain of sexual desire (SD =3.1) and pain during sexual intercourse (SD = 3.2). The patients reported a moderate level of overall satisfaction with their sexual lives (SD =4.4), orgasm (SD=4,0) and lubrification (SD=4.1).

Conclusion: There was a notable decline in the quality of the sexual lifes of patients in ET. This analysis represents an urgent symptom which is little discussed by the professionals and poorly managed during ET.

P4-11-20: Development of a method for detecting genetic mutations in early breast cancer using Plasma-Safe-SeqS technology and its clinical application.

Reika Yoshida, Naoki Akiyama, Yuka Oi, Michiko Kato, Karen Suyama, Asako Tsuruga, Sayuka Nakayama, Seigo Nakamura, Naoki Hayashi, Hiroko Masuda

Background: The detection of circulating tumor DNA (ctDNA) in blood has attracted attention and research as a way to assess the risk of recurrence and treatment effectiveness

in early-stage breast cancer (EBC). However, detecting ctDNA in blood in EBC is challenging due to its extremely low leakage, and it requires an ultra-sensitive test for clinical use.
In this study, we used a gene panel test for ctDNA in blood using the latest technology to investigate the effectiveness of mutation identification in EBC. This study also compared gene mutation identification using this method with next-generation sequencing (NGS) using tissue samples.
Methods: Among patients with hormone-positive and HER2-negative early breast cancers, which account for 60-70% of breast cancer patients, 12 patients at high risk of recurrence (Patients with four or more positive nodes, or one to three nodes and either tumor size ≥ 5 cm, histologic grade 3, or central Ki-67 ≥ 20%) were enrolled.
Blood samples for ctDNA were collected at the time of diagnosis, and for the NGS gene panel, Sysmex's Plasma-Safe-SeqS technology (PSS) was used to detect six breast cancer-related genes (AKT1, ERBB2, ESR1, KRAS, PIK3CA, and TP53) from ctDNA.
The panel can detect mutant allele frequency values of 0.05%. OncoGuide™ NCC Oncopanel was used to confirm the presence of genetic mutations in the tissue at the time of diagnosis and to measure the gene mutation identification rate.
The Institutional Review Board of Showa University Hospital issued approval 22-208-A.
Results: The OncoGuide™ NCC Oncopanel identified genetic mutations in 6 out of 12 patients , with 2 patients also found to have mutations in PSS. The gene mutations in these two cases were AKT1 and PIK3CA, respectively.
The two cases identified by PSS were both cT4 with large tumor volumes and skin invasion. One had skin and muscle invasion and was 95 cm3 in size, and the other had skin invasion and was 132 cm3 in size. On the other hand, the four cases identified only in the OncoGuide™ NCC Oncopanel were AKT1 in one case, PIK3CA in one case, and TP53 in two cases.
The detection rate of genetic mutations in operable breast cancer using ctDNA was 33%. The two cases identified by PSS were both cT4, with large tumor volumes and skin invasion. On the other hand, the reason why PSS could not identify four cases could be that the tumor volume was small and the amount of ctDNA leaked into the blood was low.
Tumor reduction rate after neoadjuvant chemotherapy by genetic mutation was as follows: two cases with AKT1 mutations averaged 81% (range: 71%-91%), one case with PIK3CA gene had 100% reduction, and two cases with TP53 gene averaged 41% reduction (range: 39%-43%). Conversely, the six patients without genetic mutations had an average reduction rate of 85 % (range: 19%-100%).
There were no differences in clinical pathological factors between the two cases with TP53 mutations and the other 10 cases, other than TP53 mutations. These two cases had a poorer response rate to chemotherapy than others, suggesting that TP53 is considered an independent predictor of reduced response to chemotherapy.
Conclusions: In this study, we found that PSS could be utilized in perioperative breast cancer treatment in clinical practice. In addition to the postoperative blood sampling described above, we are currently conducting (1) postoperative blood sampling and (2) postoperative blood sampling after completion of adjuvant therapy. We aim to ascertain whether this mutation can serve as a predictive marker for response to postoperative

chemotherapy or recurrence, especially in hormone-positive breast cancer patients at high risk of recurrence.

P4-11-21: The use of adjuvant Abemaciclib in HR+, HER2- early breast cancer: a multi-institutional UK experience.

Bahaaeldin Baraka, Owoseni Yetunde, Maryam Al-Ani, Mohammed Omar Farooq, Muhammadadeel Sarwar, Sabharwal Saksham, Balaji Varadhan, Samreen Ahmed, Sarah Khan, Olubukola Ayodele

Background: The landscape for the treatment of HR+ HER2- early breast cancer continues to evolve with an increasing focus on targeted therapies. This study explores real world experience of the use of adjuvant Abemaciclib.

Methods: This is a retrospective study of 138 patients (pts) who received adjuvant Abemaciclib in combination with hormonal treatment between September 2022 until February 2024 at Nottingham University Hospital and University Hospitals of Leicester NHS Trust. Pts' demographics, menopausal status, histological types, high-risk disease status, toxicities and reasons for discontinuation were reviewed.High-risk disease was defined as ≥ 4positive axillary lymph nodes or 1-3 positive axillary lymph nodes (LNs) with either tumour size ≥5cm or histological grade 3. Data analysis was conducted using SPSS statistics, version 28.0.ResultsThe cohort was predominantly females (99.3%) with an average age of 57 years. The majority were White-British (77.5%) and postmenopausal (69.6%). Histology characteristics showed most of patients were invasive ductal carcinoma (70.3%) with half of the cohort having tumours measuring 2-5 cms and having 1-3 positive axillary LNs.Overall toxicities was reported in 60.9% of pts. Treatment related neutropenia and diarrhoea were mostly grade 1-2 .Neutropenia occurred at Grade 1 in 13.8% (19 pts), at Grade 2 in 8% (11 pts), and at Grade 3 in 5.8% (8 pts). Diarrhea was noted in 39.9% (55 pts) at Grade 1, 18.8% (26 pts) at Grade 2, and 5.1% (7 pts) at Grade 3.Other toxicities reported included fatigue (35.2%),skin rash (11.1%), and nausea (9.3%). About 58% of pts required at least 1 dose reduction. Sixteen percent of pts discontinued treatment due to toxicity. Five (3.6%) pts progressed on treatment.
Conclusions: Our study`s results, despite its smaller size, align with the outcomes observed in the larger phase 3 trial. In comparison to the MonarchE study, our pts experienced lower incidences of G2/3 neutropenia and all grades of diarrhoea. The discontinuation rate due to intolerability was similar in this cohort compared to the phase 3 study (16%) vs (18.5%).The data is still immature for making definitive comments on survival benefits.

P4-11-22: Prognostic Value of high-risk Oncotype Recurrence Score (RS) and MammaPrint (MP) assay in Premenopausal African American (AA) Patients with Hormone-Positive (HR+), Node-Negative Breast Cancer (BC): A Study of the National Cancer Database (NCDB).

Devashish Desai, Prashanth Ashok Kumar, Dongliang Wang, Abirami Sivapirasgasam

Background: It has been hypothesized that RS score has lower prognostic accuracy in AA, compared to Caucasians. This study evaluates this difference using the NCDB, focusing on premenopausal, node-negative patients with RS ≥ 26 or MP high risk. Methods: The 2021 NCDB PUF was used to include premenopausal female BC patients aged 18-50 years. Inclusion criteria were N0, M0 patients with T1-4, RS ≥ 26 or MP high risk, estrogen and/or progesterone receptor-positive, and HER2-negative. Patients were stratified by their recorded race (Caucasians and AA). Univariate analysis was used after distributing the groups based on chemotherapy receipt. Kaplan-Meier analysis (KM) was used to evaluate survival rates. Results: 8,842 patients had RS ≥ 26 [Caucasians-7,412(83.83%), AA-1,430(16.17%)] of which 7,699 (87.07%) received chemotherapy [Caucasians-6495(84.36%), AA-1204(15.64%)] and 7,910 (89.46%) received hormonal therapy [Caucasians-6,663(89.89%), AA-1,247(87.20%)]. In the high-risk MP category, 1,524 patients were identified [Caucasians: 1,278 (82.99%), AA: 262 (17.01%)]. Among these, 1,259 (82.61%) received chemotherapy [Caucasians: 1,051 (82.24%), AA: 208 (79.39%)] and 1,365 (89.57%) received hormonal therapy [Caucasians: 1,141 (89.28%), AA: 224 (85.50%)]. The KM survival curve showed similar survival rates in Caucasians and AA among RS ≥ 26 patients who received chemotherapy [5 years – Caucasians 95.9(95.3-96.5)%, AA 95.1(93.4-96.4)%; 10 years – Caucasians 90.1(88.8-91.3)%, AA 89.2(86.0-91.7)%]. Numerically, survival rates were lower in AAs among RS ≥ 26 patients who did not receive chemotherapy [5 years – Caucasians 94.9(92.9-96.4)%, AA 90.4(84.4-94.2)%; 10 years – Caucasians 88.0(83.9-91.1)%, AA 80.2(66.1-88.9)%]. In the high-risk MP group, the 5-year survival rate with chemotherapy was 97.0% (95.5-98.1) for Caucasians and 93.9% (88.4-96.9) for AAs. Without chemotherapy, the 5-year survival rate was 95.5% (88.6-98.3) for Caucasians and 94.7% (68.1-99.2) for AAs. Conclusions: Our study shows that among high genomic risk, node-negative, premenopausal patients, the survival rates are numerically similar between Caucasians and African Americans (AAs) when chemotherapy was administered. However, when chemotherapy was omitted, there were numerical differences in the survival rates within the high-risk RS population. This trend was not observed with the MP cohort. The analysis also highlights that approximately 13% of patients with RS ≥ 26 and 17% of high-risk MP patients did not receive chemotherapy.

P4-11-23: Treatment Response to Neoadjuvant Endocrine Therapy in Hormone Receptor-Positive, HER2 Negative Early Breast Cancer Patients in Los Angeles County

Gene Yoshikawa, Krixie Silangcruz, Lauren Lewis, Katie La Barbera, Andrew Hwang, Charity Huang

Background: There has been increasing interest in utilizing the role of neoadjuvant endocrine therapy (NET) before definitive surgical resection in patients with hormone receptor (HR) positive human epidermal growth factor 2 (HER2) negative non-metastatic breast cancer [1]. Numerous studies have demonstrated that postmenopausal breast cancer patients who receive NET have improved outcomes compared to those who receive upfront surgical resection with curative intent [2][3][4]. In this study, we conducted a real-world retrospective analysis of response rates to NET in premenopausal and postmenopausal underserved women in a Los Angeles (LA) County hospital with HR-positive/HER2-negative breast cancer. In addition, this study was conducted during the COVID-19 era, when efforts were heightened to minimize non-essential interactions with the healthcare system. This context underscores the importance of exploring alternative treatment strategies such as NET, which could potentially reduce the need for immediate surgical interventions while maintaining effective management of HR-positive/HER2-negative breast cancer in underserved populations.
Methods: We conducted a retrospective analysis of 56 HR-positive/HER2-negative early breast cancer patients from a safety net hospital in LA County on NET. The primary endpoint was treatment response, determined by change in tumor size at the time of surgery. Secondary endpoints included various clinical and pathological factors, as discussed in the results section.
Results: The objective clinical response was 48.2%, and the median time on NET for all patients was 123 days. Overall, there was a reduction in median tumor size from 17.83mm before treatment to 13.69mm after treatment (p=0.012), with a combined median size reduction of 2mm. Median tumor size reduction was 2mm in non-Hispanic patients compared to 1.5mm in Hispanic patients, though this difference was not statistically significant (p=0.543). Median tumor reduction was 4mm for premenopausal women and 1.5mm for postmenopausal women but was also not statistically significant. No significant association was seen between histological subtype and response to NET. The median clinical and pathologic stages were IA and IB, respectively. No differences between ethnic groups were noted (p=0.884). The mean OncotypeDX score was 14.83 in Hispanic patients and 15.77 in non-Hispanic patients without a correlation via linear regression. Breast-conserving therapy (vs. mastectomy) showed no association with ethnicity (p=0.884) or menopausal status (p=0.383).
Conclusion: This retrospective chart review underscores the effectiveness of NET in decreasing tumor size among HR-positive/HER2-negative early-stage breast cancer patients, notably in an underserved demographic. There was no association between histological subtype and response to NET. Additionally, there were no significant differences between ethnic groups in OncotypeDX scores or breast-conserving therapy

decisions, suggesting standardized treatment approaches and similar clinical characteristics across diverse patient groups. Despite challenges such as delayed presentation and concurrent health issues, the significant reduction in tumor size post-treatment indicates a favorable response and suggests that NET has the potential to enhance surgical outcomes independent of menopausal status. Moreover, the observed difference in tumor size reduction between non-Hispanic and Hispanic patients highlights the need for further investigation into the factors influencing treatment response among diverse patient groups.

P4-11-24: Real-world data on high and intermediate-risk hormone receptor (HR)-positive HER2-negative early breast cancer patients prior to adjuvant CDK1/6i era

Winnie Yeo, Lok-Wa Yuen, Carol C Kwok, Inda Soong, Ting-Ying Ng, Joanne Chiu, Miranda Chan, Sharon Wing-Wai Chan, Ting-Ting Wong, Yolanda Ho-Yan Chan, Lawrence Pui-Ki Li, Chun-Chung Yau, Wai-Ka Hung, Polly Suk-Yee Cheung

Background: Patients with high- or intermediate- risk HR-positive HER2-negative early breast cancer (EBC) have increased risk of disease relapse. Combination of endocrine therapy (ET) with CDK4/6 inhibitors have shown to improve clinical outcomes in these settings based on MonarchE and NATALEE studies. The objective of this study was to determine the distant disease-free survival (DDFS), invasive disease-free survival (iDFS) and overall survival (OS) of HR-positive HER2-negative EBC cancer patients prior to the use of adjuvant CDK4/6 inhibitors.
Methods: This retrospective study retrieved real-world patient data from the database of the Hong Kong Breast Cancer Foundation. They were consented for data collection from 11 public and 4 private hospitals/clinics in Hong Kong. This study was approved by the regional ethics committee of individual units. Patients who underwent definitive surgery for EBC between January 2006 and December 2011 were studied. The inclusion criteria of MonarchE and NATALEE were applied. Patients were divided into 3 groups: group 1, those that satisfied both MonarchE and NATALEE criteria; group 2, those eligible for NATALEE criteria but not MonarchE; and group 3, remaining patients, who had stage 1 cancers. Patients background characteristics were collected. DDFS, iDFS and OS were evaluated using the Kaplan–Meier method. Descriptive statistics were used to report the clinical outcomes of the 3 groups.
Results: A total of 3541 ER-positive HER2-negative EBC were included. 923 (26.1%) in group 1, 962 (27.2%) in group 2 and 1656 (46.8%) in group 3. 1633 (46.1%) patients were premenopausal, 1684 (47.6%) were postmenopausal while 224 (6.3%) had unknown menopausal status at diagnosis. 1900 (53.7%) had node-negative disease. 899 (25.4%) had grade 3 cancers. High tumour Ki67 (defined as >/=20%) was reported in 825 (23.3%) patients. 2467 (69.7%) received radiotherapy, 2241 (63.3%) underwent chemotherapy. 3366 patients received ET (95.1%); information on ET of 12 (0.3%) patients were unknown. For group 1 vs group 2 vs group 3, the 10-year DDFS were 75.2% vs 90.3% vs 95.8%, the 10-year iDFS were 69.7% vs 84.2% vs 89.4% respectively, while the 10-year OS

were 79.9% vs 90.2% vs 94.5% respectively.
Conclusions: The present study confirmed that in the real-world clinical setting, patients who satisfied both MonarchE and NATALEE eligibility criteria had the worst prognosis, while patients who satisfied NATALEE but excluded from MonarchE also had poorer outcomes when compared with stage 1 EBC patients. Further studies to determine which patients would benefit most from adjuvant CDK4/6 inhibitor treatment in the real-world setting is warranted.

P4-11-25: Enhancing Care of HR+/HER2- Early Breast Cancer Patient At Risk of Recurrence Through an Expansive Curriculum

Urvi Patel, Nabil Dorkhom, Victoria Phoenix, Jordan Schwartz, Katie Lucero

Introduction: Although therapies for patients with HR+/HER2- early breast cancer (EBC) have been available for several years, a number of clinical gaps remain, minimizing the optimization of care in this patient population. In an effort to overcome these gaps, a large educational curriculum was developed to improve the learner's ability to determine which patients are at high-risk for recurrence and how to implement and maintain the patient on appropriate therapy.
Methods: The curriculum included 11 online CME activities that were distributed between October 2023 and May 2024. The goal of this curriculum was to enhance oncologist's knowledge, competence, and confidence along three core learning areas: identification of patients with HR+/HER2- EBC at high risk for recurrence, selection of optimal treatment for high-risk patients, and improvement of patient's adherence to therapy. Educational impact was assessed with repeated pairs design. Oncologists were asked pre-education and post-education knowledge/competence and confidence questions. These questions were based on the identified education gaps and designed to assess if the learning objectives were met. Data were collected from October 2023 to May 2024. Statistical significance was assessed using McNemar's test ($P < .05$ level).
Results: A total of 20456 global oncologists participated in these activities, of which 3564 completed the activities. The assessment questions and the outcomes data were divided into three core learning areas, three levels of learning, and by geographical area to determine impact of education.

(80) 21 39 18 <.05
Conclusions: The results of these activities have led to a significant increase in the knowledge, competence and confidence of oncologists through all segmentations of the core learning areas, learning levels, and geographical areas assessed. Despite this positive growth many gaps still remain, and further education is needed to minimize those gaps.

P4-11-26: Efficacy of neoadjuvant endocrine therapy versus chemotherapy in ER+ HER2-negative breast cancer: a single-center matched-cohort study. Preliminary results.

E.I. Kovalenko, Tatiana Titova, Yaroslav Zhulikov, Vladimir Fedko, Maxim Khoroshilov, Alexander Petrovskiy, Elena Artamonova

Introduction: The role of neoadjuvant endocrine therapy (NET) is still not well defined. The comparative trials with combination chemotherapy (CT) demonstrated similar rate of clinical, radiological response and breast conserving surgery. However, there are no direct comparative studies to date in terms of the pathological response of modern neoadjuvant (NA) anthracycline- and taxane- (A-T) containing regimen versus NET. It still remains unclear what role plays NET in de-escalating or sparing CT. Materials and methods. The aim of the study was to assess the rate of pCR, RCB 0+1 and axillary clearance (conversion of N+ to N0) of NET in comparison to A-T NACT in stage II-III breast cancer (BC) in postmenopausal patients. RCB 0-1 as an end point was chosen due comparable long-term results in ER+HER2- BC as per meta-analisys. The study included patients with early ER+HER2- BC who received NET or NACT in a single center from Aug 2018 to Nov 2023. Results: A total of 206 patients were included, of which 96 received NET with aromatase inhibitors (AI), 110 – CT (4 cycles doxorubicine/cyclophosphamide (AC) every 2 (dose-dence) or 3 weeks followed by 4 x docetaxel every 3 weeks or 12 x paclitaxel weekly). After propensity matching analysis to adjust for selection bias 69 patients in each treatment group were included in the final analysis. The majority of patients (94,2-91,3% in each group) had stage III disease, median age was 64,6-58,2 y.o., median ki67 34,2-39,5%. The

pCR rate was 1,4% in the NET group vs 10,1% in the CT group (p=0.06), RCB 0+1 rate 4,3% vs 20,2% (p=0,008), axillary clearance – 3,5% vs 27,6% (p 0,001). Following surgery 37 (53,6%) patients from the NET group received adjuvant CT: 14 (37,8%) - A-T, 7 (18,9%) - 6 cycles of docetaxel/cyclophosphamide (TC), 9 (24,3%) – 4 cycles of TC, 5 (13,5%) – other CT, 32 (46,3%) received no CT. 3-year event-free survival (EFS) was 92,8% vs 87,0% (p=0,6). Conclusion: Our preliminary results suggest that NET demonstrates significantly lower rate of RCB 0+1 and axillary clearance compared to A-T NACT. However, it does not translate into differences in EFS so far, probably due to adjuvant CT, which was administered to 53,6% of patients. NET allowed to avoid CT in 46,3% of patients or de-escalate it (to 6 or 4xTC) in 23,2%.

P4-11-28: Breast Cancer Recurrence Risk Stratification with the 21-Gene Recurrence Score Assay - the Portuguese National Experience

Diana Pessoa, Joana Luís, Diogo Alpuim Costa, Mário Fontes e Sousa, Idília Pina, Débora Cardoso, Isabel Andrade, Joana Simões, Ana Ferreira, Renato Cunha, Diogo Branco, José Luís Passos Coelho, for the Portugal "21-Gene Recurrence Score Assay" National Cohort Study

Introduction: The 21-gene recurrence score assay (RSA), a genomic tool to personalize therapy, avoiding over and undertreatment of breast cancer (BC) patients (pts), is available in Portugal since 2012. We aimed to characterize the population of pts with BC whose tumors were tested from 2012 until Dec 2021, analyzing prescription patterns and invasive disease-free survival (iDFS).
Methods: Observational, multicenter nationwide retrospective cohort study of pts with RH+/Her2-neg invasive BC treated by upfront surgery, in whom the RSA was performed. The cohort was identified by the national representative of the RSA manufacturer and clinical data was retrospectively collected from medical records by independent investigators.
Results: 1119 pts from 36 centers were preregistered. We weren't able to retrieve data from 7 patients; 21 pts were excluded due to insufficient clinical-pathological information; 7 were excluded for insufficient tissue, and 1 was staged pN2. Thus 1083 pts (91%) were included in the analysis: pN0 - 832 pts (76,8%), pN1 - 238 pts (22%) and pNx -13 pts (1,2%). In pN0 group 57.2% of pts were postmenopausal. Tumors were mostly no special type (NST, 76.6%), G2 (82.9%), with median (med) expression levels of ER 100%, PR 80% and Ki67 25%, pT1 (66.1%), Luminal B like (72.7%) and MINDACT clinical low risk (64.7%). The med RS was 17 (range 0-61). After publication of the TAILORx trial there was an increase in the number of tests per unit of time (248 vs 584); pts and tumor characteristics were similar but for pts > 50 yo with RS ≤ 25 (n= 412) there was an increase in the percentage of pts that didn't receive adjuvant chemotherapy (ACT, 79.3% vs 96%); for pts ≤50 yo with tumor RS 16 to 25 (n=137) there was an inversion in the percentage of pts treated with ACT (before TAILORx CT 62.2%; after 30%); after TAILORx, 22 of 70 pts ≤50 yo (31.4%) with tumor RS 16-25 who did not receive ACT, received adjuvant ovarian suppression. In pN1 group 64.7% pts were postmenopausal. Tumors were mostly NST

(76.5%), G2 (77.3%), with med expression levels of ER 100%, PR 80% and Ki67 17.5%, pT1 (61.8%), Luminal B like (55.5%), high MINDACT risk (85.7%) and with only one positive lymph node (81.9%). The med RS was 15 (range 0-63). 237 of the 238 pts with pN1 disease had the RSA requested before publication of the RxPONDER trial results. 74% of pN1 premenopausal pts with RS ≤ 25 did not receive ACT; 8 of these 54 pts (14.8%) received ovarian suppression. With a med follow-up of 29 months and 16 pts (1,5%) lost to follow up, there were 24 (2%) invasive disease recurrences (17 pN0, 6 pN1 and 1 pNx): 14 distant, 6 locoregional, 3 both and 1 contralateral. Among pN0 pts, 9 pts were premenopausal (med tumor RS of 17, range 7-21), and 2 had received ACT; of the 8 postmenopausal pts (med tumor RS of 25.5, range 10-44), 3 pts had received ACT. 6 pN1 pts recurred - 3 premenopausal with tumor RS of 9, 14 and 15 (1 treated with ACT) and 3 postmenopausal with tumor RS of 23, 28 and 29 (the last 2 treated with ACT).
Discussion/Conclusion: In this national cohort, the RSA was requested in mostly hormone receptor (HR)-strongly positive, good prognosis, BC with low risk of early recurrence disease. Pts characteristics are similar to the general characteristics of TAILORx and RxPONDER studies. The analysis of TAILORx suggested potential benefit of ACT in women ≤ 50 yo with tumours RS 16-25; however it did not result in more frequent prescription of ACT after July 2018. There was a high proportion of pN1 premenopausal pts with RS ≤ 25 that did not receive ACT (74%) but almost all pts were tested before the publication of RxPONDER. These results show that real-world studies at a national level are fundamental to evaluate clinical practice, analysing adherence to treatment recommendations and measuring pts outcomes.

P4-11-29: Clinical Impact of 18F–fluoro–17b–fluoroestradiol (18F–FES) PET in Patients with Estrogen Receptor-Positive Breast Cancer

Samer Alkassis, Mahbod Jafarvand, Jeremie Calais, David Elashoff, Marla Lipsyc-Sharf, Nicholas P. McAndrew, Kelly E. McCann, Rena D. Callahan, Ashini K. Master, Julia LaBarbera, Mina S. Sedrak, Nicolaos J. Palaskas, John A. Glaspy, Aditya Bardia

Background: Estrogen receptor (ER) status is an important factor in risk assessment for predicting response to systemic therapy for breast cancer. Currently, the gold standard for determining ER status in metastatic breast cancer is tissue immunohistochemical (IHC) testing. However, some patients have metastases that can be difficult to visualize using standard imaging techniques, particularly in the setting of invasive lobular carcinoma (ILC). ILC tends to proliferate in a single-file, sheet-line, lowly FDG-avid pattern as opposed to the more discrete, FDG avid masses which are typical of invasive ductal carcinomas (IDC). Additional clinical challenges include evaluating the ER expression of areas that are either difficult to biopsy, or difficult to interpret IHC results such as decalcified bone tissue. 18-FES PET is a functional imaging modality that can help identify lesions expressing ER as well as inter-lesion heterogeneity in expression. In this study, we evaluated the clinical impact of 18-FES PET in diagnosing metastatic disease and the utility in patients who had discordant biopsy results.

Methods: We performed a retrospective analysis of 40 patients with ER+ early breast cancer (EBC) who underwent 18-FES PET imaging between March 2022 and March 2024 at UCLA. After IRB approval, electronic medical records were reviewed and abstracted for demographics, disease, and treatment.
Results: Of 40 patients included, mean age was 61 years, 21 patients had ILC, 14 had IDC, and the rest had IDC with lobular features. ER percentage was > 70% in all patients. Eight (20%) postmenopausal patients had newly diagnosed metastatic disease by 18-FES PET; 4 (50%) with ILC and 4 (50%) with IDC. Metastatic sites of ILC included bone (2), ureter (1) and chest wall (1) while those of IDC included bone (4). Two of the eight patients were asymptomatic, one had clinical recurrence in the chest wall, three had elevated tumor markers, and two had suspicious findings on prior imaging (CT, FDG PET) that prompted obtaining 18-FES PET. Plasma circulating tumor DNA (ctDNA) testing was obtained along with FES PET in two patients; one had detectable ctDNA, but the other did not. Out of six patients with metastatic site avidity on FES-PET, one did not have feasible site to biopsy, but five patients had confirmatory biopsy. Three of them had ILC with metastases to bone (2) and ureter (1), and two had metastatic IDC to bone. For the other two patients (both with ILC and osseous metastases), negative pathologic ER expression was demonstrated despite positive FES activity; one with mild and one with intense radiotracer uptake. However, endocrine therapy was started despite biopsy findings and both patients had significant responses to endocrine therapy. Of the 32 patients (80%) with negative FES PET, no evidence of metastatic disease was observed at subsequent follow-ups.
Conclusion: FES PET was helpful in diagnosing metastatic disease and in assessing ER status in patients with ER+ EBC and suspected recurrence when the location of biopsy was challenging, particularly in setting of bone metastases in which IHC for ER expression is less reliable. FES positivity was associated with response to endocrine therapy when ER expression by IHC was negative in bone tissue. Prospective trials are needed to further characterize the role of FES PET in early diagnosis of metastatic disease and potential impact on survival for patients with ER+ breast cancer.

P4-11-30: Assessing the APIS Breast Cancer Subtyping Kit for RNA-Based Risk Stratification in Older Patients: Swiss Cohort Findings

Anna Gasior, Marcus Vetter, Elena-Diana Chiru, Joanna Gorniak, Sara Rollinson, Andreas Voss, Leanne Gough, Kimberly Howard, Mathew Harrison, Martina Sonderegger-Stalder, Matthias Matter, Simone Muenst, Christian Kurzeder

Introduction: ER, PR, HER2, and Ki67 serve as valuable prognostic and predictive markers in breast cancer (BC). APIS Breast Cancer Subtyping Kit accurately detects these markers mRNA expression, along with a with a novel four-gene proliferative signature (PS).
Objectives: We evaluate the kit's ability to distinguish between Luminal A and B subtypes and compare PS ability to predict risk of recurrence with Oncotype DX (ODx) and PAM50 tests in two cohorts of hormone receptor positive (HR+) patients, <65 and ≥65 years of age.
Methods:

Tissue of ER+/HER- BC patients (<65 N=33 and ≥65 N=28) diagnosed at Cantonal Hospital Basel-Land and Basel University Hospital (2020-2022) was included. All had received adjuvant therapy and had ODx scores available. All specimens underwent testing with PAM50 (Prosigna®). The % agreement of subtype calls among IHC, the APIS kit and PAM50 was assessed. Spearman correlation tests were applied to the data to examine concordance between recurrence tests.
Results: IHC and the APIS kit had high subtype call agreement in both patents aged <65 (73%) and patients ≥65 (68%). Strong overall agreement was observed in the ≥65 cohort between PAM50 and the APIS kit (82%) compared to the <65 cohort (61%). Agreement was lower between IHC and PAM50 for both cohorts, with 54.6% overall agreement for the <65 cohort and 57.2% for the ≥65 cohort.
Significant association was observed between the APIS kit's PS and ODx and PAM50 scores. Spearman's correlation coefficient between PS and ODx was 0.4542 (|ρ|=.0001*) for <65 cohort and 0.3799 (|ρ|=.0042*) for ≥65 cohort. Between PAM50 and PS, p = 0.3912 (|ρ|=.0244*) for <65 cohort and p = 0.5778 (|ρ|=.0013*) for ≥65 cohort. Proliferation Score was significantly higher for patients ≥65 (p=0.029). No association between age and PAM50 or ODx scores was observed.
Conclusions: The APIS Breast Cancer Subtyping Kit shows improved subtype call agreement with PAM50 in patients ≥65, indicating that molecular testing may be a more suitable method for determining proliferation and distinguishing between luminal A and B subtypes. Significant correlation between the APIS kit's PS, PAM50 and ODx indicates that APIS kit has the potential to accurately identify patients at risk of recurrence, although additional studies are needed to validate these results.

P4-12-01: Correlation between the Oncotype DX Recurrence Score® categories and progression-free survival of patients with primary metastatic estrogen-receptor positive and HER2-negative breast cancer

Marc Thill, Raissa Shvartser, Paige Innis, Purva Singla, Satish Seerapu, Katrin Ehlert

Background: The Oncotype DX Recurrence Score® assay is a 21-gene biomarker validated to provide individualized prognostic estimates of distant recurrence risk and predictive information on the benefit of chemotherapy in patients with early-stage, ER+, HER2- BC. In ER-positive, HER2-negative primary metastatic BC (PMBC), endocrine therapy (ET) is the preferred option for first-line therapy, unless there is a high visceral burden of disease in which case chemotherapy (CT) alone or chemoendocrine therapy (CET) may be considered. There are many unanswered questions related to the optimal management of endocrine responsive PBMC, including optimal drug sequencing, and the potential for individualized treatment on the basis of predictive markers. Studies are warranted to understand individualized treatment response based on PMBC tumor biology and treatment naivety. The primary objective of this retrospective study is to evaluate the association of the Recurrence Score® (RS) result with progression-free survival (PFS) in a cohort of German patients with ER+, HER2- PMBC who received treatment independent of the RS result.

Methods:
Patients diagnosed with ER+/HER2- PMBC between 2008 and 2018 were included in this retrospective analysis.
The RS result was collected retrospectively and as such was not used for clinical decision-making.
Descriptive analyses were used to characterize patient and tumor characteristics. T-tests and Wilcoxon rank sum tests were used to compare continuous characteristics between RS result groups (0-25 and 26-100). Chi-square and Fisher's exact tests were used to compare categorical characteristics between RS result groups.
Kaplan-Meier estimates and log-rank tests were used to compare PFS and 2-year overall survival (OS) between RS result groups.
Multivariable Cox regression models adjusted for age, grade, treatment, and RS result were used to examine the association between RS result with PFS and OS.

Results: A total of 75 patients were included in this analysis (47 had a RS result of 0-25 and 28 had a RS result of 26-100). Mean (SD) age differed between RS groups (p = 0.03); 69.3 (12.6) years for RS 0-25 and 60.1 (17.4) years for RS 26-100. First-line systemic therapy also differed between RS groups (p = 0.004); for patients with RS results 0-25, 38 (80.9%) received ET, 5 (10.6%) received CET, and 3 (6.4%) received (CT). For RS results 26-100, 13 (46.4%) patients received ET, 11 (39.3%) received CET, and 4 (14.3%) received CT.
For RS results 0-25, patients were older, post-menopausal, and had less CT assigned as treatment. The RS result 26-100 cohort consisted of younger, more pre-menopausal women, with a greater percentage assigned CT alone or CET.
The RS 0-25 group had significantly improved PFS (p=0.013) with a median of 35 months compared to 12 months in the RS 26-100 group.
The difference in 2-year overall survival rates between the RS 0-25 group (79%) vs. RS 26-100 group (63%) did not reach statistical signifiance (p=0.18).
In multivariable Cox regression models, the RS result was prognostic for PFS and 2-year OS (p=0.002 and 0.010, respectively).

Conclusions: In this retrospective analysis, there were differences in treatment assignments based on clinical risk of PMBC that were consistent with treatment recommendations according to RS outcomes in EBC.
The binary RS result cut offs (RS ≤25; RS >25) were prognostic for PFS and OS in this retrospective analysis of patients with ER+/HER2- PMBC.
These findings suggest that the Oncotype DX® assay also reflects tumor biology in PMBC, and genomic assays standardly used in early breast cancer might warrant further prospective investigation in the treatment-naïve advanced setting.

P4-12-02: Patterns and predictors of disease progression and their impact on survival in patients receiving Cyclin D Kinase 4/6 inhibitors (CDK4/6i) for advanced Breast Cancer (aBC).

Sudhir Kumar, Neha Pathak, Rossanna Pezo

Background: CDK4/6i-based therapy is the standard 1st line treatment for hormone receptor-positive (HR+), and human epidermal receptor-negative (HER2-) aBC, but most patients eventually progress. There is a lack of evidence on patterns of progression (POP), the clinicopathological factors that predict them, and their impact on survival after disease progression on CDK4/6i-based treatment.
Methods: In this single-center, retrospective study patients with HR+ HER2- aBC treated from January 2016 to June 2023, with at least 3 months of follow-up, and documented progression on CDK4/6i based therapy were investigated. Based on the European Society for Radiotherapy and Oncology/European Organization for Research and Treatment of Cancer consensus, patients were divided into 4 patterns, repeat oligo-progression (RO, oligo-progression with a history of oligometastatic disease), induced oligo-progression (IO, oligo-progression with a history of poly-metastatic disease)- collectively called oligo-progressive disease (OPD) and de-novo poly-progression (DP, poly-progression with a history of oligometastatic disease), repeat poly-progression (RP, poly-progression with a history of poly-metastatic disease)-together called diffusely progressive disease (DPD). Kaplan Meier survival analysis was used for time-to-event data & odds ratio (OR) was calculated with logistic regression for identifying predictors of POP.
Results: Among 200 patients who received CDK4/6i-based therapy during this period, 151 met the inclusion criteria. At the time of diagnosis of metastatic disease, the median age was 59 years, 43 (28%) had de-novo aBC & 98 (65%) had visceral disease. Palbociclib was the most common CDK4/6i used in 142 (94%) patients and the median number of lines of prior treatment received at the time of CDK4/6i start was 0 (range 0-3). At a median follow-up of 58 months, the median time to progression, next-line progression-free survival (nlPFS), and overall survival (OS) were 12 months, 7.5 months, and 56 months, respectively. Overall, 47 (31%) had OPD including 34 (22%) with RO and 13 (9%) with IO. Moreover, 104 (69%) had DPD including 93 (61%) with RP and 12 (8%) with DP. In multivariable logistic regression analysis, high tumour grade (OR 0.31, p=0.03), HER2-low (HER2 being 1+ or 2+ on immunohistochemistry but negative by in-situ hybridization) status (OR 0.34, p=0.03) and progression with in 6 months of the start of CDK4/6i based therapy (OR 0.19, were associated with lower chances of OPD while body mass index of ≥25kg/m2 at diagnosis was associated with higher chances of DPD (OR 1.8, p=0.02). The nlPFS was significantly different among the 4 POP (1-year nlPFS 52% in RO versus 39% in IO versus 30% in DP versus 26% in RP; p=0.01). The 3-year OS also differed significantly among the 4 POP (92% in RO versus 83% in IO versus 66% in DP versus 59% in RP; p=0.02).
Conclusion: The four distinct POP after disease progression on CDK4/6i based therapy significantly affect next line PFS and OS. High tumour grade, HER-low status and early progression within 6 months of CDK4/6i based treatment are associated with lower chances of oligo-progressive disease.

P4-12-03: Vepdegestrant, a PROteolysis TArgeting Chimera (PROTAC) Estrogen Receptor (ER) Degrader, Plus Abemaciclib in ER-Pos/Human Epidermal Growth Factor Receptor 2 (HER2)-Negative Advanced or Metastatic Breast Cancer: TACTIVE-U Prelim Phase 1b Results

John Hilton, Katarzyna J. Jerzak, A. Jo Chien, Jose L.M. Guimaraes, Colombe Chappey, Hechuan Wang, Stefanie K. Drescher, Elisa Dall'O', Julia Perkins Smith, Swapnil Parmar, Rachel M. Layman, Cynthia Ma

Background: Vepdegestrant (ARV-471), an oral PROTAC ER degrader, was well tolerated and showed evidence of clinical activity in the first-in-human phase 1/2 study in heavily pretreated patients (pts) with ER+/HER2- advanced breast cancer (NCT04072952). In xenograft models, vepdegestrant plus the cyclin-dependent kinase (CDK)4/6 inhibitor abemaciclib showed greater tumor growth inhibition vs fulvestrant plus abemaciclib. The open-label, phase 1b/2 TACTIVE-U umbrella study is evaluating the safety, efficacy, and pharmacokinetics (PK) of vepdegestrant in combination with other anticancer treatments in pts with ER+ advanced or metastatic breast cancer. Here, we report preliminary phase 1b results from the ongoing TACTIVE-U sub-study A (NCT05548127) investigating vepdegestrant plus abemaciclib.
Methods: Eligible pts were aged ≥18 years with confirmed ER+/HER2- advanced or metastatic breast cancer and had received up to 2 lines of prior therapy, including a CDK4/6 inhibitor-based regimen in any setting (pts with prior CDK4/6 inhibitor dose reductions due to adverse events [AEs] were excluded). Following a 7-day PK lead-in with abemaciclib administered alone, pts received vepdegestrant 200 mg orally once daily and abemaciclib 150 mg orally twice daily (both continuously). The primary endpoint of the phase 1b portion of the study was dose-limiting toxicities (DLTs) during the first cycle. Secondary endpoints of phase 1b are assessments of safety (type, frequency, and severity of AEs), PK (plasma concentrations of study drugs), and antitumor activity (objective response, clinical benefit rate).
Results: As of April 4, 2024, 16 female pts (median age: 56 years [range: 38–79]) received vepdegestrant plus abemaciclib, with 9 pts treated for ≥5 cycles; 12 remain on treatment. All pts (100%) received prior CDK4/6 inhibitors (ribociclib [n=8], palbociclib [n=7], and abemaciclib [n=1]), 14 (88%) prior aromatase inhibitors, 11 (69%) prior chemotherapy, and 5 (31%) prior fulvestrant. There were no DLTs or treatment discontinuations due to treatment-emergent AEs (TEAEs). TEAEs led to dose reduction of vepdegestrant and abemaciclib in 1 pt (neutropenia) and dose reductions of abemaciclib in 6 pts (fatigue [n=2] and fatigue/muscular weakness, neutropenia, diarrhea, and anemia [n=1 each]). Treatment-related AEs (TRAEs) to either vepdegestrant or abemaciclib that occurred in ≥20% of pts were diarrhea (69%), nausea (44%), fatigue (44%), and decreased appetite (25%). The majority of TRAEs were grade 1/2; grade 3 TRAEs were neutropenia or neutrophil count decreased in 5 pts and fatigue in 2 pts. There were no grade ≥4 TRAEs. Observed PK of vepdegestrant and abemaciclib was consistent with historical data reported in single-agent clinical studies. The exposure of abemaciclib (Cmax and AUCtau) increased slightly (15%

and 13%, respectively) when dosed with vepdegestrant compared with abemaciclib alone. Conclusions: The safety profile of vepdegestrant plus abemaciclib in pts with ER+/HER2- advanced or metastatic breast cancer was generally consistent with the known profiles of each agent, and no DLTs were observed. Neutropenia was manageable with dose modifications. The impact of vepdegestrant on abemaciclib exposure was minor and indicated no significant drug interaction. These data support further evaluation of this combination at the full standard doses of vepdegestrant 200 mg once daily and abemaciclib 150 mg twice daily in the phase 2 portion of this sub-study. Additional ongoing sub-studies for TACTIVE-U are evaluating vepdegestrant plus ribociclib (sub-study B; NCT05573555) and samuraciclib (sub-study C; NCT06125522).

P4-12-04: Real-world effectiveness of palbociclib plus an aromatase inhibitor in HR+/HER2- MBC patients living in disadvantaged neighborhoods

Filipa Lynce, Xianchen Liu, Benjamin Li, Lynn McRoy, Connie Chen, Raymond Liu, Hope S. Rugo

Background: Palbociclib (PAL) in combination with endocrine therapy (ET) has been approved for hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) advanced/metastatic breast cancer (MBC) since February 2025. Despite extensive real-world data in a variety of populations, little is known about the use and effectiveness of PAL combination in MBC patients living in disadvantaged neighborhoods. The current study aimed to compare overall survival (OS) and real-world progression-free survival (rwPFS) of first-line PAL plus an aromatase inhibitor (AI) vs AI alone in HR+/HER2 MBC patients living in disadvantaged neighborhoods in the US.

Methods: This is a retrospective observational study of HR+/HER2- MBC patients in the Flatiron Health longitudinal database. The database contains electronic health records from >280 cancer clinics, representing >3 million actively treated cancer patients in the US. Patients were included in this analysis if they had HR+/HER2- MBC, were ≥18 years, started PAL + AI as first-line therapy between February 2015 and June 2022 (index period), and lived in disadvantaged neighborhoods. Neighborhood disadvantage was measured with the Yost index, a composite measure of neighborhood social economic status. The Yost index score ranges from 1 (the first quintile) to 5 (the fifth quintile), with higher scores indicating higher socioeconomic status of the neighborhoods. Neighborhood disadvantage was defined as a Yost Index score of 1-2. Patients were retrospectively assessed from start of PAL+AI to December 2022 (data cutoff date), death, or last medical activity, whichever came first. OS was defined as months from start of PAL+AI to death. rwPFS was defined as months from start of PAL+AI to death or disease progression, evaluated based on clinical assessment or radiographic scan/biopsy. Stabilized inverse probability of treatment weight (sIPTW) was used to balance baseline demographics and clinical characteristics. 1:1 propensity score matching (PSM) was performed as sensitivity analysis.

Results: Of the 723 patients who were eligible for the analysis, 394 and 329 patients received PAL+AI and AI, respectively. Median follow-up was 27.2 months for PAL+AI and 25.7 months for AI treated patients. Compared with AI group, PAL+AI group was younger (median age 66.0 vs 69.0 years) and had higher proportions of de novo MBC (39.9% vs 24.0%) and lung/liver metastases (32.0% vs 19.8%). After sIPTW, baseline demographic and clinical characteristics were generally well balanced between PAL+AI and AI groups. After sIPTW, median OS was 57.1 (95%CI=47.2-70.8) months in PAL+AI group vs 38.2 (95%CI=29.6-48.0) months in AI group (HR=0.70, 95%CI=0.55-0.90, p =0.0053). Median rwPFS was 19.1 (95%CI = 15.8 – 24.2) months in PAL+AI group and 14.0 (95%CI=10.7-19.7) months in AI group (HR=0.66, 95%CI=0.52-0.84, p =0.0007). Sensitivity analysis with 1:1 PSM showed consistent results.

Conclusions: This real-world data analysis demonstrated that first-line palbociclib plus AI was associated with prolonged OS and rwPFS in HR+/HER2- MBC patients living in disadvantaged neighborhoods. These findings support use of first-line palbociclib in combination with endocrine therapy in this population.

P4-12-05: Prescription patterns and preferences for CDK4/6 inhibitors among oncologists in Latin America

Alejandro Aranda-Gutierrez, Andres Meraz-Brenez, Daniela Vazquez-Juarez, Agatha Reyes Morales, Ahmad Wali Mushtaq, Brizio Moreno-Jaime, Denis U Landaverde, Fernando E. Petracci, Henry Idrobo Quintero, Joel Moreno Ríos, Juan Carlos - Samamé - Pérez Vargas, Victor Acosta Marín, Wiliam Armando Mantilla, Cynthia Villarreal-Garza

Currently, three CDK4/6 inhibitors (abemaciclib, palbociclib, ribociclib) are FDA-approved as first-line agents for the treatment of metastatic breast cancer (MBC). However, no specific recommendations favor one over the others, and usage is variable between oncologists. This study aims to investigate the preferences and prescription patterns of CDK4/6 inhibitors among oncologists in Latin America.
We conducted an online survey targeting Latin American medical oncologists with experience in treating MBC with CDK4/6 inhibitors. The survey was distributed in June 2024 through email lists obtained from the databases of Latin American oncology societies and oncology-focused social media groups. Descriptive statistics were employed to summarize the collected variables.
A total of 116 medical oncologists practicing in 20 Latin American countries completed the online survey. The majority of respondents were from Mexico (45%), followed by Guatemala (11%), Argentina (8%), and Colombia (8%). Regarding their practice scope, 86% of oncologists did not exclusively treat breast cancer, while 14% did. Most oncologists (56%) primarily practiced in public healthcare settings, whereas 41% mainly practiced in private settings.
Ninety-seven oncologists (84%) had used all three approved CDK4/6 inhibitors. When

asked about their general preference, 66 (57%) preferred ribociclib, 35 (30%) preferred abemaciclib, and 15 (13%) preferred palbociclib. This preference was not impacted by country of practice, time practicing oncology, scope of practice, patient workload, or site of primary care.
The main reason for choosing ribociclib was its benefit in overall survival, noted by 77% of respondents. Abemaciclib was mainly favored due to industry-sponsored accessibility programs (62%) and palbociclib was mainly selected due to its price (38%). Regarding specific clinical scenarios, among premenopausal women, ribociclib was selected by 80% of respondents. In cases of visceral disease, visceral crisis, and bone-only disease, ribociclib was chosen by 67%, 66%, and 50% of respondents, respectively. Primary endocrine resistance (47%) and central nervous system disease (53%) were selected as scenarios in which abemaciclib was favored. When managing patients with a history of heart or liver disease, abemaciclib was preferred by 53% and 47%, respectively. Lastly, for geriatric patients and male patients, palbociclib was preferred by 58% and 50%, respectively. Ribociclib emerged as the most favored CDK4/6 inhibitor, followed by abemaciclib and palbociclib, each preferred for specific clinical scenarios. Our findings highlight the importance of overall survival in guiding oncologists' preferences for prescribing CDK4/6 inhibitors. This observation is noteworthy considering that pivotal trials evaluating these agents focused on progression-free survival, with overall survival as a secondary endpoint. This work was conducted on behalf of the Latin American Breast Cancer Association (LABCA).

P4-12-06: Real-world clinical practice PIK3CA mutation testing patterns in patients with hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2+) metastatic breast cancer (mBC)

Leah Park, Di He, Leah Park, Joy Gulla, Clara Chen

Background: With the advent of targeted therapy for PIK3CA-mutated, HR+, HER2− mBC, evidence-based guidelines recommend PIK3CA biomarker testing at initial mBC presentation and at progression on first-line mBC therapy. Real-world information on PIK3CA testing patterns and results may provide insights into unmet testing needs.
METHODS: This retrospective cohort study included US adult patients from the Flatiron Health oncology database who were diagnosed with HR+, HER2− mBC between January 2017 and April 2023, and received any systemic oncologic therapy. Eligible patients were grouped into 3 cohorts according to the year of mBC diagnosis: 2017–2018, 2019–2020, or 2021–2023. Patients were followed through October 2023. PIK3CA testing patterns, timing, biopsy types, and results were assessed. Summary statistics were used to describe baseline characteristics at mBC diagnosis. The Kaplan–Meier method was used to evaluate time from mBC diagnosis to the first PIK3CA test. A multivariate Cox regression analysis was used to identify factors associated with PIK3CA testing.
RESULTS: Of 7,018 eligible patients (median age: 66 y; 53% aged ≥65 y; 99% female), 38% were initially diagnosed with de novo mBC, and 81% were treated at a community practice.

During the study period, 2,903 patients (41%) had undergone PIK3CA testing. In the 2017–2018, 2019–2020, and 2021–2023 cohorts, 6%, 24%, and 33% of patients, respectively, were tested within 6 mo of mBC diagnosis, and the median times to first test were 52.9 mo, 35.0 mo, and 23.0 mo, respectively. Next-generation sequencing (NGS) was the most frequent first test method overall (88%), increasing in use from the 2 earlier cohorts (both 84%) to the 2021–2023 cohort (95%). The next most frequent first test method overall was polymerase chain reaction (8%), followed by other (4%). NGS was the most frequent second/subsequent test method across all cohorts (91%–94%). Of patients who underwent NGS, liquid and tissue biopsies were used in 37% and 63%, respectively, as the first test, and in 55% and 45%, respectively, as the second/subsequent test. The likelihood of PIK3CA testing (all methods) was higher since 2019 vs before 2019 (HR 2.20; 95% CI: 2.02–2.40; p<0.0001); in patients aged <50 y and 50–<65 y, respectively, vs ≥65 y (HR 1.33; 95% CI: 1.19–1.49; p<0.0001; HR 1.36; 95% CI: 1.25–1.48; p<0.0001); in patients with recurrent vs de novo disease (HR 1.28; 95% CI: 1.18–1.38; p<0.0001); in academic vs community practice (HR 1.29; 95% CI: 1.03–1.61; p=0.03); and in the Northeast vs West (HR 1.20; 95% CI: 1.05–1.37; p=0.01). Among tested patients, 43% (1,255/2,903) had a disease-documented PIK3CA mutation, which was more prevalent in patients aged ≥65 y (48%) vs <50 y (36%) or 50–<65 y (44%) and in White vs African American patients (47% [858/1,830] vs 34% [107/314]; p<0.0001).
Conclusions: PIK3CA testing rates have increased over time and the median time to testing relative to mBC diagnosis has decreased in recent years in patients with HR+, HER2− mBC. Testing rates varied by age, de novo vs recurrent disease, geographic region, and practice type, suggesting major differences in practice patterns. The presence of a PIK3CA mutation was more prevalent in patients aged ≥65 y; however, testing rates were significantly lower in these patients, who represent more than half of the HR+, HER2− mBC population, underscoring an unmet need for diagnostic testing in this age group. Given the increasing number of agents that target the PI3K/ATK pathway, increased NGS testing and reduced time to testing may positively affect treatment decisions.

P4-12-07: Cyclin-dependent kinase 4/6 inhibitors dose reduction in patients with endocrine resistant advanced breast cancer experiencing early disease progression

Marcin Kubeczko, Anna Polakiewicz-Gilowska, Konstanty Chomik, Katarzyna Świderska, Marta Mianowska-Malec, Aleksandra Leśniak, Barbarba Łanoszka, Barbara Grandys, Natalya Lisovska, Michał Jarząb

Background. Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) in combination with endocrine therapy represent the gold standard for treating patients with HR-positive/HER2-negative advanced breast cancer. However, endocrine resistance poses a risk factor for early disease progression. Escalating therapy strategies may lead to increased toxicity, resulting in dose reductions and treatment discontinuation. Notably, previous chemotherapy and concurrent radiotherapy are associated with myelotoxicity, which

constitutes the primary adverse event in the majority of patients treated with CDK4/6i. In this study, we aimed to assess the rates of CDK4/6i dose reductions in patients experiencing early disease progression, considering the context of endocrine resistance, prior chemotherapy, and concurrent radiotherapy.
Methods. We conducted a retrospective analysis of patients diagnosed with advanced breast cancer who received CDK4/6 inhibitor (CDK4/6i) treatment at our cancer center between 2018 and 2024.
Results. A total of 491 patients received treatment with CDK4/6 inhibitors (CDK4/6i). Among these patients, 242 required dose reduction due to toxicity. Patients without CDK4/6i dose reduction had a median progression-free survival (PFS) of 23.8 months, compared to 31.6 months for patients with dose reduction (difference not significant, p = 0.19). The 24-month PFS for patients without CDK4/6i dose reduction was 49.8% (95% CI 42.3-57.2%) versus 60.0% (52.8-66.5%) for patients with dose reduction. The median overall survival (OS) in patients without CDK4/6i dose reduction was 39.5 months, compared to 46.5 months for patients with dose reduction (difference not significant, p = 0.77). The 36-month OS for patients without CDK4/6i dose reduction was 56.5% (95% CI 47.2-64.7%) versus 62.7% (54.3-69.9%) for patients with dose reduction. However, in the group of patients diagnosed with early disease progression, defined as progression within 12 months from CDK4/6i commencement, dose reduction rates were significantly lower than in patients with longer response (41% compared to 55.1%, p=0.03). No significant differences in the rates of previous chemotherapy and concurrent radiotherapy were observed between these two groups. Higher rates of endocrine resistance were observed in patients experiencing early disease progression (66.7% of patients compared to 40.2% of patients, p<0.001).
Conclusions. Cyclin-dependent kinase 4/6 inhibitors dose reduction is safe, and treatment with a reduced dose remains efficacious in patients with advanced breast cancer. Lower dose reduction rates were observed in endocrine-resistant patients experiencing early disease progression. Therefore, considering treatment escalation in this population with a worse prognosis may be a feasible approach. However, further studies are necessary to address this specific patient group.

P4-12-09: Cytotoxic treatment and survival after CDK4/6 inhibitors in patients with luminal metastatic breast cancer before the era of antibody-drug-conjugates: Results from the Austrian AGMT_MBC-Registry

Gabriel Rinnerthaler, Simon Peter Gampenrieder, Angelika Pichler, Walter Herz, Renate Pusch, Clemens Dormann, Christoph Suppan, Sonja Heibl, Lukas Scagnetti, Margit Sandholzer, Thomas Winder, August Felix Zabernigg, Clemens Schmitt, Daniel Egle, Christopher Hager, Petra Pichler, Florian Roitner, Johannes Andel, Kathrin Strasser-Weippl, Rupert Bartsch, Vanessa Castagnaviz, Michael Hubalek, Michael Knauer, Christian Fridolin Singer, Richard Greil

Background: The recently published data from the DESTINY-Breast06 trial may lead to the replacement of conventional first-line chemotherapies by the antibody-drug-conjugate (ADC) trastuzumab-deruxtecan (T-DXd) in a relevant proportion of patients with luminal HER2-low or ultra-low metastatic breast cancer (MBC). While T-DXd yielded a clinically relevant improvement in progression-free survival (PFS), the question was raised if the ADC should still be administered preferentially as second cytotoxic treatment line in light of the tolerability profile and the absence of positive overall survival (OS) results. This analysis of the Austrian Study Group of Medical Tumor Therapy (AGMT) MBC-Registry describes the chemotherapy landscape before the availability of ADCs in early treatment lines in patients with luminal HER-negative MBC with a focus on the attrition rate from first- to second treatment line.
Patients and methods: The AGMT_MBC-Registry is a multicenter nationwide ongoing retrospective and prospective registry for MBC patients in Austria. For this analysis patients with known hormone-receptor (HR) and HER2 status, a CDK4-6 inhibitor treatment before the first cytotoxic treatment for MBC were included. Patients with ADC treatment in the cytotoxic first- or second-line were excluded.
Results: As of 26-June-2024, 1,605 patients with luminal HER2-negative MBC were included in the registry. Out of them, 751 fulfilled the conclusion criteria. Overall, 427 patients (57%) were still alive at data cut-off. Nearly half of the patients (46%) had HER2-low disease. CDK4/6 inhibitors were primarily used in first-line (81%), and less frequent in second-line (14%) or later lines (5%). A total of 389 patients (52%) were still on endocrine treatment without any chemotherapy treatment for MBC. Overall, 264 patients (35%), were treated with at least one line of chemotherapy for MBC. In the cytotoxic first-line, most patients received capecitabine (46%; median time to next treatment [TTNT] 8.4 months, 95% CI 7.0-11.0), followed by taxanes (33%; median TTNT 7.9 months, 95% CI 6.3-9.2), and other cytotoxic agents or combination regimens (21%; median TTMT 4.9 months, 95% CI 4.1-7.1). First-line chemotherapy was combined with bevacizumab in 75% of patients. Median overall survival (OS) calculated from the start of the cytotoxic first-line was 17.2 month (95% CI 15.0-20.3). Out of 169 patients who discontinued cytotoxic first-line treatment, 113 patients (67%) started a cytotoxic second-line. The most frequently used agents were taxanes (29%; median TTNT 5.7 months, 95% CI 5.5-8.3), capecitabine (20%, median TTNT 5.4 months, 95% CI 3.2-9.7), eribulin (12%, median TTNT 6.4 months, 95% CI 3.7-9.9) and others (39%, median TTNT 4.8 months, 95% CI 3.7-6.4). Median OS calculated from the start of the cytotoxic second-line was 11.5 (95% CI 9.4-14.0). Bone only-disease was documented in 6% and 4% of patients at the start of cytotoxic first-, and second-line treatment, respectively.
Conclusion: Median OS of patients with luminal HER2-negative MBC commencing first-line chemotherapy after a CDK4/6 inhibitor is relatively short at around 17 months in our real-world data analysis. Furthermore, only two thirds of first-line chemotherapy patients received any further chemotherapy line. This underlines the importance to implement treatments with proven survival benefit as early as possible.

P4-12-10: UNIQUE MECHANISM OF ACTION OF ELACESTRANT SENSITITIZES ESR1-MUTANT BREAST CANCER TO NOVEL THERAPEUTIC COMBINATIONS

Emily Zboril, Julia E. Altman, Rachel K. Myrick, David C. Boyd, Amy L. Olex, Carson J. Walker, J. Chuck Harrell

Estrogen receptor (ER) signaling is the main driver of tumorigenesis in ER+ breast cancers by inducing proliferation and survival through genomic and non-genomic means. Therefore inhibition of ER signaling has been a mainstay of treatment for decades. While primary ER+ breast cancer has a relatively good initial prognosis, ~30% of patients will develop treatment-refractory metastatic disease. In addition, up to 30% of advanced or metastatic tumors will acquire a mutation of ESR1, the gene which encodes ER. These mutations often make tumor cells less responsive to ER-targeting compounds. Elacestrant, a new-generation endocrine therapy, was found to out-perform the standard of care Fulvestrant in the EMERALD clinical trial [NCT03778931], specifically in patients with ESR1-mutant tumors. Preclinical studies have determined Elacestrant is a selective ER degrader, similar to Fulvestrant and it has been postulated that the increase in efficacy is the result of differences in affinity for mutated ER or increased bioavailability of Elacestrant. However, our studies determined that while Elacestrant reduces tumor burden in ESR1-mutant ER+ breast cancer Patient-Derived Xenograft (PDX) models, it does not reduce ER expression. Additionally, cells treated with Elacestrant in vivo demonstrate a unique transcriptomic profile, indicative of ER modulation rather than degradation. Elacestrant similarly reduced tumor burden in PDX models expressing only the wild-type ESR1 allele but exhibited a reduction in ER expression, consistent with previous reports. This suggests that the SERM-phenotype may be restricted to ESR1-mutant cells. High throughput screening of ESR1-mutant models with and without Elacestrant shows potentiation by compounds which target the cell cycle and the PI3K pathway, consistent with current clinical practices. Screening also determined topoisomerase inhibitors and Src family inhibitors to be synergistic with Elacestrant in ER-mutant cells. Ongoing studies include determining the mechanism of action of Elacestrant synergistic combinations and determining the role of SERM activity in treatment response in the metastatic setting.

P4-12-11: Large Oncosomes Loaded with circPEX13 Enhance Osteoclast Differentiation and Facilitate Breast Cancer Bone Metastasis

Jinpeng Luo, Qun Lin, Yu Shi, Zhuxi Duan, Jieer Luo, Ruiyu Hu, Xiaolin Fang, Chang Gong

Breast cancer (BC) demonstrates a pronounced tendency to metastasize to bone, leading to severe skeletal complications and mortality. Currently, early precise diagnosis and individual treatment for BC patients with bone metastasis are lacking in clinical practice. A critical stage in the metastatic process involves the establishment of pre-metastatic niches (PMNs) conducive to tumor cell colonization before clinical metastasis occurs. Tumor-derived extracellular vesicles (EVs) play a pivotal role as key mediators in selectively

modulating the microenvironment of distant organs to generate PMNs that promote organ metastasis. Our research found that BC with bone tropism significantly downregulated BRMS1L, leading to a reduction of its inhibitory effect on EIF4A3, a pre-mRNA splicing factor that promotes pre-mRNAs circularization by directly binding to their flanking regions. We next identified a novel circular RNA, circPEX13, highly enriched in large oncosomes (LOs), atypical large cancer-derived EVs. These LOs significantly supported bone-directed BC cell metastasis by promoting osteolytic PMN formation, which was crucial for facilitating BC cell growth in bone metastasis. Mechanistically, circPEX13 translocated to the nucleus and bound to the promoter region of NFATc1. Concurrently, circPEX13 acted as a sponge for HDAC1, thereby relieving HDAC1-mediated transcriptional repression of NFATc1.Based on these findings, we discovered that treatment with Zotatifin reduced circPEX13 expression and effectively suppressed BC bone metastasis in BC patient-derived xenograft models. In conclusion, these findings unveil a plausible mechanism whereby LOs secreted by bone metastatic BC cells mediate bone tropism by establishing PMNs in bone, and suggest a potential strategy for treating BC patients with bone metastasis.

P4-12-12: Endocrine Therapy with or without Cyclin-dependent Kinase 4/6 Inhibitor for HR-Positive, HER-Negative, advanced breast cancer following progression on a prior CDK4/6 Inhibitor plus Endocrine Therapy: A Systematic Review and Meta-Analysis

Maria Agustina Callizo Bedoya, Esteban Rodriguez, Gharira Batool, Alejandra Cuenca, Lucila Gonzalez Donna, Federico Waisberg, Cinthia Viviana Gauna

Background: The combination of Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) and endocrine therapy (ET) is the standard medical care for patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2–negative (HER2-), advanced breast cancer (ABC). However, no consensus exists regarding a subsequent treatment with CDK4/6i and ET. We conducted a meta-analysis comparing CDK4/6i plus ET versus ET alone in patients who progressed on a prior CDK4/6i plus ET.
Methods: The Medline, Embase, and Cochrane databases, as well as the American Society of Clinical Oncology (ASCO) conference abstracts were scrutinized for randomized, controlled trials comparing maintenance or alternation of CDK4/6i in combination with ET versus ET alone in patients with HR+/HER2-, ABC following progression on a prior CDK4/6i plus ET. The primary outcome was progression-free survival (PFS). The secondary outcome was the overall response rate (ORR). Statistical analysis was performed using Review Manager (Cochrane Collaboration).
Results: Four randomized clinical trials were selected after our search, including 905 patients. The mean age was 57 years, and visceral disease was present in 60.1% of patients. Palbociclib was the most common previous CDK4/6i (82%). There was a statistically significant PFS improvement for CDK4/6i plus ET compared to ET alone (hazard ratio [HR], 0.77 [95% CI, 0.62 to 0.97]; P = 0.03). There were no significant differences in ORR between groups (risk ratio [RR]: 1.61, 95% CI: 0.76 to 3.38, P = 0.21).

Conclusion: CDK4/6i combined with Endocrine Therapy demonstrated significant PFS improvement compared to Endocrine Therapy alone in patients with HR+/HER2-, advanced breast cancer with disease progression on previous CDK4/6i plus ET treatment.

P4-12-13: CDK4/6 inhibitors (iCDK4/6) in breast cancer (BC): Is it possible to predict response?

Lucas Gouvêa, Elizabeth Santana dos Santos, Solange Moraes Sanches, Marcelle Goldner Cesca, Nathália Machado Soldi, Amanda Alencar Cavalcanti Carneiro da Cunha, Victor Gabriel Bertoli, Viviane Primo Basilio de Souza, Vladmir Cláudio Cordeiro de Lima, Jeniffer Johana Duarte Sanchez, Eduardda Beatryz Silva

Background: Up to 20% of luminal BC patients presents recurrent disease in the first 10 years. The development of iCDK4/6 has changed treatment paradigms because of their significant improvement in treatment outcomes. Despite extensive translational research developed until now, no predictive biomarker has been identified so far. There is also a lack of evidence for iCDK4/6 efficacy in specific populations (such patients carrying pathogenic germline) and situations (as treatment sequencing, combinatorial strategies, and the role of post-iCDK4/6 therapy).
Methods: We performed a retrospective study of luminal BC patients treated with 3 available iCDK4/6 (abemaciclibe AB, Ribociclib RIB and Palbociclib Pb) between 2018 to 2024, with the aim of reviewing clinical, histological, and genomic profile searching for predictive variables of better responses
Results: A total of 383 patients were included. The median age of patients was 60 years old. 38% were pre-menopausal women. Median PFS and OS were 30 months (m) and 56m, respectively.The majority(65%) of patients received iCDK4/6 in the first line (1L), 15% in the 2nd line (2L), 20% in subsequent lines of treatment. PFS and OS and progressively declined in subsequent lines- 1L: 36/62m; 2L: 22/52m, others 14/33m (p<0,01).
There was no difference in PFS (p0.96) or OS (p=0,42) between iCDKs (AB 24/43m, RIB 25/45m, PB 27/45m). Patients with visceral metastasis presented worse PFS/OS (respectively, 28vs32m, p0,009 ;and 49 vs 60m, P=0,01). A higher Ki67 (>70%) was predcitive of worse outcome (PFS 15 vs 29 m p 0,009 / OS 34 vs 56m p0,017). Her2 low tumors perfomed as well as tumors with no Her2 expression (p=0,48).
Among 92 who underwent germline testing, 13 patients had a BRCA mutation(mt). There was no statistical difference in PFS (p 0.41) and OS P0,027 for this group. 129 patients underwent PIK3CA somatic sequencing (38% presented a PIK3CAmt). The PFS and cumulative OS rate were worse in PIK3CAmt patients (PFS 23x32m, p0,096 and OS 54 vs 57m, p 0.005).
Conclusion: highlighted variables with potential predictors of response to iCDK4/6. These data can serve as generators of hypotheses that must be validated in a larger cohort.

P4-12-14: Updated efficacy and safety of CDK4/6 inhibitors plus endocrine therapies in elderly HR+/HER2- metastatic or advanced breast cancer: patient-level network meta-analysis

Yun-Sheng Tai, Henry, WC Leung, Shyh-Yau Wang

Background: Breast cancer (BC) is the most common cancer in women worldwide. More than 80% of invasive BCs cases are newly diagnosed among women aged 50 years or older, and mainly present with an estrogen receptor ER-positive and HER2-negative subtype disease. About 91% of deaths occur in this age population. Cyclin-dependent kinase 4/6 (CDK4/6) inhibitors showed a significant increased survival benefits in terms of progression-free survival and overall survival (OS), but the evidence on treating older women with metastatic BC is limited. Therefore, we comprehensively evaluated the efficacy and safety of cyclin-dependent kinase 4/6 (CDK4/6) inhibitors combined with endocrine therapy (ET) in older women with HR+/HER2- metastatic or advanced BC.Methods: We comprehensive search on PubMed and EMBASE database from Jan 2018 to Dec 2024 for phase II or III randomized controlled trials (RCTs) investigating modality treatments for HR+/HER2- metastatic or advanced BC. Kaplan–Meier curves for progression-free survival (PFS) and overall survival (OS) were reconstructed to retrieve individual patient-level data to strengthen the comparison of the benefits of all modality treatments of interest. Each study was pooled in a fixed-effects or randomized-effects model based on the individual study quality in this network meta-analysis (NMA). We also performed a subgroup analysis and reported the incidence of ≧grade 3 adverse events in elderly patients (≧65 years). The primary endpoint was pooled PFS, OS and the comparable safety. The modality treatments were ranked using SUCRA scores.Results: We identified 10 phase II and III randomized controlled trials with 7 modality treatments that met the inclusion criteria. Among them, 1823 patients with PFS and 2132 patients with OS results were included in the analysis. In terms of PFS, ribociclib+letrozole (Let) ranked highest among all other treatment modalities, followed by palbociclib+fulvestrant(ful). For OS, palbociclib plus ful is the best treatment compared to other treatment options of interest. The ranking probabilities of palcociclib plus fulvestrant (97.52%) and ribociclib plus let had the highest probability of achieving superior OS and PFS (90.89%) for elderly women with mBC. In terms of safety, palbociclib plus endocrine (letrozole or fulvestrant) (55.7%), abemaciclib plus letrozole or fulvestrant (28.7%) were associated with relatively high ≧grade 3 adverse events (AE) compared to placebo plus endocrine therapy. Ribociclib plus Let (15.2%) had a relatively lower rate of ≧ grade 3 adverse events (AEs) than the other two CDK4/6 inhibitors.Conclusion: Ribociclib plus letrozole is considered effective for PFS and a relatively safe treatment option for older women with HR+/HER2- subtype metastatic or advanced BC. However, given the limited reliable evidence, comprehensive and well-designed randomized controlled trials with a large sample size are needed to confirm our results. KEYWORDS: Breast cancer, elderly patients , Abemaciclib, Ribociclib, Palbociclib, Network meta-analysis.

P4-12-15: Key Factors Affecting Clinical Investigators Use of Oral SERDs in Current Management of ER-Positive, HER2-Negative, ESR1-Mutated (ER+/HER2-/ESR1+) Metastatic Breast Cancer That Has Relapsed After Treatment w/ a CDK4/6 Inhibitor/Endocrine Therapy

Doug Paley, Taylor Wallace, Kathryn Ziel PhD, Komal Jhaveri, Trenton Cruse, Leijah Petelka, Kirsten Miller, Neil Love

Background: The January 2023 FDA approval of the novel SERD elacestrant (E) provided an important new therapeutic consideration for patients with relapsed ER+/HER2-/ESR1+ metastatic BC. More so, a host of promising data sets and ongoing studies evaluating this agent and others in the class suggest that SERDs will continue to play an important role in the disease. Relevantly, it is poorly understood how E is currently being employed in the clinic and for which types of patients clinicians favor or avoid this agent versus other available treatments.
Methods: In February 2024, 20 US-based and international CIs with a specialized interest in BC management were recruited from a proprietary database to complete a case-based survey focused on their approach to treatment for ER+/HER2-/ESR1+ advanced BC that has relapsed following treatment with a CDKi/ET in various types of patients. A modest honorarium was offered for participation. For each case question one or more variables (eg, age, time on CDKi, PIK3CA mutation status, site/extent of metastases) were altered. A number of other general queries about available and investigational SERDs were also included.
Results: For a 65-year-old woman with ER+/HER2-/ESR1+ BC who experiences a recurrence of minimally symptomatic bone metastases 18 months after treatment with CDKi/fulvestrant (ful), 19 of 20 CIs would recommend E. When the duration of benefit from the CDKi/ful was reduced to 12 months, 17 of 20 CIs continued to favor the SERD. However, when the duration was further reduced to 6 months, only 4 of the CIs selected E as their preferred approach.
Similarly, for a 65-year-old woman with ER+/HER2-/ESR1+ BC who also has a PIK3CA mutation and experiences a recurrence of minimally symptomatic bone metastases 18 months after treatment with a CDKi/ful, CIs were largely split between E (10) and capivasertib (capi)/ET (7). Again, when the duration of benefit from the CDKi/ful was reduced to 6 months, the CIs decreased their utilization of E and, in fact, none selected that agent. However, when the patient's age was increased to 80 years and the duration of CDKi benefit was maintained at 18 months, more CIs (12) selected E and fewer (4) favored capi/ET.
In terms of perspectives on the investigational SERDs imlunestrant and camizestrant, at the current time, CIs largely view their efficacy and tolerability to be similar to that of E or they are unable to make distinctions in this regard based on available data and experience.
Conclusions: CIs have rapidly incorporated oral SERDs into their current management algorithms for patients with relapsed ER+/HER2-/ESR1+ advanced BC. However, short duration of benefit from prior CDKi/ET and the presence of PIK3CA mutations appear to

decrease utilization, in some instances significantly, whereas older age may increase the use of these agents. Additional and expanded efforts are needed to further validate how CIs are employing SERDs in their practices and better understand the impact of various clinical factors as well as new research findings (eg, postMONARCH) on current treatment patterns.

P4-12-16: Identification of CGT4255 an EGFR sparing, ErbB2 clinical development candidate with activity across activating mutations in systemic and CNS tumors

Mark J. Chicarelli, Tanna Bettendorf, Abiezer Blandon, Karyn Bouhana, Richard K. Brizendine, LouAnn Cable, Michelle Crow, Brad Fell, John Fischer, Jennifer Fulton, Anna Guarnieri, Madison Hillman, Ravi Jalluri, Vijay Kumar, Cori A. Malinky, Rob Rieger, John Robinson, Lee Stunkard, Francis Sullivan, John I. Trujillo, Logan E. Vine, Shannon Winski, Yeyun Zhou

Alterations in ErbB2, including amplification, overexpression, insertions, and point mutations, are established oncogenic drivers in many solid tumors. These mutations are found in approximately 3–4% of breast cancers and 3% of advanced lung cancers and have emerged as mechanisms of acquired resistance to targeted therapies. ErbB2 alterations are also found in metastatic breast and lung cancers that have advanced to the brain and remain a major clinical challenge with limited therapeutic options. Current approved ErbB2 tyrosine kinase inhibitors have inferior potency against these mutations and lack sufficient brain penetration to be an impactful treatment option for patients. Herein, we describe advanced preclinical profiling of our EGFR-sparing, ErbB2 inhibitor clinical development candidate CGT4255 with best-in-class brain penetrance and activity against prevalent mutations.

P4-12-17: Pre-clinical data and phase I design for PQ-203: a novel peptide-drug conjugate (PDC) targeting the SORT1 receptor in hormone receptor "Triple" Negative Breast Cancer (TNBC)

Francine Lui, Andrew Zhai, Sungwon Hwang, Mitchell Elliott, Lucas Siow, Edward Garmey, David Cescon, David White

Background: Hormone Receptor “Triple” Negative Breast Cancer (TNBC) is an aggressive subtype of breast cancer with limited treatment options. Sortilin (SORT1) is a cell surface receptor involved in protein trafficking and cell signaling that is overexpressed in TNBC, making it a promising therapeutic target. We designed a novel peptide-drug conjugate, PQ-203, to selectively bind SORT1 with high affinity and deliver the cytotoxic agent MMAE directly to TNBC cells.
Methods: Here we demonstrate efficacy in pre-clinical models resistant to TOPO1-targeted ADCs as well as preliminary safety results and a human phase I study design. Binding affinity and internalization assays were performed to confirm the interaction between PQ-

203 and SORT1. The efficacy and specificity of PQ-203 were evaluated in vitro and in vivo using TNBC xenograft models. Preclinical pharmacokinetic (PK) and toxicity studies were performed to determine the safety profile of PQ203.
Results: PQ203 demonstrates high binding affinity and selectivity to SORT1. In vivo xenograft models demonstrate activity compared to sacituzumab govitecan (Trodelvy) and other biologic controls. In vivo studies reveal that PQ203 effectively reduces tumor growth in TNBC xenograft models with minimal systemic toxicity observed. Pharmacokinetic characterization of PQ203 reveals rapid clearance from plasma with corresponding sustained delivery of MMAE to tumors, highlighting a potential differentiation from MMAE-conjugated antibody drug conjugates (ADCs) that have relatively longer systemic exposures. Pre-clinical safety studies confirm that PQ203 is well tolerated in rodent and non-rodent species.
Conclusions: PQ203 exhibits promising pre-clinical efficacy and safety in targeting SORT1-positive TNBC. These findings support the initiation of a phase I clinical trial to evaluate the safety, tolerability, and preliminary efficacy of PQ203 in human cancer patients. The phase I study will follow a Bayesian Optimal Interval (BOIN) dose-escalation design, aiming to establish the maximum tolerated dose (MTD) / biologically optimal dose and to assess preliminary anti-cancer activity. Future studies will explore the potential of PQ203 as a targeted therapy for TNBC and to address the urgent unmet need for effective treatments in this challenging patient population.

P4-12-18: Discovery and characterization of ETX-636, a potential best-in-class, oral, small molecule, pan-mutant-selective PI3Kα inhibitor

Robert Koncar, Mingzong Li, Jingyan Gao, Fei Pang, Ying Lin, Raj Nagaraja, Yong Tang, Hannah Szeto, Zipeng Fan, Karan Kapoor, Robbie Chen, Eric Simone, Minghong Hao, Shengfang Jin, Tao Liu, Tai Wong, Meghana Kulkarni, Jeffery Kutok

PIK3CA, which encodes p110α, the catalytic subunit of phosphatidylinositol 3-kinase alpha (PI3Kα), is one of the most frequently mutated oncogenes, with activating mutations seen in ~16% of all solid tumors and up to 40% of breast tumors, including hormone receptor-positive/HER2-negative, advanced breast cancer. The most frequent gain-of-function PI3Kα hotspot mutations, H1047R, E542K, and E545K, are well-recognized oncogenic drivers. Cancer cells with PIK3CA activating mutations are dependent on PI3Kα signaling and HR-positive, HER2-negative breast cancer patients with PIK3CA mutations respond to alpelisib, an approved PI3Kα inhibitor. While PI3Kα is important for cancer cell proliferation and tumor growth, it is also a critical component of the insulin signaling pathway. Therefore, the use of orthosteric inhibitors like alpelisib, which inhibit both the wildtype and mutant proteins, often results in significant hyperglycemia limiting their clinical utility. We report the discovery and pre-clinical characterization of an allosteric, pan-mutant-selective PI3Kα inhibitor, ETX-636, which was designed leveraging our Kinetic Ensemble® platform for optimal binding properties. Compared to other allosteric, pan-mutant-selective PI3Kα inhibitors (ie RLY-2608 and STX-478), ETX-636 has stronger target

binding affinity, better on-target potency in biochemical and cellular pharmacodynamic and viability assays, and demonstrates superior anti-tumor activity in vivo. More specifically, ETX-636 inhibits both kinase (H1047X) and helical domain (E542K and E545K) mutant PI3Kα biochemical activity with single digit nM potency and 8-10-fold selectivity relative to wildtype PI3Kα protein. ETX-636 shows greater than 1000-fold selectivity over the β, δ, and γ class I PI3K isoforms in biochemical assays and the selectivity extends more broadly across a panel of ~350 kinases. In cellular assays, ETX-636 potently inhibits proliferation and PI3Kα signaling specifically in PIK3CA-mutant cell lines. Mechanistically, ETX-636 induces proteasome-dependent degradation of mutant p110α protein in vitro and in vivo. Consistent with the compound-mediated decrease of mutant p110α protein and the high binding affinity (slow off-rate) of the compound, ETX-636 achieves sustained PI3Kα pathway inhibition in cellular washout assays and in cell-derived xenograft (CDX) tumor models. Once daily, oral dosing of ETX-636 shows single agent efficacy at well-tolerated doses in both PI3Kα kinase and helical domain-mutant breast cancer CDX models, significantly inhibiting tumor growth or inducing regression, while suppressing PI3K pathway activity in a dose-dependent manner. In an ER-positive, HER2-negative, PI3Kα-mutant breast cancer xenograft model, ETX-636 is efficacious as a single agent and shows enhanced activity in combination with fulvestrant, inducing consistent tumor regression while being well-tolerated. ETX-636 demonstrates superior magnitude and duration of PI3Kα pathway inhibition in vivo, compared to known pan-mutant-selective allosteric PI3Kα inhibitors, as well as orthosteric inhibitors. At efficacious doses, ETX-636 has significantly less of an effect on blood glucose in mice compared to orthosteric inhibitors, demonstrating that ETX-636 can achieve potent anti-tumor activity by targeting mutant PI3Kα protein without significantly affecting the activity of the wildtype protein. In addition, based on pharmacokinetic/pharmacodynamic/efficacy and toxicology studies, ETX-636 is unlikely to pose a significant risk of hyperglycemia at predicted human efficacious doses. These data support clinical exploration of ETX-636 in mutant PI3Kα solid tumors and, potentially, mutant PI3Kα-driven rare diseases.

P4-12-19: Preclinical Characterization of a Novel PI3Kα H1047R Mutant-Selective Inhibitor

Aaron C. Smith, Ben Arwood-Levine, Abiezer Blandon, Alexandra Born, Richard Brizendine, Payal Chatterjee, Mark J. Chicarelli, Michael L. Conner, Brad Fell, Jennifer Fulton, Anna Guarnieri, Hannah Hubert, Ravi Jalluri, Hailey J. Knox, Keith Koch, Daniel Krischlunas, Vijay Kumar, Sara Kuzbiel, Colin McHugh, Brent Mclean, Kelsey W. Nassar, Brad Newhouse, Scott Niman, Rob Rieger, John Robinson, Marelí Rodriguez, Leah Salituro, Vincent Scarato, Lee Stunkard, Francis Sullivan, Patrick Sutter, Roy Turton, Robb Van Gulick, Brooklynn Venteicher, Logan E. Vine, Shannon Winski, Yeyun Zhou

PIK3CA encodes the p110α catalytic subunit of PI3-kinase alpha (PI3Kα) and is the most frequently mutated kinase in human cancer with common mutations occurring in the kinase domain (H1047R) and helical domain (E542K/E545K). The approved PI3Kα inhibitor,

alpelisib, shows promise for this targeted class of agents with improvements in progression-free survival in ER+/Her2- breast cancer patients in combination with fulvestrant. However, toxicities attributed to the inhibition of wild-type PI3Kα, such as hyperglycemia, gastrointestinal issues, and skin reactions, lead to sub-optimal target engagement due to requisite dosing modifications. A PI3K mutant inhibitor that spares WT PI3K is predicted to be better tolerated, require fewer dosing modifications, and therefore, have the potential to provide improved clinical benefit. Herein, we present the preclinical in vitro and in vivo activity of a novel, wild type sparing PI3Kα inhibitor series which is potent against the oncogenic H1047R mutation.

P4-12-20: OKI-219 enhances activity of SOC therapies in double and triple combinations in pre-clinical PI3Kα H1047R mutant breast cancer models

Molly Taylor, Maria Hoh, Qian Zhao, David A. Mareska, Mark L. Boys, Yevgeniy Izrayelit, Richard Woessner, Duncan Walker, James D. Winkler, Sam Agresta

Phosphoinositide 3-kinase alpha (PI3Kα) H1047R mutations are found in approximately 15% of breast cancers and lead to constitutive activation of the PI3K/AKT/mTOR signaling pathway. Targeting PI3Kα in cancer is a therapeutically proven strategy, with the approved drug alpelisib showing clinical activity alone and in combination with other therapies. However, non-mutant selective inhibitors of PI3Kα are associated with significant toxicities, such as hyperglycemia, rash, and diarrhea, due to on-target inhibition of the wild-type enzyme. OKI-219 is an orally bioavailable and brain penetrant PI3KαH1047R mutant-selective inhibitor with greater than 100-fold selectivity for the H1047R mutation over wild-type PI3Kα.

We have previously demonstrated that OKI-219 shows robust antitumor activity both as a single agent and in combination with SERDs or HER2-targeted agents in models of PI3KαH1047R-mutated cancer. Notably in these studies, no changes in insulin or glucose are observed, supporting the potential for OKI-219 to achieve therapeutically active exposures in the absence of on-target toxicity.

CDK4/6 inhibitors in combination with ER-targeted agents are a mainstay of the treatment of HR+ breast cancer, where activation of PI3Kα signaling is associated with a poorer outcome. We investigated the impact of combining OKI-219 with CDK4/6 inhibitors and endocrine agents in PI3KαH1047R-mutated models. In vitro, in the T47D ER+, PI3KαH1047R model, the combination activity of OKI-219 + fulvestrant + ribociclib or palbociclib was assessed in proliferation assays and evaluated for synergy using the Loewe additivity model. The triple combinations compared to doublet showed a synergistic effect. In the xxT47D xenograft model in vivo, we show that the addition of OKI-219 to standard of care therapies, such as fulvestrant and fulvestrant + a CDK4/6 inhibitor drives enhanced tumor regression beyond that seen with SOC agents alone. Importantly, in tumors that had progressed on alpelisib or alpelisib + fulvestrant, the replacement of alpelisib with OKI-219 drove tumor regression. Similarly, adding OKI-219 to tumors that progressed on ribociclib + fulvestrant drove tumor regressions. These results show that pre-clinically, OKI-219 can

restore antitumor activity in models that are resistant to alpelisib and other SOC therapies. Combining PI3K inhibition with SERDs and CDK4/6 inhibitors offers a rational strategy to overcome resistance and enhance antitumor efficacy. The data presented here supports the combination of OKI-219 with SERDs and CDK4/6 inhibitors as a promising therapeutic strategy for ER+ breast cancer, including in cancers that have progressed on prior PI3K inhibitors. These preclinical studies provide compelling evidence of synergistic antitumor effects and lay the groundwork for ongoing clinical trials. OKI-219 is being investigated clinically in the PIKture-01 study, a First-in-Human Study of OKI-219 in Advanced Solid Tumors and Advanced Breast Cancer (NCT06239467).

P4-12-21: Efficacy and Safety of MRG002 in Prior TKI-Treated HER2 Positive Breast Cancer Patients: A Single Arm, Open Label, Multicenter, Phase II Study

Qiang Liu, Shaohua Zhang, Yaping Yang, Quchang Ouyang, Tao Sun, Yongsheng Wang, Min Yan, Yongmei Yin, Xiaoyu Liu, Shusen Wang, Xinhong Wu, Qingyuan Zhang, Changlu Hu, Hui Li, Wei Li, Fuming Qiu, Jun Qian, Li Sun, Xiaojia Wang, Zefei Jiang

Background: Human epidermal growth factor receptor 2 (HER2) positive breast cancer represented approximately 15%-20% of all breast cancers. Liver metastasis was commonly observed in patients treated with trastuzumab and tyrosine kinase inhibitor (TKI), thereby further reducing the overall survival to only 8-14 months. MRG002 is a novel antibody-drug conjugate composed of recombinant humanized anti-HER2 monoclonal antibody MAB802 and potent cytotoxic small molecule MMAE linked by the vc-linker. This study was designed to evaluate the efficacy and safety of MRG002 in liver metastases breast cancer patients after the treatment failure of trastuzumab and TKI.
Method: This single-armed, open-label, multicenter, phase II study enrolled patients who had received ≥2 lines of anti-HER2 treatment (including trastuzumab and TKI) and had confirmed tumor progression during or after the most recent treatment. MRG002 was administered at a dose of 2.6 mg/kg every 3 weeks until the end of treatment, initiation of new anti-tumor therapy, withdrawal of informed consent, or death.
Result: A total of 102 females were enrolled in this study, with a median age of 53 years (range: 26-73). Forty-four patients had an ECOG score of 0, and 58 scored 1. Forty-one patients (40.2%) were immunohistochemistry (IHC) 3+, and 61 (59.8%) were IHC 2+/ISH+. All patients had liver metastasis, 55 (53.9%) had bone metastasis, and 37 (36.3%) had lung metastasis. All patients had received HER2-mAb and anti-HER2-TKI drug treatment (Pyrotinib 94 cases, 92.2%). The median treatment line was 3 (range: 2-10), wherein 39 patients (38.2%) received two treatment lines, 28 (27.5%) received three, and 35 (34.3%) received ≥ four lines.
As of July 19, 2024, the median follow-up time was 14.8 months (range: 0.4-27.2), and 7 patients (6.9%) had a treatment duration of nearly 2 years. The Independent Review Committee (IRC) evaluated the objective response rate (ORR) based on RECIST v1.1 as 60.8% (95% CI: 50.6-70.3), the disease control rate (DCR) as 86.3% (95% CI: 78.0-92.3), the

median progression-free survival (mPFS) as 8.6 months (95% CI: 6.9-11.9), and the median duration of response (mDoR) as 9.4 months (95% CI: 6.2-16.8). The investigator assessed the ORR as 56.9% (95% CI: 46.7-66.6), the mPFS as 7.5 months (95% CI: 5.7-8.0), and the mDoR as 6.8 months (95% CI: 6.0-8.9). Subgroup analysis showed that the ORR of IHC 3+ and IHC 2+/FISH+ patients were 70.0% and 60.7%, respectively. The mPFS were 11.9 months and 7.7 months, respectively.
The most common treatment-related adverse events (TRAEs) included 70.6% white blood cell count decreased, 64.7% neutrophil count decreased, 62.7% AST increased, and 54.9% ALT increased. TRAEs were mainly Grade 1-2 and recovered after treatment. TRAEs ≥ Grade 3 included 31.4% neutrophil count decreased, 13.7% white blood cell count decreased, and 6.9% peripheral neuropathy. No new safety signals were found, and the adverse events were manageable.
Conclusion: MRG002 showed a potential efficacy in trastuzumab and anti-HER2-TKI treatment failed HER2-positive liver metastasis breast cancer patients with a good tolerance and safety profile. The emergence of MRG002 presented a promising treatment option for patients.
Clinical trial information: NCT05263869

P4-12-22: Ergosterol Peroxide affects the VCP/ANKZF1 complex spatial relationship and interaction in IBC cells

Luz V. Arroyo-Cruz, Adriana Y. Aponte-Ramos, Michelle M. Martínez-Montemayor

Inflammatory breast cancer (IBC) is a highly aggressive and lethal type of breast cancer. Furthermore, patients with the triple-negative breast cancer subtype have tumors that lack the estrogen receptor, progesterone receptor, and HER2 expression. These tumors display greater invasiveness, and consequently, patients exhibit increased metastasis. Due to the lack of targeted therapies, IBC patients typically undergo multimodality therapy with cytotoxic chemotherapy like taxanes and anthracyclines, radiation, and surgery. There is an urgent need for selective therapies for IBC and natural products have gained significant attention for their potential in breast cancer therapy. In our laboratory, we work with Ergosterol Peroxide (EP), a bioactive compound extracted from the Ganoderma lucidum mushroom. Our studies indicate that EP is a unique endoperoxide that upon entrance into the cancerous cell, deploys its warhead via selective interactions with intracellular proteins, without any effect in non-cancerous cells. The Valosin-containing protein (VCP) / Ankyrin repeat and zinc finger domain-containing protein 1 (ANKZF1) complex plays a vital role in maintaining cellular proteostasis and ensuring proper protein synthesis and degradation processes. ANKZF1 interacts with VCP and translocates to the mitochondria under cellular stress conditions. We believe that EP affects this complex to induce cancer cell death. We hypothesize that EP targets the VCP/ANKZF1 complex, impairing the ability of IBC cells to clear damaged proteins and causing mitochondria dysfunction to induce IBC cell death. To validate the interruption of VCP/ANKZF1 interactions, we used Proximity Ligation Assays (PLA) with antibodies for VCP and ANKZF1 in the IBC cell model, SUM149. Veh, EP, and NMS

873 (VCP inhibitor, positive control) were administered, to detect changes in PLA signals for VCP and ANKZF1. To understand the VCP/ANKZF1 spatial relationship, under Veh, EP, and H2O2 (positive control) effects in SUM149, we used a colocalization analysis by Immunocytochemistry (ICC). Results were visualized with Gen 5 Image Prime 3.15 program in Cytation C10 Confocal Imaging Reader. The PLA preliminary results indicate that EP affects protein-protein interactions, since the intensity of green fluorescence, which indicates protein activity, is lower in the treated cells. Especially when compared to the positive control - NMS 873 the protein inhibitor. The preliminary results of ICC demonstrated that when SUM149 cells are treated with EP compound, VCP displays greater fluorescence intensity, while ANKZF1 fluorescence is diminished. In addition, cells treated with EP display a nucleus with greater size when compared to the Veh. Furthermore, ANKZF1 looks to be co-localizing with the nucleus, while VCP has an around and near localization of the nuclei when compared with the Veh. In general, EP affects VCP/ANKZF1 spatial relationship and interaction in IBC cells. Further research is needed to comprehensively understand the intricate mechanisms through which EP exerts its antineoplastic effects in IBC cells.

P4-12-23: Z-Endoxifen-PROTAC, a novel drug for chemo-sensitive and-resistant Triple Negative Breast Cancer.

Swaathi Jayaraman, Sayantani Sarkar Bhattacharya, Thomas Caulfield, Stephanie L. Safgren, Sarah A. Buhrow, Joel M. Reid, Mary J. Kuffel, Jasmine K. Farmakes, Akhilesh Pandey, James N. Ingle, Matthew M. Ames, John R. Hawse, Matthew J. Schellenberg, Matthew P. Goetz

Background: In the estrogen receptor positive (ER+) breast cancer, the tamoxifen metabolite Z-endoxifen (ENDX) potently inhibits ERα and partially degrades protein kinase C beta I (PKCβI) resulting in suppression of AKT signaling and the induction of apoptosis (Jayaraman et al, NPJ Breast Cancer, 2023). Intriguingly, at higher concentrations (5 μM and higher), ENDX inhibits the viability of triple negative breast cancer (TNBC) cells and multiple non-breast cancer and ER- cell line models. We thus surmised that ENDX may elicit its anti-cancer activity through mechanisms extending beyond inhibition of ER and PKCβI, and that development of more potent ENDX derivatives would extend the clinical utility of this molecule. Therefore, we developed a series of chemically synthesized ENDX-PROTAC (EPrC) compounds with ENDX as the warhead and cereblon (CRBN) as the E3 ubiquitin ligase recruitment moiety with the expectation that degradation of ENDX targets would elicit more potent anti-cancer activity at lower concentrations.

Methods: We characterized the anti-cancer activity of multiple EPrC compounds using multiple ER+ and TNBC cell line models and performed a series of unbiased approaches to identify novel proteins for which ENDX is a substrate.

Results: Initial studies in ER+/HER2- breast cancer cell lines showed that EPrC's resulted in no greater anti-cancer effects compared to ENDX. However, three EPrC's (EPrC 7-9)

exhibited profound anti-cancer activity at nanomolar concentrations in chemosensitive (MDAMB231, BT549, MDAMB436 and MDAMB468) as well as chemoresistant (doxorubicin-resistant and paclitaxel-resistant MDAMB231) TNBC cells. Conversely, ENDX had little activity in these models even at 5 μM concentrations. The potent anti-cancer activity of EPrC 7-9 also extended to chemoresistant TNBC patient-derived organoid (PDO) models. In contrast, EPrC 7-9 displayed no effects on proliferation or apoptosis in the non-malignant MCF10A breast epithelial cell line. We further evaluated the anti-cancer activity of EPrC's and ENDX using the NCI-60 human cancer cell line panel where broad anticancer activity was additionally observed in leukemia, lung, melanoma, and ovarian cancer cells. Mechanistically, EPrC 7-9 activity was independent of PKCβ1 expression/targeting. Therefore, we performed an unbiased SILAC and TMT-based mass spectrometry (MS) analysis utilizing MDAMB231 and MCF10A cells to identify EPrC target proteins that are ubiquitinated and degraded in MDAMB231 cells but not MCF10A cells. One of the top hits from this screen was G to S phase protein 1 (GSPT1), a conserved protein that regulates protein translation termination. We validated GSPT1 as a bona fide and rapidly targeted protein by EPrC's with near complete GSPT1 elimination occurring within four hours of treatment. The necessity of EPrC-mediated GSPT1 degradation to the anti-cancer activity of these molecules was confirmed using CRBN knockout MDAMB231 cells where EPrC 7-9 completely failed to inhibit cell proliferation, induce apoptosis, or alter GSPT1 protein levels.

Conclusion: Taken together, we have developed a new class of PROTAC drugs with ENDX as the warhead, which display potent anti-cancer activity in chemosensitive and chemoresistant models of TNBC, as well as non-breast cancer cell lines, and implicate GSPT1 as a novel and direct target of ENDX. Efforts are ongoing to elucidate the structural basis of EPrC-GSPT1 interaction, to assess GSPT1's contribution to EPrC activity and to study the pharmacology, toxicity, and in vivo antitumor activity of these molecules.

P4-12-24: Preclinical characterization of LY4045004, a next-generation, mutant-selective PI3Kα inhibitor

Raymond Gilmour, Andrew L. Faber, Weihua Shen, Harold B. Brooks, Lisa J. Kindler, Sarah M. Bogner, Loredana Puca, Viviana Volta, Michele Dowless, Jennifer R. Stephens, Anke Klippel, Rui Wang, Divya Ramchandani, Parisa Zolfaghari, Kannan Karukurichi, Alex Gousie, Robert Bondi, Gereint Sis, Ross Wallace, Ronee Baracani, Nathan Wright, Gabrielle Kolakowski, Laurie LeBrun, Steven W. Andrews

Introduction: PI3Kα mutations are oncogenic drivers found in approximately 40% of HR+ breast cancers as well as multiple other solid tumors. Approved treatments for PI3Kα mutant-driven HR+ breast cancers include direct inhibitors of either PIK3CA or downstream AKT. However, these inhibitors block PI3K pathway signaling in unmutated host tissues resulting in hyperglycemia, rash, and GI toxicity. Herein we describe the preclinical profile of LY4045004, a next-generation, mutant-selective inhibitor of PI3Kα.

The compound exhibits potent inhibition across the most common PI3Kα mutations in breast cancer (H1047R, E545K, and E542K) while sparing wild type (WT) PI3Kα. Strong efficacy in multiple PI3Kα-mutant breast cancer models is demonstrated while avoiding the hyperglycemia and insulin increases characteristic of non-selective inhibitors.
Methods: PI3Kα biochemical potency was measured using ADP Glo kinase assay. PI3Kα on-rate and off-rate were measured using Transcreener FI assay. PI3Kα cell potency was measured using cell viability and signal transduction assays. Tumor growth inhibition, pharmacokinetic (PK), and pharmacodynamic effects were assessed in in vivo studies using PI3Kα mutant cell-derived xenograft (CDX) and patient-derived xenograft (PDX)-models. Plasma insulin and C-peptide levels were measured using ELISA.
Results: LY4045004 is a potent, allosteric inhibitor of both kinase and helical PI3Kα mutations in enzyme and cell-based assays, inhibiting growth and signaling responses in multiple mutant-driven breast cancer cell lines. The compound is selective for mutant PI3Kα over WT PI3Kα in both enzyme and cell-based assays and exhibits a very slow off-rate from PI3Kα. LY4045004 demonstrates favorable in vitro ADME properties and excellent PK with high oral bioavailability across preclinical species. In vivo, orally administered LY4045004 demonstrated dose-dependent tumor regressions in PI3Kα H1047R-driven and E545K-driven breast cancer models both as monotherapy and in combination with fulvestrant without inducing hyperglycemia (no significant increase in insulin or C-peptide) or body weight change. Tumor pharmacodynamic analyses confirmed strong pathway inhibition at doses that caused regressions. Additionally, LY4045004 demonstrated tumor regressions in PI3Kα H1047R and E545K PDX models. LY4045004 was well-tolerated at efficacious doses in mice both as a single agent and in combination, and well-tolerated in rat, dog, and cynomolgus monkey toxicology studies.
Conclusions: The favorable potency, selectivity, and PK properties of LY4045004 are predicted to result in efficacy with improved tolerability in patients with prevalent PI3Kα helical- and kinase-domain mutant HR+ breast cancers. Global regulatory submissions are planned in the first half of 2025.

P4-12-25: TARGETING BRCA-DEFICIENT CANCER CELLS WITH SMALL MOLECULE RAD52 INHIBITORS

Shiva Ostadrahimi, Matthew J. Rossi, Sarah F. DiDomenico, Saiful Amin, Alexander V. Mazin

A crucial bulwark of genome stability is the DNA repair system. The homologous recombination (HR) pathway is essential for the repair of the most harmful DNA lesions, like DNA double-strand breaks. Deficiencies in this pathway result in genomic instability and contribute to tumorigenesis. BRCA1 and BRCA2 (Breast Cancer type 1 and 2 susceptibility proteins) play critical roles in HR. Germline mutations in the BRCA1 and BRCA2 genes are responsible for nearly 50% of all familial breast and ovarian cancers. BRCA1/2-deficiencies coerce tumor cells to depend on alternative DNA repair pathways. Recent studies have demonstrated that inactivation of RAD52 protein induces lethality (synthetic lethality) in BRCA1/2-deficient cancer cells, without affecting normal cells. By

exploiting this synthetic lethality relationship, targeting RAD52 with inhibitors may provide an exceptionally selective method for eliminating cancer cells. Focusing on DNA repair proteins involved in synthetically lethal relationships in cancer cells has become an important strategy in the development of specific cancer therapeutics.
Our laboratory has developed small molecule inhibitors targeting RAD52. We have successfully created small molecule inhibitors of RAD52 (RAD52i) and have shown their ability to inhibit the biochemical activities RAD52 including DNA annealing and DNA strand exchange. Using the GFP-based recombination assays, we show that small molecule inhibitors of RAD52 disrupt the homologous DNA repair (HDR) and single strand annealing (SSA) repair pathways in human cells. Our compounds exhibited a notable reduction in cell viability in BRCA deficient cells. Furthermore, our small molecule RAD52i exhibited considerable efficacy in a mouse xenograft model cells markedly suppressing growth of human BRCA1-mutated cancer cells. We aim to develop small molecule RAD52i as novel cancer therapeutics.

P4-12-26: Preclinical study of newly developed anti-breast cancer drug targeting sphingosine-1-phosphate utilizing a novel drug delivery system

Masayuki Nagahashi, Sayaka Urano, Miki Komatsu, Mamiko Kuroiwa, Yuria Takahashi, Koji Morimoto, Ambara Pradipta, Katsunori Tanaka, Yasuo Miyoshi

Background: Drug resistance is one of the major causes of treatment failure in advanced breast cancer (BC), and the development of drugs with new mechanisms of action is desirable to overcome this situation. Sphingosine-1-phosphate (S1P) is a lipid mediator that has a variety of physiological functions involved in regulation of cell survival, inflammation, and immune systems. We have reported that cancers highly express S1P-producing enzyme and that S1P plays an important role in cancer progression and metastasis. FTY720, an S1P receptor functional antagonist, has been approved by U.S. Food and Drug Administration for multiple sclerosis. FTY720 has been shown to suppress cancer progression by inhibiting S1P signaling, however, its immunosuppressive side effects have hindered its development as an anticancer agent. Now, we have newly developed prodrug-FTY720 (pro-FTY), a cancer-specific S1P signaling inhibitor, utilizing a novel drug delivery system that reacts with acrolein in cancer cells to generate the active form. The aim of this study was to evaluate the efficacy and safety of pro-FTY by in vitro and in vivo preclinical experiments.
Methods: The expression of acrolein in surgical specimens from BC patients was tested using a dedicated fluorescent probe. Eight BC cell lines including two multi-drug resistant cell lines and a normal mammary cell line were used to determine the IC50 values of paclitaxel, doxorubicin, FTY720, and pro-FTY for these cell lines. Patient-derived organoids (PDOs) and patient-derived xenografts (PDXs) were established from BC patients, including those who developed multiple-drug resistance after treatment. The IC50 values of pro-FTY and other drugs in BC PDOs were determined by 3D Cell Tite-Glo Assay. PDX mouse models were used to test the efficacy of pro-FTY, and the adverse effects were evaluated by blood analysis.

Results: We confirmed that acrolein was strongly expressed in BC tissue and was barely expressed in normal mammary tissue utilizing surgical specimens. IC50 values revealed that FTY720 and pro-FTY consistently inhibited survival of all the BC cell lines, including multidrug-resistant cells which showed resistance to paclitaxel or doxorubicin. Although FTY720 inhibited survival of normal mammary cell lines, pro-FTY did not, suggesting that pro-FTY does not act on normal mammary cells that do not contain acrolein. Pro-FTY showed consistent efficacy against multidrug-resistant PDOs, while paclitaxel and doxorubicin failed to show sufficient efficacy against multidrug-resistant PDOs. Intravenous treatment with pro-FTY showed significant tumor suppression in PDX mouse models created from multidrug-resistant PDOs. Importantly, lymphopenia was not observed in the mice treated with pro-FTY, while it was observed in the mice treated with FTY720. Finally, mass spectrometry analysis of pro-FTY-treated mice showed that FTY720 accumulated in the tumors, while it was barely detectable in the blood.
Conclusion: Pro-FTY reacts with acrolein in the cancer cell to produce FTY720, which accumulates there, and exerts specific anticancer effects on BCs that are resistant to conventional anticancer drugs. Pro-FTY does not cause adverse events, including immunosuppression, avoiding effects on normal cells.

P4-12-27: Exploring Stimulation Response of Cisplatin Prodrugs and Integrating Photothermal-Photoacoustic Dual-Modal Theranostics in Triple-Negative Breast Cancer through Ozone-mediated Photothermal Catalytic Nanosystem

Dan Zheng, Ting Luo, Hubing Shi, Tianyue Xu, Linlin Song

Background: The combination of chemotherapy with immune checkpoint inhibitors shows a synergistic anti-tumor effect. Nevertheless, the issues of chemoresistance and the significant toxicity associated with combined treatments pose substantial challenges. We have successfully synthesized a fluorocarbon chain-modified cisplatin precursor (PtF) in previous research, showing optimized controlled-release properties, robust anti-tumor activity, high efficiency, and well tolerated toxicity.
Methodology: In this study, we utilize the PtF prodrug as a delivery vehicle, encapsulating gold nanoparticles to construct the PLAOP system. The near-infrared (NIR)-I light irradiation was applied as activator of the photothermal and photoacoustic effect.Results: This study evaluated the photothermal effect of PLAOP upon NIR-I light irradiation, which enables photoacoustic imaging of tumors by inducing thermoelastic expansion of the gold nanoparticles. We also elucidated the role of the photothermal effect produced by NIR I-activated PLAOP in catalyzing the generation of reactive oxygen species (ROS) from ozone. Moreover, the synergistic application of NIR I with PLAOP leverages ROS-GSH modulation to govern the responsive release of platinum-based prodrugs, thereby achieving dual-mode photothermal and photoacoustic visualization in triple-negative breast cancer (TNBC). This strategy enables precise tumor imaging and ensures a controlled, high-efficacy release of both cisplatin and ROS, which not only potentiates the anti-tumor therapy but also triggers

immune cell death. This study presents a new strategy for theranostics for the combined treatment with ICBs in TNBC, where traditional therapeutic targets are lacking.

P4-12-28: Discovery and Validation of Novel Small G Protein Inhibitor OSURALi for Targeting Triple Negative Breast Cancer

Dillon Richardson, Jonathan M. Spehar, David T. Han, Prathik A. Chakravarthy, Sumudu Leelananda, Chad Bennett, Gina M. Sizemore, Steffen Lindert, Steven T. Sizemore

Background: Triple Negative Breast Cancer (TNBC) continues to be the deadliest subtype of breast cancer. There is an urgent need to identify novel molecular targets to be exploited. We previously identified the small G proteins Ras-Like Oncoproteins A and B, or RALA and RALB, as novel molecular targets of TNBC. The RALs, particularly RALA, were critical for tumor growth and metastasis in multiple models of TNBC. More recently, we found that TNBC cell lines are reliant on RALA and RALB expression. However, current generation RAL inhibitors are not suitable for clinical applications. There is an urgent need for better RAL inhibitors. Here, we show the discovery and validation of a novel RAL inhibitor and its efficacy in TNBC models.
Methods: Molecular docking studies were completed with drug-like and lead-like molecules from the ZINC15 database and 3D models for inactive GDP-RALA (Protein Data Bank, -2BOV). Virtual screening was performed with 500,000 molecules targeting the allosteric binding pocket of the RALA-GDP crystal structure and the homology models of RALB-GDP using Autodock. Surface Plasmon Resonance (SPR) was performed on the top 54 compounds (Reaction Biology). GTP-Pulldown assays were performed using a RAL-Activation Kits (BK040, Cytoskeleton, Inc. and #17-300 MilliPore-Sigma). Viability assays were perform using MTT (MilliPore-Sigma, 11465007001) and Growth in Low Adhesion (GILA) (G9682, Promega). Small G-Protein Assays were performed against RAS (BK008, Cytoskeleton), RAC/CDC42 (BK035, Cytoskeleton), RHOA (BK036, Cytoskeleton), and ARF (BK032-S, Cytoskeleton). For the measuring in vivo efficacy of OSURALi, MDA-MB-231 tumors in the mammary fat pad were allowed to reach ~100mm3 before being randomized into DMSO and OSURALi groups. Mice were injected with 50mg/kg OSURALi 5x/week. When early removal criteria were met, all mice were sacrificed, perfused, and organs were harvested for histological analysis.
Results: We identified a novel small molecule inhibitor we have named OSURALi. We assessed the efficacy of OSURALi against breast cancer cell lines and found OSURALi to be potent against RALA-dependent TNBC cell lines while RALA-independent SKBR3 cells and normal cell lines were more resistant to OSURALi. Current generation RAL inhibitors RBC8 and BQU57 were indiscriminately toxic to all breast cancer cell lines and normal cells regardless of their RAL-dependency. We further interrogated the drug-like properties of OSURALi. Excitingly, we found that OSURALi was well tolerated in mice and can significantly slow tumor growth and spontaneous lung metastasis in the MDA-MB-231 model.

Conclusion: Together these data suggests that OSURALi could serve as a lead compound for further drug optimization and may lead to a bona fide targeted therapy for TNBC.

P4-12-29: ETX-197/BG-68501, a potential best-in-class potent, selective, oral, small molecule CDK2 inhibitor, has anti-tumor activity in cancer models with Cyclin E amplification or deficiency in the Retinoblastoma 1 gene.

Daliya Banerjee, Alexandra Weinheimer, Jingyan Gao, Fei Pang, Ying Lin, Raj Nagaraja, Yong Tang, Zipeng Fan, Zipeng Fan, Minghong Hao, Shengfang Jin, Tao Liu, Tai Wong

In a normal cell cycle, there is redundancy in the role of the cell-cycle dependent kinases (CDKs) in regulating G1/S phase transition. In cancer cells, the regulation of G1/S transition can be subverted by (a) amplification and elevated expression of Cyclin E (CCNE), or (b) mutation/loss of the Retinoblastoma 1 (RB1) gene. Cancer cells with these genomic alterations have been shown to exhibit profound sensitivity to CDK2 depletion, validating CDK2 as a potential therapeutic target. Here, we report the discovery and preclinical characterization of ETX-197, a highly potent and selective small molecule inhibitor of CDK2 enzymatic activity. Based on known ligand-CDK2 structures, ETX-197 is designed to induce previously unexplored interactions within the CDK2 ATP binding pocket leading to improved potency and selectivity compared to other known CDK2 inhibitors. ETX-197 is >100-fold selective against other kinases in the CDK family and the selectivity extends more broadly against 385 other kinases. The affinity of ETX-197 for CDK2 results in tight binding (slow off-rate) and high potency in pharmacodynamic modulation and anti-proliferative activity in vitro and in vivo. Treatment of CCNE-amplified cancer cells with ETX-197 results in concentration-dependent inhibition of pRB phosphorylation, G1/S phase cell-cycle arrest and cell proliferation. In addition, ETX-197 treatment phenocopies CDK2 genetic knock-down in cells, as revealed by bulk-RNA Seq analysis of CCNE-amplified or wild-type cells, confirming that the cellular activity of ETX-197 is on-target and highly selective. In mouse xenograft studies using CCNE-amplified ovarian cancer cell line (OVCAR-3) or patient-derived tumors, ETX-197 treatment causes dose-dependent tumor growth inhibition with excellent tolerability. Interestingly, in RB1-deficient small cell lung cancer cell lines, ETX-197 treatment results in G2/M cell cycle arrest, accumulation of DNA damage, and apoptosis. Xenograft studies with small cell lung cancer cell lines and patient-derived tumor cells also show significant tumor growth inhibition with ETX-197. Additionally, ETX-197 has single-agent efficacy in a breast cancer xenograft model that had acquired resistance to a CDK4/6 inhibitor. These data suggest that ETX-197 has the potential to be a best-in class CDK2 inhibitor for the treatment of cancer with CCNE amplification or RB1 deficiency, including breast cancer that has progressed on treatment with a CDK4/6 inhibitor because of these genomic alterations. Currently, ETX-197 is being clinically developed by BeiGene in a first-in-human (FIH), Phase 1a/1b study to assess the safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and preliminary antitumor activity in patients with advanced, nonresectable, or metastatic solid tumors (NCT06257264).

P4-12-30: The Impact of Beta Blocker Use on the Survival of Cancer Patients: A Systematic Review and Meta-Analysis

Stephanie Chan, Adam Komorowski, Xingshan Cao, Yizhuo Gao, Kushal Kshatri, Kairavi Desai, Markus Kuksis, Michael Rosen, Anjali Sachdeva, Isabella Kojundzic, Saif Samari, Iacovos Michael, Husam Abdel-Qadir, Katarzyna J Jerzak

Purpose: Beta blockers (BBs) have long been used for the treatment of cardiovascular and other medical conditions. More recently, the role of beta-adrenergic signaling in multiple processes driving tumor progression has been highlighted by preclinical studies, generating growing clinical interest in the potential repurposing of BBs as adjunctive anticancer agents. However, observational studies thus far have yielded mixed conclusions regarding their potential clinical use in oncology, and positive results may be inflated due to time bias (ITB). The main objective of this meta-analysis was to better characterize the association between beta blockade and survival in cancer patients, considering possible biases.
Methods: OVID Medline, EMBASE, and CENTRAL were searched from database inception to September 13, 2023 for research publications comparing the survival of cancer patients using BBs to that of non-users. In the large majority of studies, BBs were used to treat relevant patient cardiac comorbidities, not as adjunctive anti-cancer agents. Data extraction and quality assessments, using ROBINS-I, were conducted in duplicate. Hazard ratios (HRs) were analyzed using a random-effects model, with heterogeneity measured by the I2 statistic. Exploratory subgroup analyses assessed the association of BB type (selective vs. non-selective), cancer stage (early vs. advanced), and cancer type with survival. Sensitivity analysis was performed to assess the influence of ITB. The systematic review was prospectively registered (PROSPERO CRD42020200238) and not funded.
Results: We identified 79 eligible studies comprising 213 distinct analyses and 492,381 total patients. 2/79 studies were prospective (2.5%), while the remainder were retrospective. The most common primary tumor types assessed included breast (n=33), ovarian (n=30), and colorectal (n=28). Advanced disease (n=56) was more commonly studied than early/non-metastatic disease (n=26). Beta-blocker use was associated with significantly longer progression-free survival (PFS) than non-use, with a pooled HR of 0.78 ([95% CI: 0.66-0.92], I2=79.8%). This remained significant after excluding studies at greater risk of ITB (HR 0.74 [95% CI: 0.61-0.91], I2=36.6%). HRs for cancer-specific survival (CSS) and overall survival (OS) were 0.95 ([95% CI: 0.91-1.00], I2 = 77.4%) and 0.99 ([95% CI: 0.94-1.04], I2 = 84.9%).
Conclusion: This meta-analysis found that beta blockade may be associated with longer PFS among patients with cancer, irrespective of cancer type or stage; these findings remained statistically significant after excluding studies at risk of ITB. There was also a trend for BB use and longer CCS, but no difference observed for OS in the overall cohort. This lack of detriment to OS in the included observational studies is notable given that BBs are most commonly prescribed to patients with cardiovascular disease who are likely at inherently higher risk of death than non-user counterparts due to cardiac comorbidities. Ultimately, conclusions of this meta-analysis are limited by the observational nature of eligible studies. However, multiple phase II trials are ongoing, including a recently registered trial

(NCT05741164) seeking to determine the efficacy of propranolol in combination with pembrolizumab in patients with checkpoint inhibitor refractory metastatic triple-negative breast cancer. If positive, findings of these trials will lay the foundation for future larger randomized controlled trials to establish the highest level of evidence in this field.

P5-01-01: Longitudinal monitoring of quality of life in patients with de novo metastatic inflammatory breast cancer (mIBC) - a protocol in progress

Faina Nakhlis, Meredith M. Regan, Elizabeth P. Troll, Sean J. Ryan, Laura S. Dominici, Shoshana M. Rosenberg, Jennifer R. Bellon, Laura E. Warren, Eren D. Yeh, Harold J. Burstein, Antonio Giordano, Sarah L. Sammons, Susan T. Schumer, Caroline C. Block, Ana C. Garrido-Castro, Tari A. King, Elizabeth A. Mittendorf, Sara M. Tolaney, Beth Overmoyer, Filipa Lynce

Background: Up to 30% of patients with inflammatory breast cancer (IBC) present with de novo metastatic disease. While systemic therapy is the mainstay of treatment for metastatic IBC (mIBC), loco-regional therapy may be considered due to the aggressiveness of loco-regional disease. At the same time, definitive local therapy (i.e., modified radical mastectomy and adjuvant radiotherapy) may adversely impact patient-reported outcomes (PRO).
Primary Objective: To establish a prospective registry of patients with de novo mIBC in order to monitor the impact of loco-regional disease and therapy decisions on PRO, arm lymphedema, skin toxicity, and decision regret.
Secondary Objective: To evaluate loco-regional progression-free survival (LRPFS), distant progression-free survival (DPFS) and overall survival (OS) in a contemporary cohort of patients with mIBC.
Methods and Study procedures: In this prospective registry, 50 patients with de novo mIBC treated at Dana-Farber Cancer Institute will be enrolled within 8 months of initiating systemic therapy. All enrolled participants will be administered the Lymphedema Survey (LSIDS-A), the PROMIS global health 2a Survey, the Skin Toxicity survey (Skindex 16) and the Decision Regret Scale every 6 months for up to 2 years. If a patient undergoes surgery, and the most recent set of the 3 study surveys is longer than 1 month prior to the operation date, then the patient will receive another set of study surveys 3 months postoperatively. Additionally, participant medical records will be accessed by the study staff every 6 months for up to 5 years from the time of diagnosis to ascertain loco-regional disease progression (and treatment details), distant disease progression and death from breast cancer or other causes.
Statistics: The primary PRO and secondary endpoints will be summarized descriptively and graphically over the two years since diagnosis. A set of clinical paths will be defined to sort patients into subgroups with clinically meaningful treatment categories, such as the receipt of loco-regional treatment or lack thereof, and/or disease progression. The analyses will be descriptive and estimation only, without statistical hypothesis tests.

This study activated in May of 2023 and is currently enrolling, with 13 participants enrolled as of June 30th, 2024. We anticipate reaching our target accrual of 50 participants in 2028.

P5-01-02: Is breast-conserving surgery after neoadjuvant therapy safe for locally advanced breast cancer?

Yedda Reis, Ana Luiza Corteletti, Lara Brandão Pereira, Milena Martello Cristófalo, Gabriela Bezerra Nobrega, Bruna Salani Mota, Yedda Nunes Reis, Angela Francisca Trinconi, Bruno Sobreira Lima, Jonathan Yugo Maesaka, José Roberto Morales Piato, Sergio Mitsuo Masili-Oku, Maria Carolina Formigoni, Fernanda Barbosa, Gabriela Boufelli de Freitas, Mila Trementosa Garcia, Rafael Pegado, Thais Perez Vazquez, José Maria Soares-Jr, Edmund Chada Baracat, José Roberto Filassi

Background: Breast-conserving surgery (BCS) is being considered as an option for women with locally advanced breast cancer (LABC) who show a good clinical response to neoadjuvant therapy (NAT). Recent research indicates that breast-conserving surgery (BCS) is linked to a higher overall survival rate compared to mastectomy in this specific group. This study aims to assess the overall survival (OS) of patients with locally advanced breast cancer (LABC) who received breast-conserving surgery (BCS) following neoadjuvant therapy (NAT) and compare it to the survival of patients who underwent mastectomy (MS). Methods: This retrospective cohort study was carried out at Instituto do Câncer de São Paulo (ICESP), according to the STROBE guideline recommendations. Inclusion criteria was female patients diagnosed with locally advanced breast cancer (LABC) with an anatomic stage of T3 or T4. Exclusion criteria was male patients, contra-indication for adjuvant radiotherapy and multiple malignant neoplasia. The neoadjuvant treatment was chemo or endocrine therapy and the surgical intervention could be mastectomy (MS) or breast-conserving surgery (BCS). The study enrolled patients between January 2010 and January 2015, and their follow-up continued until December 2023. The primary outcome was overall survival of patients who underwent BCS compared to those who underwent MS. Descriptive analysis and association measures were used for statistical analysis and Kaplan-Meier curves were utilized for time-dependent variable analysis. We performed univariate and multivariate analysis in our data and adopted $p < 0.05$ as the significance level. Results: There were 414 patients with locally advanced breast cancer (LABC) who met the criteria and received neoadjuvant treatment followed by surgery. 396 (95.7%) received neoadjuvant chemotherapy, while 18 (4.3%) endocrine treatment. The average age of the patient group was 52.7±1.2(23-95) years. Out of the total of 414 patients, 64 women (15.5%) were diagnosed with stage IIB, whereas 350 patients (84.5%) had stage III breast cancer. The histological subtypes were distributed as follows: 152 (36.7%) were luminal HER2 negative, 154 (37.2%) were triple-negative, 53 (12.8%) were luminal HER2 positive, and 55 (13.3%) were HER2 positive. PCR was detected in 12.60% (52 patients) of cases. Regarding the surgical approach, breast-conserving surgery was performed on 74 patients (17.8%), while mastectomy was performed on 340 patients (82.2%). The BCS and MS groups were different in terms of clinical characteristics. The BCS group included of elderly

patients ($p < 0.001$), early-stage disease ($p < 0.001$), higher BMI ($p < 0.001$), higher number of postmenopausal women, higher rates of sentinel biopsy ($p<0.001$). The pCR rate was significantly higher in the BCS group, reaching 27% (20 patients), compared to 9.4% (32 patients) in the MS group ($p < 0.001$). During a follow-up of 8 years, the 5-year OS rates for patients undergoing BCS and MS were 78.4% and 60%, respectively (log-rank, $p < 0.032$). The univariate analysis revealed a statistically significant correlation between clinical parameters such as menopausal status, BMI, pCR, staging tumor, ki67, breast and axillary surgery, and overall survival (OS), as indicated in table 2. After the multivariate analysis, it was found that breast surgery, postmenopausal status, BMI, tumor stage, and pCR were associated with influencing overall survival. The MS was significantly associated with worse OS compared to BCS (OR 1,7; IC 1,05-2,9), along with postmenopausal status (OR 1,61; IC 1,16-2,21), higher BMI (OR 1,03; IC 1,01 – 1,06), and more advanced staging (OR 2,5; IC 1,4-4,6). On the other hand, higher PCR was associated with improved OS (OR 2,5; IC 1,3-5,0).
Conclusions: BCS after NAT is oncologically safe and significantly associated with better overall survival for women with LABC and initial anatomic stage T3 and T4, when compared to mastectomy. Additionally, lower stage, lower BMI, PCR and being pre-menopausal remained as independent factors related to better overall survival.
Keywords: Locally advanced breast cancer, neoadjuvant chemotherapy, pathological response, overall survival.

P5-01-03: Boost delivery to the tumor bed in breast cancer patients who have achieved pCR confirmed by VAB without surgery

Zhanna Bryantseva, Irina Akulova, Alexander Emelyanov, Olga Ponomareva, Pavel Krzhivitskiy, Sergey Kanaev, Nikolay Amirov, Viktoria Mortada, Petr Krivorotko, Sergey Novikov

Purpose: We evaluate various approaches to target volume definition and boost delivery in breast cancer patients with pCR after neoadjuvant systemic therapy (NST) who were treated by radiotherapy without a surgery.
Materials and methods: A pathological complete response (pCR) was diagnosed in 20 of 27 patients included in "surgery de-escalation" prospective observation study. Clips were placed in the primary tumor volume (PrTV) before NST and during the vacuum aspiration biopsy after NST. Twenty patients with pCR underwent the whole breast irradiation and a boost to the PrTV. High-dose rate brachytherapy (HDRB) was the basic technique for boost delivery. Finally, we identified the value of fused images (computed tomography [CT] before NST with simulation CT), clips and their combination for an accurate boost delivery.
Results: A complete overlap between PrTV on pre-treatment CT with the localization of the clips on simulation CT was mentioned in 10, partial mismatch in three patients. In 12 of these 13 women, HDRB was successfully used for the boost delivery. In five cases we mentioned a marked discrepancy between the PrTV on fused images and the topography of the clips. In other two women we did not find clips on simulation CT. The fused images in

five of these seven patients showed anatomical landmarks (scar, fibrosis) used for identification of the gross tumor volume. In all 20 women with pCR (average follow-up of 16.6 months), there were no locoregional recurrences.
Conclusion: Combination of the clips with fusion of pre-NST and simulation CTs is important for an accurate boost delivery.

P5-01-04: Determination and clinical characteristics of bone pseudoprogression on advanced first-line therapy in metastatic breast cancer

Yuan Yuan, Ting Xu, Min Dong, Shiyi Li, Yikun Ma

Background: Bone is the predominant metastatic site for breast cancer. Whether new osteoblastic lesions are defined as progression is currently controversial. Computed tomography (bone window) is commonly used to monitor disease progression in bone metastatic breast cancer (MBC). In this study, we aimed to assess the clinical characteristics and determination methods of bone pseudoprogression.

Methods: This retrospective analysis was conducted among 23 MBC patients with new osteoblastic lesions during the first-line systemic therapy at Jiangsu Cancer Hospital from January 2018 to December 2023. After every two cycles by computed tomography (bone window) to assess treatment response(at least twice), all the participants did not show disease progression, which we now define as bone pseudoprogression and continued on treatment until explicit disease progression (extraosseous disease progression or progressive lysis on bone lesions). The baseline and follow-up ALP were analyzed separately at the time of bone progression and pseudoprogression.

Results: The spine (78.2%) was the predominant metastatic site. The median time of appearance of bone pseudoprogression after treatment was 1.77 months. Notably, 83.3% of patients showed bone pseudoprogression during the first 3 months after treatment. Besides, the median interval of all patients between bone pseudoprogression and true disease progression was 14.27 months. There was no significant difference in HER2-positive and HER2-negative MBC patients (15.83 months versus 14.23 months, p=0.830). The incidence of stable/decreased ALP was higher at the time of bone pseudoprogression than progression (84.6% vs. 15.4%). Multiple regression analysis revealed that stable or decreased ALP was an independent predictor for bone pseudoprogression ($p < 0.001$).

Conclusions: Osteoblastic new lesions detected on CT (bone window) may represent bone pseudoprogression, which occurs mainly in the early stages of treatment. ALP is a useful serologic marker to differentiate pseudoprogression from disease progression on CT (bone window) in patients with bone metastasis. For these patients without extraosseous disease progression or progressive lysis on bone lesions, clinicians should be cautious about the appearance of new osteoblastic lesions.

P5-01-05: Clinicopathological features and outcomes of ER-low/HER2-low expression in de novo metastatic breast cancer: a preliminary cohort study

Chongxi Ren, Jianna Sun, Lingjun Kong, Hongjun Yu, Fang Wang, Haiyan Zhao

Background: Breast cancer remains a major health problem for women worldwide, with the highest incidence and the second highest mortality rate in 2023. Breast tumors consist of distinct molecular subtypes categorized by the expression of hormone receptors (HR, including estrogen receptor [ER] and progesterone receptor [PR]) and human epidermal growth factor receptor 2 (HER2). The molecular subtype is closely related to its prognosis and also offers a basis for directed treatment. It is unclear whether ER-low-positive/HER2-low-positive (ER-low/HER2-low) biomarkers, as new biological subtypes, have different biology and clinicopathological characteristics in de novo metastatic breast cancer (dnMBC). Unfortunately, no studies on clinicopathological features of ER-low/HER2-low subtype of breast cancer have been reported to date. This retrospective cohort study aimed to investigate the clinicopathological features and prognosis of ER-low/HER2-low tumors in dnMBC patients.
Methods: Using hospital-based database, we identified patients with dnMBC diagnosed between March 2010 and December 2017,retrospectively collecting demographic data,tumor characteristics,treatment types,histopathological report and survival data.The cases were categorized according to ER, PR and HER2 status. ER-low was defined as if 1% to 10% of invasive tumor cells exhibited immunostaining for ER; HER2-low was defined as immunohistochemistry score of 1+ or 2+(negative by in situ hybridization). ER-low and HER2-low were focused,while ER-negative(ER-zero) and HER2-negative(HER2-zero) as controls.The primary outcome was overall survival (OS). It was estimated by Kaplan-Meier method and log rank test. Univariable and multivariable analyses were performed using the Cox proportional hazard model to identify statistically significant prognostic factors. All statistical analyses were performed using Stata 18.0.
Results: A total of 518 women with dnMBC who received systemic therapy met the inclusion criteria and were evaluated in this study (median age at initial diagnosis, 53 [21-82] years). Across the cohort, 338 patients (65.3%) had HR-positive/HER2-zero tumors, 115 patients (22.2%) had HER2-positive tumors, 52 patients (10.0%) had ER-zero/PR-zero/HER2-zero tumors (TNBC) and 13 patients (2.5%) had ER-low/HER2-low tumors. For ER-low/HER2-low patients, the median OS was 36 months and the 5-year OS rate was 23.1%. No significant difference was observed when it was compared separately with the OS of the clinically relevant subgroups, including HR-positive/HER2-zero(hazard ratios:0.97; 95% CI:0.508-1.856,p=.928), HR-positive/HER2-positive(hazard ratios:0.67; 95% CI: 0.335-1.366, p=.268) and HR-zero/HER2-positive(hazard ratios:0.58; 95% CI: 0.297-1.146, p=.107). Interestingly, its survival curve trajectory was close to or partially overlapped with that of the HR-positive/HER2-zero subgroup. However, it had a survival advantage compared to the TNBC subgroup(hazard ratios:0.34; 95% CI: 0.168-0.689, p=.001).
Conclusions: ER-low/HER2-low tumors are relatively small in number but is similar to

other clinically relevant subgroups in terms of biology, clinicopathological features, and prognosis, although distinct from TNBC. The findings of the present study do not support ER-low/HER2-low breast cancer as a distinct biological subtype.

P5-01-06: Discerning the consequences of type I interferon signaling in RON expressing breast cancer

Levi Fox

Metastatic breast cancers continue to drive patient mortality in United States, with a relative 5-year survival of 31%. In efforts to more effectively target aggressive breast cancers and reduce mortality, it is imperative to understand the drivers and mechanisms of metastatic breast cancer. The RON receptor tyrosine kinase is overexpressed in greater than 50% of breast cancers and is prognostic for metastatic outcomes, regardless of molecular subtyping. This presents RON as an attractive therapeutic target to effectively treat metastatic breast cancer patients. Understanding the molecular pathways regulated by RON in breast cancer may likewise identify actionable interventions. In line with this goal, we have identified that across breast cancer subtypes, RON expressing breast cancer cells suppress the production of type I interferons (IFN-I). Considering that tumor cell intrinsic IFN-I production can signal in both an autocrine and paracrine fashion, we examined the significance of IFN-I action on the tumor proper and in the host microenvironment. To accomplish this, we abrogated IFN-I signaling, through loss of IFNAR1, in breast cancer cell lines and/or in the host microenvironment using in vivo and in vitro approaches. Conversely, by treating breast cancer cell lines with IFN-I, we were able to bypass RON mediated IFN-I suppression and promote cell death. Together, these approaches of modulating IFN-I signaling have identified that RON expressing breast cancer cells are uniquely sensitive to IFN-activated host immune activity and tumor intrinsic IFN signaling. Loss of IFNAR1 in both breast cancer cells and within the host microenvironment promoted tumor growth and apoptotic evasion, while also enhancing breast cancer stemness of RON expressing breast cancer cells. Correspondingly, in vitro treatment of breast cancer cell lines with exogenous IFN-I promoted apoptosis and limited breast cancer stemness. These in vitro findings are corroborated in both spontaneous and syngeneic transplant murine models which demonstrate that IFN-I signaling limits the growth and metastasis of RON expressing mammary tumors. Together, these findings suggest that the suppression of IFN-I by RON serves to enhance tumor aggressiveness and metastatic progression, presenting IFN signaling as critical arm of RON's tumorigenic program in breast cancer.

P5-01-07: Use of Neoadjuvant Chemotherapy for Local and Regionally Recurrent Triple Negative and HER2+ Breast Cancer

Mary Mrdutt, Courtney N Day, Amy C Degnim, Judy Boughey, Robert Antonio Leon-Ferre

Introduction: Neoadjuvant chemotherapy (NACT) for early-stage breast cancer enables de-escalation of local therapy and tailored adjuvant therapy based on pathologic response. Data on the use of NACT for local and/or regionally recurrent (LRR) breast cancer (BC) is sparse. Herein, we evaluated use of NACT over time for triple negative (TN) and HER2+ LRR BC and impact of pathologic response on oncologic outcomes.
Methods: We identified patients with first TN or HER2+ invasive LRR BC treated surgically at our institution from 9/2008-5/2024. Patients presenting with distant metastasis, in situ recurrence or second LRR were excluded. We evaluated demographics, tumor characteristics of the index and LRR tumor, and treatment modalities. NACT use over time was evaluated with Cochran Armitage Trend tests. Associations between patient and tumor factors with biologic subtype and clinical nodal status were assessed with chi-square or Fisher's exact tests where appropriate. Cumulative incidence of distant recurrence was evaluated with death as a competing risk.
Results: 103 patients with LRRs were identified: 73 (70.9%) clinically node negative (cN0) local recurrences, 11 (10.7%) regional nodal recurrences, and 19 (18.4%) with both local and nodal recurrence. LRR tumor subtype was TN in 64 (62.1%) and HER2+ in 39 (37.9%; 28 hormone receptor (HR)+, 11 HR-). Proportion of cN0 recurrence was similar for TN and HER2+ disease (70.3% and 71.8%). Median time from primary cancer surgery to LRR was 4.4 years (IQR: 1.4,10.7, [TN 3.7 yr (IQR: 1.2, 11.3) vs HER2+ 5.4 yr (IQR:2.8, 10.5, p=NS)]. Data on use of chemotherapy for LRR was available in 96 patients. Of these 75 (78.1%) received chemotherapy, with no significant change over the study period (2008-2011: 73.3%, 2012-2015 76.9%, 2016-2019 70.0%, 2020-2024: 83.3%, p=NS). Chemotherapy was given neoadjuvantly in 50/75 (66.7%) with NACT use increasing over time (2008-2011 36.4%, 2012-2015 40.0%, 2016-2019 78.6%, 2020-2024 77.5%; p=0.003). The increase in NACT use was also observed for each tumor subtype (both $p < 0.05$). cN+ LRR were more likely to receive NACT (21/25, 84.0%) versus cN0 patients (29/50, 58.0%; p=0.037). Among 50 patients receiving NACT, 20 (40%) had a pathologic complete response (pCR, 13/29 [45%] for TN; 7/21 [33%] for HER2+). 11/29 (37.9%) cN0 LR had a pCR (cN0: 37.5% for TN, 38.5% for HER2) as did 9/21 (42.9%) cN+ LRR (53.9% for TN, 25.0% for HER2+). Overall median follow-up was 2.0 (IQR: 0.5, 5.5) years. Additional events included distant recurrence (20), isolated nodal recurrence (1), and radiation associated angiosarcoma (1). Following surgery for LRR, the median time to distant recurrence was 0.9 years (IQR: 0.5, 3.0). 5-year cumulative incidence of distant recurrence with death as a competing risk was 26.9% overall (95% CI: 17.5, 41.4) and was significantly higher at 43.5% (95% CI: 24.4, 77.6) among those with NACT not achieving pCR compared to 0% among those with pCR (p=0.001).
Discussion: Use of NACT for TN and HER2+ BC LRR has increased over time and was more common for LRR with nodal involvement. Among patients receiving NACT, pCR rate was 40% and associated with excellent clinical outcomes, with no distant recurrences observed in the pCR cohort. Conversely, nearly half of patients not achieving pCR experienced distant recurrence by 5 years. NACT for resectable LRR should be further studied in clinical trials.

P5-01-08: Perceptions and behaviors of US oncologists treating HR-positive HER2-negative metastatic breast cancer in second-line

Leah Park, Komal Jhaveri, Janelle Cambron-Mellott, Nicole Kashine, Emily Mulvihill

Background: The emergence of novel targeted therapies for hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (mBC) offers more treatment options in second line (2L). While biomarkers can influence 2L treatment decisions, other factors such as comorbidities, co-occurring mutations, and treatment toxicities can guide treatment selection. Amid evolving treatments and clinical complexities, this interim analysis of an ongoing study aims to understand perception and behaviors of US oncologists in molecular testing and 2L treatment decisions in HR+/HER2- mBC with one or more PIK3CA, AKT1, or PTEN alterations.
Methods: US oncologists completed a cross-sectional survey in April 2024 (interim analysis data cutoff 04-23-24). Recruitment quotas ensured diverse representation of oncologists from various practice settings. Qualitative concept elicitation and desk research informed survey development. The validity of the survey was assessed via cognitive interviews (N=8). Data were summarized with descriptive statistics.

Results: This interim analysis included 152 oncologists (70 academic, 82 community), with mean 18.1 years in practice; 40.8% practiced in the Northeast. In the HR+/HER2- mBC setting, 77.6% of oncologists reported usually or almost always conducting next-generation sequencing (NGS) testing at diagnosis/prior to first-line (1L) treatment. Of patients not tested at diagnosis, 74.5% of oncologists reported usually or almost always conducting NGS testing prior to 2L treatment. When choosing 2L treatment for patients with HR+/HER2- mBC, most oncologists consider it was very important to know gBRCA (61.8%), ESR1 (57.2%), PIK3CA (55.3%), and/or PTEN (51.3%) status; fewer oncologists rated knowing AKT1 status as very important (42.8%). When presented with multiple actionable biomarkers, 68.4% of physicians selected PIK3CA mutation, AKT1 mutation, or PTEN alteration as more important for treatment choice than ESR1 mutation.

Oncologists were asked to select 2L treatments for 12 patient profiles, which varied in age (44, 56, or 64 yr old), site of metastases (liver, lung or bone only), duration of treatment with prior CDK4/6 inhibitors (CDK4/6i) in 1L (≥12 or <12 months), comorbid conditions (diabetes, pre-diabetes, or absence of these), ECOG status (0-1 or 2), and presence of biomarkers. Treatment options, based on the mutation profile, included: alpelisib+fulvestrant, capivasertib+fulvestrant, CDK4/6i+fulvestrant, chemotherapy, elacestrant, everolimus + exemestane, or others. In only 4 profiles did most oncologists agree on the 2L treatment; these profiles involved patients with one of the following biomarker alterations: PTEN and PIK3CA (51% agreement), AKT1 and PIK3CA (52% agreement), AKT1 and no ESR1 (57% agreement), and AKT1, PIK3CA, and no ESR1 (50% agreement). In these 4 cases, ≥50% selected capivasertib+fulvestrant, while the second most common treatment selected was alpelisib+fulvestrant or CDK4/6i +fulvestrant. In 8

profiles, oncologists diverged on treatment selection which involved patients with PIK3CA mutations alone or PIK3CA and co-occurring ESR1 mutations. For these patient profiles, oncologists chose various targeted treatment options with no strong consensus.

Conclusions: Our survey findings highlight the importance of biomarker testing in treatment decision-making for patients with metastatic HR+/HER2- breast cancer, particularly in choosing 2L treatment. Notably, there is a lack of consensus on treatment selection across biomarkers in determining 2L treatment approaches. This highlights the need for robust evidence to establish best practices and guide clinical decision-making.

P5-01-09: Improving ESR1 Mutations Detection in Breast Cancer Circulating Tumor DNA: Comparative Analysis of Enrichment Techniques

Anna Gasior, Joanna Gorniak, Andreas Voss, Ryan Nana, Ava Read, Luke Matthews, Kimberly Howard, Leanne Gough, Christine Hoy, Colette Whitfield

Breast cancer is the most common cancer among women, with approximately 70% of breast cancer cases being estrogen receptor-positive (ER+). These cases are commonly treated with endocrine therapy. However, resistance mechanisms can arise during treatment such as the development of mutations in the ESR1 gene, occurring in 20-40% of patients. ESR1 mutations, which can significantly impact treatment efficacy, can be detected in circulating tumor DNA (ctDNA) before, and at the time of disease progression. However, these mutations are often present at low allele frequencies, requiring highly sensitive detection methods.

To address this challenge, various methods have been developed to enrich low-frequency allelic variants, thereby enhancing detection sensitivity. In this study, we assessed three enrichment methods, to enable ultra-sensitive detection of ESR1 mutations. The methods evaluated included ICE-COLD PCR, whole genome amplification using REPLI-g, and multiplex pre-amplification. Contrived samples of known variant allele frequencies were used to quantify the extent of enrichment achieved by each method. Mutation detection was performed using the APIS ESR1 Mutations Kit, capable of detecting eleven mutations within exon 5 (E380Q), 7 (S463P), and 8 (P535H, L536R/Q/H/P, Y537C/S/N, D538G). The limit of detection of the qPCR assay with each enrichment method was compared to determine their effectiveness.

Our findings suggest that enrichment methods notably enhance the sensitivity of ESR1 mutation detection in ctDNA. For instance, ICE-COLD PCR demonstrated potential for improving detection sensitivity by selectively amplifying mutant alleles, while REPLI-g and multiplex pre-amplification can increase the number of mutant copies in the reaction, without impacting amplification specificity. These advancements could enable more accurate systemic assessment and dynamic monitoring of ESR1 mutations in breast cancer patients, potentially before disease progression is evident. This capability allows for more tailored therapeutic approaches, improving patient outcomes by facilitating early intervention and more personalized treatment strategies.

In conclusion, employing enrichment techniques for low-allele frequency variants can improve the sensitivity of ESR1 mutation detection in breast cancer. This approach has the potential to enhance our ability to monitor and respond to disease progression dynamically, ultimately supporting more effective, individualized patient care.

P5-01-10: Clinical and pathologic factors associated with progression-free survival in patients with metastatic hormonal breast cancer treated with ICDK4/6

Juan Manuel Tovar Cabrera, Alejandro Noguez Ramos, Paula Anel Cabrera Galeana, Raquer Gerson C wilich

Background: Breast cancer (BC) is the most frequent malignant tumor worldwide. The most frequent immunophenotype is luminal. 8-13% are diagnosed in metastatic stages and it is estimated that up to 20-40% of patients in local and locally advanced stages will recur. The first line of treatment in this scenario is cyclin-dependent kinase inhibitors 4 and 6 (ICDK4/6). However, in our setting real world evidence is poor.
Methods: We conducted an observational, retrospective, descriptive, cohort study in which women >18 years with histological confirmation of breast cancer with hormone receptors (HR+) and HER-2 negative (-) in metastatic stage were evaluated at the ABC medical center. The primary objective was to evaluate clinical and pathological factors associated with progression-free survival (PFS).
Results: 70 patients were treated with ICDK4/6, 54 (77%) presented recurrence while 16 (23%) presented de novo metastases, the median age was 58 years, 52 (74%) women were postmenopausal. The functional status they presented was ECOG 0 (7%), ECOG 1 (50%) and ECOG 2 (43%). Forty-five (64%) received ICDK4/6 in first, 13 (19%) in second, 9 (13%) in third and 3 (4%) in fourth or more lines of treatment. Forty (57%) had HER-2 low. The predominant number of metastatic sites was 2 in 25 (36%). Fifty (86%) used Palbociclib, 6 (9%) Ribociclib and 6 (5%) Abemaciclib. Factors that were associated with greater PFS were: using ICDK4/6 first line 23 vs 15, 20 or 4 months; HR=0.023 [95% CI; 0.004-0.136], p=<0.001; objective response rate (ORR) of 24 vs 6 months, p=0.001; absence of HER-2 low of 25 vs 17 months (p=0.011). Factors associated with longer overall survival (OS) were ORR p=<0.001, ECOG (p=0.019), INL < 4 (p=0.031), lung metastases (p=0.011), liver metastases (p=0.015), other metastatic sites (p=<0.001) and fatigue (p=0.036). HER-2 low status had a trend to lower OS (p=0.059). Adverse events (AE's) G3-4 occurred in 70%, with no differences between ICDK4/6 types, dose adjustments were required in 30%, treatment was discontinued in 19%, The most frequent toxicity with Palbociclib and Ribociclib was neutropenia (72% and 100% respectively), no grade 3-4 toxicities occurred with Abemaciclib.
Conclusions: We present a Mexican study with real-world data in luminal breast cancer patients treated with ICDK4/6. PFS, OS, ORR and toxicity are similar to previous reported in clinical trials. Factors associated with higher PFS were the line in which ICDK4/6 was received and ORR. There was no difference between ICDK4/6 types. HER-2 low status

appears to be a predictive factor in this setting.
Keywords: breast cancer, cyclin-dependent kinase inhibitors 4 and 6, progression-free survival, overall survival, HER-2 low.

P5-01-11: HER2-low is associated with longer progression-free survival in HR+/HER2- advanced breast cancer after cyclin-dependent kinase inhibitor 4/6 failure.

José Antonio García Gordillo, Roberto Mancilla Ceballos, Andrea Maliachi Díaz, Alexandra Garcilazo Reyes, Carlos Arturo González, José Rodrigo Espinosa Fernández, Claudia Haydee Arce Salinas, Juan Manuel Tovar Cabrera, Karla Alicia Centelles López, Lorena Lagarde Nube, Javier Antonio Méndez López, Paula Anel Cabrera Galeana,

Background: HER2-low is predictive for benefit in patients who receive Trastuzumab-deruxtecan (TDxd).
Formerly, low HER2 expression was considered HER2 negative according to ASCO-CAP criteria. The benefit derived from the use of TDxd has reshaped the biological understanding of HER2-low breast cancer and has triggered important efforts to decipher its prognostic and predictive significance.
At the biological level, molecular characterization studies have not identified the HER2/low BC patient group as a distinct entity.
Other studies have linked this biomarker as mirroring the activity of cross-linked intracellular signaling pathways such as PIK3CA which may confer a similar prognosis to luminal tumors. TDxd has been positioned as the first choice
of chemotherapy in HR+/HER2- patients with advanced breast cancer. The benefit in progression-free survival is striking, with a median survival of close to 12 months. The post-iCDK scenario is an ongoing clinical need where more real-life studies are required to improve decision making.
Objetive: To inform the prognosis of HER2-low expression among patients with advanced breast cancer HR+/HER2- who failed to iCDK 4/6 therapy.
Methods: We conducted an observational study based on a cohort of patients with HR+/HER2- ABC who received treatment subsequent to progression of an iCDK4/6. After screening a cohort of 160 patients, 64 progressions and 56 patients who received subsequent therapy were documented. Finally, a survival analysis was performed among patients HER2low vs HER2 0.
Results: The study included 13 patients with low HER2 and 43 with HER2 0. No significant differences were detected between the groups with respect to the type of iCDKs (Fisher's exact test p 0.47). No statistically significant differences were found between patient groups with respect to the type of subsequent treatment (CT vs. ET p 0.82). Thirty-five PFS events were observed, where 7 (53%) occurred in the HER2-low group and 28 (65%) in the HER2 zero group. No statistically significant differences were detected (p 0.52). In the survival analysis, the median PFS in subsequent treatment reached 389 vs. 153 days, with an increased probability of PFS of 174% more compared to the HER20 group. This effect was

maintained when PFS2 was considered, from the date of iCDK initiation to subsequent treatment progression, with an HR of 2.74 (1.39-5.38) P= 0.024.
Conclusions: HER2low was associated with longer PFS and PFS2 in patients receiving treatment subsequent to iCDKs progression. Contrary to reports from other series the prevalence of low HER2 was 23%, much lower than expected (around 60-80%). These findings should be considered with caution and regarded as exploratory for designing future studies. Further follow-up is required to explore the prognostic impact of low HER2 in this setting.

P5-01-12: Subsequent Treatments After Progression On Cyclin-Dependent Kinase 4/6 Inhibitors - A Multicentric Portuguese Real-world Data Study

Ana Rita Rego Freitas, Inês F. Eiriz, Marta Vaz Batista, Andreia Chaves, Catarina Santos, Tiago Barroso, Sara Cabral, Pedro Meireles, Ana R. Fortuna, Vanessa Patel, João P. Araújo, Tânia Duarte, Tiago P. Cabral, Sandra C. Silva, Joana Gonçalves, Isabel Fernandes, Inês Dunões, Cláudia Viana, Sofia Prada, Sofia Azambuja Braga

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) (Ribociclib, Palbociclib or Abemaciclib) plus endocrine therapy (ET) is the standard first line treatment in hormone receptor-positive (HR+) human epidermal growth factor receptor two-negative (HER2-) metastatic breast cancer (MBC) patients (pts). There are no established guidelines on subsequent treatment after disease progression with CDK4/6i, especially in later lines.
Methods: We conducted a multicentric retrospective observational study including HR+/HER2- MBC pts who experienced disease progression with a CDK4/6i for metastatic disease, between January 2016 and July 2023. Data were collected from medical records. The primary objectives were to compare Progression-Free Survival (PFS) and Overall Survival (OS) across different treatment options. Survival curves were estimated with Kaplan-Meier method and compared with the pairwise log-rank test.
Results: We identified 222 pts (220 women, 2 men) with a mean age of 57.6±13.4 years at the time of metastatic disease diagnosis; 131 (59.5%) were postmenopausal. The majority had visceral disease (172 pts, 77.5%). CDK4/6i were used as a first-line treatment in 182 pts (82.0%), as second-line in 30 (13.5%) and as third-line in 10 (4.5%). After progression with CDK4/6i, the next line of treatment included ET (68 pts, 30.8%), capecitabine (62 pts, 28.1%), paclitaxel (30 pts, 13.5%), rechallenge with a different CDK4/6i (14 pts, 7.7%), other chemotherapies (12 pts, 5.4%) and other treatments (17 pts, 7.6%). After progression with CDK4/6i, PFS was higher for capecitabine treated pts (16.5 months (mo), 95% CI [7.6, 32.1]) and the lowest with paclitaxel (5.6 mo, 95% CI [3.5, 8.2]). However, the OS was higher for pts who were rechallenged with a different CDK4/6i (24.6 mo, 95% CI [18.2, not reached - NR]), followed by those on ET (14.0 mo, 95% CI [12.2, NR]) and capecitabine (15.6 mo, 95% CI [10.4, 20.8]), and it was the lowest for those treated with paclitaxel (9.0 mo, 95% CI [4.8, 15.0], $p<0.05$).
Conclusions: In our cohort, PFS was longer for pts treated with capecitabine, while OS was the highest for those treated with a different CDK4/6i or ET. The main limitation of this

study is its retrospective nature and the non-random assignment of treatments. Thus, our findings support emerging data suggesting a benefit in switching ET while maintaining CDK4/6i after progression.

P5-01-13: Efficacy of abemaciclib and endocrine therapy on the overall survival for advanced ER-positive/HER2-negative breast cancer according to the treatment of lines

Eriko Tokunaga, Yumiko Koi, Junji Kawasaki, Wakako Tajiri, Sayuri Akiyoshi, Hideki Ijichi, Chinami Koga, Yoshiaki Nakamura

Backgrounds: Combination therapy of CDK4/6 inhibitors and endocrine therapy (ET) is standard care for ER-positive/HER2-negative (ER+/HER2-) advanced breast cancer. Progression free survival of each treatment is important, however, overall survival (OS) form the diagnosis of advanced breast cancer is also important for the patients. Instead of the high efficacy, CDK4/6 inhibitors also have high cost and toxicity. Not all patients will want to use CDK4/6 inhibitors from first-line therapy, depending on their circumstances and preferences.
Objective:This study was conducted to investigate the efficacy of the combination therapy of abemaciclib and ET according to the treatment line in terms of time to treatment failure (TTF) and OS.
Patients and Methods: A total of 114 patients who started combination therapy with abemaciclib and ET between 2018/12 and 2024/1 and were followed for at least three months were included in the study. Clinicopathological characteristics and TTF, OS from the start of abemaciclib treatment, OS from the diagnosis of the advanced breast cancer were analyzed. according to the treatment lines.
Results: Median age of the patients was 61 (range 25-90) years. Twenty-nine (25.4%) were pre-menopausal and 85 (74.6%) were postmenopausal women. Abemaciclib was used as the firtst line treatment in 50(43.9%), second line 23 (20.2%) and third line or later 41 (35.9%) patients. ET for combination was aromatase inhibitor (AI) 44 (38.6%), AI +LH-RHa 8 (7.0%), fulvestrant (FUL) 44 (38.6%) and FUL+LH-RHa 17 (14.9%) patients. De novo stage IV 31 (27.2%), relapse while on the first 2 years of adjuvant endocrine therapy (adjET) 13 (11.4%), relapse while on adjET but after the first 2 years, or relapse within 12 months of completing adjET 28 (24.5%), relapse after 12 months of completing adjET 32 (28.0%), and no adjET was 10 (8.7%). Abemaciclib use from the 1st line treatment was associated with the presence of visceral metastasis, liver metastasis. Abemaciclib use from the 3rd line or later was associated with relapse after 12 months of completing adjET. Median TTF of the abemaciclib treatment was 19.6 months as the first line, 12.7 months as the second line, 14.9 month as the third or later line. Median OS from the start of abemaciclib 43.3, 40.7 and 57.8 months in which abemaciclib was used as the first, second and third or later line. Thus, there were no statistical differences in TTF of the abemaciclib treatment and OS from the start of abemaciclib according to the treatment lines of abemaciclib. Median OS from the diagnosis of advanced breast cancer was 43.7, 58.8, 135.4

months in which abemaciclib was used as the first, second and third or later line ($p<0.0001$).
Conclusion:In routine practice, abemaciclib was used in different lines of treatment, depending on physician's choice and patient preference. The TTF of the abemaciclib treatment or OS from the start of abemaciclib was not different among the treatment lines. Median OS from diagnosis of advanced breast cancer was significantly longer in patients who used abemaciclib as a third or later line treatment compared to those who used abemaciclib as a first or second line. Although there is a selection bias, the results of this study suggest that abemaciclib does not necessarily have to be used as the first line treatment for advanced ER-positive/HER2-negative breast cancer.

P5-01-14: Real world evidence of continued CDK4/CDK6 inhibition and endocrine therapy beyond progression on a prior CDK4/6i in women with hormone receptor positive (HR+), Her2 negative advanced breast cancer (MBC).

Roberto Sánchez-Reyes, Chavarri-Guerra Y, Villarreal-Garza C, Vázquez-Juárez D, Centelles K, Valdez-Sandoval P, Campos-Gómez S, Mantilla WA, Bravo-Garzón MA, Gomez H, Castro-Sánchez A, Talamantes-Gamez E

Introduction: The use of endocrine therapy (ET) in combination with CDK4/6i is considered standard of care for patients with HR+, Her2 negative ABC. However, there remains an unmet need to determine the optimal sequencing after failure of CDK4/6i therapy. Endocrine monotherapy after progression to CDK4/6i is considered suboptimal treatment and access to other target therapies is limited in several countries. Two randomized trials (MANTAIN and postMONARCH) have supported the benefit of switching a different CDK4/6i and ET after progression to first line therapy with CDK4/6i. Evidence in a real-world setting of the efficacy of this approach is limited.
Methods: In a retrospective multicenter study, we analyzed 30 Hispanic patients with HR+ Her2 negative advanced breast cancer treated with endocrine therapy and a CDK4/6i, who were switched to another ET with a CDK4/6i at progression. Primary outcome was to assess median progression free survival-1 (mPFS-1) for HR+ Her2- MBC to the first line with CDK4/6i and mPFS-2 after switching CDK4/6i and ET at progression. Secondary outcomes: To estimate mPFS-2 in relevant clinical subgroups as well as safety and tolerability.
Results: From 2021-2024, 30 women with HR+Her2 negative MBC treated with a CDK4/6i in combination with ET were included. Median age at diagnosis was 56.5 years (SD 15.18), 67% were postmenopausal, 50% presented with metastatic de novo and 50% had recurrent disease. Regarding the site of metastatic disease, 53.3% had visceral and 40% only bone metastasis. 93.3% (n=28) received a CDK4/6i + ET as first line of therapy for MBC, 24 (80%) as a second line and 6 (20%) as a third line or beyond. Among those that received a CDK4/6i in the first line, 53.5% received palbociclib in combination with an AI (93%) as backbone ET. All premenopausal women (n=10) received GnRH agonist in combination

with ET. At the second line, most patients received ribociclib (72.2%) combined with fulvestrant (87.5%). mPFS-1 to the first line with CDK4/6i was 19.7 (SD 14.1) months and 15.5 (32.0) months in the second line with the CDK4/6i continuation. In the subgroup analysis patients with only bone metastasis and a previous iCDK4/CDK6 treatment duration of more than 12 months showed a clinically meaningful benefit with a PFS of 26.8 (SD 47.7) months and 18.2 (SD 35.1) months respectively. Only 20% required dose reductions due to side effects and none had to interrupt CDK4/6i for toxicity.
Conclusions: In this international real-world data cohort of Hispanic women with HR+Her2 negative ABC, the switch of CDK4/6i and endocrine therapy after first line therapy showed a clinically significant benefit in terms of PFS, specially in patients who received palbociclib in the first line setting and then switch to another CDK4/CDK6i and fulvestrant at progression, with a favorable toxicity profile. This strategy represents an appealing option in the current treatment landscape of HR+, Her2 negative MBC, specially in well selected patients and limited access to other target therapies.

P5-01-15: Clinical verification of HR-positive/HER2-0 and HER2-low metastatic breast cancer patients treated with CDK4/6 inhibitors

Wataru Goto, Mariko Nishikawa, Yuko Kikukawa, Asuka Kouchi, Kei Nakata, Rika Sugahara, Koji Takada, Yukie Tauchi, Kana Ogisawa, Tamami Morisaki, Shinichiro Kashiwagi

Background: Cyclin-dependent kinase 4/6 (CDK4/6) inhibitors in combination with endocrine therapy (ET) are now the recommended first-line treatment for hormone receptor (HR)-positive and human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC). On the other hand, recently, the concept of HER2-low has been drawing attention as a new biomarker. HER2-low breast cancer has different molecular characteristics compared to HER2-0 or HER2-enriched type, and we evaluated the effect of CDK4/6 inhibitors for MBC patients with HR-positive/HER2-low.
Materials and Methods: A total of 152 patients with HR-positive MBC treated with CDK4/6 inhibitors between December 2017 and August 2023 were selected. We classified these patients according to HER2 expression with available immunohistochemistry (IHC) and/or in situ hybridization (ISH) results, and HER2-low-positive status was defined by IHC 1+ or 2+ with negative ISH, and HER2-zero by IHC 0. We evaluated the relationships between HER2 expression and clinicopathological features and prognosis, progression free survival (PFS) and overall survival (OS).
Results: We excluded one patient without HER2 data and 10 patients with HER2-enriched, and 141 patients were divided into two groups; HER2-0 (47 cases) and -low (94 cases). HER2-low patients were significantly associated with de novo breast cancer ($p = 0.003$) and high ER expression ($p = 0.021$), and tended to have higher ki-67 expression at diagnosis ($p = 0.093$). The median follow-up time for the assessment of prognosis was 22.4 months (2.6 – 66.8m), and there was no significant difference between HER2-0 and -low groups for PFS and OS ($p = 0.553$ and $p = 0.266$, respectively, log-rank). In univariate analysis, late treatment of CDK4/6 inhibitors (HRs = 2.265, 95%CI: 1.333–3.829, $p = 0.003$), low

expression of progesterone receptor (PgR) (HRs = 2.174, 95%CI: 1.188–4.303, p = 0.011) and low absolute lymphocyte count (ALC) at base line (HRs = 2.133, 95%CI: 1.201–3.840, p = 0.010) were independent prognostic factors for progression. However, multivariate analyses showed that high Ki-67 expression (HRs = 3.156, 95%CI: 1.338–7.855, p = 0.008) and low PgR expression (HRs = 3.368, 95%CI: 1.056–12.152, p = 0.040) were found to be independent poor prognostic factors.
Conclusions: HER2-low may not be a predictive marker of CDK4/6 inhibitor efficacy in patients with HR-positive MBC. Further work is needed to validate these findings.

P5-01-16: m6A reader YTHDF3 promotes epithelial-mesenchymal transition and metastasis through facilitating Notch2 translation in breast cancer

Hong-Yu Chen, Jing-Wen Bai, Guo-Jun Zhang

Breast cancer is a mammary epithelial tissues source tumor, the primary cause of death for breast cancer patients is distant metastasis. Epithelial-mesenchymal transition (EMT) is a crucial first step in the metastasis of the tumor. m6A methylation plays an important role in EMT of many tumors, but its role in breast cancer EMT is not completely clear. This study will reveal the new mechanism of m6A methylation-modified recognition protein YTHDF3 in regulating breast cancer EMT and explore its feasibility as a therapeutic target. Methods: First, database analysis and immunohistochemistry were used to examine the degree of YTHDF3 expression in breast cancer and related paracancer tissues, as well as its impact on patients' prognoses. The YTHDF3 gene was then stable overexpressed and knocked down in various human breast cancer cell lines. YTHDF3's impact on the EMT of breast cancer cells was then investigated in a variety of functional experiments. Then, lung metastasis and subcutaneous tumor transplantation animal models were used to study the impact of YTHDF3 on the growth and metastasis of breast cancer. By RNA immunoprecipitation, the target gene of YTHDF3 in breast cancer was examined, and function experiments were used to confirm the effect of YTHDF3 and its target gene on EMT of breast cancer cells. The precise method by which YTHDF3 regulates its target was examined using RNA stability tests, protein stability tests and so on. Finally, lipid nanoparticles (LNPs) were designed to encapsulate small interfering RNA (siRNA) targeting YTHDF3 (siYTHDF3) for the treatment of breast cancer. Results: It was found that m6A recognition protein YTHDF3 was highly expressed in breast cancer, and the high expression was associated with a shorter relapse-free survival time. Cell experiments confirmed that the EMT of breast cancer cells was significantly promoted after the overexpression of YTHDF3 in T-47D cells, while the knockdown of YTHDF3 in MDA-MB-231 cells was significantly inhibited. It was observed that the tumor volume and weight after YTHDF3 knockdown were significantly smaller than those in the control group. In the lung metastasis mouse model, the lung metastasis was significantly lower than that in the control group after YTHDF3 knockdown. RNA immunoprecipitation was conducted to determine Notch2 as the target of YTHDF3, and the mRNA site of Notch2 was identified by YTHDF3 to promote its translation, then the EMT

and metastasis of breast cancer were promoted by upregulation of Notch2. Additionally, the LNPs encapsulating siYTHDF3 exhibited tumor-specific fluorescence and effectively suppressed tumor growth and lung metastasis in vivo. Conclusions: This project reveals a novel mechanism in breast cancer EMT, that is, YTHDF3 accelerates breast cancer EMT and metastasis by promoting Notch2 translation. More importantly, the LNP/siYTHDF3 complex validates the therapeutic potential of targeting YTHDF3 in breast cancer.

P5-01-17: Unveiling epithelial cell heterogeneity in lobular breast carcinomas through single cell RNA sequencing

Silvia González-Martínez, Belén Pérez-Mies, Val Fernández-Lanza, María Gión, Javier Cortés, José Palacios

Background: Invasive lobular carcinoma (ILC) is characterized by unique clinicopathological features, distinct patterns of infiltration, specific molecular alterations such as E-cadherin loss, FOXA1, and GATA3 mutations, and distinct outcomes compared to invasive ductal carcinoma (IDC). Despite these differences, hormone receptor-positive breast cancers (BC) are often treated uniformly in clinical trials. The emergence of single-cell RNA sequencing (scRNA-seq) has revolutionized our comprehension of tumor heterogeneity. Our study first aims to evaluate scRNA-seq on formalin-fixed paraffin-embedded tissue (FFPE), compared with matched fixed fresh tissue, enabling retrospective analysis of archival BC samples. Subsequently, this pioneering study encompasses FFPE cases of ILC and control IDC, seeking to unveil detailed transcriptomic profiles of ILC epithelial cells, thus advancing diagnostics and tailored therapeutic strategies.
Methods: We performed a comparative scRNA-seq analysis with 2 fixed fresh BC tissue samples and 2 corresponding matched FFPE samples, encompassing one ILC and one IDC. Following the evaluation of these initial results, we expanded our study to include a series of 15 FFPE samples from ILC cases (11 luminal, 2 luminal Her2+, 2 triple-negative) and 4 IDC cases (luminal). Our analysis focused on exploring the heterogeneity of epithelial cells, specifically contrasting luminal subtypes between ILC and IDC and across different molecular types in ILC. We utilized 10X Genomics technology for single-cell analysis and performed bioinformatic analysis primarily using Seurat in R software. Additionally, we conducted immunohistochemistry and fluorescence in situ hybridization for result validation.
Results: The comparative scRNA-seq analysis revealed equivalent quality and representation of cellular populations between FFPE and fixed fresh samples, validating the retrospective use of FFPE samples for scRNA-seq studies. When contrasting luminal subtypes between ILC and IDC, significant epithelial cell heterogeneity was observed among the 4 IDC cases, each displaying distinct specific population with unique expression profile marked by high expression of some genes like CEACAM5, HOXC10, DCD and PROM1. In contrast, among the 11 ILC cases, heterogeneity was less pronounced, with a predominant population present in most cases and additional populations recurring in a few others, marked by genes like LTF, MYBPC1 and IGHG1. Only two ILC cases exhibited unique and

specific epithelial populations characterized by genes such as TMEM176B, TRIM9 and SCGB1D2, SCUBE3, respectively. Across different molecular types in ILC, we identified 5 distinct epithelial populations among the luminal ILC cases, as well as specific epithelial populations unique to luminal Her2+ (CRYBG3, MSMB) and triple-negative (CEACAM6) tumors, which were not present in other samples and clearly differentiated in the UMAP plot.
Conclusions: This study demonstrates for the first time that both fixed fresh tissue and FFPE routine blocks can be utilized effectively for the robust detection of clinically relevant traits at the single-cell level. Secondly, it highlights significant epithelial cell heterogeneity in luminal IDC and comparatively less heterogeneity in ILC. In addition, a shared population was identified among many ILC cases and substantial differences in epithelial cells across molecular subtypes within ILC, with each population marked by specific genes related to different biological processes, varying differentiation states, and distinct behaviors.

P5-01-18: ESRα and RASSF1A promoter methylation changed significantly in benign tumors and in the early event of breast cancer progression

Yasmine Kanaan, Sylvia Dasi, Bernard Kwabi-Addo, Desta Beyene, Robert L DeWitty jr, Kelly Bolden, Steven Nagel, Robin Williams, Babak Shokrani, Tammey J Naab, Olakunle O Kassim, Robert L. Copeland, Victor Apprey, Kelly Bolden, Andrea Hayes-Dixon

Methylation in the estrogen receptor alpha (ESRa) promoter is an epigenetic abnormality in breast cancer (BCa) and hypermethylation-mediated loss of ESRa expression could provide the cell with growth-promoting characteristics such as insensitivity to antigrowth signals. To investigate if there is a direct link between P0/P1 promoters of ESRa aberrant methylation and risk of progression of the fibroadenoma and fibrocystic diseasee to BCa.
Methodology. We used pyrosequencing to assess the DNA methylation in a panel of genes (ESRa, RASSF1A, and HIN1) in benign and cancerous human breast tissues and BCa cell lines.
Results. There was a significant elevated level of DNA methylation in ESRa P1 promoter (P=0.0001) in fibroadenoma tissues than ER-negative BCa, and 2-fold increase ESRa expression in fibrocystic, and fibroadenoma. HIN1 and RASSF1A methylation were elevated in ER-positive when compared to ER-negative BCa (P-value<0.5). To check if DNA methylation influence multiple gene networks rather than a single gene, we assessed the interaction between DNA methylation and the 3 genes within several types of breast tissues (fibroadenoma, and ER-positive and ER-negative BCa). Two-way ANOVA Univariante analysis of variance revealed a significant interaction between gene and breast types. ANOVA mixed model was further performed and revealed a significant interaction between the RASSF1A gene with fibroadenoma and ER-positive BCa (P-value=0.004). ESRa prmoter methylation in ER-positive BCa is associated with molecular subtypes (P-value=0.014) and grade (P-value=0.022). Tumors with unclassified molecular subtypes (ER-positive, PR-negative, HER2-negative) had elevated levels of methylation (P-value=0.046) in the P0 promoter compared with luminal B (ER-positive, PR-positive, HER2-positive) tumors.

Tumors with grade 3 showed a bordeline association with ESRa P1 promoter methylation when compared with grade 2 tumors (P-value=0.056). These results showed a highly methylated ESRa P0 promoter in the initial stages of breast carcinogenesis while the methylation in the P1 promoter occurs at later stages of BCa with poor prognosis. Conclusion. These findings suggest that methylation of ESRa promoter and tumor-related genes occured in pre-invasive lesions as an early event in BCa progresson. Furthermore, methylation of ESRa promoters could be consider a biomarker for the development of a diagnostic test that could predict benign breast disease that are at elevated risk of progressing to BCa.

P5-01-20: Elucidating novel pro-apoptotic consequences of an altered sphingolipidome in endocrine therapy-resistance.

Purab Pal, Daniel Lu, G. Ekin Atilla-Gokcumen, Jonna Grasor, Jonathan Coloff

Endocrine Therapy (ET)-resistant breast cancer remains a clinical problem, with approximately 40% of patients experiencing disease relapse. In our previous study, we demonstrated that preclinical models of ET-resistant breast cancer have an altered sphingolipid profile. This is characterized by decreased levels of endogenous ceramides across multiple models of ET resistance. The ET-resistant models are also more sensitive to ceramide-induced cell death compared to their ET-sensitive counterparts, suggesting a functional significance of the low levels of ceramides. Therefore, the current study is designed to identify mechanisms by which ceramides preferentially induce cell death in ET-resistant breast cancer models in order to identify novel therapeutic strategies to improve ET-resistant breast cancer patient outcomes. To understand how ceramides differentially affect ET-resistant breast cancer cells, we have performed total RNA-seq of multiple ET-resistant breast cancer cells with or without adding back ceramides. Our findings reveal that ceramide addback exclusively induces genes associated with endoplasmic reticulum stress (EnRS), particularly in the PERK/peIF2α/ATF4 pathway, in multiple models of resistance. Inhibitors of EnRS, PERK, and peIF2α partially reverse ceramide-induced cell death suggesting that ceramide-induced EnRS has lethal consequences for ET-resistant cells. We further investigated how ceramides preferentially cause a lethal EnRS in ET-resistant models. Since ceramides are well-known bioactive lipids, we hypothesized that ceramides interact with specific proteins that are instrumental in ET-resistant cell survival. We used a photoactivable-and-clickable ceramide probe and quantitative proteomics to identify differentially expressed ceramide-interacting proteins (CIPs) in ET-resistant breast cancer cells. Proteomic analyses suggest that ceramide interacts with a group of clinically relevant CIPs which are located in the endoplasmic reticulum (EnR) membrane. Higher expression of these CIPs is associated with more Luminal B disease as well as worse relapse-free patient survival. While most of these CIPs have yet to be implicated in ET resistance, a subset of these CIPs is known to be involved in attenuating EnRS. To test whether ceramide-induced EnRS is mediated by CIPs, we performed siRNA-mediated knockdown of one of the top CIPs in the EnR membrane, TRAM1. We found that TRAM1

knockdown phenocopies ceramide treatment by significantly increasing cell death and a higher level of EnRS specifically in ET-resistant but not ET-sensitive cells. These findings suggest that ceramide interaction with EnR membrane proteins, such as TRAM1, may disrupt their function to induce a lethal level of EnRS in ET-resistant cells. Together, we find that ceramide induces preferential cell death in ET-resistant cells through interactions with a novel array of proteins leading to the inhibition of key survival proteins and a consequential activation of lethal levels of EnRS. Understanding how ceramides interact with and affect these proteins could lead to the development of novel strategies to selectively treat ET-resistant breast cancers and improve patient outcomes.

P5-01-21: Epigenetic changes induced by combinatorial pterostilbene and resveratrol in Her2-positive and triple-negative mammary cancer via gut microbiome-metabolome axis modulation.

Sebanti Ganguly, Trygve O. Tollefsbol

With evolution of chemotherapy, the mortalities associated with the two most aggressive breast cancer subtypes, Her2 overexpressing and triple-negative breast cancers (TNBC), have significantly declined. The natural phytoalexins pterostilbene and resveratrol, extracted from grapes and berries, showed promising effects in inducing apoptosis and cell cycle arrest in human TNBC cell lines when administered singly and in combination, with minimal toxicity towards non-malignant cells. The primary goal of this study was to evaluate the effectivity of the phytochemicals in vivo considering the interference by tumor microenvironment, immune cells, bioavailability of the phytochemical, differential metabolism, and varied gut microbial composition. After administering a long regime of dietary intervention of the phytoalexins in transgenic mice models, we observed a delayed occurrence of mammary neoplasms with a significant decrease in progression of tumor volume and weight in treatment groups vs. the control group. The group of subjects treated with combination of 3:1 (w/w) pterostilbene and resveratrol demonstrated synergistic effects in impeding the mammary cancer phenotype. Concurrently, we discovered that these treatments increase the abundance of specifically Firmicutes phyla of bacteria which indicates recuperation from diseased condition. Simultaneous evaluation of plasma short chain fatty acid indicates an increase in butyric acid levels in pterostilbene high group and decrease in caproic acid. Our findings also reveal notable differences in expression of tumor suppressor genes associated with Her2 (Erbb2) signaling pathway such as p53, PTEN, p21 and oncogenes such as Her2/neu, Ras, Bcl2 and Myc. We also found significant changes in the expression of epigenetic modulators such as histone deacetylases (HDACs), histone demethylases (KDMs) and DNA methyltransferases (DNMTs). Overall, our results demonstrate efficacious in vivo application of combinatorial pterostilbene and resveratrol in prevention of aggressive hormone response-negative breast cancer via the modulation of gut microbiome and metabolome and suggests possible epigenetic mechanisms associated with anticancer gene regulation.

P5-01-22: Establishing an Ex-Vivo Model for Postpartum Involution and Breast Cancer Susceptibility

Samaneh Karami, Tasneem Bawa-Khalfe

Postpartum breast cancer (PPBC) increases the risk of breast cancer (BCa) for up to 10 years after childbirth, in younger women (< 45 years old), and exhibits poor prognosis and elevated risk of incurable metastasis. Epidemiological factors such as higher number of pregnancies and older maternal age increase the risk of PPBC. Postpartum mammary gland (MG) restructuring and involution are intricately linked with cancer development. Yet, how epidemiological risk factors differentially impact postpartum involution to drive PPBC still remains largely undefined. The objective of the current project is to establish a low-cost, highly reproducible postpartum involution model (PIM) to test the link with PPBC susceptibility factors and MG restructuring. Specifically, we have established a "gland-on-a-plate" model to evaluate different stages of postpartum window of susceptibility. Isolated mouse MEC on this model platform respond to hormonal cue with changes in morphology and gene expression. Like the postpartum mammary gland, PIM undergoes lactation-associated gland remodeling with the formation of bifurcating epithelial lined ducts and milk accumulation in the central lumen; hence, it recapitulates both the morphology and function of the MG in anin vitro environment. Additional studies with MECs isolated from (24-week-old) female nulliparous (no pregnancy), age-matched parous (2-3 pregnancies) mice revealed quantifiable and statistically significant differences in the remodeling potential and functional properties between the groups when cultured on the PIM. Hormone-treated nulliparous organoids, undergo a notable morphological transformation characterized by distinct secretory branching patterns. However, when subjected to hormone withdrawal, nulliparous organoids exhibit postpartum morphology characterized by a reduction in size and branching. In contrast, organoids derived from parous MECs, respond to lactation hormones but exhibit impaired involution and gland remodeling. Ongoing studies will test whether involution defect observed in multiparity organoids favor cancer development, specifically we will evaluate involution disruption in our PIM models, by assessing cell proliferation, apoptosis, and epithelial-mesenchymal transition (EMT) markers. In addition, bulk and single-cell transcriptome analysis will be conducted to identify aberrant pathways that contribute to the parity-association involution defect and subsequent support cancer transformation. These studies will enhance our understanding of possible correlation between parity hormones, involution, and the postpartum windows of BCa susceptibility. Future studies will focus on evaluating molecular mechanisms and exploring both existing and novel therapies targeting PPBC using our mice post-weaning MEC and human postpartum MEC-derived organoid models. Consistently, we expect the established model will be an excellent tool to test preventative and therapeutic approaches on the biological mechanism of PPBC.

P5-01-23: Linking Spatial Distribution of Core Fucosylated N-Glycans to Triple Negative Breast Cancer Outcomes

Jaclyn Dunne, Laura Spruill, Taylor Hulahan, Graham Colditz, Anand S. Mehta, Richard R. Drake, Marvella Ford, Peggi M. Angel

Triple Negative Breast Cancer (TNBC) is an aggressive breast cancer subtype with poor prognosis, partly due to its heterogenous molecular profile. Unlike other breast cancer subtypes, targeted therapies for TNBC are lacking, highlighting an urgent need for a better understanding of the underlying biology of the disease that can be used to develop more effective, tailored therapies. In this study, changes in glycosylation of TNBC primary tumors were analyzed in order to gain better insight into the biology of the disease with the goal of pinpointing specific glycan structures that might be useful as diagnostic and prognostic biomarkers that could assist in early detection, risk assessment and creating personalized treatments. Our past work studying glycosylation in breast cancer has linked specific glycan structural classes to different tissue regions, including stromal, necrotic and tumor areas. Fucosylation, a specific form of glycosylation, influences various immune and hormonal physiological processes and is frequently expressed by tumors. Previous studies by others have linked core fucosylation to increased proliferation, metastatic potential and therapeutic resistance in a variety of cancers, including breast cancer. Further, we have reported that tumor-associated core-fucosylated polylactosamine glycans are significantly more prevalent in metastatic breast cancers compared to non-metastatic ones.

The present study utilizes MALDI Imaging Mass Spectrometry to elucidate the spatial distribution of core-fucosylated N-glycans in TNBC tissues and assess their correlation with clinical outcome, tumor stage and patient survival status. Tissue samples were from female TNBC patients that self-identified as African ancestry (n=79). Tissues were previously banked for all research purposes and not specifically for this study; MUSC IRB approval as exemption #4. Clinical data includes tumor stage and grade, tumor nuclear grade, receptor status, metastatic sites, histology, surgical plan, chemotherapy status, BMI, age, and family history of cancer. Data showed that core fucosylation associated with stage of TNBC, with increases in stage III (ANOVA ≤ 0.001). By random forest machine learning, a set of three core fucosylated glycans were the primary differentiating factors in discriminating between stages of TNBC. We further found 9 specific core-fucosylated N-glycans that associated with survival status in the cohort (5-year survival n=39 alive; n=41 deceased; Kaplan-Meier (Log-Rank Mantel Cox test) p-value ≤ 0.01, Hazard ratio ≥ 2.5.

In summary, our analysis revealed that TNBC tumors with high levels of core fucosylation were frequently associated with advanced cancer stage and poor patient outcomes, including reduced overall survival. Further studies are warranted to explore the mechanistic role of these glycans in TNBC progression. The association between increased core fucosylation and adverse clinical outcomes underscores the potential utility for targeting core fucosylation, either alone or in combination with immune-stimulating therapies, to improve outcomes for TNBC patients.

P5-01-24: PPFIA4 mediates glucose metabolism reprogramming to alter the biological characteristics of breast cancer

Haochen Yu, Lingfeng Tang, Jihan Qiu, Shengchun Liu

Objective: Tumor growth requires a large amount of energy supply. If the energy supply can be blocked, the progress of the tumor can be slowed down or even killed. Warburg effect, which is highly dependent on glycolysis, in a variety of malignant tumors, including breast cancer. The Warburg effect limits the treatment targeting oxidative phosphorylation (OXPHOS) in breast cancer. There is an urgent need to explore new pathways and inhibitors for energy metabolism and clarify their specific mechanisms. Our team has previously found that glycolysis and OXPHOS pathways are higher in breast cancer than in normal tissues, and the antibiotic Tigecycline (Tige) may inhibit both pathways. However, whether the decreased energy metabolism changes the proliferation, invasion, migration, and other phenotypes of breast cancer needs to be further verified, and whether there are clear specific targets involved in the energy regulation process also needs to be further explored.
Methods: Bioinformatics analysis, immunohistochemistry (IHC), Western Blot (WB), glucose and lactate assays, and Seahorse energy metabolism assays were used to identify OXPHOS and glycolysis in breast cancer clinical samples and multiple cell energy knockdown models. Electron microscopy, JC1, and reactive oxygen species (ROS) fluorescence detection were used to determine the mitochondrial morphology, membrane potential, and ROS in the cells after energy metabolism down-regulation. Triple-negative breast cancer MB231 and MB468 cells and estrogen receptor-positive breast cancer MCF7 and T47D cells were treated with Tige at different concentrations for different times. CCK8 assay, colony formation assay, Edu fluorescence detection, and sphere formation assay were used to evaluate the effects of Tige on proliferation and tumor stemness in vitro. Nude mice xenograft tumor model and organoid culture were used to verify the phenotypes in vitro. Wound healing and Transwell assay were used to detect cell migration and invasion. RT-PCR and Western blot were used to detect the expression of multiple rate-limiting enzymes and other pathway markers in glucose metabolism pathways. RNA sequencing was used to explore the differentially expressed genes, analyze the related pathways, and identify the targets. Computer drug structure simulation was used to explore the binding domain between Tige and target genes. Lentiviral transfection was used to knock down and over-express the target gene, and the above phenotype and pathway exploration were repeated to prove the role of the target gene.
Results: TCGA database, IHC, WB, and Seahorse analysis of clinical specimens all showed that OXPHOS and glycolysis were more active in breast cancer than in normal tissues. Electron microscopic observations revealed alterations in the structure of mitochondrial cristae. Respiratory chain complex proteins and membrane potential of mitochondria were affected, and intracellular ROS production was increased after the energy decreased. After the down-regulation of energy metabolism, the proliferation, invasion, and migration of breast cancer cells were affected, which was mainly due to the arrest of the S phase of cell cycle, which requires a large amount of energy supply. In vivo experiments using organoids

have also obtained consistent results. The key enzymes of glucose metabolism in four breast cancer cell lines showed inconsistent decreases after Tige treatment. WB showed that in addition to the glucose metabolism pathway, the PI3K/AKT/mTOR pathway was also significantly inhibited. Bioinformatics analysis showed that the differentially expressed genes were mainly related to the inhibition of cell cycle, and the clear target may be PPFIA4. After changing the expression of PPFIA4, the rescue experiments in vivo and in vitro confirmed that PPFIA4 was involved in the energy metabolism of breast tumors. Conclusion: Both glycolysis and OXPHOS pathways are more active in breast tumors than in normal tissues. Tige treatment can successfully establish the down-regulated energy metabolism model of breast cancer and successfully inhibit the progression of breast cancer in vitro and in vivo. PPFIA4 may be involved in the regulation of PI3K/AKT/mTOR pathway and energy metabolism, which is worthy of further attention. At the same time, it also provides more theoretical support for expanding the clinical application of Tige.

P5-01-25: Romidepsin Targets HDAC1/2 to Induce Ferroptosis in TNBC Enhancing Chemosensitivity to Eribulin

Weipeng Zhao, Xichuan Li, Xing Yang, Yulong Wang, Shuling Wang, Qian Liu

Triple-negative breast cancer (TNBC) is a highly aggressive solid tumor with limited clinical treatment options, necessitating the urgent development of new drugs or therapeutic strategies. Romidepsin is a selective inhibitor of HDAC1/2 with notable antitumor activity in lymphomas, but its therapeutic efficacy in solid tumors like TNBC remains unclear. Our research reveals that romidepsin significantly induces ferroptosis in TNBC cells. Through RNA-seq analysis, we identified that romidepsin markedly alters the expression of several ferroptosis-related genes. Romidepsin regulates GSH metabolic reprogramming via the SLC7A11-CHAC1-GLS2 axis and causes iron overload in TNBC cells by modulating the Keap1-Nrf2-Hmox1 axis. Additionally, it promotes lipid peroxidation by upregulating the LPCAT3-POR-CYB5R1 axis. These biological functions of romidepsin are achieved through epigenetic modifications of target genes by HDAC1/2. Knockdown of HDAC1 or HDAC2 exacerbated romidepsin-induced ferroptosis in TNBC cells. To explore the clinical potential of romidepsin in TNBC treatment, we investigated its effects in combination with several first-line chemotherapeutic agents, including PTX and DDP, through cell viability assays. We found that romidepsin significantly enhanced the antitumor activity of multiple chemotherapy agents, with the most pronounced synergistic effect observed in combination with the anti-microtubule agent eribulin. The combination of romidepsin and eribulin effectively inhibited TNBC proliferation and promoted apoptosis and ferroptosis, demonstrating potent antitumor effects both in vitro and in vivo. Our study provides novel insights into the potential application of romidepsin in the clinical treatment of TNBC. The combination of romidepsin and eribulin holds promise for future clinical application in TNBC therapy.

P5-01-26: Selective Targeting of CDK2 Using Molecular Glue Degraders for the Treatment of HR-Positive/HER2-Negative Breast Cancer

Nina Ilic-Widlund, William Tahaney, Vasia Vafeiadou, Christelle Bianda, Liam Cheeseman, Ambika Singh, Anna Diesslin, Sophia Nguyen, Luca Moccia, Christopher King, Yimao Liu, Chao Quan, Xavi Lucas, Vladas Oleinikovas, Bradley Demarco, Laura Schwander, Vaik Strande, Jessica Alers, Rajiv Narayan, Dave Peck, Sarah Pessa, Samuel Gilberto, John Castle, Sharon Townson, Markus Warmuth, Magnus Walter, Ralph Tiedt, Andreas Ritzen, Beatrice Ranieri, Sofia Gkountela

Cyclin dependent kinases 4 and 6 (CDK4 and CDK6) and cyclin dependent kinase 2 (CDK2) act sequentially to coordinate cell cycle progression through the G1/S phases and effectively drive cell proliferation via RB phosphorylation and repression. CDK4/6 inhibitors in combination with endocrine therapy are approved agents for the treatment of hormone-receptor (HR)-positive/HER2-negative breast cancer. While these agents offer substantial benefit, patients eventually relapse. It has been reported that approximately 30% of resistant tumors following CDK4/6 inhibitor treatment exhibit upregulation of CCNE1 expression, and others are thought to adapt to chronic CDK4/6-inhibition by increased tumor reliance on the CDK2 pathway to sustain downstream signaling along the RB-E2F axis. Hence, targeting CDK2 in conjunction with CDK4/6 inhibition is expected to provide more sustained responses in this difficult-to-treat patient population. We sought to identify molecular glue degraders (MGDs) that selectively target CDK2. Using our MGD discovery engine QuEENTM encompassing biochemical and cellular assays as well as in silico modelling, we identified and further optimized molecules that induce CRBN engagement and selective degradation of CDK2, while sparing other proteins such as closely related CDKs. Unlike CDK2 inhibitors, CDK2 MGD inhibits cell proliferation in an RB-dependent manner, attesting to its superior selectivity. Furthermore, this MGD induces robust downstream pathway suppression, as evidenced by downmodulation of RB phosphorylation and E2F-driven gene expression. When dosed orally in preclinical models of HR-positive/HER2-negative breast cancer, this compound drives deep tumor regression in combination with CDK4/6 inhibitor or triple combination with endocrine therapy (fulvestrant), resulting in enhanced downstream pathway suppression compared to CDK4/6 inhibitor alone. Owing to its superior selectivity, we expect that a CDK2 MGD will avoid dose-limiting toxicities associated with less selective CDK2 inhibitors. Hence, a CDK2 MGD provides novel means to target an inadequately drugged target, offering a unique angle for populations in desperate need of treatment options.

P5-01-27: The relation between local tumor infiltrated T cells (TILs) and neutrophil-to-lymphocyte ratio (NLR) of peripheral blood in patients with De novo Stage IV breast cancer

Rie Sugihara, Uhi Toh, Hidetaka Watanabe, Shuntaro Matsushima, Shuko Saku, Mina Okabe, Nobutaka Iwakuma, Yutaro Mihara, Fumihiko Fujita

Purpose: We investigated whether the relation of tumor infiltrated T cells and neutrophil-to-lymphocyte ratio (NLR) can be a novel predictive factor for the benefit of surgery for de novo stage IV breast cancer (DnIV BC) and if primary tumor resection (PTR)'s surgical advantage related to clinical outcomes, the surgery timing in responders to systemic therapy.
Patients and Methods: We reviewed the cases of the DnIV BC patients who received systemic therapies and/or underwent PTR at our institution (Jan. 2004–Dec. 2022). Blood tests and NLR measurement were performed before and after each systematic therapy and/or surgery. The kinetics of peripheral blood lymph cell counts, NLR etc. were analyzed simultaneously. The immunopathological stain was performed using surgical specimens or biopsy samples by anti-CD3, -CD8, -CD163 and -CD25(Foxp3) antibodies.
Results: Sixty patients had undergone PTR local surgery (Surgery group); 81 patients had not undergone surgical treatment (Non-surgery group). In both groups, systemic treatment was performed as chemotherapy (95%) and/or endocrine therapy (92.5%) ($p<0.0001$). The groups' respective median progression-free survival (PFS) durations were 88 and 30.3 months ($p=0.004$); their overall survival (OS) durations were 100.1 and 31.8 months ($p=0.0002$). The Surgery-group responders to systemic therapy lasting >8.1-months showed significantly longer OS ($p=0.044$). The PFS and OS were significantly associated with the use of postoperative systemic therapy ($p=0.0012$) and the NLR ($p=0.018$). A low NLR (≤3) was associated with significantly better prognoses (PFS and OS; $p<0.0001$). The immunopathological study of surgical specimens showed the CD3, CD8+ T lymphocyte infiltration has significant increase in patients with low NLR. In contrast, there was no significant difference of CD163+ macrophage and CD25+ lymphocytes.
Conclusions: A longer effective duration of systemic therapy (>8.1 months) and a low pre-surgery NLR (≤3.0) could predict PTR's surgical advantage for DnIV BC. These variables may help guide decisions regarding the timing of surgery for DnIV BC.

P5-01-28: A comprehensive analysis of NTRK3 expression in breast cancer

Jae-Ho Lee

The ETV6-NTRK3 gene fusion is found in various cancers and showed their clinical significances. We clarified clinical and prognostic values of NTRK3 expression in breast cancer (BC) by open gene expression databases, such as TIMER, UALCAN, KM, OSlihc, and LinkedOmics, and immunohistochemistry analysis. Then, we also analyzed cell invasion and migration in BC cell lines transfected with NTRK3-siRNA. NTRK3 expression was higher in BC tissues and associated with various clinicopathological characteristics. It was also correlated with immune cell infiltration of B cells, macrophages, myeloid dendritic cells, and neutrophils. Survival analysis showed that NTRK3 expression induced favorable prognosis in BC patients. The expression level of NTRK3 as significantly downregulated in both MCF-7 cell line transfected with NTRK3-siRNA compared to that in cells transfected with NC siRNA. NTRK3 significantly affected cell viability and wound healing. This result suggested that NTRK3 expression contribute to BC pathogenesis and prognosis.

P5-01-29: Development of a Novel Antigen Presentation Assay in Triple-negative Breast Cancer

Mei Li, Falak Harshit Sharma, Marco Esteban Araneda, Amy Hammett, Derick Miller, Lilly Pearce, Kuanhui Ethan Chen

Triple-negative breast cancer (TNBC) is the most lethal form of breast cancer, partly due to its ability to significantly reduce antigen presentation, allowing the tumor to evade immune surveillance. As a result, accurately measuring tumor antigen presentation could provide critical insights into the immune response against TNBC. However, existing methods for studying antigen presentation are cumbersome and time-consuming. These methods typically rely on known peptide sequences and antibodies that recognize those peptides. A major concern with using specific peptide sequences is the potential for unstable presentation and antigen loss during the antigen editing process in endoplasmic reticulum/endosomes, thus leading to inconsistent results.
In this study, we present a novel and cost-effective approach to examine breast cancer antigen presentation using Click-it chemistry. This reaction specifically occurs between azides and alkynes/cyclooctenes. By pre-labeling tumor antigens with azides or alkynes, these antigens can be taken up by antigen-presenting cells, and their presentation can be detected through interactions with fluorophore-conjugated alkyne/cyclooctene or fluorophore-conjugated azide, respectively.
We employed two types of antigen-presenting cells—dendritic cells and macrophages—and used tumor antigens collected from two TNBC cell lines. Our results demonstrated successful and very stable antigen presentation on the surface of both macrophages and dendritic cells. Additionally, we found that breast cancer antigens remained stable within the phagolysosomes of these cells. Importantly, antigens labeled via click chemistry throughout the tumor antigen fragment showed better presentation via MHC class II compared to antigens labeled only at the terminus. This method also allows for the natural antigen editing process within the endoplasmic reticulum or endosomes to select high-affinity antigens for MHC presentation, resulting in a more stable presentation than conventional methods.
In conclusion, our novel antigen presentation assay offers several advantages over existing methods, including faster turnaround times, cost-effectiveness, stable antigen presentation, and reliable detection signals. When combined with mass spectrometry, our method has the potential to identify specific tumor peptides that are stably presented and could serve as valuable targets for the development of immunotherapies to treat TNBCs.

P5-01-30: Prolactin-Enhanced Iron Uptake via CD44 and Its Impact on Breast Cancer Metastasis

Reagan Farrell, Trevor Jones, Kuan-Hui Ethan Chen

Metastasis is the leading cause of cancer mortality, with the epithelial-to-mesenchymal transition (EMT) serving as an early event in tumor invasion and metastasis. Iron, abundant

in the tumor microenvironment (TME), plays a crucial role in cellular processes, including metastasis, and tumor cells are "ferrophilic," showing a high iron dependence. In our previous work, we found that breast cancer cells secrete the autocrine hormone prolactin into the TME, enhancing iron uptake via the cell-surface glycoprotein CD44, bound by hyaluronate. To date, there are more than 50 spliced transcripts of CD44, with at least 27 of them leading to protein translation. However, the role of CD44 spliced variants in iron regulation and EMT remains unclear. This study aims to investigate the correlation between CD44 splicing and iron-dependent EMT. Examining two human breast cancer cell lines, MCF7 (Luminal A) and MDAMB 468 (Triple Negative Breast Cancer, TNBC), we demonstrated a positive correlation between mesenchymal transition and intracellular iron content. To determine which specific CD44 isoform(s) are involved in iron uptake and drive EMT, we examined gene expression across a broad panel of CD44 spliced variants using quantitative PCR. In both cell lines, we observed consistent upregulation of the CD44 V3 and V5 isoforms following prolactin treatment. In the more aggressive TNBC cell line, MDAMB468, additional CD44 spliced isoforms of bulk cultures, including V6 and V9, were also upregulated. Given the critical role of cancer stem cells in metastasis, we extended these analyses to CD44 splicing in cancer stem cells. Prolactin stimulation consistently induced overexpression of CD44 V3 and V5 in stem cells, with an overall higher CD44 expression compared to bulk tumor cultures. We observed an overall upregulation of CD44 expression in MCF7 stem cell cultures compared to bulk cultures. Notably, neutralizing CD44 V5 reduced intracellular iron levels and reversed EMT, highlighting its specific role in these processes. Thus, our study establishes the prolactin-CD44 axis as a key regulator of EMT, specifically identifying CD44 V5 as a potential therapeutic target for disrupting iron uptake and metastasis in breast cancer.

P5-02-01: Does Community-Level Distress Correlate with the Risk of Developing Lymphedema Among Breast Cancer Patients?

Fardeen Bhimani, Andreina Giron, Priyanka Parmar, Gabrielle Safian, Kaiyu Tio, Anna Lasak, Sheldon Feldman, Anjuli Gupta, Jessica Pastoriza, Maureen McEvoy

Background: Lymphedema is a debilitating condition that significantly affects the quality of life of breast cancer survivors. Breast cancer-related lymphedema (BCRL) occurs in 3-8% of patients undergoing sentinel lymph node biopsy (SLNB) and 13-60% of those undergoing axillary lymph node dissection (ALND), with rates being two-fold higher in low-income and ethnic minority groups. While the risk of lymphedema development from breast cancer treatments has been well documented, there is scarcity of literature focusing on the socioeconomic factors impacting lymphedema development socio-geographically. The Distressed Communities Index (DCI) is a validated socio-geographic measure of economic well-being that provides a comprehensive assessment of community-level distress. Results from a recent study, utilizing a similar index, found correlation between patients from deprived areas, risk for lymphedema, and odds of lymphedema diagnosis. Therefore, our study aims to investigate whether higher distressed communities, as measured by DCI

quintiles, is associated with an increased risk of developing lymphedema in breast cancer patients.
Methods: This retrospective study examined the association between DCI quintiles and the incidence of lymphedema among breast cancer patients aged 18 years and older who were treated or diagnosed at Montefiore Medical Center between 2011 and 2022. The study population was extracted from two databases: one with patients who had been referred to physical medicine for lymphedema therapy, where those who developed lymphedema in the arms were selected, and the other from the institutional tumor registry. Patients' zip codes were matched into the corresponding DCI score and DCI quintiles and stratified into low distressed (quintiles 1-3) and high distressed (quintiles 4-5) groups. A DCI quintile above 3 indicates a highly distressed area. Chi-square tests and logistic regression were performed to determine the association between DCI quintiles and lymphedema, when controlling for race, insurance status, and ethnicity.
Results: Our study included 650 breast cancer patients, with 80.6% from higher distressed areas (DCI quintiles 4-5) and 19.4% from less distressed areas (DCI quintiles 1-3). The mean BMI and age for patients from low distress areas were 28.0 ± 6.86 and 56.2 ± 12 years, respectively, while those from high distress areas had a mean BMI of 30.6 ± 5.72 and a mean age of 59.1 ± 11.8 years. The chi-square test showed a significant association between DCI quintile and lymphedema when grouped into high and low distress groups ($p = 0.005$). Controlling for race, ethnicity, and insurance status, patients in higher distressed areas had a 20% increased risk of developing BCRL compared to those in less distressed areas (OR 1.20, 95% CI [1.00, 1.43], $p = 0.049$). Ethnic minorities had about twice the risk of developing BCRL compared to white patients (OR 1.91, 95% CI [1.40, 2.62], $p < 0.0001$). Stratifying by race, patients who identified as black ($p = 0.001$), "Other" ($p = 0.009$), or "Unknown" ($p = 0.002$) had higher risk of lymphedema compared to white patients. Additionally, patients with Medicare (OR 0.478, 95% CI [0.326, 0.703], $p = 0.0002$) or Medicaid (OR 0.670, 95% CI [0.458, 0.980], $p = 0.048$) had lower risk of lymphedema compared to those with private insurance.
Conclusion: Patients in higher distressed communities (DCI quintiles 4-5) have a 20% increased risk of developing lymphedema compared to those in less distressed areas (DCI quintiles 1-3), when controlling for race, ethnicity and insurance. Furthermore, race and insurance status had a significant impact on the risk of BCRL.

P5-02-02: Gender Disparities in the National Institutes of Health Funding for Gastrointestinal Oncology.

Janta Ukrani, Aruba Sohail, Sara Khan, Deepak Kumar, Muhammad Zain Farooq, Michael Vishal Jaglal

Background: Reportedly, there has been an under-representation of women in academic medicine, resulting in discriminatory distribution of research grants. This study examines the trend of funding allocation of R01 grants in Breast oncology by the National Institutes of Health with specific focus on the distribution of funding between gender.

Methods: The data were retrieved from the NIH RePORTER (Research Portfolio Online Reporting Tools Expenditure) using breast oncology-related search terms from 2018-2021. The gender was categorized using Genderize. The number of citations, publications, H-index, and seniority were obtained from Scopus and Web of Science in December 2022. Consumer Price Index was used to adjust funding amount to 2021 equivalent U.S. dollars. Linear regression was used for analysis.
Results: A total of 885 NIH-funded R01 grants amounting to $444.6 million were awarded for breast oncology research. Women (n=390; 44.1% [95% CI: 40.8%-47.3%]) received relatively fewer grants than men (n=495; 55.9% [95% CI: 52.7%-59.2%]). From 2018-2021, there was a significant increase in the number of grants awarded among both men (90 to 155, $p<0.01$) and women (71 to 115, $p=0.036$). Similarly, there was a significant increase in the grant amount (in millions) awarded among men (43.4 to 76.5, $p<0.01$) but not in women (36.7 to 56.1, $p=0.11$). Of the 212 co-PIs, 133 (62.7% [95% CI: 56.2%-69.2%]) were men and 76 (37.3% [95% CI: 30.8%-43.8%]) were women.
There was no significant difference in h-index (48 vs 44, $p=0.12$), number of publications (158 vs 138, $p=0.08$), and citations (13272 vs 8092, $p=0.06$) between the male and female PIs. Funding amount was significantly associated with number of publications ($\beta=0.35$, $p<0.01$), seniority ($\beta=0.25$, $p<0.01$) and institution ($p<0.01$).
Conclusion: Our analysis shows continued gender disparity as only 44% of total R01 grants were awarded towards females for breast oncology between the fiscal years 2018 to 2021. Though the proportion of discrepancy is lower as compared to other malignancies. A collaborative effort is still needed to bridge the gap and advance gender equality.

P5-02-03: Racial Disparity in the Genomic Landscape of Patients with Breast Cancer and Association with Clinical Outcomes

Arya Mariam Roy, Jun Arima, Kohei Chida, Jayasree Krishnan, Malak Alharbi, Kriti Ahuja, Zunairah Shah, Dionisia Quiroga, Shipra Gandhi

Introduction: Several studies have shown that African Americans (AA) with breast cancer have inferior clinical outcomes. The underlying reasons for this racial disparity are multifactorial, including lack of access to healthcare, and several socioeconomic factors such as lower income and education. In addition to the social determinants of health, tumor biology may also play a crucial role in this disparity. However, there is limited data on the role of tumor biology in the survival outcomes of breast cancer among different races. We aim to analyze the prevalence of somatic mutations among different races and their association with survival outcomes in breast cancer.
Methods: Clinical and transcriptomic data were obtained from the TCGA Breast Invasive Carcinoma PanCancer Atlas database from cBioPortal. Patients with breast cancer were stratified into different racial groups, including Whites, AAs, Asians, and Others. We studied the incidence of commonly altered genes in breast cancer such as TP53, PIK3CA, BRCA1/2, ATM, CDH1, ESR1, and PTEN among different racial groups. Furthermore, we investigated the role of these mutations in the survival outcomes of patients across different racial

groups. Clinical and genomic characteristics were compared using Fisher's exact test for categorical variables. Cox proportional hazard ratio and log-rank test were employed for survival analysis.
Results: A total of 1,084 patients were included in the analysis. The majority of the patients self-identified as White (69.3%, n=751), followed by AAs (16.8%, n=182), Asians (5.5%, n=60), and Others (8.4%, n=91). Most of the tumors were luminal A (46%) and AJCC T2 stage (57.7%). PIK3CA and TP53 were the most commonly altered somatic mutations (32.6% each) in the analyzed samples. The frequency of CDH1, PTEN, BRCA2, BRCA1, ATM, and ESR1 mutations was 12.2%, 5.4%, 2.7%, 2.5%, 2.3%, and 0.8%, respectively, in the entire cohort. AAs had more TP53 (47% vs 31%, p= 0.001) and fewer PIK3CA (21.6% vs 36.7%, p= 0.001) and CDH1 (5.6% vs 14.6%, p= 0.001) mutations compared to Whites. There was no statistically significant difference observed in other somatic mutation distributions among AAs and Whites (PTEN: 5.6% vs 6.4%, p= 0.71; BRCA1: 5% vs 2.5%, p= 0.27; BRCA2: 1.9% vs 2.7%, p= 0.66; ATM: 2.5% vs 2.9%, p= 0.92; ESR1: 1.2% vs 1.6%, p= 0.97). AAs had significantly higher odds of TP53 (odds ratio (OR) 1.79, 95% CI 1.27-2.50, p= 0.0008) and lower odds of possessing PIK3CA (OR 0.45, 95% CI 0.30-0.67, p<0.001) and CDH1 (OR 0.35, 95% CI 0.17-0.70, p= 0.001) mutations compared to Whites. AAs also had higher odds of carrying BRCA1 (OR 2.14, 95% CI 0.90-5.07, p= 0.11) and lower odds of developing ESR1 (OR 0.76, 95% CI 0.16-3.43, p= 1), PTEN (OR 0.84, 95% CI 0.40-1.76, p= 0.86), ATM (OR 0.83, 95% CI 0.28-2.45, p= 1), BRCA2 (OR 0.65, 95% CI 0.19-2.22, p= 0.78) mutations; however these were not statistically significant. The 5-year disease-free survival (DFS) of AAs with PTEN (75% vs 97%, p=0.04) and PIK3CA (77% vs 88%, p=0.04) mutations was lower than that of Whites. The 5-year overall survival (OS) was also observed to be lower in AAs with PTEN (76% vs 87%, p=0.23) and PIK3CA mutations (85% vs 90%, p=0.46); however, it was not statistically significant. Survival analysis of other mutations among AAs vs Whites was not statistically significant.
Conclusion: In our study, we observed disparities in the prevalence of somatic mutations and associated survival outcomes among different races. TP53 mutations were observed more frequently in AAs, while PIK3CA and CDH1 mutations were observed more frequently in Whites, emphasizing the need to target these mutations in these races to address the disparity. Larger studies are necessary to identify biological and non-biological risk factors for acquiring these somatic mutations and their impact on clinical outcomes.

P5-02-04: Factors Predicting Transition to Independent Grants among NIH K awardees in Breast Oncology

Jayasree Krishnan, Archit Patel, Arya Mariam Roy, Malak Alharbi, Asha Gandhi, Kriti Ahuja, Zunairah Shah, Kayla Catalfamo, Han Yu, Song Yao, Pawel Kalinski, Kazuaki Takabe, Shipra Gandhi

Introduction: The transition from NIH mentored career development (K) awards to independent funding (R01/R01 equivalent grants) is a crucial milestone in the career of biomedical scientists. There is evidence of gender disparity among K-awardees and K-to-R

transition rates, with female scientists less likely to receive K awards and convert them to R grants. Multiple factors such as family commitment and resulting career interruptions, limited institutional support, and societal factors represent barriers in academic success for women while cultural and language barriers, or reduced peer support present unique challenges for foreign graduates in career advancement. We evaluated the factors predicting success in obtaining independent grants in breast oncology and the K-award distribution and K-to-R transition by gender and education background between 1997 and 2021.

Methods: We queried the NIH rePORTER database to identify K awardees (K01, K07, K08, K22, K23, K99) in breast oncology from 1997 to 2021. Data on Principal Investigator (PI) name, year beginning the K award, organization and subsequent R01 or equivalent grants, if obtained, were abstracted from the database. PI gender was inferred by using their first name in genderize.io and confirmed with their LinkedIn or institutional profiles. Terminal degree and education details were collected from institutional, or LinkedIn profile and foreign graduates (medical or gradual school and/or doctoral programs outside US) were identified. Median time to first independent grant was calculated. Univariate and multivariate logistic regressions models identified predictive factors for attaining independent grants.

Results: We identified a total of 497 K awardees (PI) in breast oncology. Among them, 306 (61.6%) were females and 191 (38.4%) were males. Majority had a PhD degree (65%), followed by an MD (24%) and an MD/PhD degree (11%). A total of 35% of the PIs came from institutes ranked in the top 20 for NIH funding. About 25% of the PIs were foreign graduates, with fewer female foreign graduates compared to males (19% vs. 34%, respectively, P=0.0002). Overall, male PIs were more likely to receive subsequent R01 or R01 equivalent grants compared to females (62.6% vs. 54.6%, P=0.09) and more likely to receive a single PI grant for their first independent grant (86% vs. 80%, respectively, P=0.27), though not statistically significant. The median time from the K award starting date to the first independent grant was 4.6 years among male PIs compared with 5.4 years among females (P= 0.04). There was no significant difference in median K-to-R time between foreign and US graduates (4.8 vs. 5.02 years, P=0.65); even when stratified by gender. The distribution of female and male K awardees (60-64% female and 36-40% male, P= 0.97) and R01 or equivalent grant recipients (56-58% female and 42-44% male, P= 0.46) has remained stable from 1996-2020. The multivariate analysis did not identify a definitive association with K grant type, K award start time, NIH funding tier, or having a PhD degree in obtaining an R01 level grant in this cohort. Additionally, neither female gender (OR 0.67, CI 0.43-1.03, P= 0.07) nor foreign graduate status (OR 1.35, CI 0.82-2.21, P=0.24) significantly predicted the attainment of subsequent independent grant.

Conclusion: Female K-awardees in breast oncology took a longer time to obtain their first independent R01-level grant than males. Only 25% of the K awardees were foreign graduates, with fewer female foreign graduates compared to males. Neither gender nor foreign education status of K awardees was predictive of subsequent independent grant achievement. This study underscores the need to further study the underrepresentation of

female foreign graduates among K awardees and the need for greater support and mentorship for women in academia to reduce the K-to-R transition time.

P5-02-05: OncotypeDx Molecular Assay Association with Breast Cancer Outcomes in Different Racial Groups

Reine Abou Zeidane, Samuel Lichtman-Mikol, Courtney Pisano, Benjamin Hauk, Yilun Sun, Priyanka Shailendra Rana, Citlally Lopez-Flores, Breanna N. McBean, Kassidy M. Jungles, Philip Bomeisl, Amanda L. Amin, Alberto J. Montero, Janice Lyons, Corey Speers

Background: The OncotypeDx (ODX) score is widely used to guide adjuvant treatment decisions in hormone receptor-positive (HR+) breast cancer. However, racial disparities in breast cancer outcomes raise questions about the prognostic utility of ODX across different populations. This study investigates the differences in ODX scores and associated outcomes among women of diverse racial backgrounds treated at University Hospitals Seidman Cancer Center in Cleveland, OH.
Methods: We conducted a retrospective analysis of 1,122 women diagnosed with early-stage breast cancer who had clinical ODX testing performed from 2013 to 2023. Patients were categorized by self-reported race: African American (AA), White, Asian, and other racial groups. ODX scores were classified into low (0-18), intermediate (19-30), and high (31-100) risk categories. Clinical outcomes, including overall survival (OS) and recurrence-free survival (RFS), were analyzed using Kaplan-Meier survival analysis and Cox proportional hazards models.
Results: The cohort included 1,122 women: 142 (12.7%) AA, 967 (86.2%) White, 10 (0.9%) Asian and 3 (0.3%) patients from other racial groups. Median follow up time was 5.5 years. AA women had higher mean ODX scores compared to White women (18.6 vs. 17.9). AA women had a higher proportion of intermediate-risk ODX scores (34.5% vs. 31.3%) and high-risk ODX scores compared to White women (12.7% vs. 9.0%). The 5-year OS rates were similar between AA and White women (94.0% vs. 93.2%), but the 10-year OS rates showed a slight advantage for AA women (78.2% vs. 74.8%). Similarly, the 5-year RFS rates were also comparable (90.7% for AA vs. 90.4% for White), with a 10-year RFS of 76.8% for AA and 74.6% for White. Multivariable analysis revealed no significant differences in OS (HR 1.12, 95% CI 0.57-2.21, p=0.735) or RFS (HR 1.25, 95% CI 0.72-2.19, p=0.426) between AA and White women after adjusting for ODX risk groups and other clinical factors, though on interaction testing there was a trend towards worse RFS for AA women than White women with intermediate-risk scores. Higher risk level (intermediate and high vs. low, larger T stage, nodal involvement, and older age were all significantly associated with RFS and OS, with diabetes also associated with worse OS but not RFS in this cohort ($p<0.01$). Race was not associated with differences in RFS or OS at any time point. 5-year RFS was similar for low-risk AA and White patients (97.4% vs. 92.1%) and high-risk AA vs. White patients (92.9 vs. 86.9%). There was, however, a trend toward worse RFS for women with intermediate-risk scores between AA and White patients (88.1 vs 80.5%) interaction models indicating that AA women with intermediate-risk scores had a higher hazard ratio

for RFS compared to White women (HR 7.32, 95% CI 2.58-65.43, p=0.07).
Conclusions: Our study found that AA women with early-stage breast cancer had higher proportions of intermediate- and high-risk ODX scores compared to White women. Despite this, the long-term RFS and OS outcomes were generally similar between the two groups, with some suggestion of worse outcomes for AA with intermediate-risk scores. ODX remained prognostic for RFS across all racial groups. These findings suggest that while ODX scores indicate higher risk, they do not fully account for the observed survival outcomes across different racial groups. Further research is needed to understand the underlying factors contributing to these disparities and to optimize the use of genomic tests like ODX in diverse populations.

P5-02-07: Racial Disparities in Breast Cancer Outcomes Based on MammaPrint Scores

Reine Abou Zeidane, Samuel Lichtman-Mikol, Reine Abou Zeidane, Benjamin Hauk, Courtney Pisano, Yilun Sun, Citlally Lopez-Flores, Priyanka Shailendra Rana, Kassidy M. Jungles, Breanna N. McBean, Philip Bomeisl, Amanda L. Amin, Alberto J. Montero, Janice Lyons, Corey Speers

Background: MammaPrint (MP), a 70-gene expression profile, is used to guide treatment decisions in early-stage breast cancer by classifying patients into high or low risk of recurrence categories. However, racial disparities in breast cancer outcomes necessitate an evaluation of MP's prognostic utility across diverse populations. This study explores differences in MP scores and associated outcomes among women of various racial backgrounds treated at University Hospitals Seidman Cancer Center in Cleveland, OH.
Methods: This retrospective cohort study included women diagnosed with early-stage breast cancer from 2013 to 2023 who underwent MP testing at University Hospitals Seidman Cancer Center. Patients were stratified by self-reported race: African American (AA), White, Asian, and other racial groups. MP scores were categorized into high- and low-risk. Clinical outcomes, including recurrence rates and overall survival (OS), were analyzed, and compared across racial groups using Kaplan-Meier survival analysis and Cox proportional hazards models.
Results: The cohort comprised 1349 women with MP testing performed: 212 (15.7%) AA, 1125 (83.4%) White, 8 (0.6%) Asian and 4 (0.3%) patients from other racial groups. In the overall cohort, 873 patients (64.7%) had low-risk MP and 476 (35.3%) had high-risk scores. AA women had a significantly higher proportion of high-risk MP scores compared to White women (49.1% vs. 32.7%). Although the 5-year RFS rates were comparable between AA and White women (76.5% vs. 77.2%), the 5-year OS rates were slightly lower for AA women compared to White women (77.8% vs. 78.2%). MP remained prognostic for RFS at 3-, 5-, and 10 years regardless of race. Multivariable analysis revealed no significant differences in OS (HR 0.94, 95% CI 0.47-1.89, p=0.866) or RFS (HR 0.83, 95% CI 0.43-1.59, p=0.572) between AA and White women after adjusting for MP risk groups and other clinical factors. High-risk MP scores were associated with worse OS (HR 3.06, 95% CI 1.64-

5.70, p<0.001) and RFS (HR 2.68, 95% CI 1.55-4.62, p<0.001) compared to low-risk scores. Other factors associated with worse RFS and OS on MVA were larger tumor size, nodal involvement, and age. Interaction models indicated no difference is OS or RFS in AA women and White women with either low-risk or high-risk MP, respectively.
Conclusions: AA women with early-stage breast cancer were more likely to have high-risk MP scores compared to White women. Despite the higher risk classification, the long-term RFS and OS outcomes were similar between AA and White women. MP remained prognostic for RFS at 3-, 5-, and 10 years regardless of race. These findings suggest that MP scores alone do not fully capture the survival differences across racial groups. Further research is needed to understand the underlying factors contributing to these disparities and to refine the use of genomic tests like MP in diverse populations.

P5-02-08: Assessing Medical Mistrust among Black Adults with and without a Family History of Breast Cancer

Mya Roberson, Laura Crandon, Jordyn A. Brown, Mahima Reji

Background: Medical mistrust is a significant barrier to healthcare utilization and outcomes, particularly in Black communities where historical and systemic inequities persist. Understanding factors influencing medical mistrust is crucial for developing strategies to improve healthcare engagement. This study aims to assess differences in medical mistrust among Black individuals with and without a family history of breast cancer, hypothesizing that a familial history might influence mistrust levels.
Methods: Using community-based recruitment methods in partnership with national Black-led organizations, we conducted an online survey on family history of cancer in Black communities. Individuals could participate if they self-identified as Black or African-American, were 18 or older, resided in the US, and could complete a survey in English. In the survey, participants were asked if members of their immediate families had ever been diagnosed with cancer, and if so, which type of cancers. Participants were then dichotomized into having a family history of breast cancer or not. Medical mistrust was measured using a 5-item validated patient trust in the medical profession scale. Participants were asked to rate their level of agreement with the following statements: Sometimes doctors care more about what is convenient for them than about their patients' medical needs; Doctors are extremely thorough and careful; You completely trust doctors' decisions about which medical treatments are best; A doctor would never mislead you about anything; All in all, you trust doctors completely. Scores on the scale could range from 5 to 25 with higher scores indicating more medical mistrust. The primary outcome was the median mistrust score, and differences between groups were assessed using Wilcoxon rank sum tests.
Results: A total of 95 participants were included, with 39% (n=35) reporting a family history of breast cancer and 61% (n=60) without. The overall population exhibited high mistrust, with a median score of 18. The median mistrust score for those with a family history of breast cancer was 18 (IQR: 16-21), compared to 18 (IQR: 16.5-21) for those

without. The Wilcoxon rank sum test showed no statistically significant difference in median mistrust scores between the groups (p = 0.87).
Conclusion: In this community-based survey of Black adults, medical mistrust was uniformly high, regardless of a family history of breast cancer. These findings underscore the need for interventions that promote trustworthiness in medical institutions to mitigate high levels of mistrust in Black communities.

P5-02-09: Evaluating the Clinical Utility of Bioimpedance Spectroscopy for Early Detect of Breast Cancer-Related Lymphedema in Ethnic Minority Populations

Fardeen Bhimani, Yu Chen, Sheldon Feldman, Priyanka Parmar, Andreina Giron, Gabrielle Safian, Kaiyu Tio, Anjuli Gupta, Jessica Pastoriza, Maureen McEvoy

Background: Advances in breast cancer treatments have significantly improved long-term survival rates. With increased survivorship, addressing the long-term outcomes of breast cancer treatments is crucial. Breast cancer-related lymphedema (BCRL) is a chronic complication that significantly impacts the quality of life of affected patients. Historically, BCRL occurs in 3-8% of patients undergoing sentinel lymph node biopsy (SLNB) and 13-60% of those undergoing axillary lymph node dissection (ALND). These rates are two-fold higher in low-income and ethnic minority populations, with Black women showing a greater susceptibility to BCRL. Early detection is crucial, and SOZO®, a device utilizing bioimpedance spectroscopy (BIS), has proven to be an accurate tool in detecting lymphedema. However, there is a paucity of literature examining the utility and applicability of BIS in diverse ethnic populations. Therefore, the aim of our study was to evaluate the clinical utility and applicability of SOZO® in diagnosing BCRL within ethnic minority groups.
Methods: A retrospective chart review of patients who underwent axillary surgery between January 2019 to December 2023 was conducted. Demographic and clinical data were collected for all patients. Patients undergoing axillary surgery were assessed for their preoperative L-Dex score and then followed up postoperatively with measurements at 3-month intervals. Clinical lymphedema was defined as having an absolute L-Dex score of ≥ 10 and an increase of 6.5 or more from the baseline. Descriptive and Chi-square analyses were performed on the data.
Results: Of the 427 patients, 80% were from ethnic minority backgrounds (Black race and Hispanic ethnicity). SLNB was performed in 83.6% of cases, ALND in 16.4%, and 67.2% underwent radiation therapy. In total, 40 patients developed BCRL, with 33 cases being transient lymphedema and 7 persistent. No significant difference in BCRL incidence was observed across different racial groups. The overall lymphedema rate was 1.64%. Compared to a historical BCRL incidence of 40.4% following ALND in ethnic minorities, our study reported a significantly lower rate of 12% ($p < 0.001$).
Conclusion: SOZO® can accurately detect BCRL, aiding in its early detection and management. Despite historical data indicating higher BCRL rates in low-income and

minority groups, our study found significantly lower rates among our Black race cohort compared to historical controls. Of the 40 patients who developed BCRL in our study, 33 experienced transient lymphedema, while 7 had persistent lymphedema. Early recognition through SOZO® led to the resolution of lymphedema in 33 patients, preventing progression and reduced quality of life. However, future studies with larger sample sizes across multiple institutions are needed to bolster our findings.

P5-02-10: Factors and Trends in Place of Death Among Breast Cancer Patients: A Population-Based Study in Brazil

Jesse Lopes da Silva, Natalia Cristina Cardoso Nunes, Livia Costa de Oliveira, Lucas Zanetti de Albuquerque, Pedro Henrique Souza, Andreia Cristina de Melo, Luiz Claudio Santos Thuler

Background: The quality of death serves as an indicator of the quality of care, shaped by factors such as the place of death, access to palliative care, and symptom management. In the context of Brazil, a diverse landscape with regional social disparities can lead to unequal access to healthcare, particularly in breast cancer (BC), which is the leading cause of cancer-related deaths among Brazilian women. Unlike in developed countries, dying at home in Brazil may suggest inadequate end-of-life care. Understanding the patterns of place of death and their association with social inequalities is crucial for developing effective end-of-life care policies for women with breast cancer in Brazil.
Methods: This cross-sectional study in Brazil used data from the Mortality Information System (2001-2021) to analyze breast cancer deaths (ICD-10 C50) based on place and year of death. Deaths were categorized as hospital or home deaths, and evaluated variables included age, race, education, marital status, and regional Human Development Index (HDI). Trends in death rates were assessed by using Joinpoint Regression, and the relationship between home deaths and regional HDI was assessed by Pearson correlation. Univariate logistic regressions calculated odds ratios to determine factors influencing home deaths, with statistical significance set at $p<0.05$.
Results: Between 2001 and 2022, there were 303,279 BC deaths in Brazil, with 299,775 cases included in the study after excluding men (3,329) and patients with missing data on sex (17) or place of death (158). Of these, 253,581 (84.6%) occurred in hospitals, while 46,194 (15.4%) occurred at home. Home deaths were more frequent in the Northeastern (15,438, 25.1%) and Northern (2,255, 20.4%) compared to the Southern (8,367, 15.6%), Central-Western (2,647, 14.4%), and Southeastern (17,487, 11.3%) regions. Patients from the lower HDI regions of the North, Northeast, and Central-West had higher rates of home deaths (OR = 2.04, 95% CI = 2.00-2.08) compared to those in the higher HDI Southeastern and Southern regions, showing a strong inverse correlation between home death proportion and regional HDI (Pearson's Correlation Coefficient = −0.932, p = 0.021). Temporal trend analysis indicated a significant continuous reduction in home deaths from 2001 to 2017, decreasing annually by 2.6% from 19.1% to 12.5% (APC = −2.6%, 95% CI = −3.0 to −2.3, $p < 0.001$). This was followed by an increase to 17.7% in 2020 (APC = 12.4%,

95% CI = 4.3 to 21.2, p = 0.005) and a return to a non-significant decrease to 16.2% by 2022 (APC = −4.3%, 95% CI = -10.4 to 2.2, p = 0.172). Higher rates of BC home deaths were associated with older age (≥ 60) (OR = 1.79, 95% CI = 1.75–1.83), lack of formal education (OR = 3.02, 95% CI = 2.92-3.13), absence of a partner (OR = 1.28, 95% CI = 1.25-1.30), and self-reported ethnicity, with black and mixed-race (OR = 1.14, 95% CI = 1.11-1.16) and indigenous women (OR = 1.92, 95% CI = 1.45-2.56) having higher home death rates compared to white women.
Conclusions: The study underscores a high rate of home deaths among BC patients in Brazil, highlighting the absence of national end-of-life care programs and palliative care structures, especially in underdeveloped regions. Home death rates were inversely correlated with regional HDI. Temporal trends showed a continuous reduction in home deaths, with a temporary increase likely linked to the COVID-19 pandemic. Factors such as ethnicity, educational level, and marital status also influenced the place of death. These findings underscore the need for policies addressing the impact of social factors like race, education, and HDI on the location of end-of-life care for BC patients in Brazil.
Keywords: Breast cancer; endo-of-life, social disparities, place of death.

P5-02-11: Health-care disparities between ethnically and religiously diverse population with advanced breast cancer

Shani Paluch-Shimon, Inbal Fuchs, Gil Goldzweig, Yehosua Akerman, Daniel Yusovich, Luna Kaduri, Ofra Maimon, Irit Marle, Beatrice Uziely, Noa Shafri, Yael Wygoda, Michal Braun

Background: In Israel all residents are covered by universal health care and yet disparities in health care access and utilization exist. Jerusalem is the largest and poorest city in Israel, with significant Jewish ultra-orthodox and Arab communities. These two groups have shared reproductive factors, similar patriarchal community structures and often live in poverty. Under-utilization of health care services exist and yet no research has been performed on these populations in the advanced breast cancer (ABC) setting.Methods: Women with ABC were prospectively recruited after consenting and self-identified their religion & level of religiosity. Clinical and demographic data were collected from the electronic medical record. Statistical comparisons were performed of demographic, clinical data and patient outcomes. Comparison of categorial variables was conducted by means of Chi Square calculations. Survival analyses were conducted by Kaplan-Meier analysis and Cox regression analysis. Focus groups and cross-sectional surveys of health care professionals (HCPs) were performed to assess perceived barriers to care. All analyses were conducted using the Statistical Package for the Social Sciences (SPSS) (version 28.0).
Results: The study included 179 patients, of whom 139 (77.7%) identified as Jewish Israeli and 39 (21.8%) as Arab. Amongst the Jewish patients, 31.4% identified as ultra-orthodox and 88% of the Arab patients identified as Muslim. 57% of patients were under the age of 50 with no difference between ethno-religious groups. Ultra-orthodox patients had a median of 6 children (range 0-16), the Muslim 4.5 (range 0-8) and the Jewish-other 3 (range 0-10), p<0.001. Menopausal status differed between groups - 55.5% of Jewish-other

patients were post-menopausal, as compared to 20.9% of ultra-orthodox and 39.4% of Muslim patients, p=0.032. At diagnosis, 75% of ultra-orthodox patients and 63.6% of Muslim patients had stage IV disease as compared to 34.3% of secular, 26.9% of traditional and 59.4% of orthodox Jewish patients, p<0.001. 87.9% of Muslim patients had HR+/HER2-neg subtype compared to 68.2% of the ultra-orthodox, 67.7% of orthodox, 68% of traditional and 57.1% of secular patients, p=0.006. Once diagnosed with metastatic disease, there were no significant differences in standard of care management as measured by performance of biopsy at recurrence, administration of standard of care therapies and performance of genetic and genomic testing when indicated.
Overall survival (from initial diagnosis until death) adjusting for age & stage at diagnosis & subtype was significantly worse for the Muslim patients, followed by the ultra-orthodox as compared to the Jewish-other population (p<0.001). Hazard ratio (HR) for death for an ultra-orthodox patient compared to Jewish-other was HR 3.61 [95% CI 1-13] and for a Muslim patient compared to Jewish-other was HR 4.64 [95% CI 1.2-17.]
Key themes amongst the HCPs with regards to both minority groups was the perception that both receive sub-optimal care and that many barriers exist including poor communication, poor understanding of culture and norms of these groups as well as a sense of judgment towards these groups. This led to strong feelings of helplessness and frustration amongst the HCPs. The findings were similarly expressed towards both minority groups. However, regarding the Arab patients the main barrier identified was language.
Conclusions: Significant health care disparities exist amongst women with ABC in terms of disease characteristics and patient outcome, with less favorable characteristics and outcomes amongst Muslim Arab and Ultra-orthodox Jewish patients compared to the general Jewish population in Jerusalem. Further research is needed to understand the cause of these disparities and to create effective interventions to bridge these gaps.

P5-02-12: Increasing clinical trial enrollment rates of black women with breast cancer through Patient Navigation and Community Education programs

Tina Chai, Sonya Reid, Tuya Pal, Emma Schremp, Clorissa Campbell, Meredith Smalls, Courtney Thomas, Debra Friedman

Background: While Black women represent 12% of breast cancer cases in the US, they comprise only 3% of participants in clinical trials. At the Vanderbilt Ingram Cancer Center (VICC), Black patients represent 9% of all breast cancer patients, but only 4% of those are enrolled in clinical trials.
Objective: This pilot study evaluated the role of Patient Navigators (PNs) to increase knowledge of clinical trials among Black women with breast cancer at the Breast Cancer Clinic at VICC. Concurrently, we provided community-based education focused on breast cancer and clinical trials.
Methods: All Black women in the Breast Clinic at VICC were offered PN services. Those who agreed were asked to complete a needs assessment and provided with PN resources as

needed throughout the duration of their treatment. As part of the PN program, patients were provided with educational material about clinical trials as well as assistance with identified needs. Patients were surveyed one-month following the start of the navigation experience and at the end of their navigation experience. For the community education component, a trained educator presented information on breast cancer and the importance of clinical trials at established community events and participants were asked to complete a post-education survey.
Results: From February through May 2024, 29 of 33 (88%) of eligible patients joined the PN program. Of 14 patients who completed the first post-navigation survey, all found meetings with PNs to be valuable. Additionally, 11 (79%) reported that they knew very little to nothing about clinical trials prior to PN intervention with 8 of 11 (73%) reported having increased knowledge following PN. Of 12 respondents, 6 (50%) reported that they would be more likely to enroll on a clinical trial as a result of PN, and 9/14 (64%) indicated that they would share information about clinical trials with others. We have held 4 community-based education activities since February 2024, with an average of about 21 attendees per event. Of 56 patients who completed the post-event survey, 54 (96%) indicated they were satisfied with the information presented, 45 (80%) stated that they are willing to advance new medicine and treatments by participating in clinical trials, and 53 (95%) agreed that mistrust, being uninformed, and being uninsured are reasons racial and ethnic groups do not participate in research.
Conclusions: Implementation of patient navigation services for Black patients with breast cancer coupled with community-based education is an effective approach to increase knowledge of and identifying barriers to enrollment on clinical trials. As accrual continues in our pilot study, we will examine the impact of patient navigation on the patient care experience and enrollment in clinical trials and the knowledge about clinical trials gained from community-based education.

P5-02-14: The Value of RNASeq in Addressing Breast Cancer Disparities Among Minority Populations: A Focus on African American Women

Catalina Esguerra, Roy Khalife, Shahla Masood, Anthony Magliocco

Background: Breast cancer is a heterogenous disease with diverse behavior, the basis of which is unclear. Breast cancer (BC) is a significant health concern for women globally, but it manifests with notable disparities across different ethnic groups. African American (AA) women experience a paradox in breast cancer—they have a lower incidence rate of breast cancer compared to their white counterparts, yet they suffer from a higher mortality rate. This disparity spotlights a gap in understanding the underlying biological factors contributing to these outcomes. Genetic factors play a crucial role in breast cancer risk and prognosis. In complement to DNA, RNA sequencing (RNASeq) is able to demystify these pathways. Unlike DNA sequencing, which provides static information about genetic mutations and variants, RNASeq offers dynamic insights into gene expression levels and patterns, revealing how genes are regulated and expressed in different tissues and

conditions. There is a significant lack of research exploring gene expression and patterns prevalent in African American women and other minority groups. Methods: Differential expression was run on a pilot study of 10 subjects via RNAseq data. An AA BC group (n=5) and a White (W) BC group (n=5). When comparing W tumor to W normal, 2921 genes were significantly different; comparing AA tumor to AA normal, 4913 genes were significantly different. These lists were filtered to only contain log2fold changes of the absolute value of 3 or greater, which filtered W to 108 genes and AA to 149 genes. These lists were uploaded to NIH's DAVID Bioinformatics, which provides functional annotation clustering. Results: Using NIH's DAVID Bioinformatics, a general overview of the two racial groups was assessed. The W BC subgroup was characterized to have significant enrichment in oxidoreductase pathways. Genes highlighted are STEAP4, ACADL, ADH1A, ADH1C, AOX1, AKR1C1, CDO1, CYP3A5, MAOA, RRM2. This cluster is statistically significant demonstrated by a P-value of 2.6E-5 and a Benjamini value of 7.6E-3. The AA BC subgroup was characterized to have significant enrichment in genes involved with mitosis and cell proliferation. Genes identified under this subgroup are NEK2, NUF2, TPX2, ASPM, AURKA, AURKB, CDC20, CDCA8, CENPA, CENPF, and KLHL13. This cluster is statistically significant demonstrated by a P-value of 3.8E-7 and a Benjamini value of 2.1E-5. Outside of DAVID, significant genes were assessed for each racial group. The white group had significant mutations in EGFR, ESR1, FGF10/12/13, and IDH1. While the African American group had significant mutations in CDH1, CDK4, FGF7, FGF9, FGFR4, HRAS, KDM6A, MSH3, MSH6, and PTEN. Both groups were noted to have unique fusion patterns. Conclusion: Each subgroup exhibited unique key genes that were significantly upregulated or downregulated. While mutations in genes such as EGFR and ESR1 in the W group are extensively studied, several genes identified in the AA group, except for CDK4, require further research to elucidate their roles in breast cancer. According to the DAVID analysis, the AA BC group exhibited significant enrichment clusters under mitosis. CDK4/6 inhibitors, a popular BC treatment that targets cell proliferation, might be beneficial for AA women. However, since African American women also have a higher incidence of triple-negative BC, where CDK4/6i (HR+/HER2− monotherapy) is not indicated, the BC treatment guidelines for AA women can be unclear. Understanding unique gene signatures in African American women with breast cancer is essential. Incorporating novel technologies like RNASeq into treatment plans can help address disparities between populations. This approach can lead to more comprehensive BC prevention, diagnosis, and treatment strategies. Ultimately, this will not only improve outcomes for African American women but also enhance our overall understanding of breast cancer across diverse populations.

P5-02-15: Impact of socioeconomic factors on stage of diagnosis and mortality among breast cancer patients

Yolcar Chamorro, Muni Rubens, Mukesh Roy, Reshma Mahtani, Naomi Dempsey, Lauren Carcas, Manmeet Ahluwalia, Ana Sandoval-Leon

Background: Breast cancer (BC) is the most common cancer and the second leading cause of cancer deaths among US women. From 1989 to 2017, mortality rates dropped by 40%, largely attributed to the widespread adoption of mammogram screening and advancements in treatment. However, disparities persist with Black women experiencing 40% higher mortality than White women. Delays in diagnosis due to limited access to screening and treatment contribute to this disparity. Social determinants of health further impact the accessibility and quality of healthcare received. This study examines socioeconomic influences on BC stage at diagnosis and mortality.

Methods: We conducted a retrospective analysis of data from the National Cancer Database (NCDB), a joint project of the Commission on Cancer of the American College of Surgeons and the American Cancer Society. All female patients (pts) ≥18 years with a diagnosis of stage 0-IV breast cancer (BC) treated from 2004 to 2020 were included. Race/ethnicity included White (W), Black (B), Hispanic (H), and Other (O). Income and education were categorized into quartile (Q) I, II, III, and IV from lowest to highest per NCDB definitions. Kaplan Meier analysis with log rank test was done to compare the overall survival from diagnosis and Cox proportional analysis was done to estimate hazard ratio.

Results: A total of 1,826,818 pts were included in the analysis. Of these, 79.5% were White (W), 11% Black (B), 4.9% Hispanic (H), and 4.6% Other (O) that includes (Asian, American Indian, and other). Overall, most pts were in income and education Quartile 4 (38.1% and 42.4%). W pts had a higher proportion of stage I disease at diagnosis (47%) when compared to B (35.6 %) and H (38.2%) pts ($p<0.001$). In contrast, W had a lower proportion of stage III (7.9%) when compared to B (11.2%) and H (10.7%) ($p<0.001$). B pts had a higher proportion of stage IV (5.2%) compared to W (3%) and H (3.4%) pts ($p<0.001$). Income Q4 had a higher proportion of stage I (46.6%) compared to Q1 (41.2%). Income Q4 had a lower proportion of stage III (7.3%) and IV (2.7%) compared to income Q1 (10.3% and 4.4% respectively). Similarly, education Q4 had a higher proportion of stage 1 (47.1%) compared to Q1 (40.3%). Education Q4 had a lower proportion of stage III (7.3%) and IV (2.7%) compared to Q1 (10.5% and 4.4% respectively). All these differences were statistically significant $p<0.001$. Income distributions among race/ethnicity showed that W had a lower proportion in Q1 (10.9%) compared to B (38.4%) and H (22.4%). In contrast, W had a higher proportion in Q4 (40.5%) compared to B (18.2% and H (26.9%). We found similar disparities when we evaluated education distributions among race/ethnicity. Kaplan Meier analysis showed that mortality was significantly higher for B, lowest income quartile, and lowest education quartile for all stages (log rank $P<0.001$). Cox proportional analysis showed that mortality was highest for B (HR: 1.12; 95% CI, 1.11-1.13, $P<0.001$), lowest income quartile (HR: 1.22; 95% CI, 1.21-1.24, $P<0.001$), and lowest education quartile (HR: 1.09; 95% CI, 1.08-1.10, $P<0.001$).

Conclusion: Results of this study show that race and ethnicity as well as pt income and education level were associated with stage of diagnosis and mortality among BC pts. Identifying barriers to accessing screening imaging and adequate BC treatment can help us develop systems that will give extra support to pts in need. Future studies should focus on developing interventions to decrease these disparities and improve outcomes.

P5-02-16: Thymidine kinase activity as a prognostic biomarker for first line CDK4/6 inhibitor efficacy in the Personalised Disease Monitoring in Metastatic Breast Cancer study

Sacha Howell, Bergqvist Mattias, Williams Amy, Mouhanna Pia, Albu-Kareem Ahmed, Elinder Ellinor, Eriksson Olle, Kavanagh Amy, Larsson Karolina, Uminska Monika, Ekholm Maria

Background: There is an unmet need for biomarkers that improve prediction of treatment efficacy in metastatic breast cancer (MBC). Thymidine kinase (TK) is an enzyme with a critical role in DNA synthesis downstream of the CDK4/6 pathway. We assessed serum TK activity (TKa) as a prognostic biomarker in the Personalised Disease Monitoring in Metastatic Breast Cancer (PDM-MBC) study.
Method: The PDM-MBC study (NCT04597580) is a biomarker development study that enrolled 97 patients with estrogen receptor-positive, HER2-negative MBC treated with an aromatase inhibitor (AI) plus a CDK4/6 inhibitor as 1st line endocrine therapy. Follow-up is ongoing until May 2026. Computed tomography (CT) assessed by RECIST 1.1 (and magnetic resonance imaging (MRI) in case of bone-predominant disease) was performed every 3 months year 1 and every 3-4 months thereafter or earlier if clinically indicated. Serum samples were collected at baseline (BL), day 15 of cycle 1 (C1D15), day 1 of cycle 2 (C2D1), thereafter at each imaging timepoint and subsequent doctor's visit until disease progression. TKa was analyzed with the FDA cleared DiviTumÒ TKa assay (Biovica). The association between TKa levels and early TKa dynamic patterns and progression-free survival (PFS) and overall survival (OS) was evaluated using the Kaplan–Meier method, logrank test and univariable Cox regression analysis.
Results: In total, 86 patients had TKa results available at BL and 77 had results for all three timepoints. The median PFS and OS were 20.8 and 51.8 months, respectively. High TKa (above the FDA stipulated cut-off 250 DuA) at BL was associated with shorter PFS (median 13.5 months vs not reached [NR], p=0.002), shorter OS (median 30.3 months vs 51.8, p=0.017), higher risk of progression (hazard ratio [HR] 2.46, 95% confidence interval [CI] 1.37 to 4.44, p=0.003) and higher risk of death (HR 2.53, 95% CI 1.15 to 5.58, p=0.022). Using ≥100 DuA to define high TKa, four patterns of early TKa dynamics were observed during the first treatment cycle (BL, C1D15 and C2D1) based on BL TKa and the level of subsequent suppression. PFS (p=0.003) and OS (p=0.03) differed significantly by logrank test between the four groups:
Low-Low-Low (n=14) median PFS and OS not reached;
High-Low-Low (n=26) PFS 23.8m (95%CI can't be calculated) and OS 51.8m (95%CI 15.4 to 88.1);

High-Low-High (n=24) PFS 17.5m (95%CI 10.2 to 24.8) and OS 34.3m (95%CI15.1 to 53,7)
High-High-High PFS 10.3m (95%CI 1.73 to 18.9) and OS 30.3m (95%CI 15.1 to 45.6)
In exploratory analyses no significant differences between median TKa at C1D15 or C2D1, or early TKa dynamic patterns were observed between patients treated with palbociclib (n=48) vs ribociclib (n=29), p=0.33 to 1.0.
Conclusions: In the PDM-MBC study, we confirm that TKa is a valuable prognostic biomarker in patients treated with AI and CDK4/6 inhibitor as first-line therapy for MBC. TKa dynamics during the first cycle identifies patients at risk of early progression and those with more prolonged response. TKa analysis at later time points is ongoing. TKa is an encouraging biomarker for personalized disease monitoring in MBC.

P5-02-17: Concordance Analysis of Non-Invasive determination techniques of PIK3CA and ESR1 mutations in patients with advanced luminal breast cancer. Study CANIPE

Teresa Curiel, Carmela Rodriguez, Aitor Rodriguez Casanova, Nerea González, Ramón Lago-Lestón, Martín Giráldez, Alicia Abalo, Carmen Abuín, Maribel Aibar, Patricia Palacios, Juan Cueva, Marta carmona, AlexiaCortegoso, Serafín Morales, Josep Gumá, Mariana López Flores, Yolanda Fernández, Isaura Fernádez, Ignacio Fernández, María Gión, Carolina Pena, Jesús García Mata, Andrea Saenz de Miera, Angel Díaz Lagares, Laura Muinelo Romay, Clotilde Costa, Rafael López López

Approximatly 70% of breast cancer (BC) patients are Hormone Receptors (HR) positive, the most common subtype with the best prognosis. The combination of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) with Endocrine Therapy (ET) is tje standard firs-line therapy for HR+/HER2- metastatic BC. However, 20% of patients are intrinsically resistant, and those who initially respond often develop acquired resistance, making the management of resistant HR+/HER2- metastatic BC a significant clinical challenge. Clinical guidelines emphasize the need of comprehensive real-time monitoring of the dynamic mutational landscape during and after treatment to improve resistance prediction. Early detection of mutations in ESR1 and the PIK3 pathway usinf circulating tumor DNA (ctDNA) may allow the ending of ineffective endocrine therapies and initiation of alternative treatments for these patients, without performing tissue biopsies before radiological progression occurs. To achieve this, it is crucial to implement non-onvasive genotyping that allows better-adapted pharmacologiical interventions. However, clinical trials have been predominantly carried out with selected populations and single drugs (Palbociclib, Ribociclib or Abemaciclib). There is a lack of studies of optimal agreemnt between diagnostic methods, especially in liquid biopsy. There is no relieble data abaout PIK3CA or ESR1 status in ctDNA from real-world cohorts that could help to define the best testing strategy for the clinica routine.
Therefore, it is imperative to establish evidence that the use of ddPCR is equally or more sensitive for ctDNA analysis than qPCR or NGS, the current gold standard methods.

Aim: This study aims to perform a concordance analysis between NGS and ddPCR technologies for detecting mutations in PIK3CA and ESR1 by testing the ctDNA from HR+/HER2- metastatic breast cancer patients.

M&M: CANIPE is a randomised, open-label study performed al 14 Spanish hospitals in 6 autonomous communities. Patients aged 18 years or older, with confirmed HR+/HER2- breast cancer, stage IV, Eastern Cooperative Oncology Group performance status (ECOG-PS) of 0 to 2, who iniciate first-line tratment with CDK4/6i plus aromatase inhibitors. All procedures followed the Helsinki Declaration guidelines and were approved by the Ethics Commitee of Santiago-Lugo under approval reference number 2022/386. All patients provide written informed consent. A total of 60 women were recruited at baseline (before therapy initiation) while 21 patients at 10 months after treatment. 40 mL of blood was obteined from each patient at both time points. For ddPCR, cfDNA was isolated from 5 mL of plasma using the QIAamp Circulating Nucleic Acid Kit (Qiagen, Venlo, The Netherlands). Multiplex ddPCR was performed with de Bio-Rad QX-200 system to identify PIK3CA mutations, including the most frequent variants (E542K, E545K, H1047L, H1047R, R88Q, N345K, C420R, E545A, E545G,Q546K), and ESR1 mutations (L536R, D538G, E380Q, Y537C, /537S, Y537N,S463P). A mutation was considered present if at least 6 mutated events were detected by ddPCR. Additionally, for NGS, cfDNA was isolated from 4 mL of plasma and analysed with the AVENIO ctDNA Expanded kit (Roche Diagnostics), which includes 77 genes, including PIK3CA and ESR1. An allele fraction od 0.5 % or higher was consideredindicative of a mutation.

Results: At baseline, and considering the pre-defined criteria, ctDNA analysis detected PIK3CA mutations in 32.25% and 44.44% of patients by AVENIO and ddPCR, respectively. ESR1 mutations were detected in 3.22% and 9.37% by AVENIO and ddPCR, respectively. For PIK3CA mutations, the Kappa value was 0.62 (p-value: 0.0004) and 0.47 for ESR1 mutations (p-value: 0.0039). However, when NGS data was included for mutations with allele fraction less than 0.5%, the Kappa value was 0.92 for PIK3CA and 1 for ESR1, indicating almost perfect agreement bvetween the two technologies (p-value < 0.0001).

Conclusion: The analysis of ctDNA bu Multiplex ddPCR of HR+/HER2- metastatic breas cancer patients represent a sensitive tool to identify PIK3CA and ESR1 mutations with a high concordance compared with the NGS, which is currently the reference technology.

P5-02-18: mRNA Expression of ER, PR, Her2 and Ki67 compared to immunohistochemistry in 374 breast cancer core needle biopsies to validate and benchmark routine diagnosis using the APIS Breast Cancer Subtyping Kit

Anne-Sophie Wegscheider, Incken Kramme, Michael Behr, Joanna Gorniak, Anna Gasior, Sara Rollinson, Andreas Voss, Bernhard Ulm, Axel Niendorf

Determination of the Estrogen- as well as Progesteronreceptor (ER and PR), Her2 (ERBB2) and Ki67 are fundamental in the first line diagnostic of breast cancer diagnosed on core needle biopsy (CNB) with important implication on further individualized clinical management. With the intention to first benchmark routine diagnostic results and furthermore validate the APIS Breast Cancer Subtyping Kit in a large cohort of breast cancer cases (n=374) immunohistochemistry (IHC) as well as mRNA expression ER; PR, Her2 and Ki67 were compared. The APIS Breast Cancer Subtyping Kit included an additional set of proliferation-relevant genes that could be compared to Ki67.
Case characteristics were the diagnosis of invasive carcinoma on CNB with tumour Nottingham grade “1” (n=58/16.1%), “2” (226/62.8%), “3” (76/21.1%) and undetermined (14/na). The APIS Breast Cancer Subtyping Kit is a multiplex RT-PCR based test that has previously been developed by our groups and is described in detail with training and test results (Diagnostics 2024, 14, 2411). Here we report the prospective application of this test. Using IHC as a gold standard the overall performance for the different biomarkers is shown in the sequence of sensitivity, specificity and accuracy as well as the kappa value with 95% CI in brackets:
ER: 83.7% (79.1-87.3) / 100% (94.1-100) / 86.3% (82.4-89.6) / 0,626; PR: 89.9% (85.9-92.9) / 82.1% (72.6-88.9) / 88.2% (84.4-91.3) / 0.761; ERBB2: 80.0% (68.2-88.2) / 98.7% (86.7-99.5) / 86.8% (82.9-90.1) / 0.831; MKI67: 88.6% (82.8-92.5) / 70.3% (63.7-76.2) / 78.5% (73.9-82.6) / 0.575; Proliferation (V KI67 IHC): 86.7% (80.7-91.1) / 70.3% (63.7-76.2) / 77.7% (73.1-81.8) / 0.559
Discordance could be largely explained by tumour-heterogeneity and threshold values which were predetermined, for both methods, and not adopted within this study. However, re-evaluation with an alternate technique might well be suitable to redefine these threshold values which can be especially important in general determination of KI67 or other proliferation relevant genes/proteins and in addition to better define the so far not sufficiently described “Her2-low”-group. Since the ground truth is finally unknown there will also be further studies to investigate the functional and clinical relevance of these respective approaches using endpoints like outcome and chemo-endocrine responsiveness.
In conclusion this approach is suitable to determine ER, PR, Her2 and Ki67 in cases where 1) IHC is not available, 2) where IHC should be benchmarked as a quality control measure and 3) in critical cases where IHC-results are inconclusive.

P5-02-19: Why Are We Failing to Cure So Many Cases of Lobular Breast Cancer?

Robert Smith, Renáta Bozó, Peter B. Dean, Katalin Ormándi, Olga Puchkova, Orsolya Oláh-Németh, István Balázs Németh, Zoltán Veréb, F. Lee Tucker, Amy Ming-Fang Yen, Li-Sheng Chen, Hsiu-Hsi Chen, András Vörös, László Tabár

Invasive lobular cancer of the breast (ILC) is responsible for more than its share of treatment failures. Long-term survival of women with classic ILC has not improved significantly over the past half century, despite major improvements in breast cancer therapy and diagnosis. Foote and Stewart considered lobular carcinoma in situ (LCIS) to be the precursor of ILC, and that the "the mass eruption of tumor cells" occurred through "some lytic action of the tumor cells, naturally not to be detected by anatomic study." Ackerman and Del Regato accepted this proposed mechanism, concluding that ILC arises from the acinar epithelium of the breast lobule. Despite the absence of clear evidence, these speculations were accepted as established fact more than 70 years ago. An inconvenient observation, the lack of E-cadherin staining, was assumed to result from a "loss" of that protein during tumor development. Our research group, the Swedish Organized Service Screening Evaluation Group, has examined all histologically proven ILC cases from Dalana County Sweden diagnosed from 1996-2019 with follow-up to the end of 2021. Histopathologic study of large section (8x10 cm) pathology slides, imaging and molecular biomarkers of 329 consecutive diffuse form of ILC showed a macroscopic structure unlike breast cancers of epithelial origin, a 19-year survival (56 %), poorer than expected from the histochemical biomarkers, and a growth pattern closely resembling that of normal breast tissue, hindering mammographic detection. Our group considered that ILC may originate from mesenchymal hybrid cells through the process of mesenchymal-epithelial transition (MET). Our cell culture studies from typical ILC cases progressed through more than 10 cell cycles in one year's time and produced cells with the properties of mesenchymal hybrid cells. Histopathology-breast imaging correlation indicated two ILC subgroups with separate sites of origin. The classic, diffuse type of ILC appears to evolve from the extralobular mesenchyme of the breast. A second subgroup appears to evolve from and generally remain within the intralobular mesenchyme of the breast, appearing as multiple small colonies, each surrounding the acini and terminal ducts of the lobule, which invariably have normal, non-malignant epithelium. This intralobular subgroup has distinctly different imaging biomarkers, appearing as a distinct tumor mass easily detected at mammography. The 231 consecutive intralobular cases had 84% survival at 19-year follow-up. Differentiating the two is difficult based on the limited field of view offered by the conventional 1x3 inch glass slides. However, low-power histopathology of large sections correlates well with imaging findings and assists in differentiating these two subtypes. This translational research is consistent with new directions in precision medicine. Conclusions: The accepted terminology and assumptions of the nature of "ILC" must be reconsidered if we are to improve the poor survival rate of this misunderstood malignancy. Therapies, such as radiation and chemotherapy, are effective in treating epithelial breast cancers but are less effective in treating classic ILC, possibly due to a stem

cell origin. Likewise, the IHC biomarkers are less predictive of prognosis in classic ILC for the same reason. Further, surgical removal of this diffuse malignancy is often incomplete as the full disease extent is difficult to evaluate by any imaging technique. So long as this unusual breast malignancy is termed "classic diffusely infiltrating lobular carcinoma," implying that it has its origin in the acinar cells of the terminal ductal lobular units (TDLUs), we are unlikely to achieve any real progress in our efforts to control it. Appreciation of its mesenchymal stem cell origin offers a radically new approach to research and treatment.

P5-02-20: Clinicogenomic landscape and function of PIK3CA, AKT1, and PTEN mutations in breast cancer

Jacqueline Tao, Saumya Sisoudiya, Smruthy Sivakumar, Ethan Sokol, Neil Vasan

Background: The AKT inhibitor capivasertib was recently approved in the 2L+ setting for patients (pts) with hormone receptor-positive metastatic breast cancer with alterations in PIK3CA, AKT1, and/or PTEN. There is a need to further characterize the landscape of PIK3CA, AKT1, and PTEN mutations in breast cancer and their functions, to improve our understanding and therapeutic targeting of PI3K-driven breast cancer.

Methods: 51,767 pts with breast cancer who underwent tumor sequencing using FoundationOne®CDx or FoundationOne® were included in this analysis. We assessed the frequency, type, and pathogenicity of genomic alterations found in PIK3CA, PTEN, and AKT1 overall and stratified by receptor subtype, patient ancestry, and sample type. Co-occurrence with other pathogenic variants was explored using a Fisher's exact test with a FDR correction. We correlated PTEN mutations with functional data from deep mutational scanning.

Results: The most frequently altered PI3K-pathway gene was PIK3CA (37.4%, 19,384/51,767), followed by PTEN (13.5%) then AKT1 (5.4%), including both pathogenic and VUS alterations in all genes. Among 1,024 distinct PIK3CA alterations identified, 690 (67.4%) were missense mutations. The most common missense mutations were H1047R (35.6% of PIK3CA-altered cases), E545K (19.7%), and E542K (11.7%). Among 288 AKT1 alterations identified, 205 (71.2%) were missense mutations. The most common missense mutation was E17K (69.7% of AKT1-altered cases) followed by gene amplification (14.0%). The most common alteration among patients bearing PTEN alterations was gene deletion (37.3% of PTEN-altered cases). Among 1,723 distinct PTEN alterations identified, 721 (41.9%) were frameshift mutations, 494 (28.7%) were missense mutations, and 246 (14.3%) were splice site mutations. To determine function, PTEN mutations were correlated with existing PTEN deep mutational scanning datasets; these data will be presented.

PIK3CA pathogenic alterations were more prevalent in estrogen receptor (ER)+/HER2- and HER2+ cases (40.3% and 37.6% of cases) versus triple negative breast cancer (TNBC;

20.9%), consistent with previously described data. Among all pathogenic PIK3CA alterations, those outside the 542, 545, and 1047 codons were more common in TNBC (42%) compared to ER+/HER2- or HER2+ (33%, p=0.002 and 33%, p=0.002). AKT1 mutations were more prevalent in ER+/HER2- disease (6.0%) than HER2+ or TNBC (1.7%, p=4.7x10^-20 and 3.0%, p=3.5x10^-5). In contrast, PTEN alterations were more commonly found in TNBC (17.9%) than in ER+/HER2- and HER2+ cases (11.3%, p=1.8x10^-8 and 3.9%, p=2x10^-57). PIK3CA alterations were enriched in metastases compared to local tumors (39.6% vs 33.2%, p=6x10^-41) and were less prevalent in African American pts than other groups (27.1% v 38.6% in Europeans, p=9.6x10^-81), while PTEN and AKT alterations were similar across ancestries.

PIK3CA, AKT1, and PTEN pathogenic alterations are all mutually exclusive to each other. Statistically significant co-occurring mutations included PIK3CA with CDH1, MAP3K1, SOX2, TBX3, and PRKCI; PTEN with FAS, TP53, and RB1; and AKT1 with NF1.

Conclusions: Here we describe the clinicogenomic landscape of PIK3CA, AKT1, and PTEN alterations in a large breast cancer cohort. Our results corroborate previously reported findings that PIK3CA alterations are present in around 40% of ER+/HER2- breast cancer and concentrated in 3 hotspots. However, one-third of patients have variants beyond E542, E545, and H1047 with less certainty about targetability. The preponderance of rare PIK3CA mutations and co-occurrences between PIK3CA, AKT1, and PTEN with genes outside the PI3K pathway merits functional investigation.

P5-02-21: Tumorspheres derived from circulating cancer stem cells in breast cancer patients exhibit elevated levels of immune regulatory molecules

Monika Pizon, Dorothea Schott, Erika Schill, Katharina Pachmann

Background: Circulating tumor cells, particularly a rare subpopulation of them known as circulating cancer stem cells (cCSCs), play a significant role in cancer recurrence and metastasis. While the exact mechanism of cCSCs evasion by the immune system remains unclear, recent studies suggest that increased expression of certain immune checkpoint molecules in cancer stem cells may contribute to immune evasion and promote cancer stem cells self-renewal. Our study was designed to assess the number of tumorspheres and the expression levels of PDL-1, PDL-2 and CTLA-4 on tumorspheres derived from cCSCs in breast cancer patients.
Methods: The study included 110 patients with breast cancer at various stages of disease. Determination of circulating cancer stem cells was performed using the sphere formation assay. Staining with anti-PDL-1, anti-PDL-2 and anti-CTLA-4 antibodies was used to examine the expression of PDL-1, PDL-2 and CTLA-4 on breast tumorspheres.
Results:
We have developed an innovative in vitro platform for detection of cCSCs from peripheral

blood of cancer patients. The number of tumorspheres increased significantly with tumor progression and aggressiveness of primary tumor. Patients with metastatic disease had statistically more tumorspheres as compared to patients without metastasis (30 vs 10/100µl blood, $p<0.05$). Patients with multiple metastasis had more tumorspheres compared to patients with single metastases (60 vs 30/100µl blood, $p<0.05$). The number of tumorspheres was positively correlated with triple-negative histopathology. We observed elevated expression of PDL-1, PDL-2 and CTLA-4 and their considerable heterogeneity in enriched tumorspheres.
Conclusion: The number of tumorspheres cultured from peripheral blood directly reflects the aggressiveness and proliferative capacity of the primary tumor. The presence of tumorspheres with enhanced expression of PDL-1, PDL-2 and CTLA-4 may indicate their immunoregulatory potential. A better understanding of the interaction between cCSCs and tumor immunology could help to identify strategies to target the small subpopulation that escapes conventional therapy.

P5-02-22: Urinalysis of breast cancer patients identifies disease-specific miRNA patterns.

Elmar Stickeler, Jochen Maurer, Matthias Rübner, Chao-Chung Kuo, Peter Fasching, Elmar Stickeler

Background: One in eight women will suffer from breast cancer. Markers, ideally non-invasive, for early detection, diagnosis and progression monitoring are key in future therapy. Small RNA molecules, like miRNAs, are very stable in almost all body fluids and could serve as these sought-after markers,
Methods: Using an isolation of total miRNA from 4 milliliters of urine samples (slightly less than a teaspoon), 82 women (50 healthy individuals and 32 breast cancer patients) were studied using miRNA-sequencing to determine whether consistent patterns of miRNA regulation could be found despite this small amount.
Result: From a still small group of patients we generated the first data using miRNA chip analysis, but these are already very promising for the possibility of valid testing of the disease by urinalysis. The primary goal was to validate the patterns found in a larger group of patients. Therefore, we subsequently validated and evaluated the recently tested method of miRNA sequencing in our clinic on the larger (82) sample cohort and investigated to what extent the predictive power for breast cancer subtype patterns of miRNAs holds up or can even be improved in this larger cohort. The sequencing analysis reliably detected over 4000 individual miRNAs in each patient. Analysis revealed subcategory specific miRNA patterns that allowed us to stratify patients according to urinalysis.
Discussion: Our data indicate that urinalysis could be a valuable tool in the non-invasive detection and monitoring of breast cancer patients. Clearly this first patient cohort is still too small to make predictions for the disease as a whole but the distinct patterns of breast cancer subclasses with only very few overlapping miRNAs between them makes a prognostic value for these analyses highly likely.

Conclusion: We identified miRNA patterns in small urine samples from breast cancer patients by using miRNA sequencing with Random forest analysis allowing us to distinguish healthy individuals from cancer patients.

P5-02-23: Unveiling the Antitumor Mechanism of abemaciclib in Human Breast Cancer Through Circulating Tumor Chromatin Analysis

Mamoru Takada, Sakuntha Gunarathna, Hideyuki Yamada, Muhan Yu, Takeshi Nagashima, Hiroshi Fujimoto, Junta Sakakibara, Hiroto Yamamoto, Regina Nguyen, Tsutomu Kawaguchi, Otsuka Masayuki, Motoki Takaku

Background: The study of circulating tumor DNA (ctDNA) and cell-free chromatin (cf-Chr) has become instrumental in advancing our understanding of cancer biology. This research delves into the antitumor mechanism of abemaciclib in ER-positive, HER2-negative metastatic breast cancer patients by examining cf-Chr fragmentation patterns.

Methods: In this investigation, 72 ER-positive, HER2-negative metastatic breast cancer patients, as defined by ASCO/CAP guidelines and treated with abemaciclib at Chiba University Hospital in Japan from 2020 to 2022, were enrolled. Pre- and post-treatment serum samples were analyzed, with nucleic acids extracted for whole-genome sequencing (WGS) and differential enrichment analysis. Given the observed correspondence of cf-Chr fragment patterns with open chromatin regions (OCRs), indicative of gene activation zones, differential enrichment analysis was specifically focused on cell type-specific regulatory regions—namely enhancers and promoters—in luminal breast cancer cells and T cells, to elucidate the transcriptionally active regions within the genome.

Results: Our investigations have revealed a significant decrease in cf-Chr concentrations, showing a 50% reduction following treatment with abemaciclib. The analysis of cf-Chr in breast cancer patients, both pre- and post-abemaciclib treatment, unveiled differential chromatin enrichment within regions tied to antitumor pathways that are modulated by the drug. Notably, the cf-Chr analysis preceding treatment disclosed disturbances in the Notch signaling pathway, thereby revealing an aspect of abemaciclib's antitumor mechanism that has not been previously established in human clinical specimens.

Conclusions: Our study suggests for the first time alterations in cf-Chr in human patient specimens that may reflect the antitumor activity of abemaciclib that had previously been confirmed only in vitro. Our study presents a pivotal step in understanding the impact of abemaciclib on the tumor chromatin landscape, providing a direct observation of the drug's mechanism of action in patients. These insights pave the way for future research into the mechanisms of existing therapies and their optimization for treating metastatic breast cancer.

P5-02-24: Targeting FOXK2 signaling in breast cancers with FOXK2 amplification/overexpression and PIK3CA oncogenic mutations: a promising therapeutic strategy?

Hong Zhang, Yang Yu, Weng-Ming Cao, Feng Cheng, Edaise da silva, Higinio Dopeso, Hui Chen, Xiaosong Wang, Chunchao Zhang

Oncogene activation through DNA amplification or overexpression plays a critical role in cancer initiation and progression. Chromosome 17 harbors numerous cancer-associated genetic anomalies, some of which are strongly linked to poor prognosis in breast cancer patients. The FOXK2 gene, located on 17q25, encodes a transcription factor with a forkhead DNA binding domain. Integrative analyses of publicly available genomic datasets reveal that FOXK2 is frequently amplified and overexpressed in breast cancer, correlating with poor overall survival. FOXK2 knockdown via shRNA significantly inhibited the proliferation, migration, and anchorage-independent growth of breast cancer cells, causing G0/G1 cell cycle arrest. The C-terminal nuclear localization signal (NLS) is crucial for FOXK2's oncological function. Additionally, FOXK2 knockdown in MCF7 breast cancer cells delayed tumor growth in a xenograft mouse model. Inhibiting FOXK2 expression also sensitized breast cancer cells to frontline chemotherapy agents, including doxorubicin, 5-fluorouracil, and etoposide in vitro. Co-overexpression of FOXK2 and PI3KCA with oncogenic mutations (E545K or H1047R) induced the transformation of non-tumorigenic MCF-10A cells, suggesting that FOXK2 acts as an oncogene in breast cancer and contributes to PI3KCA-driven tumorigenesis. CCNE2, PDK1, and ESR1 were identified as direct transcriptional targets of FOXK2 in MCF-7 cells. Moreover, co-inhibition of FOXK2 function, either through knockdown or inhibition of its transcriptional targets (CCNE2/CDK2 by Dinaciclib or PDK1 by DCA) and PI3KCA by alpelisib, had synergistic anti-tumor effects in breast cancer cells with FOXK2 overexpression and PI3KCA oncogenic mutations. FOXK2 functional inhibition by the CDK2 inhibitor Dinaciclib enhanced the tumor-suppressive effect of alpelisib in a MCF7 breast cancer xenograft mouse model. These findings provide compelling evidence that FOXK2 plays an oncogenic role in breast tumorigenesis. The combination of PIK3CA and CCNE2/CDK2 inhibition by alpelisib and Dinaciclib offers a potential therapeutic strategy for breast cancer with FOXK2 overexpression and PIK3CA oncogenic mutation.

P5-02-25: Deciphering the transcriptomic landscape of early HR+/HER2- breast cancer in very young women

Marta Tapia, Iris Garrido-Cano, Juan Carbonell, Carlos Peña, Sandra Torres-Ruiz, Anna Ágreda-Roca, Cristina Tébar, Octavio Burgués, Cristina Hernando, Ana Lluch, Begoña Bermejo, María Teresa Martínez, Juan Miguel Cejalvo

Introduction: Breast cancer (BC) in very young women (VYBC), specifically those under 35 years old, presents biological and clinical differences compared to older patients with breast cancer (OBC). Previous studies have shown discordance in tumor characteristics and treatment responses between younger and older patients, notably within HR+/HER2-

subtype. This study aims to elucidate the transcriptomic landscape of HR+/HER2- in VYBC compared to OBC, focusing on identifying age-associated molecular differences that could decipher personalized treatment strategies for these patients.
Methods: This study included 49 BC patients treated at Hospital Clínico Universitario de Valencia. RNA sequencing was performed on formalin-fixed samples from 22 VYBC (age ≤35 years) and 27 OBC (≥50 years) patients. Differential expression analysis and gene set enrichment analysis (GSEA) were performed to identify differentially expressed genes. Deconvolution analysis using MCP-counter and quanTIseq algorithms was employed to evaluate tumor cellular composition. Histological examination described tumor infiltrating lymphocytes (TILs) and tertiary lymphoid structures (TLS). Statistical analyses were assessed using R (version 4.0.2).
Results: The BCVY cohort included 12 (55%) luminal, and 10 (45%) non-luminal BCs while the OBC cohort were 17 (63%) luminal and 10 (37%) non-luminal patients. Transcriptomic analysis revealed significant age-associated differences particularly in HR+/HER2- subtype (133 and 106 genes down- and up-regulated (log2 fold change < ± 2, adjusted p value < 0.05). HR+/HER2- VYBC tumors exhibited greater proliferation signatures (p = 5.17e-05) and ki67 (IHC, p = 0.021), increased chromosomal instability (CIN70, p = 1e-06), and higher expression of immune-related gene signatures compared to OBC tumors. Interestingly, despite no differences in estrogen and progesterone receptor by IHC, lower expression was found at RNA level in HR+/HER2- VYBC patients (ESR1: p= 0.0027, PGR: p= 0.0476). Deconvolution analysis confirmed an enhanced infiltration of immune cells in HR+/HER2- VYBC tumors, identifying them as immunoreactive tumors, characterized by high infiltration of cytotoxic T lymphocytes and overexpression of immune checkpoint molecules such as PD-1 and its ligand PD-L1. Histological validation confirmed increased TILs and TLS in VYBC tumors. Finally, PAM50-based chemoendocrine score (CES) was also determined for HR+/HER2- samples showing higher levels of CES, which are predictive of better response to chemotherapy in HR+/HER2- VYBC patients.
Conclusions: Our study provides a comprehensive understanding of the molecular landscape of HR+/HER2- BC in very young women. We found age-related gene expression changes not only in cancer cells but also in the tumor microenvironment. These data suggest that HR+/HER2- tumors from VYBC patients could be more endocrine-resistant and immunoreactive than those from OBC patients. Accordingly, personalized therapeutic strategies in this subgroup are needed.

P5-02-26: Trial in progress: Imatinib to convert triple negative breast cancer into estrogen receptor (ER) positive breast cancer - a window of opportunity trial

Sophie Lehn, Barbro K. Linderholm, Elisabeth Kapocs, Anikó Kovács, Elisabeth Werner Rönnerman, Kristian Pietras

Background: A large component of the tumor microenvironment in breast cancer consists of cancer-associated fibroblasts (CAFs), a cell type which can influence tumor progression,

angiogenesis and therapy resistance. Receptors on CAFs are activated by ligands in the tumor microenvironment, resulting in establishment of a malignant paracrine crosstalk supporting the tumor as a whole. Preclinical data suggest a specific role for tumor cell-secreted Platelet-derived growth factor-CC (PDGF-CC) in maintaining the triple-negative breast cancer (TNBC) phenotype through paracrine activation of PDGFR (Platelet-derived growth factor receptor) on CAFs. PDGF-CC expression in tumor cells has been shown to be significantly associated with the basal-like PAM50 molecular subtype. We have previously reported that inhibition of PDGF-CC, and thereby the paracrine signaling between tumor cells and CAFs, in preclinical TNBC models results in tumors converting to a luminal Estrogen Receptor (ER) positive subtype sensitive to endocrine treatments. Imatinib, a PDGFR inhibitor, was also tested in the preclinical setting yielding similar results. Based on these results, a window-of-opportunity trial was launched to test if ER expression can be induced in TNBC by inhibiting CAFs.
Methods: The study is a window-of-opportunity, single center clinical trial investigating the efficacy, safety and feasibility of short term imatinib (400 mg per day for 10 days) for TNBC patients planned for surgery, who are not eligible for neoadjuvant chemotherapy (Clinical Trial Identifier NCT05722795, EudraCT 2020-005200-19). The primary endpoint is to determine changes in Estrogen Receptor (ER) expression before and after imatinib treatment by analyzing the diagnostic biopsy and the surgical specimen. If ER expression is changed from 0% to 2% or more, or ER is changed from 1-9% to either ≥10% or at least 2% increase combined with a significant increase in luminal gene transcripts, the primary endpoint is met. Secondary endpoints include determining safety of short-term imatinib and assessing blood and tissue markers such as ctDNA (circulating tumorDNA), immune cell markers and analyses of activity in luminal gene expression programs, and PAM50 gene signatures before and after imatinib treatment. Thirty-five patients will be recruited with an interim analysis planned after recruitment of 20 patients. The study is open for inclusion and 4 patients have been included as of 10th of June 2024.

P5-02-27: Investigating the Prognostic Significance of Circulating Tumor Cells in Ductal Carcinoma In Situ Patients

Neha Nagpal, Brittany Rupp, Yan Hong, Fariba Behbod, Max Wicha, Sunitha Nagrath

Raised awareness of the importance of early diagnostics in breast cancer is leading to an increased incidence of ductal carcinoma in situ (DCIS) being detected through mammographic screening. DCIS is widely defined as a ‘Stage 0’ carcinoma with neoplastic cells still confined to the basement membrane. However, while most DCIS patients will receive widespread overtreatment for their carcinoma, the 20-year breast cancer mortality rate following a DCIS diagnosis, with or without treatment, remains at 3.3%. To better understand breast cancer carcinogenesis, recent studies have drawn attention to the clonal diversity within the DCIS tumor microenvironment and the presence of disseminated tumor cells in DCIS patients. However, there still exist gaps in understanding of characteristics at the time of diagnosis that make certain DCIS patients more likely to progress or recur.

Ultimately, the goal of the project is to better inform DCIS patient risk stratification via the high throughput isolation and analysis of circulating biomarkers.
In this study, we establish a workflow that targets the gaps in traditional tissue-based diagnostics by pivoting towards liquid biopsies. Our study not only builds on emerging literature on the early dissemination of breast cancer cells during carcinogenesis, but also investigates the value of circulating tumor cells (CTCs) as a biomarker in DCIS. To achieve a more holistic understanding of a patient's carcinoma, we supplement our study with the Mouse INtraDuctal (MIND) models - an animal model that recapitulates the tumor microenvironment of DCIS in the mammary ducts of mice.
We employed a high throughput, label-free microfluidic platform to enrich CTCs from DCIS patient samples. CTCs isolated from the unbiased platform were processed for single cell RNA sequencing along with white blood cells, red blood cells, and platelets that enabled further investigation of the circulating microenvironment and potential inter-cellular interactions. Further, to correlate findings in patient samples to an animal model wherein the timeline of progression to invasive disease can be shortened to 9 to 12 months (vs. 10+ years in patients), we analyzed blood samples from three different MIND models in a time course study over 12 months.
Applying our workflow to 26 patient samples and 10 healthy controls, we identified CTCs in 96% of the patient samples. The average concentration of CTCs per mL of blood across all DCIS patients was significantly greater than that in the healthy controls ($p < 0.0001$, Mann-Whitney U Test). Through single cell RNA sequencing, inferred CNVs were found in two cell clusters that also encapsulated potential CTCs based on presence of canonical epithelial cell markers but absence of white blood cell genes. An epithelial to mesenchymal cell phenotype score was calculated (scale 0 to 100, respectively) for each potential CTC, and it was found that the median score tended around 50 to 60, supporting expanding literature on the hybrid epithelial-to-mesenchymal state of CTCs. In addition, during the MIND model time course study, CTCs were found in circulation as early as 3 months after formation of the models and while the models were still pre-invasive.
Overall, our study enables the assessment of CTCs as a prognostic biomarker for DCIS patients. By studying CTCs in patient samples and their derived MIND models in parallel, we aim to continue to build an understanding of the drivers behind early dissemination. Further experimentation is also being planned to study the original tumor at a single cell level in comparison to the blood sequencing that has already been performed. The overarching goal is to compose a more holistic understanding of the origin of these malignant cells in circulation. Ultimately, we hope to investigate the value of CTCs as a clinical biomarker to inform personalized risk stratification for DCIS patients.

P5-02-28: Genomic markers of sacituzumab govitecan (SG) response in metastatic triple-negative breast cancer and hormone receptor-positive breast cancer

Alexis LeVee, Megan Wong, Christina Wei, Nora Ruel, Kevin McDonnell, Daniel Schmolze, Joanne Mortimer

Background: Sacituzumab govitecan (SG), an antibody-drug conjugate comprising an anti-Trop-2 antibody coupled to the irinotecan analog, SN-38, is currently approved for use in metastatic triple-negative breast cancer (TNBC) and hormone receptor-positive (HR+) breast cancer. Preclinical studies demonstrate that SG results in increased activity in tumors with homologous recombination deficiency, which may be attributed to the SN-38 payload increasing double-strand DNA breaks. However, biomarker analyses of SG show that patients benefit regardless of germline BRCA 1/2 mutation status and that patients with TNBC expressing higher Trop-2 expression benefit more from SG. Utilizing next-generation sequencing (NGS) data, we sought to identify whether genomic biomarkers were also associated with response to SG in patients with metastatic breast cancer (MBC).
Methods: NGS of tissue and circulating tumor DNA from patients with MBC treated with SG were obtained by chart review. Genomic data was obtained through routine clinical practice. Progression-free survival (PFS) was determined from the first day of treatment until disease progression or death. Oncogenic alterations from NGS were analyzed according to PFS with univariate cox proportional hazards analysis.
Results: 128 patients treated with SG between April 2020 and November 2023 were included in the analysis. 95 (74%) patients had TNBC, while 33 (26%) had HR+ breast cancer. 32 (25%) patients received SG in the 1st or 2nd line, while 96 (75%) received SG in later lines. The median PFS was 2.7 months (95% CI, 2.4-4.1). 115 (90%) patients had NGS tests available, with a total of 211 NGS tests included. Of these, 160 (76%) tests were performed prior to SG, 46 (22%) after SG, and 5 (2%) at unknown date. 78 different oncogenic alterations were identified in 2 or more patients. Of the 128 patients, the most common oncogenic alterations were TP53 (69%), PIK3CA (20%), PTEN (14%), ERBB2 (12%), and MYC (10%). Five alterations were significantly associated with shorter PFS, including KIT (HR 20.9, p = 0.0001, n=2), MAP3K1 (HR 5.0, p = 0.002, n=4), RAD21 (HR 8.3, p = 0.004, n=2), MTAP (HR 4.5, p=0.01, n=3), and TSC1 (HR 5.0, p = 0.03, n=2). In TNBC, the alterations MTAP (HR 5.8, p=0.004), MAP3K1 (HR 4.8, p=0.01) and CDKN2A (HR 2.5, p=0.02) were associated with shorter PFS. In HR+ disease, the alterations KIT (HR 14.9, p=0.004), FGF19 (HR 6.3, p=0.02), and FGF3 (HR 6.3, p=0.02) were associated with shorter PFS.
Conclusions: Five oncogenic alterations were associated with a poor response to SG in MBC, including KIT, MAP3K1, RAD21, MTAP, and TSC1. In TNBC, MTAP, MAP3K1, and CDKN2A were associated with a poor response, whereas in HR+ disease, KIT, FGF19, and FGF3 were associated with a poor response. These results suggest that alterations in these genes may be potential resistance mechanisms to SG which merits further exploration.

P5-02-29: Redefining PARP inhibitor paradigms to target DNA repair dysfunction in lobular breast cancer

Matthew Sikora, Joseph L. Sottnik, Madeleine T. Shackleford, Jordan M. Swartz, Camryn S. Nesiba, Carmen E. Rowland, Margaret Musick, Sanjana Mehrotra, Jennifer R. Diamond

PARP inhibitors (PARPi) transformed the treatment of BRCA1/2-associated cancer by leveraging that tumors with homologous recombination DNA repair (HR) deficiency are vulnerable to PARPi. However, PARPi use is uncommon for patients with invasive lobular carcinoma (ILC), as ILC are rare among BRCA-mutation carriers, and ILC have very low 'BRCA-like' genomic scarring of HR deficiency. Importantly, though most ILC appear "low risk" (e.g. ~95% are estrogen receptor α/ER-positive), ILC have poorer long-term outcomes than other breast cancers, are associated with treatment resistance, and lack ILC-targeted therapies. Novel treatments for ILC are needed, and our work suggests PARPi target a unique vulnerability in ILC and provide an opportunity for precision treatment.

We identified a novel crosstalk between ER and DNA repair in ILC – via mediator of DNA damage checkpoint 1 (MDC1), a key double-strand break repair protein – that facilitates endocrine response and anti-estrogen resistance, but compromises DNA repair downstream of MDC1. We find homologous recombination (HR) induction and resolution is limited and inefficient in ILC; e.g., in I-SceI assays for HR versus non-homologous end-joining activity, ILC cells (MDA MB 134VI, SUM44PE) showed ≤10% of repair events via HR, while ≥40% of repair events were via HR in non-ILC breast cancer cells (MCF7, T47D). Importantly, these cell line data are paralleled by ILC tumor data, wherein subsets of ILC are defined by elevated DNA repair protein levels and increased tumor mutational burden. These ILC have the poorest disease-free and overall survival, supporting that high-risk ILC tumors also present with a novel DNA repair dysfunction.

Based on this putative HR dysfunction, we tested PARPi talazoparib against ILC models. In vitro, talazoparib was equipotent against proliferation in ILC and non-ILC breast cancer cell lines (IC50 ~25nM). However, non-ILC cells recovered after talazoparib washout, but ILC cells remained growth suppressed 7d post-washout with outgrowth reduced by 50-80%. In vivo, we tested talazoparib (0.33mg/kg p.o. 5d/w) alone ± estrogen withdrawal (to mimic aromatase inhibition/AI), with 6 weeks treatment against MDA MB 134VI or SUM44PE xenografts. In MM134, talazoparib suppressed tumor growth vs control (ANOVA $p=0.0016$) and durably suppressed growth as seen in vitro. Combining talazoparib with AI was superior to single agents (ANOVA $p=0.0006$ vs talazoparib, $p= 0.0037$ vs AI) and best prolonged host survival (cohort survival: ctrl = 158d; AI = 175d, log rank vs ctrl $p=0.054$; talazoparib = 182d, $p=0.069$; AI + talazoparib = >209d, $p=0.0021$). Combined AI + talazoparib also best suppressed SUM44PE xenograft growth (ANOVA AI vs combination, $p<0.0001$), and median time to tumor progression (doubling in size: ctrl = 104d; AI = 130d, log rank vs ctrl $p=0.11$; talazoparib = 121d, $p=0.68$; AI + talazoparib = >153d, $p=0.0018$; survival study ongoing).

Our work suggests that despite the absence of the BRCA-like phenotype, ILC have a previously unappreciated form of DNA repair dysfunction that makes cells sensitive to PARPi. PARPi represent potential first-in-class precision treatments specifically targeting ILC biology. Understanding HR dysfunction in ILC can broaden PARPi use paradigms and build new conceptual frameworks for understanding DNA repair capacity and associated therapeutic vulnerability.

P5-03-01: Open-label, randomized, multicenter, phase 3, ELAINE 3 study of the efficacy and safety of lasofoxifene plus abemaciclib for treating ER+/HER2-, locally advanced or metastatic breast cancer with an ESR1 mutation

Matthew Goetz, Seth A Wander, Thomas Bachelot, Giuseppe Curigliano, Alexandre de Nonneville, Einav Nili Gal-Yam, Sarah L Sammons, Sherry Shen, Chris Twelves, Paul V Plourde, David J Portman, Senthil Damodaran

Background: Most patients with estrogen receptor-positive (ER+), metastatic breast cancer (mBC) treated with endocrine therapy (ET) will ultimately develop resistance to treatment. A large unmet medical need exists especially when resistance occurs following a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i), potentially driven by a mutation in the ERa-coding gene, ESR1. Lasofoxifene (LAS), an oral, next-generation ET and ER breast antagonist, was evaluated in two phase 2 studies of women with ER+/HER2- mBC and an ESR1 mutation who had disease progression on previous ET and CDK4/6i. In the ELAINE 1 trial, LAS monotherapy provided numerically greater progression-free survival ([PFS] median, 5.6 mos vs 3.7 mos; HR 0.669 [95% CI, 0.445-1.125]; P=0.138), objective response rate (ORR, 13% vs 3%; P=0.124), and clinical benefit rate (CBR, 37% vs 22%; P=0.117) compared with the ER degrader fulvestrant (fulv), and a favorable safety profile (Goetz MP, et al. Ann Oncol. 2023;34:1141-1151). The single-arm, ELAINE 2 trial showed that LAS combined with abemaciclib (Abema) was well tolerated with a median PFS of ~13 mos, ORR of 56%, and CBR of 66% (Damodaran S, et al. Ann Oncol. 2023;34:1131-1140). Based on these promising earlier-phase data, the phase 3, registrational, ELAINE 3 trial was initiated. Other recent results from postMONARCH confirmed superior efficacy of fulv/Abema versus fulv/placebo (median PFS, 6.0 mos vs 5.3 mos; HR 0.73 [95% CI, 0.57-0.95], nominal P=0.02) in non-biomarker–selected mBC that progressed on a prior CDK4/6i and aromatase inhibitor (Kalinsky K, et al. J Clin Oncol. 2024;42[suppl 17]: abstract LBA1001 [slides]). The ELAINE 3, global trial will compare LAS/Abema with fulv/Abema in a post-CDK4/6i, ESR1-mutation–selected mBC population.
Methods: ELAINE 3 (NCT05696626) is an open-label, phase 3, multicenter study evaluating the efficacy, safety, and tolerability of LAS plus Abema versus fulv plus Abema. Study enrollment is currently underway at sites in the United States, Canada, France, Italy, Israel, and Spain, and is planned for expansion into Australia, Belgium, China, Germany, Hungary, Poland, Romania, Singapore, South Korea, Taiwan, and the United Kingdom. Key inclusion criteria are pre- and postmenopausal women and men aged ≥18 yrs; ER+/HER2-, locally advanced and/or mBC (measurable and/or non-measurable disease); ≥1 acquired ESR1 mutation; progression on an aromatase inhibitor plus palbociclib or ribociclib as their first hormonal treatment for advanced/mBC; and ≤1 line of chemotherapy in the advanced/metastatic setting. Patients will be randomized 1:1 to receive LAS 5 mg/day plus Abema 150 mg BID, or fulv 500 mg IM on days 1, 15, and 29, then once monthly plus Abema 150 mg BID. Treatment will continue until progression, death, unacceptable toxicity, or withdrawal from the study. The primary endpoint is PFS by blinded independent central

review (BICR); key secondary endpoints are ORR, overall survival, CBR, duration of response, and time to response. Time to cytotoxic chemotherapy, quality of life, and safety will also be evaluated. Blood samples for circulating tumor DNA (ctDNA) will be collected for genomic analyses at screening, at weeks 4 and 8 and every 8 weeks thereafter, and at the final visit. Outcomes with LAS/Abema and fulv/Abema will be compared using a stratified Cox proportional hazards model and stratified logrank test with an expected PFS hazard ratio of 0.68 at final analysis. To achieve 90% power with a one-sided type I error rate of 0.025, the target sample size is 400 patients. Full recruitment is expected to occur over 18 mos.

P5-03-03: Pertuzumab and Trastuzumab Biosimilars in Real-Life Association for the First-Line Treatment of HER2-Positive Metastatic Breast Cancer: the prospective, observational PETRA study

Gilles Freyer, Angélique Stuani, Aurélie Comte, Dorothée Chocteau, Louis Doublet, Johanna Wassermann, Mireille Mousseau, Angélique Denis, Marie Béguinot, Elise Deluche, Pauline Corbaux, Thibaut Reverdy

Background: Trastuzumab biosimilars (TBs) have been available in Europe since 2018 and are widely prescribed for HER2-positive breast cancer. However, reported data on their efficacy and tolerance, especially when used in combination with pertuzumab and chemotherapy in a first-line metastatic setting, are lacking.
Methods: The observational, multicenter Pertuzumab – Trastuzumab (PETRA) study prospectively enrolled French patients with HER2-positive metastatic breast cancer (MBC) receiving chemotherapy (CT) plus pertuzumab (P) plus TB, regardless of the EMA-approved product. Eligible patients may have received adjuvant or neoadjuvant TB and/or P, with an interval of at least 12 months between the completion of the adjuvant or neoadjuvant anti-HER2 therapy and the diagnosis of metastatic breast cancer. The primary endpoint was the progression-free survival at 6 months (PFS-6), defined as patients with stable, partially responsive, or completely responsive disease at that time. Secondary endpoints included safety, patient exposure to the treatment combination (defined as the number of cycles of CT, P, and TB received, and the relative dose intensity of CT in milligrams per day [RDI]), and the percentage of treatment discontinuation due to side effects.
Result: Between February 3, 2021, and July 31, 2023, 112 patients from 30 centers were included: median age 59.0 years [50.5 – 71.5]; PS 0: 38.9%, PS 1: 53.7%, PS 2: 7.4%; median baseline left ventricular ejection fraction (LVEF): 65.5% [60.0 – 69.0]; HR+: 63.4%; de novo metastatic: 58.9%; visceral metastases: 55.4%; previous (neo)adjuvant trastuzumab: 23.2%. Median follow-up was 5.7 months [4.5-6.3]. TBs used were Trazimera® in 39 patients (34.8%), Ontruzant® in 27 (24.1%), Herzuma® in 23 (20.5%), Ogivri® in 19 (17.0%), and Kanjinti® in 4 (3.6%). The majority of chemotherapy regimens were paclitaxel in 90 patients (80.4%), followed by docetaxel in 18 (16.1%) and vinorelbine in 4 (3.6%). The PFS-6 was 80.36% [95% CI: 71.78, 87.26]. The objective response rate (ORR) was 69.64% [95% CI: 60.24, 77.98]. There were 3 deaths unrelated to treatment (2.7%) and

18 tumor progressions (16.4%). The median number of TB cycles was 7.0 [5.5 – 9.0], with 41 patients (36.6%) starting maintenance treatment with trastuzumab and P before 6 months. The median number of CT cycles was 6.0 [4.0-6.0], with 54 patients (48.2%) receiving fewer than 6 cycles. The median RDI was 14.6 mg/day [10.8-17.0]. Grade 1-2 side effects were observed in 61.6% of patients, grade ≥ 3 in 36.6%, primarily peripheral neuropathy in 22.6% (including 5.4% grade 3); diarrhea in 20.3% (including 0.9% grade 3); and asthenia in 15.7% (including 13.8% grade 3). Fifteen patients had infusion reactions, including 3 related to TB (1 grade 3). Three patients had adverse effects leading to the permanent discontinuation of the biosimilar: 1 due to interstitial lung disease (attributable to BS) and 2 due to heart failure. Twelve patients experienced cardiac dysfunction at 3 or 6 months: among them 3 had previous exposition to anthracycline in adjuvant setting, 11 had an absolute decrease in LVEF ≥ 10%, 5 had LVEF < 50%, and 3 presented symptomatic grade 3 cardiac dysfunction (2 had received anthracyclines). All were alive by the time of final analysis.
Conclusions: Trastuzumab biosimilars appear to be similar to Herceptin when combined with pertuzumab and chemotherapy in the first-line treatment of metastatic HER2-positive breast cancer. However, 13% of patients experienced a decrease in LVEF during follow-up, which is significant. Systematic and regular monitoring of cardiac toxicity is mandatory.

P5-03-04: The effectiveness of post-T-DXd treatments in patients with HER2-positive metastatic breast cancer: A nationwide Japanese cohort study (EN-SEMBLE)

Kazuki Nozawa, Hiroji Iwata, Toru Mukohara, Tetsuhiko Taira, Shigenori E. Nagai, Jun Hashimoto, Kazuo Matsuura, Toshiro Mizuno, Yoshiaki Shinden, Mitsugu Yamamoto, Saori Kawai, Makoto Wakahara, Hirohumi Terakawa, Takashi Yamanaka, Yasuyuki Kojima, Takahiro Nakayama, Yuji Hirakawa, Kiyoka Kuge, Ayumi Tanabe, Junji Tsurutani

Background: Trastuzumab deruxtecan (T-DXd) is a new standard of care for human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer after treatment with anti-HER2 antibody and taxane. In clinical practice, some patients (pts) discontinue T-DXd treatment due to progressive disease (PD) or adverse events (AEs). Thus, an unmet medical need remains to determine optimal post-T-DXd treatment regimens. The EN-SEMBLE study investigated post-T-DXd treatments in terms of effectiveness and incidence/exacerbation of interstitial lung disease (ILD) in the Japanese real-world (rw) setting.
Methods: This study was a multicenter cohort study (jRCT1030220506). Among pts who received T-DXd from May 25, 2020, to November 30, 2021, and had been registered for the Japanese post-marketing all-patient surveillance, this study enrolled pts who discontinued T-DXd and received subsequent anti-tumor therapy for metastatic breast cancer from May 25, 2020, to May 31, 2023, and were followed up until November 30, 2023. The endpoints were the distribution of post-T-DXd treatment regimens, effectiveness (rw progression-free survival [rwPFS], rw time to next treatment [rwTTNT], overall survival [OS], etc.) and ILD

incidence/exacerbation rate by subsequent anti-tumor therapies. Reasons for T-DXd treatment discontinuation were also analyzed.
Results: A total of 664 pts were registered from 222 sites nationwide in Japan: median age, 60.0 (range 30–89) years; female, 99.5%; ECOG-PS ≥2, 8.6%; visceral and brain metastasis, 79.7% and 23.0%; de novo stage IV and recurrent breast cancer, 37.7% and 59.3%. The median treatment line for T-DXd was 4th regimens (range 2–43). The most common reason for T-DXd discontinuation was PD, 67.5% (448/664), followed by ILD, 22.0% (146/664), and AEs other than ILD, 5.1% (34/664). The subsequent regimens (1st post-T-DXd treatment) after T-DXd discontinuation were anti-HER2 antibody (trastuzumab, pertuzumab)–containing regimens, 54.4% (361/664); anti-HER2 TKI–containing regimens (lapatinib, other anti-HER2 TKIs), 17.0% (113/664); ADC (trastuzumab emtansine), 1.8% (12/664); and others, 26.8% (178/664). In overall population, anti-HER2 antibody, anti-HER2 TKI, and ADC regimens, rwPFS were 4.1 (3.9–4.5), 4.1 (3.8–4.6), 4.3 (3.8–6.2), 2.6 (1.0–4.7); rwTTNT, 5.0 (4.6–5.5), 5.1 (4.5–5.7), 5.3 (4.4–6.8), 3.0 (1.0–5.9); and OS, 16.2 (13.8–17.2), 17.2 (15.1–19.8), 16.3 (12.2–18.7), 9.3 (4.3–not reached) (respectively; all shown as median [95% CI] months). The HR (95% CI) for anti-HER2 TKI to anti-HER2 antibody was 1.06 (0.84–1.34) for rwPFS, 1.07 (0.85–1.35) for rwTTNT, and 1.17 (0.88–1.54) for OS. Among the anti-HER2 antibody–containing regimens, the HR (95% CI) for a trastuzumab + pertuzumab–containing regimen (n=203) to a trastuzumab-containing regimen (n=157) was 0.94 (0.74–1.20) for rwPFS, 1.00 (0.79–1.26) for rwTTNT, and 0.98 (0.73–1.30) for OS. For pts who discontinued prior T-DXd treatment due to PD or AEs including ILD, rwPFS were 3.5 (3.0–3.8), 7.3 (5.7–10.3), rwTTNT, 4.2 (3.8–4.6), 8.3 (6.2–11.3), and OS 12.0 (10.9–13.6), 32.4 (22.3–not reached), respectively (median [95% CI] months). The incidence of ILD was observed in 10 pts during the first post-T-DXd treatment: 4 pts were new onset, 5 pts were recurrent or exacerbation (3.4%, 5/146), and 1 pts was unknown.
Conclusion: About half of the pts received anti-HER2 antibody regimens in the 1st treatment after T-DXd. No differences were observed between anti-HER2 antibody and TKI-based regimens in terms of rwPFS, rwTTNT, or OS. Post-T-DXd treatments were generally safe in pts who had discontinued T-DXd due to ILD, with 3.4% of exacerbation.

P5-03-05: AI Based Quantitative Estimation of HER2 Protein Expression in Low and Ultra Low Ranges

Anya Tsalenko, Frederik Aidt, Elad Arbel, Itay Remer, Oded Ben-David, Amir Ben-Dor, Daniela Rabkin, Kirsten Hoff, Karin Salomon, Sarit Aviel-Ronen, Jens Mollerup, Lars Jacobsen

The anti-HER2 monoclonal antibody drug trastuzumab (Herceptin®) was approved for treatment of HER2 positive breast cancer by the FDA in 1998. Concurrently, the HER2 IHC assay HercepTest™ was approved as an aid in the assessment of breast cancer patients where trastuzumab treatment was considered (review by Jørgensen et al. 2021). Recently, FDA approved antibody drug conjugate (ADC) trastuzumab deruxtecan (T-DXd; Enhertu®)

for the treatment of metastatic HER2-positive and HER2-low breast cancer. Results from the Destiny Breast-06 clinical trial showed that T-Dxd provides statistically significant and clinically meaningful benefits to HER2-ultralow breast cancer patients as well.
However, sensitive, accurate and quantitative evaluation of HER2 expression based on currently approved IHC assays remains challenging, especially in low and ultra-low ranges of HER2. Advanced computational approaches could improve the interpretation of such IHC assays and could be of high benefit for identifying treatment options for current and future HER2 targeted therapies. More importantly, it could provide a basis for objectively assessing the lower level of HER2 protein expression that maximizes therapeutic benefits, while minimizing drug exposure risks for patients.
Here we demonstrate a novel AI-based method that quantifies HER2 protein expression following staining using the HercepTest™ mAB pharmDx (Dako Omnis, GE001) assay (HercepTest™ (mAB)) for breast cancer cases characterized as HER2 IHC 0 or 1+. We inferred HER2 expression spatially across the entire breast cancer tissue section and quantified its heterogeneity. We identified low levels of HER2 expression that are challenging to detect by the human eye and provided a graphical overlay of stained tissues for visualization and quantification of the heterogeneity of HER2 expression.
We used the quantitative IHC (qIHC) method described by Jensen et al. (2017) to quantitively measure the HER2 expression in invasive breast carcinomas. These measurements were used to train an AI model to predict the expression based on the HercepTest™ (mAb) stain which was previously demonstrated to detect HER2 expression with higher sensitivity in the lower ranges of HER2 compared to PATHWAY 4B5 (Ruschoff et al, 2022). Note that quantitative analysis of the qIHC assay could also be used to directly quantify HER2 expression.
82 formalin fixed, paraffin embedded (FFPE) tissue blocks of invasive breast carcinoma with HER2 IHC scores 0 or 1+ and with areas of solid tumor tissue were selected for this study. Serial sections from each tissue block were stained with H&E, HercepTest™ (mAB), qIHC and p63 (GA662, Dako Omnis). Stained tissues were scanned on the Philips Ultra Fast Scanner and digitally aligned. Tumor areas were manually selected and reviewed by expert pathologists in HercepTest™ (mAB) using aligned H&E and p63 IHC staining information on consecutive tissue sections to help identify tumor areas and separate invasive tumor areas from carcinoma in situ. HER2 expression was evaluated based on the qIHC assay in each 128μm2 area within tumor regions. The differences in average qIHC expressions across tumor areas were found to be statistically significant between IHC 0, IHC>0 and IHC<1+, and IHC 1+ groups. We observed high level of spatial heterogeneity of the HER2 expression levels within the same tissue, up to five-fold in some cases. Using these qIHC based estimates of HER2 expression as ground truth, we trained an AI based interpretation of HercepTest™ (mAB) assay. K-fold cross validation scheme was used to separate train and test slides, with test folds aggregated for model evaluation. We demonstrated high slide-level agreement of the AI-based estimate of HER2 expression in tumor regions and the ground-truth with Pearson correlation of 0.94, and R2 of 0.87.
In the future we expect AI-assisted quantification and visualization of HER2 expression to enable fast and safe treatment decisions.

P5-03-06: Correlation of Mutational Changes in Circulating Tumor DNA with Clinical Outcomes in HER2 Positive Metastatic Breast Cancer

Surbhi Warrior, Natalie K. Heater, Diana Jaber, Anna Ma, Lisa Flaum, Huiping Liu, Patricia Robinson, Regina Stein, Claudia Tellez, Zequn Sun, Qiang Zhang, Massimo Cristofanilli, William Gradishar, Janice Lu

Background: The presence of certain genetic mutations can be correlated with a poor response to HER2 directed therapies. Circulating tumor DNA (ctDNA) is a noninvasive tool to assess genomic alterations in progressive metastatic breast cancer (MBC). Understanding mutational changes in patients' ctDNA at disease progression can aid prognostication and identify potentially targetable mutations associated with resistance to specific therapies in HER2 positive MBC.
Materials/Methods: Patients with HER2 positive breast cancer either at diagnosis on pathology or by ctDNA were included in the analysis. Patients were prospectively enrolled from 2016-2024 under an IRB approved clinical trial (NU16B06) at Northwestern University. Plasma ctDNA was analyzed by Guardant 360 and tissue NGS was performed using commercially available tests such as FoundationOne® or TempusX. Specific mutations that have known clinical relevance (e.g. PIK3CA, ERBB2, ESR1, TP53, MYC, and FGFR) were identified via ctDNA and/or tissue NGS. Additional clinical, pathologic, treatment, and response data was retrospectively collected as well. Statistical analyses were completed via a multivariate regression model.
Results: One hundred and twenty patients met inclusion criteria for the analysis. Seventy-four percent of patients were HER2 positive at initial diagnosis while twenty six percent developed HER2 positivity at time of metastatic spread. Hormone Receptor positivity (ER or PR) was seen in 77% of HER2 positive patients. Visceral involvement of metastatic disease was identified in 52% of patients and bony involvement in 45% of patients. NGS and ctDNA findings showed PIK3CA mutation in 26% of patients, ERBB2 in 30%, ESR1 in 8%, TP53 in 53%, MYC in 15%, FGFR in 15% of patients. Mortality rate of the cohort was 41%. There were 86% of patients who received HER2 directed therapies. The median progression free survival (PFS) was 3.5 months (95% CI 2.6, 5.3). Patients with PIK3CA mutations (p=0.028) and TP53 mutations (p=0.042) had a worse 10-year survival rate than those without. Patients with PIK3CA and TP53 co-mutations had a worse 10-year survival rate (p=0.21) than those with neither mutation or having either PIK3CA or TP53 alone. Patients with TP53 and PIK3CA co-mutations had worse PFS HR 1.90 (1.02-3.55, p=0.044). Patients with TP53 and PIK3CA co-mutations also had worse PFS when being treated with Trastuzumab (HR 0.07, p=0.003) compared to patients with other mutational changes. Patients with PIK3CA and TP53 co-mutations were more likely to have evidence of progression to visceral metastatic disease on Trastuzumab, OR 0.16 (0.02-0.70, p=0.028).
Conclusion: Molecular alterations identified in ctDNA at progression of disease in HER2 positive MBC can aid in understanding genomic evolution and drift as well as pathways to treatment resistance. This analysis of ctDNA in HER2+ MBC shows that patients with TP53 and PIK3CA co-mutations are shown to have poorer 10-year survival rates, shorter PFS, worse response to Trastuzumab, and overall evidence of more aggressive cancers

progressing into visceral metastatic disease. Understanding how the presence of these mutations correlate with resistance to specific therapies can guide individualized treatment decisions on which line of therapies will be most effective for patients with progressive HER2 positive MBC.

P5-03-07: 64Cu-DOTA Trastuzumab -PET to predict CNS response to Trastuzumab-deruxtecan (TDXd) in patients with metastatic HER2 low and HER2 positive breast cancer

Joanne Mortimer, Beth Chen, Erasmus Poku, Jessica Liu, Irene Kang, Thanh Nga Doan, Paul Frankel, Russell Rockne, Ryan Woodall, Vikram Adhikarla

Background: We have utilized 64Cu-DOTA-Trastuzumab-PET to image patients with advanced HER2+ breast cancer. In our experience, uptake on 64Cu-DOTA-Trastuzumab-PET correlated with the qualitative assessment of HER2 by IHC. In women treated with the antibody-drug conjugate (ADC), ado-Trastuzumab emtansine (TDM1), we identified a threshold level of 64Cu-DOTA-Trastuzumab-PET uptake that predicted for lack of response to TDM1. The ADC, Trastuzumab-deruxtecan (TDXd), has demonstrated activity in patients with metastatic HER2 positive breast cancer with brain metastases. The DESTINY 04 trial included patients with HER2 1+ and 2+ disease and demonstrated superior survival compared to standard of care. Only 5% of patients enrolled had CNS metastases making efficacy of TDXd difficult to assess. As it is not always feasible to biopsy brain metastases to determine tumor markers, we initiated a pilot study to determine if functional imaging could predict response or lack of response to TDXd in patients with HER2 low and HER2 positive breast cancers that have metastasized to the brain. We hypothesize that uptake on pretreatment 64Cu-DOTA-Trastuzumab PET/MRI would predict response of brain metastases in patients treated with TDXd.
Primary Endpoint:
64Cu-DOTA-Trastuzumab PET/MRI will identify tumor heterogeneity in patients with HER2 low and HER2+ brain metastases.
1. The level of uptake of 64Cu-DOTA-Trastuzumab on PET/MRI will predict for CNS response to TDXd.
Secondary Endpoint:
1. Uptake of 64Cu-DOTA-Trastuzumab on PET/MRI will be predictive of response duration to TDXd.
Eligibility:
Patients with recurrent HER2 1+, 2+ or 3+ breast cancer that has metastasized to the brain as detected by CT or MRI, and are to undergo treatment with TDXd.
Methods: Pretreatment staging workup included the following: pathologic review of HER2 status, disease staging with 18FDG-PET or CT of the chest/abdomen/pelvis and bone scan, and 64Cu-DOTA-Trastuzumab PET/MRI of the brain. TDXd was administered every 3 weeks per standard of care. After initiation of TDXd, MRI of the brain and systemic staging were repeated every 6 weeks for the first 24 weeks and every 9 weeks thereafter. Post-

contrast MRI scans were used to delineate tumors for analysis of 64Cu-DOTA-Trastuzumab uptake and tumor perfusion. SUVmax on the PET, as well as the Ktrans (volume transfer constant) and vp (plasma volume fraction) on the brain MRI were analyzed.
Progress: We have enrolled 5 patients, with 4 having HER2+ cancer by IHC and 1 HER2 1+; 3 having cancer confined to the brain, and 2 having additional systemic disease. Three patients demonstrating tumor regression on post-treatment MRI had higher uptake of 64Cu-DOTA-Trastuzumab (SUVmax: 6.1 +/- 1.5, Ktrans: 0.12 +/- 0.049, vp: 0.016 +/- 0.0038). Two patients with lower 64Cu-DOTA-Trastuzumab (SUVmax: 1.8 +/- 0.1, Ktrans: 0.13 +/- 0.028, vp: 0.020 +/- 0.0041) did not respond to therapy. An SUVmax greater than 2 was predictive of tumor response to TDXd in the initial cohort. To date, the responding patients continue therapy for 8-10 months. Non-responding patients experienced disease progression within 2 to 3 months. On average, responding tumors had lower plasma volume fraction as measured by DCE-MRI (n=5, not significant). The goal is to accrue 10 patients to this pilot study, to investigate the combined value of brain MRI perfusion parameters and 64Cu-DOTA-Trastuzumab uptake values.

P5-03-08: Characteristics of ESR1-Mutant HER2 Positive Metastatic Breast Cancer (MBC)

Natalie Heater, Surbhi Warrior, Diana Jaber, Lisa Flaum, Huiping Liu, Patricia Robinson, Regina Stein, Claudia Tellez, Qiang Zhang, Youbin Zhang, William Gradishar, Janice Lu

Background: It is well established that ESR1 mutations encode resistance to endocrine therapies in Estrogen Receptor positive (ER+) metastatic breast cancer and portend a worse prognosis. However, studies on ESR1 mutations have excluded patients with HER2 positive (HER2+) disease to date. We report a first-of-its kind finding of ESR1 mutations in HER2+ mBC.
Methods: This study included 120 patients with HER2+ MBC who received systemic treatment under an IRB-approved clinical trial (NU16B06) at Northwestern University Robert H. Lurie Cancer Center (2016–2024). Patients were considered HER2+ if, at time of ESR1 mutation detection, they had either biopsy-proven HER2+ disease or HER2+ circulating tumor cells (CTCs). Plasma ctDNA was analyzed by Guardant360 NGS. CTC enumerations were performed via CELLTRACKS (Menarini). ER, PR, HER2 and Ki67 in each patient's biopsy tumor tissue before surgery, surgical tumor tissue and metastatic tumor tissue were evaluated by NU PathCore. Additional clinical, pathologic, therapy, and response data were retrospectively collected and analyzed.
Results: Twelve patients with ER+/HER2+ mBC developed ESR1 mutations. One patient had HER2+ disease since primary diagnosis, one patient developed HER2+ at time of metastatic spread, and all twelve patients shed HER2+ CTCs at time of ESR1 detection with a median 16 HER2+ CTCs (range 2–114). Median age of diagnosis was 57 (range 43–80). Patients were 66% White, 25% Asian, and 8% African American. Patients received a median of three hormonal therapies including an aromatase inhibitor prior to ESR1 detection. Most patients (92%) were treated with a CDK4/6 inhibitor prior to ESR1 detection. Median time from

metastatic diagnosis to detection of ESR1 mutation was 40.2 months (range 24.6–105.9). ESR1 point mutations in codons L536 (4 patients), E380 (3 patients), D538 (3 patients), Y537 (2 patients), P353 (1 patient), and K362 (1 patient) were identified. Co-mutations included PIK3CA (58%), TP53 (42%), PTEN (33%), and ERBB2 (17%). Median PFS after detection of ESR1 mutation was 3.2 months (range 1.9 –30.7), with all patients receiving HER2-directed therapy and four patients receiving Fulvestrant. No patients received Elecestrant. Patients most often developed metastasis to bone (92%), followed by liver (67%), CNS (50%), lymph nodes (42%), and lungs (33%). All patients died, with median time to death after ESR1 detection of 15.1 months (range 1.9–62.8).
Conclusions: Patients who develop ESR1 mutations in the setting of HER2+ mBC most often had point mutations in L536, E380 and D538, and had high rates of co-mutation with PIK3CA, which may have prognostic implications. To date, clinical trials regarding ESR1 mutations in breast cancer have excluded patients with HER2+ disease. These patients should be included in future studies of ESR1-targeted therapies.

P5-03-09: Evaluating Post-T-DXd Treatment Strategies in HER2-positive Metastatic Breast Cancer

Sophia Zelizer, Grace Gallagher, Emanuela Ferraro, Chau Dang, Mithat Gonen, Shanu Modi, Sarat Chandarlapaty, Josh Drago

Background: Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate (ADC) that has proven highly effective in the treatment of HER2-positive metastatic breast cancer (MBC). However, drug resistance and disease progression eventually occur in the majority of patients. A critical examination of treatment strategies in the post-T-DXd setting is imperative in order to appropriately care for patients with TDXd-resistant breast cancer.
Methods: We retrospectively examined baseline characteristics and clinical outcomes for patients after they had received T-DXd for HER2-positive metastatic breast cancer at MSKCC. We delineated six categories of treatment in the post-T-DXd setting: monoclonal antibodies (mABs), ADC, chemotherapy-based treatment, hormone therapy, tyrosine kinase inhibitor (TKI) based therapy, and clinical trials/novel combinations. Median overall survival time (OS) and progression free survival (mPFS) were estimated, as well as the mPFS per treatment line, further stratified by treatment type, using the Kaplan-Meier method. Progression free survival (PFS) analyses were performed using Cox proportional hazards regression, clustering by patient and in multivariate analysis, adjusting for treatment line, T-DXd stop reason, hormone receptor (HR) status, and the presence of brain metastases.
Results: We identified 81 patients with HER2-positive MBC who continued treatment after T-DXd. The median age was 52 years, 60% had ER+ disease, and 54% had brain metastases. T–DXd was given as the 4th line of therapy, on average, in this population. Median OS from the time of T-DXd completion was 19 months; 52% of patients had died at the time of data cutoff. Of the patients included in this study, 78% stopped T-DXd due to disease progression, 11% stopped due to pneumonitis/ILD, and 11% stopped due to other toxicity

complications. After T-DXd, patients received a median of 2 lines of further therapy (range 1-9) with a mPFS of 3.7 months per treatment line; a total of 199 lines of treatment were included in this analysis. Chemotherapy (including eribulin or gemcitabine plus trastuzumab) was the most frequently given treatment, received by 50 patients (62%), with mPFS of 3.4 months. Forty-two (52%) patients received TKI-based treatments (with trastuzumab, tucatinib, and capecitabine being the most common), and exhibited a mPFS of 3.9 months. Twenty-one (26%) patients were enrolled in clinical trials or received novel drug combinations, demonstrating a mPFS of 4.2 months. ADCs (most commonly T-DM1) were given to 16 (20%) patients, with a mPFS of 2.4 months. Eleven (14%) patients received hormone therapy, and 7 (8.6%) received mAB, with a mPFS of 9.1 months and 14 months, respectively. In multivariate analysis, patients who stopped T-DXd due to toxicity (rather than disease progression) had a dramatically improved mPFS on subsequent lines of treatment (HR 0.35; p <0.001). Later treatment line and the presence of brain metastases were numerically associated with shorter mPFS (HR 1.06; p=0.06 and HR 1.23; p=0.2 respectively), and HR status had no effect.
Conclusion: We observe that prognosis is generally poor in the post-T-DXd setting. No therapeutic approach could be identified as clearly superior in our cohort, however, a subset of patients seemed to benefit from hormone therapy or TKI-based therapy, which warrants further investigation. Of special note, the reason for ending T-DXd treatment was a strong predictor of response to subsequent therapies, such that patients who stopped treatment due to toxicity had a 65% reduction in risk of disease progression or death. Overall, our study indicates that patients emerge from T-DXd treatment with highly refractory disease. Characterizing T-DXd resistance and finding new therapeutic options for this population represents an urgent clinical need.

P5-03-10: Safety and Preliminary Efficacy of Tucatinib and Alpelisib in Patients with HER2-positive PIK3CA-Mutated Metastatic Breast Cancer

Elena Shagisultanova, Chelsea D. Gawryletz, Colleen Dougherty-Gray, Leah Adams, Amelia Hardeman, Michelle Loch, Marina Sharifi, Peter Kabos, Virginia Borges

Background: Activating mutations in the gene of phosphotydylinisotol-3 kinase catalytic subunit alpha (PIK3CA) are present in up to 40% of breast cancers overexpressing human epidermal growth factor receptor 2 (HER2). These mutations are linked to resistance to HER2-targeted agents and poorer patient outcomes. Based on preclinical efficacy, we are conducting a study to evaluate the combination of HER2-inhibitor tucatinib and PI3Kα-inhibitor alpelisib in patients with HER2-positive (HER2+) PIK3CA-mutated metastatic breast cancer (MBC) (NCT05230810).
Methods: This phase IB study aims to determine the maximal tolerated doses of tucatinib and alpelisib using the Time-to-Event Bayesian Optimal Interval Design, with dose limiting toxicity (DLT) window of 28 days. Safety is evaluated by CTCAE v.5.0 with standard definition for DLTs. Eligible participants include post-menopausal women or pre-menopausal women undergoing ovarian suppression, diagnosed with HER2+ PIK3CA-

mutated MBC, and previously treated with at least two HER2-targeted agents. Patients are allowed 1 prior line of HER2 tyrosine kinase inhibitor for MBC, including prior tucatinib. Treatment consists of twice-daily tucatinib and daily alpelisib at prespecified dose level (DL) with concurrent fulvestrant for hormone receptor-positive cases.
Results: As of July 1st, 2024, 8 patients have been treated. The median age was 53 years (range: 45-66), with a median of 2 prior lines of therapy for MBC (range: 1-4). Prior HER2-targeted therapies included trastuzumab and pertuzumab (8 patients), T-DM1 (5 patients), tucatinib (4 patients), T-DXd (4 patients), and margetuximab (1 patient). Six patients had visceral metastases and 4 had CNS metastases.
No DLTs were observed in 4 patients treated at DL1 (tucatinib 300 mg BID, alpelisib 250 mg daily), with one additional patient in the DLT window at the time of data cut-off. At DL2 (tucatinib 300 mg BID, alpelisib 300 mg daily), all 3 patients experienced DLT. Two patients had grade 3 (G3) diarrhea despite maximal anti-diarrheal regimen that resolved with treatment hold and dose reduction. One patient developed G3 rash with mucositis, eosinophilia and G4 elevated creatinine and came off study, all symptoms resolved without sequelae with hydration and steroid treatment. Other notable adverse events, primarily G1-2, included hyperglycemia (6 patients), decreased appetite (5 patients), weight loss (5 patients), fatigue (5 patients) and elevated liver enzymes (4 patients). These side effects were managed with supportive medications, nutritionist consultations and avoidance of hepatotoxic agents. No new safety signals were observed from the study drugs. One heavily pretreated patient developed progressive CNS metastases after 6 months on study and died on hospice within 30 days of follow up. At the time of data cutoff, 5 patients were evaluable for tumor response: 2 had stable disease, and 3 had partial response (PR). All patients who experienced PR had PIK3CA H1047R mutation. All PRs occurred after 2 cycles of therapy and included significant reduction of breast tumors, liver and lung metastases and resolution of cancer lymphangitic spread in the lungs. Four out of 8 patients remained on the regimen for more than 6 months. The longest treatment duration is 15 months and ongoing.
Conclusions: The combination of tucatinib and alpelisib is tolerable at DL1 and shows remarkable antitumor activity with partial responses in 3 out of 5 evaluable patients (60% overall response rate), including responses in patients treated with prior tucatinib and T-DXd. Enrollment continues at DL1. Updated safety and efficacy findings will be presented at SABCS 2024 conference.

P5-03-11:DEMETHER: A single-arm phase II trial to evaluate the efficacy & safety of subcutaneous pertuzumab & trastuzumab maintenance after induction treatment w/ trastuzumab deruxtecan (T-DXd) for previously untreated HER2-positive advanced breast cancer

Javier Cortés, Juan José García-Mosquera, Gabriele Antonarelli, Alessandra Gennari, Carlos Barrios, Giuseppe Curigliano, Hope Rugo, Joseph Gligorov, Nadia Harbeck, Sara M. Tolaney,

William J. Gradishar, Peter Schmid, María Gion, Rui Rui Zhan, Emilia Szosta, Paula González-Alonso, Michela Verbeni, José Manuel Pérez-García, Antonio Llombart-Cussac

Background: HER2 (human epidermal growth factor receptor 2) is overexpressed in 15-20% of all breast cancers. Pertuzumab combined with trastuzumab and taxanes is the standard first-line therapy for HER2-positive advanced breast cancer (ABC) based on the results from CLEOPATRA trial. T-DXd has demonstrated unprecedented antitumor activity in patients (pts) with previously treated HER2-positive ABC and has the potential to move into the first-line treatment of this patient population (DESTINY-Breast09). Despite a manageable toxicity profile, prior studies have raised safety concerns about potential serious adverse events associated with its use and a potential negative impact on quality of life (QoL). Taking this into consideration, the rationale of the DEMETHER study is to find the right balance between T-DXd shorter treatment duration and subcutaneous fixed-dose combination of pertuzumab and trastuzumab maintenance therapy to ensure efficacy and tolerance in previously untreated HER2-positive ABC pts. Trial Design DEMETHER (NCT06172127) is an international, multicenter, open-label, single-arm phase II trial. Key inclusion criteria include: (a) Pts aged ≥18 years with centrally-confirmed HER2-positive ABC; (b) No prior chemotherapy and/or HER2-targeted therapy for advanced disease. Participants who have received chemotherapy and/or HER2-targeted therapy in the neo(adjuvant) setting are eligible if ≥ 12 months from completion of systemic treatment to metastatic diagnosis; (c) ECOG performance status of 0-1; (d) Evaluable disease according to RECIST v.1.1. Pts will first receive an induction treatment consisting of 6 cycles of T-DXd (5.4 mg/kg, intravenously, on day 1 of each 21-day cycle). If any T-DXd unacceptable toxicity occurs during the induction phase, participants may receive taxane-based chemotherapy concomitantly with subcutaneous fixed-dose combination of pertuzumab and trastuzumab treatment at the discretion of the Investigator. In the maintenance phase, all participants will be treated with a subcutaneous fixed-dose combination of pertuzumab and trastuzumab each 21-day cycle until disease progression, unacceptable toxicity, patient withdrawal, or up to 3 years after T-DXd initiation. During the maintenance phase, hormone receptor-positive pts will also receive concomitant endocrine therapy. The primary objectives are: 1-year (1-y) progression-free survival (PFS) rate, as locally determined by the Investigator according to RECIST v.1.1; and 3-year (3-y) overall survival (OS) rate. Secondary objectives are median PFS and OS, objective response rate, clinical benefit rate, time to response, duration of response, best percentage of change in tumor burden as per RECIST v.1.1, changes in health-related QoL assessments from baseline (EORTC QLQ-C30, QLQ-BR45, and EQ-5D-5L), and safety and toxicity profiles according to the NCI-CTCAE v.5.0. The primary analyses will be performed using the maximum likelihood method for exponential distributions, with a one-sided significance level of 2.5% for both endpoints. Applying sequentially rejective test, the type I error will be controlled at 5% level. A sample size of 165 patients will allow to achieve 80% power. Date of registration: May (Europe), July-August (FDA-IRB, US), December (Brazil), 2024. First patient enrolled: June (Europe), September (US), December (Brazil), 2024.

P5-03-12: Liquid Cytopathology for HER2 Status in Breast Cancer: Beyond Tissue Biopsy

Elisabetta Molteni, Lorenzo Foffano, Letizia Pontolillo, Eleonora Nicolò, Mara Serena Serafini, Laura Munoz-Arcos, Caterina Gianni, Nadia Bayou, Giuseppe Damante, Huiping Liu, Lorenzo Gerratana, Carolina Reduzzi, Massimo Cristofanilli

Background: Around 15% of breast cancers (BC) are considered human epidermal growth factor receptor 2 positive (HER2+). HER2 status is assessed on tissue biopsies which, despite being the gold standard for tumors' molecular characterization, present limitations. These limitations could be overcome by using liquid biopsy. In particular, circulating tumor cells (CTCs) allow an in-depth characterization of the disease at various levels (DNA, RNA, protein) and can be used as a surrogate of tissue biopsy, also for HER2 evaluation. In this work, we investigated the potential of CTCs to assess HER2 status in BC patients, in comparison to HER2 evaluation on tissue.
Methods: Blood samples were collected from 318 patients (pts) with metastatic BC treated at Northwestern University (Chicago, IL) between 2016 and 2021. CTCs were enumerated and stained for HER2 using the CellSearch® platform. Only patients with ≥5 CTCs were considered for correlation between tissue and CTCs HER2 status. HER2 expression on CTCs was quantified using the ACCEPT software and each CTC was categorized as HER2-negative, HER2 2+ and HER2 3+ (moderate and strong expression, respectively). For each sample a CTC-HER2ratio was calculated as the number of HER2 2+ and 3+ CTCs divided by the total number of CTCs. Tissue HER2 status (evaluated on the available biopsy collected nearest in time to the blood draw) was compared to the HER2 expression on CTCs. Receiver operating characteristic (ROC) curves were used to define the optimal CTC-HER2ratio cutoff associated with HER2 tissue status.
Results: The study cohort included 143 patients with metastatic BC and ≥5 CTCs. Of these, 15% (N=22) had HER2+ and 85% (N=121) had HER2 negative (HER2-) BC. Among the pts with HER2- BC, 36 were further categorized as HER2zero and 46 as HER2low (for 39 patients the information was not available). HER2+ CTCs (including HER2 2+ and 3+) were detected in 91% and 96% of patients with HER2+ and HER2- BC, respectively. Despite a similar incidence, the median CTC-HER2ratio was significantly different among the 2 subgroups: 0.30 (interquartile range [IQR] 0.10-0.73) for the HER2+ cohort vs 0.09 (IQR 0.03-0.18) for the HER2- one, p-value = 0.00028, indicating a higher proportion of HER2+ CTCs in HER2+ BC pts. When comparing HER2zero and HER2low BC cohorts, we could not observe a difference in the proportion of HER2+ CTCs. The median CTC-HER2ratio was 0.08 (IQR 0.03-0.16) and 0.12 (IQR 0.03-0.21) for HER2zero and HER2low, respectively (p-value = 0.32708). Both were significantly lower than the CTC-HER2ratio of the HER2+ BC cohort (p-value = 0.00076 and 0.00614 for HER2zero and HER2low, respectively). The ROC curve analysis for HER2+ and CTC-HER2ratio resulted in an area under the curve (AUC) of 0.7417, with an optimal cutoff at 0.22. At this threshold, sensitivity was 63.64% and specificity reached 82.64%. The positive predictive value was 40.00% while the negative predictive value was 92.59%. The ROC curve analysis for HER2-low and CTC-HER2ratio resulted in an AUC of 0.5646, with an optimal cutoff at 0.13. At this optimal cutoff, sensitivity was 50% and

specificity was 72.22%. The positive predictive value was 69.70% while the negative predictive value was 53.06%.
Conclusion: It is possible to identify and quantify HER2 expression on CTCs. HER2+ CTCs were detected in a high percentage of patients regardless of their HER2 status on tissue, indicating high intra-patient heterogeneity. HER2+ BC cohort exhibited a significantly higher proportion of HER2+ CTCs compared to the HER2- BC cohort. No difference was instead observed when comparing HER2zero with HER2 low subgroups. Moreover, we showed that the CTC-HER2ratio is a good predictor of HER2+ status on tissue suggesting a potential application of liquid cytopathology for molecular markers.

P5-03-13: Trastuzumab emtansine versus disitamab vedotin for HER2-positive metastatic breast cancer: a multicenter retrospective real-world study

Huihui Li, Jie Huang, Dongdong Zhou, Fei Pan, Zheng lv, Wei Li, Yuhua Song, Yu Hu, Changping Shan, Li Meng, Li Xiang, Fei Qu, Lihua Song, Baoxuan Zhang, Fangchao Zheng, Liang Xu, Xinzhao Wang, Jiale Zhang, Shujuan Sun

Background: An estimated 15–25% of breast cancer patients exhibit overexpression or amplification of human epidermal growth factor receptor 2 (HER2), characterized by high invasiveness and poor prognosis. The antibody drug conjugate (ADC) drugs, especially trastuzumab deruxtecan (T-DXd), have tremendously improved efficacy in HER2-positive metastatic breast cancer (MBC). However, there is as yet no consensus on the superiority-inferiority differentiation of other anti-HER2 ADC drugs, especially trastuzumab emtansine (T-DM1) and disitamab vedotin (RC48).
Methods: This multicenter retrospective study included 180 HER2-positive MBC patients initially treated with T-DM1 (n=105) or RC48 (n=75) from July 2017 to March 2023. Enrolled patients had received T-DM1 (3.6 mg/kg iv q3w) or RC48 (2.0 mg/kg iv q2w) until disease progression, intolerable toxicity, or death. Baseline characteristics were balanced using inverse probability of treatment weighting (IPTW). The primary endpoint was progression-free survival (PFS) and secondary endpoints were objective response rate (ORR), disease control rate (DCR), overall survival (OS), and adverse events (AEs). The study was approved by the Institutional Review Board of Shandong Cancer Hospital and Institute (No. SDTHEC2023004017).
Results: The clinical data was retrospectively collected up to 31 October 2023. All baseline characteristics were comparable between the two groups after IPTW. In the unmatched cohort, the median PFS of T-DM1 was significantly superior compared to the RC48 group (7.8 months vs. 5.5 months; p = 0.002); and the patients in T-DM1 group had a longer trend of OS (26.8 months vs. 18.0 months; p = 0.240). The ORR (40.0% vs. 29.3%, P=0.141) and DCR (74.3% vs. 61.3%, P = 0.064) of patients with T-DM1 were better than that of patients with RC48. After IPTW adjustment, T-DM1 was still associated with improved survival, with median PFS of 6.2 versus 5.5 months (p = 0.002) and median OS of 25.5 months versus 17.8 months (p = 0.240). In the subgroup analyses of PFS, T-DM1 groups were favored over

RC48 groups in all pre-specified subcohorts. Moreover, T-DM1 treatment improved ORR (odds ratio [OR] 1.08, 95% CI 0.91-1.27, p = 0.380) and DCR (OR 1.10 95% CI 0.93-1.30, p = 0.286) compared with RC48 group. Grade 3 AEs occurred in 28.6% and 33.3% of patients in the T-DM1 and RC48 groups, respectively (p = 0.494). The most predominant grade 3 AE in the T-DM1 group and the RC48 group were reduced platelet count (13.3%) and neutropenia (13.3%), respectively. No grade 4 and 5 AEs occurred.
Conclusions: T-DM1 treatment showed a significant improvement in progression-free survival versus RC48 in patients with HER2-positive metastatic breast cancer. Moreover, both drugs demonstrated good tolerability. And prospective randomized studies are needed for further verification.

P5-03-14: Efficacy and safety of inetetamab-containing regimens in patients with HER2-positive metastatic breast cancer in first-line/second-line setting

Yuxin Mu, Hui Zhang, Chao Deng, Jiao Yang, Lu Gan, Qingmo Yang, Xuefeng Xu, Wanping Liang, Xiaowei Qi, Liang Xu, Jian Zhang

Inetetamab is a novel recombinant humanized anti-Human epidermal growth factor receptor 2 (HER2) monoclonal antibody. This real-world retrospective study assessed the efficacy and safety of inetetamab-containing regimens in first-line/second-line treatment of HER2-positive metastatic breast cancer (MBC). This study retrospectively recruited HER2-positive MBC patients who received inetetamab- containing regimens from June 2020 to May 2023. The outcomes included progression-free survival (PFS), objective response rate (ORR), and disease control rate (DCR). A total of 329 patients were enrolled and included in the efficacy analysis. The most frequently used treatment strategy was contained inetetamab plus pyrotinib (205/329, 62.3%). Of 329 patients for efficacy evaluation, the median PFS was 14.5 months. Patients treated with first-line regimens benefited the most, with a median PFS of 15.0 versus (vs.) 10.0 months (first-line- vs. second-line inetetamab plus pyrotinib, p <0.001), 19.0 vs. 17.0 months (first-line- vs. second-line inetetamab plus pertuzumab, p=0.096), and 14.0 vs. not reached months (first-line- vs. second-line inetetamab plus chemotherapy, p=0.229). The inetetamab plus pertuzumab group had the longest survival compared with inetetamab plus pyrotinib and inetetamab plus chemotherapy group in first-line (mPFS, 19.0 vs. 15.0 vs. 13.0 months) and second-line (mPFS, 17.0 vs. 10.0 vs. not reached months) settings. The ORR was 54.4% (95%CI, 49.0%-59.7%), with 14 (4.3%) complete response (CR) and 150 (45.6%) partial response (PR). Besides, 148 (45.0%) patients had stable disease (SD) for a disease control rate (DCR) of 99.4% (95%CI, 97.8%-99.8%). Grade 3 or higher adverse events (AEs) were observed in 29.5% of all 329 patients and mainly included diarrhea (38/329, 11.6%), white blood cell decreased (32/329, 9.7%), myelosuppression (18/329, 5.5%), neutrophil count decreased (7/329, 2.1%). No treatment-related deaths were reported. Compared with the other two subgroups, the incidence AEs of any grade (205/329, 62.3%) and grade ≥3 (80/329, 24.3%) in inetetamab plus pyrotinib group was the highest. Following the first- and second-line of

treatment, inetetamab- containing combinations demonstrated promising clinical activity and a manageable safety profile in patients with HER2-positive MBC, especially in the first-line treatment.

P5-03-15: EmpowHER 303: A phase 3 study to evaluate the efficacy and safety of zanidatamab vs trastuzumab with chemotherapy in patients (pts) with metastatic HER2-positive breast cancer who have progressed on, or are intolerant to, trastuzumab deruxtecan

Sara M Tolaney, Javier Cortes, Erika Hamilton, Hiroji Iwata, Yeon Hee Park, Debasish Tripathy, Romualdo Barroso-Sousa, Giuseppe Curigliano, Nadia Harbeck, Hope S Rugo, Shanu Modi, Stephanie L Graff, Carlos Barrios, Hartmut Kristeleit, Barbara Pistilli, Philippe Aftimos, Shigehira Saji, Angelos Koutras, Debasis Chakrabarti, Kamalnayan Bhatt, George Cai, Xiaoyan Wang, Sara Hurvitz

Background: HER2-targeted therapies have revolutionized the treatment of HER2-positive (HER2+) breast cancer (BC). However, there is a need for novel treatment options after progression on available therapies, including trastuzumab deruxtecan (T-DXd). Zanidatamab (zani) is a HER2-targeted IgG1-like bispecific antibody that binds two non-overlapping HER2 domains in a trans configuration, leading to crosslinking of adjacent HER2 molecules. In preclinical studies, zani was associated with multiple mechanisms of action, including HER2 internalization and downregulation, complement-dependent cytotoxicity and antibody-dependent cellular cytotoxicity, and phagocytosis. As a monotherapy or in combination with other agents, zani has shown clinically meaningful efficacy against multiple HER2+ tumors, including metastatic BC (mBC). We describe an ongoing phase 3 study assessing zani in combination with chemotherapy in pts with HER2+ mBC whose disease has progressed on, or who are intolerant to, T-DXd.
Methods: EmpowHER 303 (NCT06435429) is a phase 3, randomized, open-label, multicenter study evaluating the efficacy and safety of zani vs trastuzumab (T) both in combination with physician's choice of chemotherapy in pts (≥18 years old) with histologically confirmed HER2+ mBC (per ASCO-CAP guidelines) and measurable disease (per RECIST version 1.1). Pts with tumors locally assessed as IHC 3+ can be randomized while HER2-positivity is centrally confirmed. Pts with tumors locally assessed as IHC2+/ISH+ cannot be randomized until their HER2 status is centrally confirmed. Eligible pts must have progressed on, or be intolerant to, prior T-DXd treatment and have received ≥2 but ≤4 lines of prior HER2-directed therapies for metastatic disease. Prior HER2-directed therapy after T-DXd (e.g. tucatinib-based regimen or trastuzumab emtansine) is allowed based on physician's choice, pts' eligibility, and institutional and local guidelines. Pts must be eligible to receive one of the following physician's choices of chemotherapy: eribulin, gemcitabine, vinorelbine, or capecitabine. Pts with central nervous system (CNS) metastases may be eligible if their CNS metastases have been treated or are clinically inactive. Pts must also have adequate hematologic parameters and hepatic function, LVEF ≥50% as determined by an echocardiogram or multiple gated acquisition scan, Eastern

Cooperative Oncology Group performance status of 0 or 1, and a life expectancy of at least 6 months. Exclusion criteria include known or suspected leptomeningeal disease, uncontrolled or significant cardiovascular disease, uncontrolled infection, history of hypersensitivity to monoclonal antibodies, or inability to receive zani or T. An estimated 550 pts will be randomized 1:1 to zani (1800 mg [pts <70 kg] or 2400 mg [pts ≥70 kg] intravenous [IV]) or T (8 mg/kg IV loading dose, then 6 mg/kg), + physician's choice of chemotherapy in 3-week cycles. Randomization will be stratified by number of prior lines of HER2-directed therapies, prior tucatinib use, geographic region, CNS metastases, and chemotherapy choice. Mandatory prophylaxes for diarrhea and infusion-related reactions are required starting cycle 1 for pts receiving zani + chemotherapy. The primary endpoint is progression-free survival (PFS) assessed by blinded independent central review (BICR). Secondary endpoints include overall survival, confirmed objective response rate, and duration of response (by BICR and investigator-assessed), investigator-assessed PFS, safety, patient-reported outcomes, pharmacokinetics, and immunogenicity for zani. Exploratory endpoints will assess biomarkers of treatment response/resistance.

P5-03-23: Unveiling Guillain-Barre Syndrome as a Paraneoplastic Sequelae of Breast Cancer

Rachelle Diane Maravilla, Agnes E. Gorospe

Paraneoplastic neurological syndromes (PNS) are immune-mediated conditions triggered by an underlying cancer. Classically, PNS have been correlated with onconeuronal antibodies that target intracellular proteins, showing limited direct pathogenic significance. Nevertheless, detection of such antibodies indicates a strong association with certain tumor types such as lung, ovarian, breast and lymphatic systems. PNS are extremely rare especially in subsets of breast cancer patients, and an incidence of 1-8 per 100,000 person-years. Symptoms include visual and gait disturbances, hypotonia, dysphagia, poor fine motor coordination, cognitive dysfunction, and epileptic seizures. We report a case of a 40-year old female with early-stage BRCA1 mutated, triple negative breast cancer. She underwent definitive surgery followed by adjuvant chemotherapy. However, after 4 cycles of dose-dense adriamycin and cyclophosphamide, evaluation scan showed tumor recurrence to the liver. She proceeded with Paclitaxel for 12 weeks with complete response of liver metastases. A month after, she presented with blank stares, generalized tonic-clonic seizures, dizziness and parieto-occipital headache. Cranial MRI showed multiple enhancing parenchymal foci in the left occipital, bilateral temporal lobes, pons and cerebellum. Among these, the largest lesions measured 1 x 2.4 x 1 cm and 1.7 x 2.5 x 2.1 cm in the right cerebellum. She was started on dexamethasone, leviteracetam and lacosamide, and was referred to Radiation Oncology. She then received 10 fractions of whole brain radiotherapy (WBRT), amounting to 3000 cGy. Despite this, however, her seizures persisted along with new onset bilateral lower extremity motor weakness (MMT 3-/5 on the right and 1/5 on the left). Leptomeningeal metastasis was considered but MRI of the spine was negative. Progression of neurologic deficits was noted, now with areflexia and bilateral upper

extremity weakness (MMT 4-/5, bilateral). Electromyography and nerve conduction velocity (EMG-NCV) showed probable early or beginning axonal polyneuropathy, absence of voluntarily activated motor units with apparently normal motor and sensory conduction velocities. Primary consideration at this time was Guillain-Barré Syndrome (GBS) specifically the acute motor axonal neuropathy (AMAN) variant. Cerebrospinal fluid was sampled which tested negative for infection. She was given 20 mg of intravenous immune globulin 5% (IVIG) for 5 days with minimal improvement of symptoms. At present, treatment plan is to give either targeted therapy for BRCA1 mutation or antibody-drug conjugate to address her malignancy and its possible underlying paraneoplastic process. For this case, the diagnostic confirmation of GBS secondary to the patient's concomitant breast carcinoma proved to be challenging especially since available data regarding the condition is limited. There is heterogeneity in timing, symptomatology, and presence of certain onconeural antibodies. These antibodies are usually seen in 60-70% of breast cancer patients exhibiting paraneoplastic symptoms. Hence, antibody testing may be helpful if detected but its absence cannot fully rule out PNS. To address this dilemma, four components were defined for the diagnosis of PNS: (1) presence of neurologic symptoms, (2) diagnosis of malignancy within 4 years from onset of neurologic manifestations, (3) exclusion of other neurologic diseases, and (4) at least one of the following: CSF analysis with inflammation and negative cytology, temporal lobe lesion on MRI, or epileptic activity in the temporal lobes by EEG. Since our patient fulfilled all four diagnostic components, the likelihood of her disease course being secondary to PNS is further strengthened. At present, however, there are no specific guidelines for such cases but treatment of the underlying malignancy is recommended.

P5-03-25: Trastuzumab deruxtecan (T-DXd) in leptomeningeal metastases from HER2-altered cancers

Qian Ma, David Rogawski, Toni Cao, Meaghan Roy-O'Reilly, Lilian Yao, Nova Xu, Seema Nagpal

Purpose: Emerging data suggest that trastuzumab deruxtecan (T-DXd) is an active treatment for brain metastases from HER2 + breast cancer. We aimed to characterize the activity of T-DXd in the treatment of leptomeningeal metastases (LM) from a range of HER2-altered cancers.
Methods: We reviewed neuro-oncology clinic records between July 2020 and December 2023 at Stanford Neuro-oncology clinic to identify patients who received T-DXd to treat LM.
Results: Of 18 patients identified, 6 had HER2 + breast cancer, 8 had HER2-low/negative breast cancer, 2 had HER2 + gastroesophageal cancer, and 2 had HER2-mutant non-small cell lung cancer (NSCLC). 10/18 (56%) patients had cytologically confirmed LM by CSF cytology or circulating tumor cell (CTC) capture. A partial response (PR) on MRI using the EORTC/RANO-LM Revised-Scorecard occurred in 4/6 (67%) patients with HER2 + breast LM, 2/8 (25%) patients with HER2-low/negative breast cancer, and 0/4 (0%) patients with HER2 + gastroesophageal cancer or HER2-mutant NSCLC. Median overall survival after

initiating T-DXd was 5.8 months. Survival after initiating T-DXd was numerically longer for HER2 + breast cancer patients compared with HER2-low/negative breast and HER2-altered non-breast cancer patients (13.9 months vs. 5.2 months and 4.6 months, respectively). Landmark analysis showed that patients with radiologic LM response to T-DXd by 2.5 months had longer survival than non-responders (14.2 months vs. 2.6 months, HR 0.18, 95% CI 0.05-0.63, $p < 0.05$), and landmark analyses at 3.5 and 4.5 months after starting T-DXd showed a similar but nonsignificant trend.
Conclusion: T-DXd induces LM responses in a subset of patients, and such responses may be associated with prolongation of survival. Prospective trials are needed to clarify the role of T-DXd in treating LM and which patients are most likely to benefit.
Keywords: Antibody-drug conjugate; HER2-altered cancers; Leptomeningeal metastases; Trastuzumab deruxtecan.

P5-03-26: Concurrent use of trastuzumab deruxtecan and radiation therapy in HER2-positive and HER2-low metastatic breast cancer: a single-center experience and review of the literature

Jihane Bouziane, Pierre Loap, Kim Cao, Sofiane Allali, Yacine Gounane, Loganadane Gokula, Laurence Escalup, Jean-Yves Pierga, Youlia Kirova

Purpose: Recent DESTINY-Breast trials have demonstrated trastuzumab deruxtecan's effectiveness in HER2-positive and HER2-low metastatic breast cancer. However, safety concerns remain regarding its combination with radiation therapy (RT). The purpose of this work is to assess the toxicity profile of combining trastuzumab deruxtecan and RT in patients with HER2-positive and HER2-low metastatic breast cancer to address these concerns.
Materials and Methods We conducted a retrospective study which included patients treated at Institut Curie Paris between November 2020 and January 2024. Patients with HER2-positive and HER2-low metastatic breast cancer who received concurrent trastuzumab deruxtecan and RT were identified. Data on patient demographics, treatment regimens, radiation doses, toxicity profiles, and treatment discontinuations were collected. Follow-up was conducted from the last day of radiotherapy until death or the last examination and toxicities were graded using the CTCAE V5.0.
Results The studied population includes all 33 patients with HER2-positive and HER2-low metastatic breast cancer who underwent concurrent treatment with trastuzumab deruxtecan and radiotherapy. The median follow-up was 11 months. The most common acute grade 1 toxicity was nausea. Grade 2 toxicities affected 21.2% of patients, including asthenia, mucositis, cardiac decompensation, and diarrhea. Trastuzumab deruxtecan discontinuation occurred in 5 patients due to systemic treatment-related toxicities, including nausea, thrombocytopenia, neutropenia, and cardiac decompensation. 21.2% of patients reported late toxicities, with nausea being the most prevalent.
Conclusion Our series of patients who received concurrent treatment of radiotherapy and

trastuzumab deruxtecan are showing acceptable toxicity. Larger prospective studies are needed to evaluate the toxicity and efficacy of this combination.

P5-03-27: Updated Real-World Evidence on the Efficacy and Safety of Inetetamab-Based Therapy in HER2-Positive Metastatic Breast Cancer Patients Previously Treated with Trastuzumab

Yangyang Duan, Tao Sun, Zhanhong Chen, Quchang Ouyang, Kai Li, Min Yan, Zheng Lv, Zhaohui Li, Li Man, Xu Luo, Yuyang Dong, Mingxi Jing, Yan Wang, Xiangyu Guo, Junnan Xu, Xiaorui Li, Cui Jiang, Ying E, Lei Jiang, Hui Cao, Yufeng Jia, Jie Wu, Huan Li, Liang Zhang, Yujun Jiang, Zhichao Gao, Fangyuan Dong

Background: Despite the clinical advancements made in the management of metastatic breast cancer (MBC), a notable void persists in the comprehensive evaluation of the therapeutic potential of inetetamab, a novel recombinant humanized anti-HER2 monoclonal antibody, among HER2-positive MBC patients who have previously undergone trastuzumab treatment. This study aims to bridge this gap by conducting a thorough, real-world analysis of inetetamab's efficacy and safety in this specific patient population.
Methods: A multicenter, retrospective, real-world study was conducted, enrolling 500 HER2-positive MBC patients between July 2020 and October 2023. Clinical and pathological data were systematically collected and analyzed to assess the progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and the incidence of adverse events (AEs) among patients receiving inetetamab therapy.
Results: In the overall cohort, inetetamab therapy resulted in a median PFS of 8 months, with a median number of treatment lines being three. Notably, an ORR of 28.6% and a DCR of 89.2% were observed. Furthermore, patients receiving a combination regimen of inetetamab with tyrosine kinase inhibitors (TKIs) and chemotherapy achieved the longest PFS of 9.0 months, accompanied by an even higher ORR of 29.3%. The primary treatment-related AEs were neutropenia and leukopenia, both of which were generally well-tolerated by the patients.
Conclusions:
This study underscores the promising efficacy and safety profile of inetetamab in HER2-positive MBC patients with prior trastuzumab exposure, particularly when utilized in combination with TKIs and chemotherapy. These findings provide invaluable insights into the real-world application of inetetamab and serve as a foundation for further exploration of its optimal utilization strategies in clinical practice.

P5-03-28: Case report: interstitial lung disease in a paciente with metastatic breast cancer treated with radiotherapy and trastuzumab deruxtecan

Thamilyn Saruwatari, Marcelle Goldner Cesca, Monique Celeste Tavares

Introduction Pneumonitis or interstitial lung disease (ILD) is an adverse event associated with trastuzumab deruxtecan (T-DXd or DS-8201) described in up to 10 to 12% of cases, mostly classified as grade II or III. Fatal outcomes due to ILD and/or pneumonitis occurred in 1,0% and there are few cases reported in clinical practice.1 In this case report, we present a patient with metastatic breast cancer to the lung, pretreated, receiving T-DXd and pulmonary radiotherapy, who unfortunately progressed fatally with severe pneumonitis. Keywords: drug-induced pneumonitis; interstitial pneumonitis; trastuzumab-deruxtecan; radiotherapy Case report S.S, female, 64 years old, Asian ethnicity, ECOG 0, previously healthy. In May 2020, she began investigation for a nodular lesion in the right breast, core biopsy revealed invasive carcinoma of no special type, grade III, positive for ER 95%, PR 70%, HER2 3+, Ki67 80%, luminal B HER2 3+ phenotype. Initial staging examinations including total chest and abdomen CT showed multiple thoracic lymphadenopathies in the right axillary, right supraclavicular, right paratracheal, and subcarinal regions, multiple solid pulmonary nodules bilaterally suggesting secondary neoplastic involvement. Bone scintigraphy showed no evidence of bone metastases. Brain MRI revealed no lesions. In May 2020, she started first-line treatment for metastatic luminal B HER2 3+ breast cancer with docetaxel, trastuzumab, and pertuzumab (THP, administered IV every 3 weeks; pertuzumab 840mg on Day 1 of the first cycle followed by 420mg on Day 1 of subsequent cycles; trastuzumab 8mg/kg on Day 2 of the first cycle followed by 6mg/kg on Day 1 of subsequent cycles; docetaxel 75mg/m2 on Day 1 of each cycle). Response assessment after 3 months showed abnormal metabolic activity on PET CT (infraclavicular lymph nodes with SUV 4.4, mediastinal lymph nodes with SUV 5.6 and 8.1, subpleural pulmonary nodules with SUV 3.1 and 3.3, right breast lesion with satellite nodules and SUV between 3.9 and 17.3), and partial response by RECIST on total chest and abdomen CT. She continued THP until November 2020, when she experienced nodal disease progression and initiated second-line treatment with T-DM1, which she used for 6 months before switching due to further oncologic progression. Biopsy of the supraclavicular lymph node confirmed luminal B HER2 3+ phenotype. Third-line treatment was proposed with capecitabin and lapatinib (used for 4 cycles from May 2021 to August 2021), with disease progression noted in the breast, axillary lymph node, and pulmonary lesions. Fourth-line treatment with vinorelbin (August 2021 to November 2021) was initiated, with new nodal and pulmonary disease progression. Fifth-line treatment with trastuzumab and capecitabine was started and continued for 3 cycles (December 2021 to January 2022), but PET CT showed disease progression in the pulmonary and nodal regions. Sixth-line treatment with trastuzumab deruxtecan began in February 2022, with concurrent radiotherapy to pulmonary lesions (35 Gy in 10 fractions of 300 cGy) and mediastinal lymph nodes (30 Gy in 10 fractions of 300 cGy). After Cycle 27 of T-DXd, the patient presented to the emergency room with progressive dyspnea and syncope episode, oxygen saturation of 82% requiring 2L/min oxygen via nasal cannula. Vasovagal causes or central nervous system disease progression were ruled out, and transthoracic echocardiogram showed normal findings. Chest CT revealed consolidative and ground-glass opacities associated with septal thickening and sporadic bilateral fibroatelectatic changes, excluding viral and bacterial infectious causes. Evaluation by a pneumologist confirmed the diagnosis of T-DXd-associated pneumonitis.

Treatment was initiated with corticosteroids at 500 mg/day for 3 days, but clinical deterioration necessitated escalation to high-flow nasal cannula oxygen therapy, and a single dose of infliximab was administered. Corticosteroid therapy continued at 2 mg/kg/day. Unfortunately, the patient clinically deteriorated with progressive worsening of respiratory status and passed away after 36 days of hospitalization. Discussion Trastuzumab deruxtecan (also known as T-DXd and DS-8201) is an antibody–drug conjugate consisting of a humanized anti-HER2 monoclonal antibody linked to a topoisomerase I inhibitor payload through a tetrapeptide-based cleavable linker.2 Approximately 20% of women with breast cancer have tumors that overexpress human epidermal growth factor receptor 2 (HER2) and will receive anti-HER2 therapies.3 We present a case of pneumonitis and acute lung injury in a patient on T-DXd treatment. Trastuzumab-associated pneumonitis is not well described in the literature and the mechanism of trastuzumab-associated lung injury is not clear as well as risk factores, mainly after radiotherapy and polytreated patients. In the DESTINY-Breast04 Trial it has been documented that drug-related interstitial lung disease or pneumonitis occurred in 12.1% of the patients who received trastuzumab deruxtecan; In the trastuzumab deruxtecan group, the median time to onset in patients with interstitial lung disease or pneumonitis was 129 days.4 Similiar data was found in the DESTINY-Breast03 trial, where most cases of adjudicated drug-related interstitial lung disease or pneumonitis were mild or moderate. Cases of pneumonitis was identified in 27 patients (10.5%) who received trastuzumab deruxtecan (7 patients had grade 1 events, 18 had grade 2 events, and 2 had grade 3 events) and in 5 patients (1.9%) who received trastuzumab emtansine (4 had grade 1 events and 1 had a grade 2 event) (Table 2). No such events of grade 4 or 5 occurred in either treatment group, and most of the patients recovered by the time of the data cutoff. 5 When a case of pneumonitis is identified, discontinuation of T-DXd is recommended and early initiation of corticosteroid treatment is advised to minimize severity and morbidity. In some reported cases, prior thoracic radiotherapy increases the risk of acute lung injury in lung cancer patients.6 And identifying specific causative agents is challenging in oncology when drugs are given in combination regimens, or in association with thoracic radiotherapy, which is independently associated with lung fibrosis. Currently, there is no consensus regarding the use of T-DXd and radiotherapy, nor whether it could lead to cases of fulminant pneumonitis. Bibiliography: 1. ENHERTU. Prescribing information. P5-03-29: Impact of the PIK3CA mutation on clinical outcomes of patients with HER2+ metastatic breast cancer; a real-world study

Pegah Farrokhi

Introduction: Activating PIK3CA mutations occur in 30-40% of HER2-positive breast cancers, impacting the PI3K pathway essential for HER2 signaling. These genetic alterations are a known mechanism of resistance in HER2+ breast cancer and are linked to more aggressive tumors and poorer clinical outcomes. However, the clinical significance of PIK3CA mutations varies across treatment settings. In the neoadjuvant context, a correlation exists between PIK3CA mutations and reduced rates of pathological complete response. Conversely, in metastatic breast cancer (mBC), the prognostic and predictive value of PIK3CA mutations remains controversial, with conflicting results from various clinical trials. This heterogeneity in findings underscores the necessity for further investigation. The current study aims to elucidate the impact of activating PIK3CA mutations in HER2-positive mBC on clinical outcomes utilizing real-world data, thereby addressing the existing knowledge gap regarding the predictive and prognostic relevance in this patient (pt) population.
Methods: This was an observational cohort study utilizing the Flatiron Health-Foundation Medicine clinicogenomic database (FH-FMI CGDB), originated from ~280 US cancer clinics (~800 sites; primarily community oncology settings). Adult pts (≥ 18 years of age) diagnosed with HER2-positive mBC from January 1, 2011, to September 31, 2022, were included. Pts with clinical trial participation or less than 6 months of follow-up were excluded from the study. Descriptive statistics were used to summarize demographic and clinical characteristics. Overall survival (OS) and progression free survival (PFS) were assessed using the Kaplan-Meier method and Cox regression analyses.
Results: There were 1,325 HER2+ mBC pts included in the study. Activating PIK3CA mutations were identified in 44.7% of pts. Among pts, 148 (11.2%) pts were Black and 869 (65.6%) White pts. The median age was 63.0 years. The cohort contained 76.8% HR+/HER2+ and 23.2% HR-/HER2+ pts. The following alterations were also present in the tumors: BRCA1&2 (22.1%), ESR1 (17.3%), PTEN (9.9%), and AKT1 (4.4%). First-line treatment was administered to 86.7% of all pts. First-line HER2-targeted therapy was present in 49.9% of all patients; and use was higher in HR-/HER2+ (78.5%) pts compared to HR+/HER2+ (41.7%) pts. Pts with a PIK3CA mutation had shorter OS compared to wild-type pts but this difference was not significant in the overall population, (50.6 vs 57.1 months, long-rank= 0.073). However, among pts who received HER2 targeted therapy in the first-line treatment setting, those with a PIK3CA mutation demonstrated significantly shorter OS (45.8 vs 61.3 months, p=0.04) and PFS (9.0 vs 11.1 months, log-rank p=0.025) compared to wild-type pts. Cox regression analysis, after adjusting for demographic and clinical characteristics, further demonstrated that patients with activating PIK3CA

mutations who received first-line HER2 targeted therapy had significantly lower OS rates (HR=1.45, p=0.008) and PFS (HR=1.39, p=0.002) compared to PIK3CA wild-type pts. Conclusions: Based on our results, activating PIK3CA mutations are associated with lower overall and progression-free survival in HER2+ mBC patients who received first-line HER2 targeted therapy. Studies are warranted assessing the impact of targeting both the PI3K/AKT/mTOR and HER2 pathways to individualize treatment and mitigate resistance to HER2-directed therapy thereby improving clinical outcomes in this pt population.

P5-03-30: Real-world data on the use of trastuzumab deruxtecan in breast cancer patients at a tertiary hospital in Ourense, Spain.

Leticia Iglesias Rey, Paula Sampedro Domarco, Jesús García Gómez, Jesús García Mata

Acoording to the European Medicines Agency (EMA), Enhertu is for unresectable or metastaic Her2-positive breast cancer previously treated with antiHer2, and breast cancer with low Her2 expression that is unresectable or metastatic after chemotherapy in the metastatic or if there is recurrence during or within 6 moths after the end of adjuvant chemotherapy.
Our group evaluated patients with recurrent or metastatic breast cancer treated with trastuzumab deruxtecan at the Ourense University Hospital Complex, from May 1, 2021 to May 31, 2024. 19 female patients were included, 85% with ductal infiltrant carcinoma breast. At diagnosis, 52% were postmenopausal women. Initial staging showed that 10% were in stage I, 48% in stage II, 37% in stage III, and only 5% in satge IV.
Ehertu was administered most frequently in the thrid line of treatment or later in 63% of cases; 42% had previously received another ADC (TDM-1, sacituzumab govitecan, etc). 53% of the patients had a good general condition (ECOG 0) at the beginning of treatment. The most common metastases were lymph node and bone, although 32% had lung and liver metastases. The mean number cycles administered was 9 (range 1-31), and it was necessary to reduce the dose in 42% of patients to continue treatment. Thirteen patients continue with the same treatment, five changed therapeutic lines due to disease progression and one by their own decision. Of the 19 patients, 17 are still alive, indicating low mortality since the start of treatment with Enhertu.
It should be noted that 6 patients (31%) were initially diagnossed as her2 negative (1+,2+/ISH -) and throughout the course of the disease they transformed into Her 2+++, wich highlights the importance of rebiopsy of patients throughout their illness, in order to provide the most appropiate treatment. 7 patients were Her2+++ patients from the debut, and 6 patients were treated in the indication of Her2 low (Her2 1+,2++/ISH-)
100% of Her2 +++ patients initially received a pertuzumab+trastuzumab+taxane regimen (Cleopata regimen). In Her2 negative patientes (1+,2++/ISH-) at diagnosis, the most common first-line treatment was cyclin inhibitors with aromatase inhibitors, given that they were hormone receptor-positive patients.
Conclusions: These data undeline the effectiveness of trastuzumab deruxtecan in a heterogeneous and highly pretreated population. More follow-up is required to evaluated

the impact on overwall survival, but preliminary results indicate that it is an effective treatment with tolerable toxicity in a high percentage of patients with advanced breast cancer. This drug should be considered in all who present any percentage positivity (measured by immunohistochemistry) in Her 2.

P5-04-02: The Breaking Point: Understanding Healthcare Costs, Financial Strain, and Coping Mechanisms Used by Metastatic Breast Cancer Patients with Medicare Coverage

Fran Castellow, Megan Schoonveld-Diaz, Kathleen Gallagher, Rebekah Angove

Background: Cancer-related expenses, including provider services, medications, insurance premiums and non-medical expenses like transportation and food, continue to rise, forcing patients to shoulder an ever-growing out-of-pocket financial burden. Metastatic breast cancer (mBC) treatments are among the most expensive due to the need for lifelong therapy, regardless of income or insurance. The Inflation Reduction Act of 2022 (IRA) includes several consequential provisions aimed at reducing drug spending and thereby increasing access to more affordable pharmaceuticals for millions of Americans, including instituting an out-of-pocket (OOP) maximum in the Part D prescription drug benefit that is being phased in during the 2024 and 2025 plan year. Beginning in 2024, IRA encompasses measures that reduced the OOP patient responsibility to around $3300 and eliminated the 5% cost share in the catastrophic coverage phase. The purpose of this brief survey was to ask questions to better understand financial stress, experiences with healthcare costs and coping mechanisms experienced by patients in the past 12 months.
Methods: This cross-sectional analysis used data from a nationwide survey distributed in June 2024 by Patient Advocate Foundation (PAF). Inclusion criteria included a valid email address, age >19, self-reported mBC diagnosis and Medicare coverage. Descriptive statistics were calculated using medians and IQR for continuous variables and frequencies for categorical variables.
Results: Of 103 female mBC patients, 38% were <56 years, 32% identified as non-white, 57% were disabled, 83% had a household income <$50,000, 75% household of 1-2 people, and 27% lived in a rural location. Most patients (91%) were currently in treatment. Primary sources of household income were disability payments (55%) or Social Security income (36%). One-third (33%) reported a decrease in household income over the past 12 months. Average monthly healthcare spending included provider visits ($154; IQR $351), pharmacy prescriptions ($101; IQR $209.5), and insurance premiums ($174; IQR $250.50). Over half of reported increases in at least one of these costs in the past 12 months. Coping mechanisms for increased healthcare costs included; credit cards (42%), receiving charitable co-pay assistance (37%), lifestyle changes (36%), payment plan/charity assistance from provider (33%), or delaying care/treatment (26%). Sixty-one percent reported already being financially stressed and a $40 monthly increase in healthcare costs would be unaffordable. When asked about behaviors related to medication adherence, 43% reported if costs increased, they would change the way they are filling or taking

prescriptions.
Conclusion: For mBC patients, there is a low threshold of increased financial burden that, when reached, forces them to start making difficult choices about their care plan adherence and daily living expenses. The insights received from the survey respondents show that they are experiencing higher healthcare costs, including medication costs, despite the lowering of the OOP maximums. To mitigate the impact of rising healthcare costs on low-income cancer patients insured through Medicare, it is essential for policymakers, healthcare providers, and community organizations to collaborate to design solutions that address the total costs of care, and ensure access to support services, and charitable financial assistance programs. Additionally, raising awareness about the challenges faced by this vulnerable population and advocating for policies that address their needs can help alleviate some of the burdens imposed by inflation. While the IRA is a step in the right direction, its financial impact on mBC patients insured through Medicare appears to be limited.

P5-04-03: The impact of neighborhood-level social determinants on breast cancer mortality after a second primary breast cancer.

Ifeoma Nwigwe, Michael Desjardins, Kala Visvanathan

Background: Our team has shown that younger versus older women, and both Blacks and Hispanics breast cancer (BC) survivors versus White women have a higher mortality after a second cancer. We have also shown that county-level neighborhood poverty is associated with increased cancer mortality after a BC diagnosis. In this study, we assess to what extent neighborhood-level socioeconomic status (SES) contributes to high BC mortality after second cancers and compare the association to BC mortality after a first cancer. We hypothesize that social determinants are critical to address in women who develop a second cancer despite now being part of the health system.
Methods: Women diagnosed with a first BC and/or second cancer after first BC between 2007 and 2019 were identified from the Maryland (MD) Cancer Registry. Census tract-level neighborhood SES environments for poverty and median income were determined using local spatial autocorrelation analysis with Local Moran's I of MD's five-year census-tract estimates from the American Community Survey. MD census tract estimates above or below the state mean were identified as high (H)- or low (L)- tracts, respectively. We defined four neighborhood environments for each SES indicator as H-tracts among H-tracts (HH-tracts); L-tracts among L-tracts (LL-tracts); H-tracts among LL-tracts (HL-tracts); L-tracts among HH-tracts (LH-tracts). Women at least 20 years of age diagnosed with a local or regional primary BC, received surgery, and survived more than 365 days were assigned a tract-level neighborhood SES environment for each SES indicator associated with their first and second BC diagnosis. Time-to-event analyses were used to compare BC deaths across each tract-level SES indicator neighborhood environment separately. The data was analyzed using Multivariate Cox proportional hazard regression models adjusted for age at diagnosis,

tract median income, cancer stage, treatment, and Estrogen Receptor status. Models were also stratified by race/ethnicity (Non-Hispanic White, Non-Hispanic Black), age at diagnosis (<50, 50-69, =>70), and treatment (hormone therapy and chemotherapy).
Results: The analytical population included 15,149 MD women diagnosed with early-stage BC, of which 2,436 developed a second cancer, and BC deaths after first BC and second cancer diagnosis was 2039 and 315, respectively. We detected a 66% (HR=1.66, 95%CI=1.09, 2.53), 14% (HR=1.14, 95%CI=0.66,1.97), and 15% (HR=1.15, 95%CI=0.73,1.81) increase in BC death for women in LL, LH, and HL median income census tracts when compared to HH median income census tracts in the neighborhood income model after second cancer diagnosis. A 30% (HR=1.30, 95%CI=0.89, 1.90), 31% (HR=1.31, 95%CI=0.90, 1.93), and 20% (HR=1.20 95%CI=0.80, 1.79) increase in BC deaths for women in HH, LH, and HL poverty census tracts when compared to LL poverty census tracts was observed in the neighborhood poverty model after second cancer diagnosis. Notably, we observed increased BC death for women in LL, LH, and HL income neighborhood environments as well as in HH and HL poverty neighborhood environments at first BC diagnosis though not as robust as the second cancer neighborhood environment observations. Finally, neighborhood-level SES environments at first BC diagnosis were not statistically associated with BC death upon second diagnosis.
Conclusion: Overall, our findings highlight the importance of neighborhood-level SES, such as poverty and median income, at the time of second cancer diagnosis as a strong indicator of BC mortality after second cancer, possibly even more than after a first BC. These findings provide initial evidence of the need for continued surveillance of neighborhood-level SES factors after a first BC diagnosis, and early interventions to improve survival among this group of high-risk women.

P5-04-04: Comprehensive Analysis of Breast Cancer Treatment Delays in Brazil: A Six-Year Study

Marcelo Antonini, Andre Mattar, Sofia Naira Barbosa Freitas, Eduardo de Camargo Millen, Denise Joffily Pereira da Costa Pinheiro, Felipe Zerwes, Fabrício Palermo Brenelli, Francisco Pimentel Cavalcante, Marina Fleury de Figueiredo, Antônio Luiz Frasson, Odair Ferraro

Background: Breast cancer is the most common cancer among women in Brazil and timely treatment initiation is crucial for improving prognosis and survival rates. Despite the 60-day rule established in 2012, which mandates the start of treatment within 60 days of diagnosis, significant delays continue to be reported.
Objectives: This study aims to assess the interval between diagnosis and the commencement of breast cancer treatment in Brazil from 2017 to 2022. Secondary objectives include examining the association between the duration before treatment and both the type of treatment and cancer stage, as well as analyzing annual trends in treatment initiation times.
Methods: This ecological study employed a descriptive observational approach, analyzing data from the Oncology Panel of the Brazilian Unified Health System's Department of

Informatics (DATASUS). The data encompassed female breast cancer cases across Brazil's regions and states over a six-year span (2017-2022). Variables analyzed included time to treatment initiation, cancer staging, and type of therapeutic intervention. Trends in time-to-treatment were evaluated using chi-square tests and joinpoint regression, with the Annual Percent Change (APC) quantifying changes over time. Given the study's reliance on public datasets, ethical committee approval and informed consent were not required.
Results: The study identified 237,073 breast cancer cases in women from 2017 to 2022. During this period, 24.4% of patients began treatment within 30 days, 21.3% waited between 31 and 60 days, 16.8% between 61 and 90 days, and 37.2% took more than 91 days, with statistically significant differences ($p < 0.001$). Radiotherapy displayed the longest delays, with 85% of patients waiting over 61 days to commence treatment, followed by chemotherapy (57.2%) and surgery (30.8%), each with significant variances ($p < 0.001$). Patients in early stages (0, I, and II) experienced longer delays compared to those with advanced cancer (stages III and IV), with significant timing differences ($p < 0.001$). Trend analysis revealed a decrease in patients starting treatment after more than 121 days, but also a decrease in those starting within 30 days (APC -1.15, $p = 0.461$), and an increase in the 61 to 91 days bracket (APC 4.03, $p = 0.027$), surpassing the 31 to 60 days bracket (APC 3.27, $p = 0.080$).
Conclusion: The study highlights significant delays in the initiation of breast cancer treatment for most women in Brazil, often exceeding the recommended 60-day threshold and leading to treatment at more advanced disease stages. The longest delays were observed in radiotherapy, and patients with early-stage cancer faced the longest wait times. Trend analysis indicates an elongation in treatment initiation times post-implementation of the 60-day rule, underscoring the need for targeted efforts to expedite the onset of breast cancer treatment nationwide.

P5-04-05: Impact of racial and socioeconomic disparities on overall survival in Invasive Lobular Carcinoma

Toru Yoshino, Ryota Sato, Stnaley Lipkowitz, Takeo Fujii

Background: Invasive Lobular carcinoma (ILC) is the second most common histology and accounts for 10-15% of all breast cancers. ILC has molecular and clinical characteristics distinct from Invasive Ductal Carcinoma (IDC). The loss of E-cadherin expression is a hallmark of ILC and clinically ILC has a linear growth pattern, resulting in delaying radiographical detection with larger sizes and more lymph node involvement at the time of diagnosis. Although ILC has better short-term outcomes than IDC, its overall survival (OS) is reported to be worse due to late recurrences and resistance to chemotherapies. In breast cancer in general, it is well known that racial and socioeconomic disparities are crucial factors associated with poor prognosis. However, the impact of them on the survival outcomes of ILC in particular is not well understood, regardless of the unique features of ILC. In this study, we investigated how the racial, social economic factors as well as clinicopathological factors affect OS in ILC. Our primary objective was to test the association

between racial and socioeconomic factors and OS among patients with ILC.
Methods:The data was obtained from the Surveillance, Epidemiology, and End Results (SEER) Plus Data 17 registry. Female patients with ILC who were diagnosed from 2010 to 2015 were included. Patients with missing racial information were excluded. Age (50 or more), race, tumor grade, subtype, stage, types of surgery of the primary site, types of systemic therapies, types of radiation therapies, median household income, geographic location, and marital status were collected. Racial categories were classified into White (W), Black or African American (B), American Indian or Alaska Native (AIAN), Asian (A), and Native Hawaiian or Other Pacific Islander (NHPI) based on the U.S. Office of Management and Budget (OMB) standard. Univariate and multivariate Cox proportional hazards models were used to test the association between variables of interest and OS. P value less than 0.05 was considered as statistically significant.
Results: A total of 33,239 patients with ILC were included in the analysis. Among them, 28,401 (85.4%) were W, 2,780 (8.4%) were B, 1,708 (5.1%) were A, 176 (0.5%) were AIAN, and 174 (0.5%) were NHPI. B and NHPI were diagnosed with more advanced stage (Stage III and IV; 25.5% [B], 24.2% [NHPI] vs 20.8% [W]). B and AIAN had lower household incomes in ILC patients (<$65,000; 51.3% [B], 48.8% [AIAN] vs 34.8% [W]). Sixty percent of B were unmarried compared to 39.3% in W.In the multivariate analysis, lower household incomes and unmarried status remained significantly associated with short OS, which is consistent with prior reports. Interestingly, B, AIAN, or NHPI race or distant geographical location were not a significant factor in OS among this ILC patient population (B race; HR 1.00, 95% CI, 0.92-1.09, P=0.97; AIAN race; HR 1.1, 95% CI, 0.76-15.7, P=0.62; NHPI race; HR 1.07, 95% CI, 0.74-1.54, P=0.72; non-metro non-adjacent to metro location; HR 0.96, 95% CI, 0.93-1.16, P=0.56).
Conclusions: Our study demonstrated that lower household incomes and unmarried marital status but not race or geographical location were significant prognostic factors associated with short OS. This suggests that addressing the challenges in financial and social support could be effective to improve the OS of the patients with ILC. Biological differences of ILC in each race need to be investigated further.

P5-04-06: Demographic differences in an SHG-based prognostic indicator.

Tresa Elias, Edward B Brown IV, Bradley Turner

Improved prognostication of metastasis and prediction of therapeutic efficacy can enhance patient-tailored care. Recent studies suggest that several second harmonic generation (SHG)-based measurements of fibrillar collagen properties in the primary tumor may help improve current prognostication and prediction methods. One of these SHG-based measurements is the ratio of forward-scattered to backward-scattered SHG signal (F/B) from collagen pixels, which has been shown to be prognostic of metastasis when measured in the tumor stromal interface. Another SHG-based measurement is the variability in overall orientation of imaged collagen fibers, i.e. the average fiber angle variability (FAV), which has been shown to be prognostic of metastasis when measured in the tumor bulk.
For an improved metastasis prognostication tool to have clinical impact, a multicenter trial

must eventually take place. Unfortunately, minorities are typically underrepresented in research cohorts. Here we explore how patient race affects these prognostic signals in breast cancer. This will provide insight into the influence of patient demographics on the design of any future trial of these prognostic methods. Archived formalin fixed paraffin-embedded sections of 246 estrogen receptor positive invasive ductal carcinoma (IDC) were acquired, with 19 African-Americans (AAs) and 227 Caucasian-Americans (CAs). Sections were imaged with SHG in both the forward-scattered and backward-scattered direction. Specifically, three regions in the tumor-stromal interface (for F/B analysis) and three regions in the tumor bulk (for FAV analysis) were imaged. This sample set behaved similarly to previous sets, with F/B values in the tumor bulk being lower than in the tumor-stromal interface (10.55±4.88 vs 15.04±5.78, respectively, $p<0.0001$). In terms of patient demographics, we found that AA IDC tumors displayed a statistically significantly lower F/B than CA IDC tumors (11.98±5.27 vs 15.34±5.68, respectively, $p=0.014$). FAV was not different between the two groups (47.15±8.93 vs 46.01±9.20, respectively, $p=0.60$). The lower F/B found in AA patients is indicative of a more aggressive phenotype which is consistent with literature evidence of similar demographic differences in other tumor properties. Since we now see that SHG F/B varies with race, it is possible that the relationship between SHG F/B and metastatic outcome also varies with race. If this is true, then training a prognostic algorithm with a random cohort of patients (who would be overwhelmingly Caucasian-Americans) would disproportionately yield inaccurate predictions for demographics other than Caucasian Americans. Therefore, it should be a priority to recruit enough African-American patients for this future research cohort to develop an SHG-based prognostic algorithm that equally serves both demographics. If it is found that the relationship between SHG F/B and metastatic outcome does vary with race, then different prognostic algorithms can be developed for different demographic groups.

P5-04-07: Assessing COVID-19 vaccination status and symptoms in persons with a history of breast cancer

Iqra Siddiqui, Nikita Nikita, MD, Ana María López

Background: Persons with a history of cancer are at higher risk for adverse COVID-19 outcomes due to their immunosuppressed status. Vaccination to COVID-19 has proven effective in decreasing complications from COVID-19 infection. This study explored the vaccination status of persons with a breast cancer diagnosis receiving cancer care who had received the COVID vaccine 1st dose/2nd dose and/or COVID booster along with their consequent symptoms

Methods: Persons with a cancer diagnosis receiving care at a cancer center clinical site were randomly invited to complete a voluntary survey regarding their experience with COVID vaccinations via email, the electronic medical record, or during an in-person appointment. Paper surveys were completed in the clinic, placed in a sealed collection bin, and collected

by research staff weekly. Responses were anonymous. Participants were asked if they had received their 1st/2nd COVID-19 vaccine, their symptoms, and if they had received or intended to receive the subsequent booster. The study was conducted between September 2021 to September 2022. An EMR review of vaccination uptake was conducted to assess representativeness of our sample. We used a crude logistic regression model to assess the differences in post-vaccination symptoms reported by persons with breast cancer who were vaccinated. We stratified the results by race (Black versus white, non-Hispanic) and age (< 65 years and >=65 and older).

Results: Of the 532 persons with breast cancer who completed the COVID vaccination survey, 155 (31.6%) were Black and 335 (68.4%) were white, non-Hispanic. 255 (47.9%) were <65 years of age and 277 (52.1%) were greater 65 years of age. We found that patients older than 65 years of age were less likely to experience fever (by 58.8%), pain (by 58.3%), fatigue (by 48.9%), and headache (by 49.4%). Person over 65 years of age were 55.9% more likely to have received their second COVID vaccination and 67.3% more likely to have received their booster. Persons who identified as Black reported a different symptom profile--61.9% less likely to experience fever and 56.3% less likely to report fatigue following vaccination compared to their white, non-Hispanic counterparts.

Conclusion: In our data set, persons with a history of breast cancer older than 65 years were less likely to have experienced fever, pain, fatigue, and headache after COVID vaccination. Black persons were less likely to report fever and more likely to report pain. Anticipating differences in COVID-19 vaccination symptoms allows for the development of tailored education and resources for self-management and care.

P5-04-08: The role of sexual orientation in mammogram screening adherence among deaf, deaf blind, and hard of hearing women.

Erika Bergeron, Sowmya Rao, Poorna Kushalnagar

Background: Deaf, deafblind, and hard of hearing (DDBHH) women using American Sign Language (ASL) experience disparities in cancer screening and cancer-related health outcomes. There is a need for data on breast cancer screening among DDBHH women, specifically considering differences in sexual orientation, and whether they adhered to U.S. Preventive Task Force screening guidelines or not. The study objective is to assess the role of sexual orientation on mammogram adherence among DDBHH women adjusting for other characteristics. Methods: Using the NCI Health Information National Trends Survey in ASL (Kushalnagar et al., 2015), we surveyed adult participants to assess the U.S. Preventive Services Task Force (USPSTF) guidelines' age-appropriate adherence to mammogram. We used Fisher's Exact test to assess the independent relationship of sexual orientation with mammogram. Further, we obtained odds ratios (OR) and 95% confidence intervals (CI) from a multivariable logistic regression evaluating the same relationship adjusting for age,

race (Non-Hispanic White, Others), education (less than college, college graduate, post-graduate), marital status (married/living with partner, divorced/widowed/separated/never married) and whether they had a pap test (no, yes). A two-sided p<=0.05 was considered significant. Results: Survey response rate within three weeks of mail out in July 2023 was 17%. Participants were recruited in-person between September and November 2023 and virtually in March and April 2024. A total of 293 DDBHH adult participants (45-74 years) answered screening questions for breast cancer in ASL and English. Within this group, 91.5% self-reported screening adherence for mammogram. In a published study, similarly aged hearing women reported 75.6% adherence in the English version of the National Health Interview Survey (NHIS). After adjusting for correlates within the DDBHH sample, LGBTQA+ respondents were less likely (not statistically significant) to have a mammogram than straight persons [0.43 (0.16, 1.20); p=0.11]; adherence increased with increasing age [OR (95% CI): 1.17(1.08,1.26); p<0.001]. Discussion: With the 91.5% adherence rate, the DDBHH community has greater adherence to the recommended screening guideline compared to the general population of hearing adults. Yet, within this group, those identifying as LGBTQA+ exhibit lower adherence to breast cancer screening guidelines. Bridging these gaps is essential to achieve the Healthy People 2030 target of 80.3% screening adherence. Such research will aid the Center for Deaf Health Equity in actively working with the DDBHH community, particularly among LGBTQA+ individuals, to improve strategies for increasing breast cancer screening.

P5-04-09: A nationwide database study breast cancer in younger women: Chile 1997-2023

Claudio Salas, Iris Delgado, Yanara Bernal

Introduction: In Chile, official databases related to mortality and hospitalization record all events. The Chilean healthcare system is segmented, with 80% of the population belonging to the public system and 20% of higher-income individuals accessing the private system, which provides greater access to healthcare and personalized technology. Objective: to describe the evolution of the magnitude and risk of mortality and hospitalization of BC in women, according to epidemiological variables of time, place, person and socioeconomic level with an emphasis on women those < 40 years of age (younger). MATERIAL AND

Method: Descriptive analytical study with official secondary databases from Chile, to examine mortality from years 1997 to 2023, and hospitalization from 2001 to 2021, both sources having nearly 100% of total population coverage. Study variables: time (year of event occurrence), place of residence (urban/rural), person (age), and C50 code (ICD-10) to identify BC cases. Socioeconomic status was proxied by educational level for mortality and health insurance (public/private) for hospitalization. Due to the number of cases for mortality, the evolution was studied over three-year periods (triennia), and annually for hospitalization. Crude and age-adjusted rates were calculated, and the percentage change was analyzed using regression models with the Joinpoint Regression Program V5.2

software. All rates were calculated according to age range variables, place and health insurance. Data reading and analysis was carried out using Software R V6 (2023).

Results: Between 1997-2023, 35,540 women died from BC, of which 1,507 were <40 years old and 33,772 were 40 years old or older. In the 1997-1999 triennia, the crude mortality rate of women aged 40 and over was 20 times higher than that younger woman; at the end of the period (2021-2023) this ratio had decreased to 12 times. During the years studied, the risk of dying from BC increased by 19.2% in younger women, while in women 40 years of age and older, the risk decreases by 21%. From 1997 to 2014, the percentage change in mortality over triennia for in younger women was not significant. However, from 2015-2017 triennia onwards, the trend showed a statistically significant percentage increase of 10.3%. Regarding the analysis by place of residence, mortality in younger women increased in rural areas than in urban areas. Regarding education, younger women, on average, more than 3 years of schooling compared to those 40 years old and older. In relation to hospitalization between 2001-2021 there were a total of 179,999 events, with 9.5% (16,818) are younger women. The increase in magnitude was 300% in the group <40 and 320% in those aged 40 and over. The risk of hospitalization in younger women increased 1.5 times during the period, while for older women, it increased by 1.13 times. The analysis of insurance membership showed that women in the private system had greater access to hospitalization than those in the public system. This inequity was more accentuated in younger women, with a gap of 2.4 times greater access to hospitalization for those in the private system compared to the public system. In older women, this gap was 1.8 times.

Conclusions The analysis of public data includes the last 27 years, a period in which an increase in mortality from BC in younger women of 19% has been observed, increasing from 2015 onwards. The rise in mortality from BC in young women is multifactorial, it is diagnosed in more advanced stages, more aggressive tumor biology with a predominance of triple-negative disease, but it could also be influenced by an increase in incidence, as indicated by BC hospitalization rates. This analysis reveals significant gaps in the Chilean healthcare system, indicating higher mortality rates from BC cancer in young women from rural areas and within the public health sector. It provides empirical evidence to support targeted interventions for women with limited access to healthcare.

P5-04-10: Age at Breast Cancer Diagnosis and Associated Demographic Factors: An Epidemiological Study in Brazil

Jesse Lopes da Silva, Natalia Cristina Cardoso Nunes, Lucas Zanetti de Albuquerque, Pedro Henrique Souza, Andréia Cristina de Melo, Luiz Claudio Santos Thuler

Background: In recent years, shifts in the median age at breast cancer (BC) diagnosis have been observed in various countries. Multiple factors influence these changes, including demographic shifts, sex, lifestyle modifications, and genetic factors. As populations age and demographics change, there may be significant impacts on these trends. Lifestyle factors such as diet, exercise, and environmental factors also play a role. Genetic research has

emphasized the role of inherited factors in BC age onset. This study aims to analyze the trends in median age at BC diagnosis in Brazil, focusing on sociodemographic aspects like the distribution of the Human Development Index (HDI), sex, and variations among different racial and ethnic groups based on race/skin color.
Patients and methods: Data from 32 Brazilian Population-Based Cancer Registries spanning 1990 to 2020 were used to analyze BC median age trends based on age at diagnosis, sex, racial group, and geographical region. Racial and skin color information was collected through self-declaration aligning with categories like white, indigenous, yellow (Asian), black, and mixed race set by the Brazilian Institute of Geography and Statistics. Due to limited HDI data for Brazilian states and municipalities in 2000 and 2010, a mean HDI estimated for 2005 was utilized. Variations in the mean HDI for the year 2005 were observed across municipalities, with classifications ranging from low HDI (0.50 to 0.59) to moderate HDI (0.60 to 0.69), high HDI (0.70 to 0.79), and very high HDI (0.80 to 1.00). Analysis of median age trends employed Joinpoint models, with the Joinpoint Regression Program providing confidence intervals to assess the null hypothesis of APC = 0 and p-values to evaluate potential trend changes. Statistical significance was determined at $p < 0.05$.
Results: Between 1990 and 2020, there were 227,896 new documented cases of breast cancer (BC). After excluding 7,850 cases with missing sex or age data, 225,436 cases were analyzed. Among these cases, 99.2% were female and 0.8% were male, resulting in a ratio of 1 man for every 120 women diagnosed. The median age at diagnosis in Brazil was 56 years. Municipalities with lower and moderate HDI levels had a lower median age at diagnosis of around 53 years. Conversely, regions with higher and very high HDI levels showed a higher median age at diagnosis, ranging between 56 and 58 years, respectively. Black and Indigenous patients had a younger median age at diagnosis (54 years) compared to white patients (58 years). The median age at diagnosis of breast cancer has shown an increase over the last decade, attributed to improvements in HDI, with the most significant rise observed in the northern region of Brazil.
Conclusion: This study highlights significant differences in the median age at breast cancer diagnosis across different regions, with earlier onset associated with lower HDI areas. Furthermore, Black and Indigenous patients exhibited a younger median age of diagnosis, reflecting previous research that has shown disparities in BC within the Brazilian population concerning race.
Keywords: Breast cancer; median age; disparities; incidence.

P5-04-11: Quality of life and psychosocial disparities between ethnically and religiously diverse population with advanced breast cancer

Michal Braun, Gil Goldzweig, Noa Shafri, Yehosua Akerman, Daniel Yusovich, Inbal Fuchs, Shani Paluch-Shimon

Background: In Israel all residents are covered by universal health care and yet disparities in health care access and utilization exist. Jerusalem is the largest and poorest city in Israel,

with significant with significant Jewish ultra-orthodox and Arab communities. These groups have shared reproductive factors, similar patriarchal community structures and often live in poverty. No research has been performed on these populations in the advanced breast cancer (ABC) setting with respect to quality of life (QOL) and psychosocial wellbeing

Methods: Women with ABC were prospectively recruited after consenting and self-identified their religion & level of religiosity. The following measurement tools were implemented: QOL - Functional Assessment of Cancer Therapy-Breast (FACT-B) Version 4, Spiritual wellbeing - The FACIT-Sp, Depression and Anxiety - Patient-Reported Outcomes Measurement Information System and demographic questionnaire. Comparisons between groups were conducted and the role of religion and depression in the explanation of differences of QOL between the groups was tested by moderated mediation model.

Results: 160 ABC patients were recruited. 39 (24.4%) identified themselves as Ultra-Orthodox Jews, 35 (21.9%) as Arabs and 81 (50.6%) as non-ultra-orthodox Jewish. Groups differed in their health related QOL($F(2,150) = 10.49$, $p<.001$); Spiritual wellbeing ($F(2,150) = 26.09$, $p<.001p<.001$) and depression ($F(2,134) = 9.61$, $p<.001$).
Ultra-Orthodox patients reported higher levels of QOL and spiritual wellbeing compared to the other groups and lower levels of depression compared to the Arab patients. Arab patients reported lower levels of QOL and higher levels of depression compared to the other groups. In addition, they reported lower levels of spiritual wellbeing compared to Ultra-Orthodox patents.
There were significant differences between groups in physical ($F(2,152) = 13.96$, $p<.001$); functional ($F(2,151) = 7.12$, $p<.001$); emotional ($F(2,151) = 8.81$, $p<.001$) and breast cancer wellbeing ($F(2,152) = 10.21$, $p<.001$) as measured by FACT-B.
Throughout the different domains of QOL Arab patients did worse (except the social/family subscale) than the Ultra – Orthodox patients. In addition, they reported on lower levels of QOL than the general population in total QOL, physical and functional wellbeing. Ultra – orthodox patients reported on higher levels of QOL in comparison to the general population in Total QOL, emotional well- being and breast cancer wellbeing.
The study's moderated mediation model was found to be significant ($F (2,126) = 121.16$, R-sq = 65.8%, $p < 0.000$). The differences between Arab and Jewish patients in Health related QOL were found to be mediated by depression, with group-depression relationship moderated by religiosity levels.

Conclusions: Significant health care disparities exist amongst women with ABC in terms of QOL, psychosocial and spiritual wellbeing. Although the current study examined two minority groups who have shared low socio-economic status, similar reproductive habits (multiple pregnancies from an early age), paternalistic and patriarchal community structure and challenges in health care access for cultural-ethnic-social reasons, different patterns of well-being were found. Ultra-Orthodox patients reported superior health related QOL, spiritual wellbeing, and lower levels of depression compared to other groups. Arab patients

reported poorer health related QOL, higher levels of depression and lower levels of spiritual wellbeing and religiosity compared to Ultra-Orthodox patients. Further research is needed to create effective, culturally appropriate interventions.

P5-04-12: Comparative Analysis of Female Breast Cancer: Incidence, Mortality, and 5-Year Survival Rates Across Races and Diagnosis Stages in Different Age Groups

Navneet Kaur

Background: Significant advancement has been made in breast cancer care, resulting in improved outcomes, largely due to enhanced screening and targeted management. However, these benefits are not equally distributed across all population subgroups. Factors such as genetics, access to healthcare, racial identity, social determinants of health, education, and clinical trial enrollment opportunities all contribute to persistent disparities in breast health. This study aims to compare female breast cancer incidence, mortality, and 5-year survival rates based on age, race, and stage at diagnosis.
Method: Data were extracted from the SEER 22 registries database, focusing on age, stage at diagnosis, and race. Rates are per 100,000 and age-adjusted to the 2000 US Standard Population (19 age groups - Census P25-1130). Mortality data was sourced from U.S. Mortality Data (1969-2022), National Center for Health Statistics, CDC. We compared incidence, mortality, and 5-year survival rates across different racial groups and age categories.
Results: The incidence rate in Hispanic women was 101.2 (100.5-101.9), in Black women was 129 (128.3-130.3), and in White women was 139.0 (138.5-139.4). The rate for localized breast cancer was 60.7 (60.2-61.2), 74.1 (73.3-74.8), and 93.7 (93.3-94.1) in Hispanic, Black, and White women, respectively. The rate for distant breast cancer was 6.4 (6.2-6.5), 11.5 (11.2-11.8), and 7.5 (7.4-7.6) in Hispanic, Black, and White women, respectively. The incidence rate in women aged 15-39 years was 19.8 (19.4-20.3), 27.2 (26.4-28.0), and 24.3 (23.9-24.7), and for ages 40-64 years was 175 (174.2-177.3), 218.4 (216.1-220.7), and 234.5 (233.3-235.7) for Hispanic, Black, and White women respectively. For women aged more than 75 years, the incidence was 291.6 (286.0-297.4), 408.8 (401.0-416.7), and 454.8 (451.8-457.8) for Hispanic, Black, and White women, respectively.
The mortality rate was 13.7 (13.5-13.9), 26.8 (26.5-27.1), and 19.4 (19.3-19.5) in Hispanic, Black, and White women respectively. For ages 15-39 years, the mortality rate was 1.8 (1.7-1.9), 3.8 (3.6-4.0), and 2.0 (1.9-2.1). For ages 40-64 years, the mortality rate was 17.8 (17.4-18.2), 37.1 (36.4-37.7), and 22.7 (22.5-22.9). For ages 65-74 years, the mortality rate was 43.4 (42.0-44.9), 85.0 (83.2-87.0), and 63.3 (62.6-63.9) in Hispanic, Black, and White women, respectively.
The 5-year survival rates (%) for Hispanic, Black, and White women were 88.4 (88.1-88.7), 83.8 (83.4-84.3), and 93.0 (92.8-93.1) respectively. Age- and race-adjusted 5-year survival rates were as follows: for ages 15-39, 84.6% (83.5-85.6) for Hispanic, 79.7% (78.3-81.0) for Black, and 89.1% (88.5-89.7) for White women. For ages 40-64, 89.4% (89.1-89.8) for

Hispanic, 84.6% (84.1-85.1) for Black, and 93.4% (93.2-93.6) for White women. For ages 65-74, 91.2% (90.4-91.9) for Hispanic, 86.3% (85.3-87.2) for Black, and 94.4% (94.1-94.7) for White women. For ages 75 and over, 79.7% (78.0-81.3) for Hispanic, 78.7% (76.7-80.5) for Black, and 90.6% (90.0-91.2) for White women.
Conclusion: White women had the highest incidence rate of breast cancer, followed by black and Hispanic women. Localized breast cancer incidence was highest in white women, while distant breast cancer incidence was highest in black women. Young black women (ages 15-39) had the highest incidence rates for their group. Mortality rates were highest among black women across all age groups. Overall and age-adjusted 5-year survival rates were lowest for black women, followed by Hispanic and white women.

P5-04-14: Variants of PEAK1, SLC2A4RG, PALB2, and XIRP2 and their relationship with Genetic Ancestry across Breast Cancer Patients from different Racial/Ethnic groups.

Grace Vélez Crespo, Julie Dutil, Vivian Colón López

Breast cancer is the second leading cause of cancer deaths worldwide, affecting 1 in 8 women. Disparities in breast cancer incidence and mortality have been observed across different racial and ethnic groups, with Hispanic and African American women experiencing higher incidence and mortality rates. Differences in the genomic landscape of breast cancer patients have been linked to early age at diagnosis, worse disease progression, drug resistance, and relapse.
Using the All of Us research hub, one of the largest biomedical databases, we are investigating genetic variants and the genetic ancestry related to PEAK1, PALB2, SLC2A4RG, and XIRP2 across racial and ethnic groups to identify potential variations that can contribute to differences observed among these groups. These genes are involved in DNA repair, epithelial-to-mesenchymal transition (EMT), and cell cycle regulation. PEAK1, for instance, regulates cell proliferation, promotes invasion and metastasis in various cancers, including breast cancer, and is associated with drug resistance. PALB2 functions as a tumor suppressor involved in homologous recombination repair, with pathogenic variants linked to hereditary breast cancer in Hispanics. SLC2A4RG acts as a tumor suppressor by regulating the cell cycle and has been studied in glioblastoma and breast cancer. XIRP2, known for its roles in cardiovascular diseases, is implicated in breast cancer metastasis and colon cancer promotion.
Despite identifying many genes involved in breast cancer development and metastasis, there remains a need to understand genetic variability across different populations to develop better diagnostic tools and improve treatment for breast cancer patients. Our cohort includes 6,056 cases of breast cancer, from which our preliminary results showed that Hispanics and African Americans are diagnosed with breast cancer at an earlier age (median = 64 and 67 years, respectively) compared to Non-Hispanics (median = 71 years). Using a genetic ancestry approach and in accordance with other studies, we identified that the majority of our Hispanic population are related to the Admixed American ancestry, with

smaller portions of European and African ancestry. By accessing the All of Us research hub's control tier for genetic data, we identified the frequency of genetic variants of PEAK1, PALB2, SLC2A4RG, and XIRP2. Using a Minor Allele Frequency (MAF) of 0.01 as a parameter, we identified 27 variants for PEAK1, 12 for PALB2, 2 for SLC2A4RG, and 99 for XIRP2.
Our current and upcoming analyses include associating the identified genetic variants with ancestry and race/ethnicity among cases already identified in our cohort and dataset, and comparing them with our control groups to identify possible genetic variants involved in breast cancer development across the different populations under study.

P5-04-15: Examining the association between biological age, stress, and resilience among diverse breast cancer survivors using the NIH All of Us Dataset

Bathsheba Aklilu, Erica Tate, Dr. Cathy Samayoa

Breast cancer disparities exist by race and ethnicity. This includes disparities in age at diagnosis, quality of life, and health outcomes. These disparities may be due to chronic stress, which can result in premature aging. Telomere shortening, a hallmark of biological aging, is a promising biomarker that has been associated with adversity, chronic stress, and health outcomes. However, most studies lack racial and ethnic minorities and thus biological age among diverse breast cancer survivors remains unknown. This study aims to investigate the factors associated with telomere length attrition among diverse breast cancer survivors using the NIH All of Us research dataset. Using Python and Jupyter Notebook within the NIH All of Us dataset, we will examine whole genomic data to quantify telomere length via a short-read whole genomic sequencing average telomere length analysis. We will also examine the relationships between telomere length and stress and resilience factors. We hypothesize that telomere length will be shorter among racial and ethnic minorities, and also in women who report higher levels of stress. We expect telomere length to be positively associated with resilience. This study will provide a greater understanding of the biological mechanisms driving breast cancer health inequities.

P5-04-16: Stromal tumor-infiltrating lymphocytes-based model predicts efficacy for neoadjuvant therapy in HER2-low early breast cancer

Zhuxi Duan, Yuan Xia, ,Qun Lin, Yu Shi, Jinpeng Luo, Jieer Luo, ,Xiaolin Fang, Chang Gong

Human epidermal growth factor receptor 2 (HER2)-low early breast cancer (EBC) is less sensitive to neoadjuvant therapy (NAT) and lacks effective biomarkers to predict treatment response. Existing prediction models and biomarkers for pCR in HER2-negative EBC patients are not tailored specifically for HER2-low EBC and often involve complex variables that are challenging to obtain. To date, only one messenger RNA-based multi-omics prediction model has been reported, showing excellent performance in predicting pCR to

NAT in HER2-low EBC. However, this model is complex and difficult to implement. Thus, there is an urgent need to develop predictive models based on easily available measurements to identify HER2-low EBC patients who can mostly benefit from NAT. In this study, we evaluated baseline sTIL numbers and composition in HER2-low EBC and found that sTIL levels were higher and the proportion of immune-promoting cells was higher in patients achieving pCR following NAT, particularly notable in those treated with neoadjuvant chemotherapy and immunotherapy. Furthermore, we investigated the correlation between baseline stromal tumor-infiltrating lymphocytes (sTILs) levels and pathological complete response (pCR) status in 293 eligible HER2-low EBC patients across two prospective studies. Our analysis revealed that patients achieving pCR following neoadjuvant chemotherapy exhibited higher levels of sTILs and a greater proportion of immune-promoting cells compared to non-pCR patients. Subsequently, we randomly divided patients into a training set (n=205) and a validation set (n=88) to develop and validate a sTILs-based predictive model for pCR, which incorporated sTILs, lymph nodal status, hormone receptor status, and Ki67. With favorable discrimination, calibration, and clinical value, the areas under the curve of the model (0.884 in the training set; 0.891 in the validation set) were significantly higher than that of the model without sTILs (0.811; 0.785; both $P<0.05$) and the sTILs-alone model (0.774; 0.792; both $P<0.05$) for predicting pCR. Importantly, patients with a high nomogram score (≥ 106) had significantly better disease-free survival and overall survival compared to those with a low nomogram score (< 106). Additionally, the model also exhibited an encouraging predictive ability for pCR in HER-low/HR-negative EBC patients who received neoadjuvant chemotherapy plus immunotherapy. In summary, HER2-low EBC patients achieving pCR demonstrated elevated sTILs levels and an anti-tumor immune-inflammatory microenvironment at baseline, potentially contributing to the improved efficacy of NAT. The sTILs-based model exhibited excellent predictive ability, offering potential for personalized treatment strategies and improved prognosis in HER2-low EBC patients.

P5-04-17: Association Between Ki-67, Body Mass Index, and Stromal Tumor-Infiltrating Lymphocytes in Hormone Receptor-Positive, HER2-Negative Breast Cancer Patients

Tanmayi Pai, Rhonda Ly, Yaohua Ma, Saranya Chumsri, Miglena K. Komforti

Background: Stromal tumor-infiltrating lymphocytes (sTILs) and the tumor microenvironment are a growing research focus in breast cancer. Previous studies established the prognostic role of sTILs in triple-negative and human epidermal growth factor receptor 2 (HER2)-positive tumors, but the role of sTILs remains unclear in hormone receptor-positive (HR+) tumors. A preclinical study demonstrated that obesity exacerbates immune aging, with diet-induced obese mice showing higher frequency of CD8+ TILs, higher PD-1 expression, and decreased Ki-67; donor cells from healthy obese human patients also showed higher PD-1 expression and lower proliferation rate [1]. Hypothesizing that similar patterns might be seen in patients with HR+ HER2-negative

breast cancer, we assessed for associations between Ki-67, body mass index (BMI), and sTILs in a cohort of these patients who did not receive neoadjuvant systemic therapy.

Methods: We performed a retrospective review of patients with HR+ HER2-negative breast cancer who underwent upfront surgery at Mayo Clinic in Jacksonville, Florida, between January 1, 2022, and June 1, 2023. Height and weight were obtained from the initial breast oncology or breast surgery visit note in the medical record. BMI was calculated using the standardized National Institutes of Health calculator [2]. BMI was categorized as normal (BMI <25), overweight (25 ≤ BMI <30), or obese (BMI 30). sTILs and Ki-67 were evaluated by a breast pathologist. Continuous variables were summarized with the median and interquartile range. Pearson correlation coefficient was estimated to assess for an association between Ki-67, sTILs, and BMI. Wilcoxon rank sum test was performed to identify significant differences of Ki-67 or sTILs between BMI categories. All statistical tests were two-sided, and p-values <0.05 were considered statistically significant. Statistical analysis was performed using R Statistical Software (version 4.2.2; R Foundation for Statistical Computing, Vienna, Austria).

Results: A total of 176 patients were included in the analysis. A moderate correlation was seen between Ki-67 and sTILs percentage (%) with Pearson correlation coefficient of 0.37 (95% CI 0.21-0.52, p <0.001), but there was no significant correlation seen between BMI and sTILs % (r = -0.05, 95% CI -0.2-0.01, p=0.51) or BMI and Ki-67 (r = 0.12, 95% CI -0.06-0.29, p=0.18). When we compared BMI categories, there were no significant differences in Ki-67 (p=0.098) or sTILs % (p=0.735). However, there was a trend towards higher Ki-67 and lower sTILs % in the patients with obese BMI as compared to those with normal or overweight BMI. Median Ki-67 % was 11.9, 11.9, and 16.2 for patients with normal BMI, overweight BMI, and obese BMI, respectively. Median sTILs % was 5, 5, and 3.2 for patients with normal BMI, overweight BMI, and obese BMI, respectively. When grouped by normal/overweight BMI versus obese BMI, Ki-67 was significantly higher in the obese BMI group (11.9 vs. 16.2, p=0.033).

Conclusion: Tumors of HR+ HER2-negative breast cancer patients with BMI in the obese range had significantly higher Ki-67 compared to tumors of patients with lower BMI. Ki-67 correlated with sTILs %; however, we did not identify a significant association between BMI and sTILs %. These findings suggest that BMI 30 might be associated with a more aggressive luminal B subtype of HR+ HER2-negative breast cancer, but it might not be a useful predictive biomarker of benefit of immune checkpoint inhibitor therapy. Larger patient cohorts are needed to validate and clarify these findings.

P5-04-18: Clinical Validation of an Ultra-Sensitive ctDNA NGS Assay in HR-Positive, HER2-Negative Breast Cancer Patients

Haoran Tang, Cancan Jia, Feng Xie, Hao Liao, Yaxin Liu, Xiaoran Liu, Hanfang Jiang, Shidong Jia, Huiping Li

Introduction: Breast cancer remains the most common cancer diagnosis among women worldwide, with the majority of cases being hormone receptor (HR)-positive and HER2-negative. Although endocrine therapies have significantly improved patient outcomes, the risk of disease progression persists, sometimes even during the initial treatment phases. Current diagnostic techniques lack the sensitivity needed for patients with low tumor fractions and circulating tumor DNA (ctDNA) shedding in the early stages of disease or during early disease progression. This study presents the clinical validation of an ultra-sensitive ctDNA Next-Generation Sequencing (NGS) assay, for comprehensive genomic profiling in HR-positive, HER2-negative patients receiving endocrine therapy and experiencing minor progression.

Methods: PredicineCARE Ultra is an ultra-sensitive liquid biopsy assay featuring a proprietary NGS panel targeting key oncogenic genes. This assay utilizes ultra-deep sequencing, surpassing 100,000x coverage, allowing for the detection of genomic alterations with a sensitivity far exceeding that of standard ctDNA NGS assays, which typically achieve around 20,000x coverage. In this study, we enrolled 58 patients with advanced HR-positive, HER2-negative breast cancer. Plasma samples were collected after first-line aromatase inhibitor (AI) therapy and before initiating second-line treatment with Fulvestrant. These samples were analyzed using the ultra-sensitive ctDNA assay to detect potential residual or progressive disease and to profile gene alterations.

Results: Among the 58 patients, the ultra-sensitive assay detected positive tumor fractions in 43 individuals. The median tumor fraction among these 43 patients was 1.98%, ranging from 0.50% to 58.5%. In total, the assay identified 193 somatic mutations, 95 gene copy number variations (CNVs), and one FGFR3 gene fusion (FGFR3-BAIAP2L1). The five most frequently mutated genes were TP53 (25.9%), PIK3CA (20.7%), ATM (19.0%), ESR1 (17.2%), and BRCA2 (15.5%).
These results were compared against a down-sampling algorithm simulating standard ctDNA assays with 20,000x coverage. The PredicineCARE Ultra cfDNA NGS assay detected 31.3% more mutations (193 mutations vs. 147 mutations) and 30.1% more CNVs (95 CNVs vs. 73 CNVs). It was particularly effective in identifying mutations with allele frequencies (MAF) below 0.1%, uncovering 10 additional mutations not detected by standard sensitivity

assays, with the lowest MAF being 0.03% compared to the 0.10% threshold of standard assays. This increased sensitivity was notable in genes linked to targeted therapies and drug resistance, revealing 30.7% more variations in PIK3CA and 11.1% more in ESR1, with the lowest MAFs of 0.08% and 0.06%, respectively. Moreover, the FGFR3-BAIAP2L1 gene fusion was uniquely detected by the ultra-sensitive assay at a MAF of 0.09%.

Conclusion: The PredicineCARE Ultra ctDNA NGS assay showcased a superior ability to detect low tumor fractions and low-frequency mutations in HR-positive, HER2-negative breast cancer patients, significantly outperforming standard liquid biopsy assays. This enhanced sensitivity offers substantial benefits for early identification of treatment resistance and disease progression, potentially allowing for more timely and tailored therapeutic interventions.

P5-04-19: Gene variants in circulating tumor cells as markers of resistance in patients with metastatic breast cancer receiving CDK4/6 inhibitors

Sabine Kasimir-Bauer, Stefanos Moukas, Hans-Christian Kolberg, Mitra Tewes, Markus Storbeck, Peter Hahn, Siegfried Hauch, Oliver Hoffmann, Rainer Kimmig, Corinna Keup

Background: Predictive biomarkers for the stratification of patients with metastatic (M), hormone receptor-positive/HER2-negative (HR+/HER2-) breast cancer (BC) to receive CDK4/6 inhibitor (i) treatment before therapy start are still missing to protect patients with primary resistant disease from starting ineffective therapies and minimize unnecessary toxicities. Here, we aim to identify markers of primary and acquired resistance to CDK4/6i therapy by sequencing genomic (g) DNA of circulating tumor cells (CTCs) at baseline and at the time of progression.
Patients and Methods: CTCs were isolated from 10 ml EDTA blood of 33 HR+/HER2- MBC patients at baseline of CDK4/6i plus endocrine therapy (TX) and at the time of progression using positive immunomagnetic selection (AdnaTest EMT2/StemCell Select). mRNA-depleted CTC lysates were used to isolate gDNA by a newly established workflow (AllPrep DNA/mRNA Nano) and libraries were constructed with a customized QIAseq® Targeted DNA Pro Panel, targeting hotspots or all exonic regions of 20 genes (AKT1, AR, BCL11B, CXCR4, EPCAM, ERBB4, FAT1, FGFR1, FGFR2, HLA-A, KRAS, MAPK1, MET, MLH1, NF1, NFKBIA, RB1, STAT1, STAT3, YAP1). All consumables: QIAGEN, Germany. Pooled libraries were analyzed by 150bp paired-end sequencing on an Illumina NovaSeq instrument. Buffy coat DNA samples as germline controls were available from 24/33 patients. Statistical analysis was conducted by log-rank testing, multivariate Cox regression and two-sided exact Fisher test. Non-Responders were defined as patients showing a progression-free survival (PFS) of six months or less (primary resistance).
Results: Variants in all of the 20 genes were found by sequencing CTCs and matched buffy coat samples (mean UMI coverage: 665) – in total, 225 different variants were called. Comparing the prevalence of variants in CTCs at baseline and at the progressive disease time point revealed increased variant counts after CDK4/6i TX in MET and RB1,

respectively. Patients with at least one variant in BCL11B in their CTCs at baseline showed a significantly decreased PFS (p=.042). In contrast, patients with FAT1 p.S3554A or FAT1 p.I2718V detected in their CTCs at baseline had a significantly prolonged PFS (p=.046/.027). In CTCs at baseline, HLA-A variants [p.T345S (log-rank p=.034, Fisher p=.010), p.K335N (log-rank p=.011, Fisher p=.015), p.I306V (log-rank p=0.011, Fisher p=.015), p.R138H (log-rank p=.002, Fisher p=.010), p.Y123F (log-rank p=.011, Fisher p=.015), p.F33S (log-rank p=.015, Fisher p=.010)] significantly correlated with a reduced PFS and their prevalence was significantly different in Responders (n=19) compared to Non-Responders (n=13). HLA-A p.L180* in CTCs at baseline significantly related to a reduced PFS (p=0.011), but not to response. The prevalence of the latter variant increased after CDK4/6i TX in comparison to the baseline time point. Interestingly, HLA-A variants in the matched buffy coat samples did not significantly correlate with PFS. Patients with at least one variant in NFKBIA in their buffy coat showed a significantly prolonged overall survival (p=.019) – even significant in the multivariate Cox regression analysis (p=.024) accounting for age, number of metastases, therapy line, de novo/recurrent metastatic status and visceral or only non-visceral metastases.
Conclusion: BCL11B variants as well as different HLA-A variants in CTCs before therapy initiation might be primary resistance markers for CDK4/6i TX and thus, predictive markers for TX stratification. Acquired resistance could be related to variants in MET and RB1 as well as specific HLA-A variants. We further suggest two FAT1 variants in CTCs at baseline as markers to indicate sensitivity to CDK4/6i TX.

P5-04-20: Predictive and Prognostic Value of Magee Equation 3 and Tumor-Infiltrating Lymphocytes in HR+ HER2-Negative Breast Cancer: A Retrospective Cohort Study in a tertiary hospital in Sao Paulo, Brazil.

Thais Perez Vazquez, Jose Roberto Filassi, Fernando Nalesso Aguiar, Fernando Wladimir Silva Rivas, Laura Testa, Edmund Chada Baracat, Rodrigo Goncalves

Background: The Magee Equation 3 (ME3) is a mathematical model that correlates histopathological variables of breast cancer (BC) with the Oncotype DX recurrence score. ME3 also predicts pathological complete response (pCR) in patients with hormone receptor-positive (HR+) and HER2-negative (HER2-) BC undergoing neoadjuvant chemotherapy (NAC). Besides molecular tests, prognostic factors and tools, such as the Residual Cancer Burden (RCB) index and tumor-infiltrating lymphocytes (TILs), are valuable for predicting outcomes, especially the latter in triple-negative BC. This study aims to analyze overall survival (OS) and disease-free survival (DFS) in relation to ME3 scores and TIL levels in HR+ HER2- BC patients. Secondary objectives include evaluating the associations between ME3 and RCB, and between TILs and pCR.
Methods: A retrospective cohort study was conducted at the Instituto do Câncer do Estado de São Paulo (ICESP) from January 2011 to January 2024. The study included women with HR+ and HER2- BC, stages I-III, who completed NAC followed by surgical treatment. ME3 scores were categorized as low (<18), intermediate (18-25), and high risk (>25). Their

association with RCB categories [RCB-0 (pCR), RCB-1, RCB-2, and RCB-3] was evaluated using the Chi-square test. TIL percentages were classified as greater than 5% or less than 5%, and their association with pCR was also examined using the Chi-square test. OS and DFS were assessed using the Kaplan-Meier method (KM) and the Log-Rank test. All statistical analyses were performed using SAS, with a significance level set at $p < 0.05$.
Results: A total of 151 women were included, with a mean age of 50.3 years (range: 25-85). 61.6% of patients identified as white and the average BMI was 28.02 kg/m^2. Additionally, 11.9% were nulliparous and 49.0% were post-menopausal. Before NAC, 57.6% had tumors > 5 cm, 64.2% were node-positive (N+), and 84.7% of BC cases were invasive carcinoma of no special type, with an average Ki67 index of 21.7%. 21.8% (33/151) of cases had ME3 scores greater than 25, while 78.2% had ME3 scores less than 18 (59/151) or between 18-25 (59/151). All patients underwent the same NAC regimen (AC-T). Regarding surgical treatment, 60.3% underwent mastectomy, and 76.2% had level I and II axillary lymphadenectomy.
The median follow-up time was 82.7 months (range: 4-145 months). Median OS and DFS were not reached according to ME3 categories. There was a statistically significant association between DFS and ME3 categories (log-rank p=0.0473). At 60 months, the DFS rate for ME < 18 was 83.9%, 69.0% for ME 18-25, and 76.7% for ME > 25. In a Cox multivariate analysis, ME3 remained associated with DFS with an HR of 2.48 (95% CI 1.18-5.21) for intermediate risk (p=0.017) and an HR of 1.82 (95% CI 0.74-4.48) for high risk (p=0.193). This association was not observed for OS and ME3 (log-rank p=0.07). At 60 months, the OS rate was 94.6% for ME < 18, 82.5% for ME 18-25, and 83.3% for ME > 25. However, in a Cox multivariate analysis, ME3 was associated with lower OS in the intermediate risk group with an HR of 2.81 (95% CI 1.10-7.19, p=0.031). The KM curves and the log-rank test suggested no association between TILs and OS or DFS (p=0.733 and p=0.183 respectively).
There was a significant association between RCB and ME3 (p<0.001): 71.4% of patients with RCB-0 had ME3 > 25, 14.3% had ME3 scores of 18-25, and 14.3% had ME3 < 18. A significant association (p<0.001) was identified between pCR and TILs after NAC, indicating that higher TIL expression was associated with lower pCR rates.
Conclusion: ME3 is a free online tool that demonstrated significant predictive and prognostic value for DFS in our study, serving as a low-cost alternative to Oncotype DX. While our results indicate a trend towards a statistically significant association between ME3 and OS (p=0.07), this finding should be further evaluated in larger studies. TILs were not associated with OS or DFS in our cohort; however, our results showed an inverse association with pCR.

P5-04-21: Decoding breast cancer: unveiling the role of hallmark genes in tumor progression and prognosis

Balazs Gyorffy, Otilia Menyhart, William Kothalawala

The hallmarks of cancer framework offer a valuable paradigm for understanding the fundamental organizing principles shared across various cancers. However, the absence of a standardized gene set for these cancer hallmarks has led to inconsistent biological interpretations across different studies, complicating data comparison and integration efforts. In this study, we aimed to establish a consensus cancer hallmark gene set by integrating data from available mapping resources. We utilized this consolidated gene set to identify overrepresented cancer hallmarks associated with breast cancer progression.
By synthesizing data from seven independent projects, we identified 6,763 genes linked to the ten cancer hallmarks. Then, we performed a cancer hallmarks enrichment analysis for prognostic genes associated with overall survival in the KM-plotter database, including 494 genes with a hazard rate (HR) over one and 650 genes with a HR below one (at a False Discovery Rate below 10% and with a cutoff value over 100). "Evading immune destruction" was the most significant hallmark (n=55, p=3e-05), followed by "Tumor promoting inflammation" (n=51, p=7.3e-04), and "Resisting cell death" (n=101, p=0.01) when analyzing genes whose higher expression correlated to lower hazard rate. When examining the genes linked with higher HR values, no cancer hallmark reached statistical significance. The results can be validated using our established online tool (www.cancerhallmarks.com) that also allows the identification of cancer-associated hallmarks from new gene sets.
In summary, we established a consensus list of cancer hallmark genes. We identified evading immune destruction and tumor promoting inflammation as key cancer hallmarks linked to breast cancer prognosis. Our project enhances the utility of the hallmark concept as an effective organizational tool, facilitating the assignment of genes to specific biological functions.

P5-04-22: Prognostic value of circulating tumor DNA (ctDNA) in early triple-negative breast cancer (TNBC): A systematic review and meta-analysis

Diana Zhang, Shayesteh Jahanfar, Judy B Rabinowitz, Joshua Dower, Fei Song, Cherng-Horng Wu, Xiao Hu, Phillip Tracy, Michael Johannesmeyer, Mark Basik, Lori Pai, Mary Buss, Heather Parsons, Ilana Schlam

Introduction: TNBC accounts for ~15% of all breast cancers and carries the worst prognosis and the highest risk of recurrence relative to other breast cancer subtypes. There is an unmet need to identify novel biomarkers to stratify the risk of recurrence and to optimize the utilization of neoadjuvant and adjuvant therapies. We performed a systematic review and meta-analysis to evaluate the prognostic value of ctDNA in patients with non-metastatic TNBC who have received treatment with curative intent.
Methods: A literature search was conducted using Ovid Medline, Elsevier EMBASE, Cochrane Central Register of Controlled Trials, and Web of Science Databases for publications up to 11/16/2023, which identified 3,526 studies. Results were uploaded to Covidence and assessed by two independent reviewers. Studies assessing the role of ctDNA

in predicting recurrence- free survival and/or overall survival (OS) were included. All recurrence outcomes were combined for this analysis. Statistical analysis was performed using Revman Web. Log-hazard ratios (HR) were pooled for studies reporting recurrence and death as a time-to-event outcomes. Odds ratios (OR) were calculated and pooled for studies reporting patient-level data on recurrence, death, and pathological complete response (pCR). The Cochrane Q chi-square test and I2 statistic was used to examine heterogeneity across studies. P values <0.05 and I2 >40% were considered significant. Quality assessment was performed using the Quality in Prognostic Studies tool. Prospero ID: CRD42023492529.
Results: A total of 16 publications (n=1,106 TNBC patients) were included: 8 prospective observational studies (n=361), 7 clinical trials (n=703), and 1 prospective case-control study (n=42). Tumor-informed assays were used by 10 studies (n=561), while 5 used tumor-agnostic assays (n=509), and 1 did not specify (n=36). ctDNA analysis was done using polymerase chain reaction (PCR) in 5 studies (n=327), and next-generation sequencing (NGS) in 9 (n=734), with 2 using other methods (n=45). For studies that reported recurrence as a time-to-event outcome, pooled log-HR showed that post-neoadjuvant ctDNA+ is associated with a higher likelihood of disease recurrence (HR 3.79; 95%CI 2.62-5.48). Similarly, for studies that reported patient-level data, pooled OR showed that post-neoadjuvant ctDNA+ is associated with higher odds of disease recurrence (OR 6.59; 95%CI 3.40-12.75). Subgroup analysis separating ctDNA+ before surgery versus after did not significantly impact the results. Pooled log-HR also revealed that ctDNA+ in the post-neoadjuvant setting is associated with worse OS (HR 3.47; 95% CI 2.17-5.56). Furthermore, ctDNA+ after neoadjuvant therapy (before surgery) is associated with lower odds of achieving pCR (OR 0.12; 95%CI 0.04-0.36). ctDNA+ during or after adjuvant chemotherapy is similarly associated with a higher likelihood of disease recurrence (HR 7.51; 95%CI 4.80-11.74) and worse OS (HR 7.96; 95%CI 1.59-39.78).
Conclusions: We found that ctDNA+ in the post-neoadjuvant setting (both before and after surgery) is correlated with a higher likelihood of disease recurrence and worse OS. These findings suggest that ctDNA has potential prognostic value in early TNBC. However, it remains unclear if therapeutic intervention for patients who are ctDNA+ can improve outcomes. While there is a strong correlation between ctDNA+ and worse outcomes, many of the results included in this meta-analysis are observational or secondary endpoints of clinical trials. The studies are heterogeneous in terms of treatments and methodologies for ctDNA assessment. While more studies are needed before incorporating ctDNA into clinical practice, the findings of this meta-analysis are reassuring and show the promise of ctDNA as a biomarker.

P5-04-23: Genomic Investigation of Angioma in Mammary Cancer

Rachel Geiser, Lorinda Baker, Peaches Ulrich, Albert Wendt

We aim to identify a genomic driver leading to overexpression of benign hamartomatous growths seen in the excessive thoracic angiomas of breast cancer patients. In our practice, we have observed that 4% of Caucasian postmenopausal and 1% of premenopausal breast

cancer patients demonstrate large numbers of cutaneous angiomas, largely on the anterior trunk. Genetic analysis of "cherry angiomas" have found that they frequently carry specific somatic missense mutations in the GNAQ and GNA11 (Q209H) genes. Tumorigenesis has been correlated with abnormal expression and receptors, and associated G proteins (GNAS, GNAQ, or GNA11). Oncogenic mutations in G protein coupled receptors and guanine protein encoding genes have been identified in a significant number of tumors such as uveal melanoma and other malignancies. If a common genomic driver is identified in these breast cancer patients with excessive thoracic angiomas, there may be targeted treatment available for this genetic tumor subset in the future. To test the hypothesis that a driver for increased number of angiomas may also be a driver for developing breast cancer, ten breast cancer patients with 100 or more thoracic angiomas were consented to have somatic whole exome sequencing of their archival breast cancer tissue through CARIS Life Sciences. At the time of abstract submission, the batch of 10 patients' tumor samples have been sent to CARIS for sequencing. Once the results are received, we will include further specific information on distribution of angiomas in Caucasian women in pre-and post-menopausal breast cancer patients.

P5-04-24: ATV-1601 is a Potent and Selective Allosteric Inhibitor of AKT1E17K and Shows Profound and Durable Regressions in AKT1E17K-Driven Patient Derived Xenograft Models

Shomit Sengupta, Anna C. Schinzel, Aaron Coffin, Truc Pham, Benjamin Brigham, Gianna Iantosca, Rajiv Govindaraj, Josepha LaPointe, Joann Prescott-Roy, David Church, Gordon Murray, Thomas Roddy, Anil K. Padyana, Marion Dorsch, Maria-Jesus Blanco

Background: The AKT pathway modulates cell survival and proliferation in response to insulin and growth factor signaling. A gain-of-function mutation in the AKT1 Pleckstrin-Homology domain from glutamic acid to lysine (E17K) leads to constitutive activation resulting in tumorigenesis. AKT1E17K driver mutations are predominantly found in ER+/HER2- breast cancer and occur as a mechanism of acquired resistance to PIK3CAi treatment in these tumors. Additionally, AKT1E17K mutations are found in triple negative breast cancer, endometrial cancer, prostate cancer and meningiomas among other solid tumors. The therapeutic benefit of inhibiting the AKT/PI3K pathway has been well established in the clinic. However, AKT/PI3K pathway inhibition has been shown to lead to a broad range of adverse events including hyperglycemia, which in the case of pan-AKT inhibitors is primarily driven by inhibition of AKT2. To maximize tolerability and efficacy in AKT1E17K mutant patients, we have developed ATV-1601, a novel orally bioavailable, non-covalent, allosteric AKT1E17K inhibitor.
Methods: ATV-1601 was developed using structure-based drug design and driven by incorporating molecular interactions observed between AKT1E17K and mutant-selective metabolite binders discovered using Atavistik's proprietary Atavistik Metabolite-Protein Screening (AMPS) technology. A combination of biophysical, biochemical, and cell-based methods were used for lead optimization. Potency and selectivity were assessed in BaF/3

cells engineered to be dependent on AKT1E17K or AKT2 in the absence of IL-3. A PK/PD relationship was established in vivo using a CDX model. AKT1E17K target engagement was measured by phospho-AKT1E17K and off-target activity was measured by phospho-AKT2, insulin and glucose levels. In vivo efficacy was assessed in cancer patient derived xenograft (PDX) models.
Results: ATV-1601 is potent on AKT1E17K and highly selective over AKT2 in a BaF/3 cellular proliferation assay. Biophysical characterization of ATV-1601 binding kinetics demonstrated significant differences between AKT1E17K and AKT2. In vivo, ATV-1601 shows good oral bioavailability and exposure across species. In CDX models ATV-1601 demonstrated a strong dose-proportional exposure and achieved >90% AKT1E17K inhibition for 24 hours. AKT2-driven hyperglycemia was not detected across multiple in vivo studies. ATV-1601 demonstrated profound tumor regressions with long durations in ER+/HER2- and triple negative breast cancer PDX models and is well-tolerated in multiple preclinical species at the projected efficacious exposure.
Conclusion: ATV-1601 demonstrates exceptional efficacy with a favorable in vivo tolerability profile and data supports advancing toward clinical development.

P5-04-25: Detection of Human Epidermal Growth Factor Receptor 2 (HER2) in Cultured Circulating Tumor Cells (CTCs) Isolated from Peripheral Blood of Breast Cancer Patients

Ying Chang, Wen-Hung Kuo, Yen-Jang Huang, Jia-Yang Chen, Aurin E. Liu, J. Patrick Kampf, Yi-Chun Wu,

Background: Overexpression of HER2 is indicative of a subset of breast cancers that are characterized by rapid growth and poor prognosis. The advent of HER2-targeted therapies has transformed the treatment landscape, making accurate detection and quantification of HER2 expression critical for guiding treatment decisions. Typically, HER2 status is determined through invasive tissue biopsies, which pose risks to patients and logistical and financial burdens. Analysis of CTCs from liquid biopsies offer a minimally invasive alternative, but the rarity of CTCs in peripheral blood and the technical challenges associated with their isolation and characterization have hindered the widespread adoption of this technique for protein biomarker analysis. In response to these challenges, we propose a novel approach to enhance the detection and quantification of HER2 using liquid biopsies by cultivating CTCs ex vivo, thereby amplifying their numbers to a level that allows for more reliable detection.
Methods: Adult breast cancer patients at least 18 years of age with tumor size of at least 1 cm were prospectively enrolled for this study. Breast tumor tissue was acquired via core needle biopsy and tested for HER2 protein expression following the hospital's standard procedures for immunohistochemistry (IHC) and, if needed, for HER2 gene amplification with fluorescence in situ hybridization (FISH) as recommended per the ASCO-CAP Guideline. The peripheral blood mononuclear cell (PBMC) layer was isolated from whole blood for culturing of CTCs on the 3D organoid culture platform, Rapid, Reproducible, Rare

Cell 3D Expansion (R3CE) (AcroCyte Therapeutics, Inc., New Taipei City, Taiwan). After 7 days of culture, a multiplex immunofluorescence (IF) staining protocol targeting cell nuclei (DAPI), CD45, EpCAM, and HER2 was employed to identify and enumerate HER2-positive CTCs. Mean CTC counts were compared using Student's t-test.
Results: Ten female breast cancer patients with a mean (standard deviation) age of 55 (8) years were included in the study. One (10%), 5 (50%), and 4 (40%) patients had stage I, II, and III cancer, respectively. Two (20%) and eight (80%) patients had grade 2 and 3 cancer, respectively. Based on tumor tissue pathology, three (30%) were HER2-positive (IHC 3+). FISH was conducted for two patients with IHC 2+, and both were negative. For the remaining 5 patients, 4 were IHC 1+ and one was IHC 0. After 7 days of culturing, CTCs were identified for 8 (80%) of the patients. Mean CTC counts were higher for grade 3 cancer [261 (435)] than grade 2 cancer [80 (113)], but the difference was not statistically significant (p=0.33). Positive HER2 IF staining was observed for all cases in which CTCs were identified. The percentage of CTCs with positive HER2 staining ranged from 38% to 100%, with a median of 77%. No significant difference in percentage of CTCs with positive HER2 staining was observed between patients who were HER2-positive and HER-2 negative by tissue pathology.
Conclusion: Our study demonstrated the feasibility of culturing and IF staining CTCs from breast cancer patients for HER2 analysis. Additional investigations of the association between HER2 expression in CTCs and tumor tissue are needed to realize the potential of CTCs for guiding treatment with HER2-targeted therapies.

P5-04-26: Prevalence of BRCA1, BRCA2, and PALB2 genomic alterations among 924 Taiwanese breast cancer assays with tumor-only targeted sequencing: extended data analysis from the VGH-TAYLOR study

Han Fang Cheng, Yi-Fang Tsai, Chun-Yu Liu, Chih-Yi Hsu, Pei-Ju Lien, Yen-Shu Lin, Ta-Chung Chao, Jiun-I. Lai, Chin-Jung Feng, Yen-Jen Chen, Bo-Fang Chen, Jen-Hwey Chiu, Ling-Ming Tseng, Chi-Cheng Huang

Background: The discovery of BRCA1 and BRCA2 genes in 1994 and 1995 led to increased focus on the homologous recombination (HR) repair pathway in cancer research and therapy. Preclinical studies in 2005 demonstrated that poly ADP-ribose polymerase (PARP) inhibitors selectively target BRCA-deficient cells. Numerous phase III clinical trials have shown that PARP inhibitors can improve treatment outcomes in both early and advanced germline BRCA1/2 (gBRCA1/2)-mutant breast cancer, as well as achieve a better quality of life compared to cytotoxic chemotherapy.
However, the prevalence of gBRCA1/2 mutations is estimated to be only 2-5% in the unselected general population. Therefore, it's important to identify patients beyond gBRCA1/2 carriers whose cancers may be sensitive to PARP inhibition. Studies in prostate and ovarian cancer have suggested that some patients with somatic BRCA1/2 (sBRCA1/2) mutations or mutations in HR-related genes other than BRCA1/2 may benefit from PARP inhibitors.

Among HR-related genes, PALB2 is responsible for loading RAD51 onto ssDNA, stimulating RAD51-mediated strand exchange and D-loop formation via the BRCA complex (BRCA1-PALB2-BRCA2-RAD51). Germline PALB2 mutation is estimated to be present in about 1% of breast cancer patient populations and is associated with an increased risk of breast and pancreatic cancer.
The epidemiology of breast cancer differs between Taiwanese (ethnically Han Chinese origin) and Caucasian populations. Taiwanese breast cancer patients have a younger median age of disease onset and carry a greater risk for disease progression and shorter interval to secondary contralateral breast cancer than Western women. As the early onset and bilaterality of breast cancer are more likely to be related to genetic predisposing factors, it is important to identify potential genetic alterations underpinning Taiwanese patients.

Methods: This study aimed to assess the prevalence of BRCA1, BRCA2, and PALB2 mutations in Taiwanese breast cancer patients using targeted sequencing on tumor-only samples. The Institutional Review Board of Taipei Veterans General Hospital approved the study (protocol number: 2018-09-007A). Written informed consent was obtained from all participants prior to enrollment.
A total of 879 consecutive breast cancer patients, representing 924 assays, were enrolled in the study. Patients were assigned to different groups based on their treatment plans: Group 1 [planned to receive surgery as the first-line treatment and followed by adjuvant therapy], Group 2 [planned to receive neoadjuvant therapy as the first-line treatment and followed by surgery], and Group 3 [diagnosed with de novo and treatment naive stage IV breast cancer, or stage IV breast cancer with recurrence beyond three years after surgery].
Formalin-fixed paraffin-embedded specimens were assayed using the Ion Torrent Oncomine™ Comprehensive Assay v3 (Thermo Fisher Scientific, Waltham, MA), enabling the detection of 161 cancer-related genes and identification of single nucleotide variants (SNVs), copy number variations (CNVs), gene fusions, and indels.
Variants were filtered with the Oncomine™ Knowledgebase Reporter and the online VariED tool to filter out Taiwan Biobank polymorphisms. The mutational consequences of filtered variants were determined using the ClinVAR database, OncoKB™, and SNPnexus.
Reflex germline testing was conducted for patients with pathogenic or likely pathogenic variants using whole exome sequencing (WES) or whole genome sequencing (WGS) through blood sample collection.
To distinguish germline from somatic mutations with tumor-only sequencing, algorithms including the LOH-germline inference calculator (LOHGIC) and the somatic-germline-zygosity (SGZ) method were employed as alternatives for patients not ready for germline testing.

Results: Of the 924 assays, 281 were positive for mutant BRCA1, BRCA2 and PALB2 in 130 patients. These mutations impacted 27 patients (3.1%) for BRCA1, 76 patients (8.6%) for BRCA2, and 46 patients (5.2%) for PALB2. In total, genetic alterations were noted in 14.8%

(130 patients) of the cohort.
The BRCA1 mutation cohort was associated with a higher proportion of advanced stages compared to those without. The BRCA2-mutant patients showed a higher incidence of family history of ovarian cancer, resulting in a significant difference in the number of mutant patients with a family history of ovarian cancer.
In terms of IHC phenotypes, 13 (2.3%) of the BRCA1 mutant breast cancers were HR+/HER2−, 3 (3.3%) were HR+/HER2+, 2 (2.6%) were HR−/HER2+, and 9 (6.9%) were HR−/HER2−. For BRCA2 mutated cases, 51 (9.0%) were HR+/HER2−, 9 (9.9%) were HR+/HER2+, 6 (7.9%) were HR−/HER2+, and 9 (6.9%) were HR-/HER2-. Among the PALB2 mutated patients, 30 (5.3%) were HR+/HER2−, 4 (4.4%) were HR+/HER2+, 3 (3.9%) were HR−/HER2+, and 9 (6.9%) were HR−/HER2−.
Co-occurrence was found between BRCA1/2 in 13 samples (log2 odds ratio: > 3, p-value < 0.001, and q-value < 0.001), BRCA1 and PALB2 in 8 samples (log2 odds ratio: > 3, p-value < 0.001, and q-value < 0.001), and BRCA2 and PALB2 in 8 samples (log2 odds ratio: 2.401, p-value < 0.001, and q-value < 0.001). Five patients had both BRCA1/2 mutations, 1 had both BRCA2 and PALB2 mutations, none had both BRCA1 and PALB2 mutations, and 7 had all three mutations.
The study analyzed various genetic variants and identified 176 amino acid (AA) changes. There were four variants that did not notice any AA change, and three novel splice site variants (BRCA1 c.5256+1G > A, BRCA1 c.5215+1G > A, and BRCA2 c.-38-3CAG > C) were identified. Notably, 60.2% (106) of the discovered AA changes were not documented in either ClinVAR or the Oncomine™ Knowledge database. Using the OncoKB™ for annotation, 171 (97.2%) AA changes were found to have clinical implications.
The most common mutations were p.K654fs (3 cases) for BRCA1, p.N372H (26 cases), p.S2186fs (5 cases), p.V2466A (5 cases), and p.X159_splice (5 cases) for BRCA2, and p.I887fs (30 cases) for PALB2. It should be noted that although p.N372H was observed 26 times in BRCA2-mutated assays, it has been confirmed to be a benign variant.
Reflex germline testing was conducted for patients until November 20, 2023. Specifically, 48 cases (36.9%) were identified with pathogenic or likely pathogenic variants via tumor-targeted sequencing, as classified by the ClinVar database, and were subsequently recalled for further investigation through WGS or WES. Among 130 cases examined, 7 cases (5.4%) completed WGS uncovering crucial genetic variations. None harbored germline mutations in BRCA1/2 and PALB2. Another 20 cases (15.4%) were reached and 9 had completed WES (6.9%). The study group encountered enormous challenges including loss of follow-up and 14 were deceased.
The reflex germline testing results showed that three variants (BRCA1 c.1969_1970del, BRCA1 c.3629_3630del, BRCA2 c.8755-1G > C) were classified as Pathogenic/Likely pathogenic (P/LP) by ClinVar and as likely loss-of-function or likely oncogenic by OncoKB. One variant (PALB2 c.448C > T) was not listed in ClinVar, but OncoKB annotated it as likely loss-of-function or likely oncogenic. Additionally, there were 2 cases (1.5%) of germline mutations with uncertain significance, and 5 cases (3.8%) with benign germline alterations, emphasizing the genetic intricacy involved in breast cancer development.
Using alternative methods as the results of LOHGIC and SGZ analyses for determining

germline and somatic mutations, among the 281 samples, 40 were identified as germline mutations, and 169 samples (60.1%) were of somatic origin. Borderline cases comprised 26 samples (9.3%), and 46 samples (16.4%) were unclassifiable due to missing data on tumor purity.

Discussion: This study presents one of the largest cohorts of breast cancer patients with BRCA1, BRCA2, and PALB2 mutations detected through tumor-only sequencing in Taiwan. The high detection rate of breast cancer susceptibility genes could lead to more patients undergoing germline testing and receiving appropriate treatments.

The study revealed a significant tendency of co-occurrence between BRCA1/2, BRCA1-PALB2, and BRCA2-PALB2 mutations. This finding may have implications for understanding breast carcinogenesis and creating genetic panels for predicting and prognosing hereditary breast cancer.

Tumor-only targeted sequencing has gained increasing attention due to its ability to reveal pathogenic/likely pathogenic variants in genes associated with cancer predisposition and potential therapeutics with a higher level of coverage. The Dana-Farber/Harvard Cancer Center study found that over half (52.9%) of the tumor-identified P/LP patients did not meet any personal or family history criteria for clinical genetic testing (CGT). These results show the potential of tumor-only sequencing in detecting P/LP mutations in cancer predisposition genes across malignancies.

Both germline and somatic alterations can affect treatment decisions and outcomes. The results of the TBCRC-048 and TBB trials suggested further exploration of PARP inhibitors in metastatic or advanced breast cancers with HR-associated mutations beyond BRCA1 and BRCA2. Identifying additional biomarkers to expand this treatment in somatic BRCA1/2-mutant or HR-related-gene-mutant advanced breast or ovarian cancers could significantly benefit patients who would otherwise receive chemotherapies as the only regimen.

The significance of reflex germline testing cannot be overemphasized. However, the extent of reflex testing conducted to date is still limited. This has led to the exploration of alternative methods to determine whether the reported mutation is of germline or somatic origin. The refined LOHGIC and SGZ methodologies are designed to assess three crucial factors: tumor purity, allele frequency, and confirmation of a diploid genome. Although these algorithms are useful, they have their limitations; in an analysis of 130 cases, 10 could not be conclusively classified as either germline or somatic due to varying origins of the mutations.

Accurate interpretation of genetic variants is critical in both clinical and research settings. The classification criteria can vary between submitters, and the evidence for a particular variant may be conflicting, leading to difficulties in unbiased interpretation. Numerous studies have explored potential indicators for reinterpreting pathogenic variants within specific databases, as well as across distinct platforms. The reinterpretation of cancer predisposition genes requires a multidisciplinary effort involving clinicians, genetic counselors, bioinformaticians, and researchers.

This study has several strengths, including being the first large-scale analysis of its kind in

Taiwan and Asia, the availability of data on family history, molecular subtypes, and early or advanced breast cancer status, and the utilization of updated annotation databases and guidelines during interpretation and annotation. However, it also has limitations, including limited additional germline sequencing with compromised recalled rates, varying sample sizes among different clinical groups, focus on only three genes, and the need for more in-depth evaluation of clinical outcomes and subgroup analyses.

Conclusion: This study reported a cohort of Taiwanese breast cancers harboring mutations in BRCA1, BRCA2, and PALB2 through tumor-only sequencing, which underscores the impact of these genes on breast cancer risk and potential therapeutic opportunities. Tumor-only sequencing has enabled a greater number of patients to uncover their genomic alterations, offering additional insights for management strategies. These include recommendations for germline testing and the prospective utilization of PARP inhibitors to augment treatment efficacy. Nonetheless, supplementary germline testing remains critical, and investigating alternative methods for distinguishing whether variants are germline or somatic origin are invaluable. The use of updated annotation and rigid guideline follow-up and the integration of multiple types of genomic data can help improve the accuracy of cancer risk assessment and inform personalized prevention and treatment strategies.

P5-04-27: A Novel Patient-Derived Xenograft Model of Inflammatory Breast Cancer

Yun Yun Su, Pushpinder K. Bains, Daniel Campo, Patrick McIntire, Alexander Ring, Gregor Krings, Karin List, Ruth Keri, Julie E. Lang, Tiffany Cheung

Background: Inflammatory breast cancer (IBC) is one of the most aggressive forms of breast cancer, but few models exist for studying experimental therapeutics. Inflammatory breast cancer research urgently needs additional models to allow pre-clinical testing of experimental therapeutics. The objective of our study was to establish and characterize a novel patient-derived xenograft (PDX) from a HER2 positive IBC patient refractory to neoadjuvant chemotherapy to better understand the biology of IBC resistance.
Methods: We derived a novel PDX from a patient with hormone receptor negative, HER2 positive IBC refractory to neoadjuvant chemotherapy with Docetaxel, Carboplatin, Trastuzumab, and Pertuzumab (TCHP). Tumor was implanted into NOD SCID gamma mice and used for serial propagation of PDX. We performed short-tandem repeat (STR) profiling, plotted tumor growth curves for mice treated with alpelisib/everolimus vs. untreated, and immunohistochemistry (IHC). Paired Student's t-tests were used to compare tumor growth curves. We used 10X genomics for single cell transcriptome analysis of 1000 cells derived from the PDX, ctDNA, whole exome and RNA sequencing to further characterize the genetic landscape of the PDX model.
Results: Tumor next generation sequencing (NGS) showed a mutation in PIK3CA (H1047R), a variant associated with resistance to HER2 targeted therapy and chemotherapy, but sensitivity to everolimus. Using STR profiling, we were able to prove the PDX and primary

tumor were derived from the same patient. By the 3rd generation transplant, 15/15 orthotopically transplanted mice produced PDX. The mean tumor size was 619 mm3. Five mice were then treated with a combination of alpelisib and everolimus for 20 days to block signaling of the PI3K/AKT/mTOR pathway. Tumor growth was compared over 21 days. After treatment with alpelisib/everolimus, the tumor size decreased significantly (869.9mm3 vs. 45.8mm3, p = 0.006). No mice (0/15) had metastasis on necropsy at the time of meeting humane endpoints.

We performed IHC to assess the intensity of protein expression in the treated vs untreated tumors. All tumors strongly expressed JAK2. The tumor appeared to have changed receptor expression after neoadjuvant TCHP (from HER2 positive to triple negative). The group treated with alpelisib/everolimus had higher expression of PIK3CA, CD24, and HER2. Only the treatment group expressed HER2 and ALDH1. E-cadherin, PIK3CA, and CD24 were stronger in the treatment group when compared to control.

10X Genomics UMAP (Uniform Manifold Approximation and Projection) plots showed a snapshot of the transcriptome with 6 unique clusters in the PDX. RNA Seq showed genes with differential expression between primary tumor and PDX. Whole exome sequencing identified copy number variants and single nucleotide variants.

Conclusion: We established a PDX of a HER2 positive IBC tumor with a PIK3CA hotspot mutation (H1047R) refractory to trastuzumab. Few PDX models have been created to study IBC. Alpelisib/everolimus decreased tumor growth in our model. JAK2 was strongly expressed in both treated and untreated tumors. TCHP resistant tumor cells downregulated HER2 expression, which was re-expressed after treatment with alpelisib and everolimus. Targeting the PI3K/mTOR pathway may be useful to overcome resistance in HER2 positive IBC with a H1047R mutation in PIK3CA.

P5-04-28: Subtype by PAM50 changes after Neoadjuvant Endocrine therapy, from A Phase III Randomized, Double-Blind, Neoadjuvant Study of Hormonal Therapy plus Palbociclib versus Hormonal Therapy plus Placebo in ER+HER2- Operable Breast Cancer

Rie Nakagawa, Nobuko Kawaguci-Sakita, Adrian Harris, Takayuki Ueno, Louis Chow, Wonshik Han, Chiun-Sheng Huang, Gregory Bruce Mann, Satoshi Morita, Masakazu Toi, Hironori Haga, Masahiro Takada, Shigeru Imoto, Yuko Tanabe, Toshinari Yamashita, Hiroji Iwata, Hiroko Bando, Hirofumi Suwa, Eriko Tokunaga, Yasuaki Sagara, Norikazu Masuda, Elham Fakhrejahani

Background: Luminal B breast cancer has heterogeneity which leads to unmet medical needs for cure. HER2-enriched type identified by PAM50 is occasionally found in luminal B subtype breast cancer by immunohistochemistry, leading to resistance to endocrine therapy (ET). To understand biological change following ET and to predict efficacy of ET, and consider additional therapies, we analyzed sequential samples from a neoadjuvant ET trial for exploratory analysis.

Patients and Methods: This study was conducted as translational research for a phase III

randomized, double-blind study of neoadjuvant hormonal therapy with or without palbociclib in untreated pre/peri- and post-menopausal women with operable, hormone receptor-positive (estrogen receptor and/or progesterone receptor), HER2-negative breast cancer (NCT03969121). Other major inclusion criteria included tumor size ≥ 15mm, T1c-3N0-1, Ki67 LI ≥14% by central assessment, and no previous history of radiotherapy or systemic therapy for breast cancer. Patients were randomly assigned 1:1 to receive 16 weeks of hormonal therapy plus palbociclib (125mg/day, 3W1R) or hormonal therapy plus placebo. Hormonal therapy consisted of letrozole for post-menopausal patients and tamoxifen plus LH-RH agonist for pre/peri-menopausal patients. The co-primary endpoints included PEPI score and EPclin Risk Score, a score combining EndoPredict® molecular score with clinical factors. The primary outcome was reported previously that the addition of palbociclib to neoadjuvant hormonal therapy did not improve efficacy measured by PEPI score. From 141 cases in the trial, 60 samples from 20 cases, who had sufficient tissue from biopsies at screening, cycle 1 day 15 (C1D15) and surgery, were analyzed by PAM50 for intrinsic subtype and risk of recurrence (ROR).
Result: The distribution of cases (subtype and Ki-67) is shown in Table 1 and 2. Among 20 cases, 13 cases were in Palbociclib arm, and 7 in Placebo arm. There were 3 Her2-enriched cases in Palbociclib group (1 case at both screening and surgery, 1 case at screening only, 1 case at surgery only). As for ROR, there were no low-risk cases, 4 intermediate-risk cases, and 16 high-risk cases at screening. There was a shift to lower scores at C1D15: 10 low-risk cases, 9 intermediate-risk cases, and 1 high-risk cases. By surgery, however there seemed to be some rebound, but still lower than before treatment: 8 low-risk cases, 6 intermediate-risk cases, and 6 high-risk cases. Average of ROR was 69 at screening, 33 at C1D15, and 38 at surgery. In analysis of 17 luminal A/B cases (without 3 HER2-enrich cases), baseline data are not significantly different between Palbociclib arm and Placebo arm. Ki-67 at C1D15 was lower in palbociclib arm than in placebo arm (Average 1.5% (95% CI 0.4-3.4), 6.0% (1.5-10.6) respectively, p=0.027). At surgery, there were 8 PR cases and 2 SD cases in palbociclib arm, 3 PR cases and 4 SD cases in placebo arm. There were no significant differences between the two arms in Ki67(%), PEPI score, EP clin risk score and ROR at surgery.
Conclusion: Neoadjuvant endocrine therapy for 16 weeks changes subtype classification by PAM50 from luminal B to luminal A and the ROR drastically. Greater effects were noted for the combination, not statistically significant, but this warrants further investigation in a larger cohort. There were 3 HER2-enriched cases with poor response, but this was not significant because of the small sample size. These 3 cases probably reflect tumor heterogeneity on the baseline biopsy. Neoadjuvant 16 weeks endocrine therapy may work to screen for ET resistance, and help select a switch in therapy, or those benefitting most from Palbociclib. Further research will be necessary including PAM50, Oncotype Dx and those with high Ki67.

Clinical trial identification: NCT03969121
Funding: Pfizer Inc.

P5-04-29: Investigating the expansion of 95-gene signature (Curebest® 95GC Breast) indication for predicting the risk of recurrence in patients with ER-positive and lymph node-positive breast cancer.

Asako Tsuruga, Sachiyo Tada, Hayato Niiro, Kei Hagino, Yusuke Tsukuda, Motonari Daito, Kazuya Kashiwa, Yuka Matsushima, Moeka Tanaka, Reika Yoshida, Seigo Nakamura, Naoki Hayashi, Hiroko Masuda

Background: Gene profiling technology, which assesses multiple genes, has garnered attention as a research tool for personalized cancer treatment and its use is recommended in several international guidelines.
Currently, postoperative adjuvant therapy for ER-positive and HER2-negative breast cancer includes a wide range of options, including anthracyclines and taxanes, CDK4/6 inhibitors, and TS-1, in addition to hormone therapy.
21-gene signature assay categorizes patients into two groups for assessing adjuvant chemotherapy efficacy: RS 0-25 and RS 26 or higher for N1 patients. However, the broad clinical range of RS 0-25 complicates treatment decisions when relying solely on this cutoff. And over-treatment of the good prognosis group cannot be ruled out. Moreover, in premenopausal patients with N1, optimal prognostic tools have not been established.
Curebest™ 95GC Breast (95GC) provides a 95-gene signature that stratifies patients into two groups: high-risk (95GC-H) and low-risk (95GC-L), predicting the recurrence risk and is clinically indicated only for ER-positive, HER2-negative, node-negative invasive (ER+/HER2-/N0) invasive breast cancer.
This study aims to investigate the applicability of 95GC in N1 cases and also to discuss the correlation between RS of 21-gene signature assay and 95GC determination.

Methods: We reviewed our institutional databases to identify patients with ER-positive, HER2-negative, node-positive breast cancer who had 21-gene signature assay data available and who had undergone definitive surgery between April 2005 and May 2018 and adjuvant endocrine therapy without any cytotoxic agents. We included only patients for whom archival FFPE tissue from definitive surgery was available. We excluded patients with pathological node-negative, distant metastatic disease, and male patients. The Fisher exact test was used to compare variables between 95GC groups. A Kaplan-Meier estimate with a log-rank test was used for survival analysis.

Results: A total of 58 patients from our institution were initially included in the analysis; one patient was excluded due to indeterminate HER2-ISH results, resulting in a final cohort of 57 patients including premenopausal patients.
When the index cutoff value to distinguish between the 95GC-H and 95GC-L groups was set at 50, the 5-year recurrence-free survival (RFS) rate and the lower limit of the 95% confidence interval were significantly higher in the L group. The L group showed a markedly better prognosis compared to the H group (92.8% and 64.8%; p=0.0063). This

cutoff value was consistent with the reference value used for N0 patients.
We classified 48 patients (84.2%) as 95GC-L; 9 patients (15.8%), as 95GC-H.
The median follow-up duration was 87.3 months. There were no statistical differences in age, menopausal status, T stage, nuclear grade, histological grade, or PR status between the 95GC-H and 95GC-L groups.
There were 6 patients (10.5%) of recurrence within 5 years after surgery and 2 of which were distant metastases, both in the 95GC-H group. 5-year distant recurrence-free survival (DRFS) was significantly better in the 95GC-L group than in the 95GC-H group (100% and 77.8%; p=0.0164).
The sensitivity and specificity of 95GC for predicting recurrence were 44.4% and 89.6%, respectively. Comparable calculations were conducted for the RS0-25 and RS≥26 groups of 21-gene signature assay, revealing sensitivity and specificity values of 11.1% and 100%, respectively. These results indicate that 95GC demonstrates a higher sensitivity equivalent index compared to 21-gene signature assay.

Conclusions: 95GC can predict recurrence risk in patients with ER+, HER2-, N1 breast cancer. It also suggested that it may be able to predict the risk of recurrence better than RS of 21-gene signature assay.

P5-04-30: Holographic and molecular characterization of early disseminated cells from breast cancer patients

Justin M. Drake, Kaylee Judith Kamalanathan, Catalina Galeano-Garces, Song Yi Bae, Nathaniel R. Bristow, Kevin Mallery, Alexa Hesch, Grant Schaap, Yash Travadi, Yulia Olimpiadi, Sarah Peterson, Jiarong Hong, Jayant Parthasarathy, Badri R. Konety

Growing evidence suggests that cancer cells disseminate into blood vessels at an early stage, seeding metastatic sites in breast cancer. These early-stage tumor cells that lodge or extravasate at metastatic sites can enter dormancy, marking a potential source of late recurrence and therapy resistance. Thus, the presence of early disseminated cells poses risks to patients but also holds potential benefits for early detection and opportunities for possibly curative interventions. We evaluated this in a cohort of women with newly diagnosed early-stage breast cancer (Stage 0, 1, 2). Blood samples were collected prior to initiation of therapy and analyzed by Astrin Biosciences' AI-empowered proprietary holographic imaging platform combined with in-flow protein marker expression for the presence of disseminated tumor cells. The platform was previously trained on holographic signatures (encoding both optical and morphological signatures) of 100 million+ individual cells and could differentiate healthy from cancer cells with greater than 99% accuracy. Preliminary data from this study revealed that blood samples from the majority of early breast cancer patients exhibited disseminated cancer cells. Gene expression patterns from the enriched cancer cells were further profiled via quantitative PCR using a selective gene panel consisting of breast-specific and cancer-specific genes. We were able to identify selective sets of breast and cancer-specific genes in these patients confirming breast origin with cancer-like features. In summary, we utilized holographic imaging coupled with

proprietary deep learning approaches to identify early disseminated cells in women who are undergoing screening for breast cancer. Molecular analyses of these cells confirmed breast cancer origin. Combined, this work enables Astrin Biosciences to develop a two-pronged assay consisting of holographic plus molecular characterization of disseminated cells for early detection of breast cancer.

P5-05-01: Real World Treatment Patterns and Outcomes in Her-2 Positive Metastatic Breast Cancer Patients with Brain Metastases

Mariella Mestres-Villanueva, Yevgeniya Gokun, Sierra Daniel, Rituraj Upadhyay, Sachin Jhawar, Therese Andraos, Rebekah Young, Jacob Eckstein, Erin Healy, Nicole Williams, Joshua Palmer, Sasha Beyer

Background: Approximately 50% of HER2+ metastatic breast cancer (MBC) patients will develop brain metastases (BMs). While traditional treatment for BMs consisted of radiation +/- surgery, optimal treatment now involves a multi-disciplinary approach of local and CNS-penetrating Her-2 targeted systemic therapies since their FDA approval in 2020. First line systemic therapy for HER2+ MBC is trastuzumab (H), pertuzumab (P), and Taxol (T). Subsequent therapy options include trastuzumab emtansine (T-DM1), tucatinib/H/capecitabine triplet therapy (TUC), and trastuzumab deruxtecan (T-DXd). This study aimed to examine real-world treatment patterns and clinical outcomes of HER2+ breast cancer BMs.
Methods: This single institution retrospective study included HER2+ MBC patients with BMs treated between Jan 2017 - Feb 2024, with at least 6 months of follow-up after BM diagnosis. Primary objective was to evaluate treatment sequence and duration after BM diagnosis. Overall survival (OS) was defined from date of BM diagnosis to date of death. Systemic progression-free survival (PFS) and CNS-PFS were defined from systemic therapy initiation date to systemic or CNS disease progression, respectively. Kaplan-Meier method was used for survival analysis. Time to systemic therapy discontinuation (due to toxicity or progression) was also evaluated. Radiation necrosis (RN) was diagnosed by MRI perfusion imaging +/- biopsy and multi-disciplinary review.
Results: 78 patients with HER2+ MBC with BM met the eligibility criteria, including 36 (46.2%) patients with BMs at initial MBC diagnosis and 42 (53.8%) subsequently diagnosed with BMs. Median number of systemic therapies received prior to BMs diagnosis was 3 (range 0-13). Patients had a median of 2 BMs (range 1-40) at diagnosis, and median total BM volume was 7.29 (range 0.09-105.22) cm3. 72 (92.3%) patients received stereotactic radiosurgery (SRS); 25 (32.1%), WBRT; and 40 (51.3%), neurosurgical resection. Of 129 total SRS courses, 40 (31.0%) were treated with 18-22 Gy in 1 fraction (fxn), 67 (51.9%) with 21-24 Gy in 3 fxns, and 17 (13.2%) with 25-30 Gy in 5 fxns. For patients with a diagnosis of BM before 2020 (n=45), the 1st systemic therapy prescribed after BM diagnosis consisted of HPT (n=6; 13.3%), T-DM1 (n=2; 4.4%) or other (n=37; 82.3%). After 2020 (n=33), the 1st systemic therapy prescribed after BM diagnosis was HPT (n=4; 12.1%), T-DM1 (n=2; 6.1%), TUC (n=8; 24.2%), T-DXd (n=8; 24.2%), or other (n=11; 33.4%). The

median duration for each systemic therapy was 6.0 mo, 12.9 mo, 7.3 mo, and 3.2 mo for T-DM1, TUC, T-DXd, and other treatments, respectively (p=0.27). For the entire cohort, median OS was 36.8 mo (95% CI 21.9-79.2), median systemic PFS was 13.4 mo (95% CI 8.7-16.0), and median CNS-PFS was 14.7 mo (95% CI 11.3-25.5). Twenty-three (29.5%) patients developed RN (any CTCAE grade) with a median time to RN after initial SRS treatment of 26.5 months (range 2.0-220.5 months). Of the patients with RN, 7 (30.4%) received antibody-drug conjugates (ADC) concurrently with SRS.
Conclusions: Since 2020, TUC and T-DXd were increasingly prescribed as initial systemic treatment after BM diagnosis. The combination of SRS and HER2 targeted systemic therapies in this cohort resulted in excellent survival outcomes but some risk of RN. Interestingly, TUC trended toward a longer treatment duration than T-DM1 or T-DXd. Further investigation into reasons for discontinuation of each systemic therapy (toxicity vs. progression) is warranted. Limitations of this study include the retrospective design, small cohort size, and limited follow-up. Future studies and longer follow-up will allow for a better understanding of how treatment patterns affect survival outcomes and patient quality of life.

P5-05-02: Pharmacokinetic profile and preliminary efficacy of GQ1001, a next generation HER2-targeting ADC, combined with pyrotinib in pretreated patients with HER2-positive metastatic breast cancer: A phase 1b clinical trial

Chengcheng Gong, Leiping Wang, Xichun Hu, Ting Li, Zhonghua Tao, Mingchuan Zhao, Yannan Zhao, Biyun Wang

Background: GQ1001 is a novel HER2-targeted antibody-drug conjugate (ADC) that was generated by conjugating trastuzumab to DM1 via a unique open-ring containing linker and the enzymatic site-specific conjugation technology, which significantly improves homogeneity and stability of the study drug[1]. Preclinical studies showed robust anti-tumor activities in multiple HER2+ PDX and CDX models, and excellent pharmacokinetics and safety profiles in rats and cynomolgus monkeys. Phase 1a study (NCT04450732) showed superior tolerability and promising antitumor efficacy in heavily pretreated HER2-positive advanced solid tumors[2]. In vivo study also demonstrated a synergistic anti-tumor efficacy of GQ1001 combined with pyrotinib, an irreversible pan-HER2 receptor tyrosine kinase inhibitor (TKI)[1]. Thus, a phase 1b study (NCT05575804) was designed to investigate the safety and preliminary efficacy of the combination of GQ1001 and pyrotinib in pretreated patients with HER2-positive metastatic breast cancer.

Methods: In the “3+3” dose-escalation phase, the dose of GQ1001 was 6.0 mg/kg, 7.2 mg/kg and 8.4 mg/kg intravenously in a 21-day cycle, and pyrotinib was taken orally in a fixed dose of 320 mg once daily in 28-day cycles. The dose escalation or de-escalation was based on the incidence of specified dose-limiting toxicities (DLTs) in the initial dose group. DLTs were observed for the first 21 days. Blood samples were collected at pre-dose, within 10min

of EOI of cycle1 and cycle3 for GQ1001 and TAb; collected at pre-dose, 4h and 24h after dose in D1 and D8 for pyrotinib; and collected integrally at pre-dose, within 10min of EOI, 0.5h, 2h, 8h, 24h, 48h, 72h, 168h, and 336h after dose from different patients. Concentrations of GQ1001, TAb and pyrolizinib in serum and fDM1 in plasma were quantitated using enzyme-linked immunosorbent assay (ELISA) and liquid chromatography and tandem mass spectrometry separately.

Results: A total of 15 HER2-positive metastatic breast cancer patients received GQ1001 and pyrotinib treatment. All patients (15/15) had failed on previous trastuzumab (or its biosimilars) containing therapy. And 33.3% of the patients (5/15) had been treated with pertuzumab. Dose escalation has been completed with no DLT reported. In HER2-positive advanced breast cancer, the combination of GQ1001 and pyrotinib (320mg, qd) did not significantly change the plasma concentrations of GQ1001 at BI and the end of infusion and each time point of DM1 in Cycle1and Cycle3 compared with GQ1001 alone. Compared with pyrotinib alone (320mg, qd), there was no significant change in the plasma concentration of pyrotinib at D1-4 hours after a single dose. The results showed that there were no significant changes in the plasma concentrations of GQ1001, DM1 and pyrotinib after the combination of GQ1001 (6.0mg/kg, 7.2mg/kg, 8.4mg/kg, ivgtt, 3W) and pyrotinib (320mg, qd). At the data cut off date (June 30th, 2024), the median follow-up time was 8.61(95CI% 6.83-15.08) months. Ten patients were still on going, with the longest treatment duration of 523 days.The 12-month-PFS rate was 73.5% and the objective response rate (ORR) was 80% (12/15) in all patients enrolled. At 6.0 mg/kg, 7.2 mg/kg and 8.4 mg/kg dose level, the ORR was 75% (3/4), 100% (5/5), 66.7% (4/6), respectively. No new safety signal was observed.

Conclusion: No significant changes were observed in the plasma concentrations of GQ1001, DM1 and pyrotinib after the combination of GQ1001 and pyrotinib. This combinaiton demonstrated promising preliminary antitumor activity among pretreated patients with HER2-positive metastatic breast cancer.

P5-05-03: Neratinib-based combination treatments for patients with HER2-positive breast cancer brain metastases

Sarah L. Sammons, Rachel A Freedman, Ahmad Awada, Adam M Brufsky, Sara A Hurvitz, Cristina Saura, Sheri Leung, Bethann S Hromatka, Nancy U Lin

Background: Breast cancer brain metastases (BCBM) contribute to substantial morbidity and mortality in patients (pts) with HER2+ metastatic BC (mBC). The central nervous system (CNS) is a common site of recurrence in pts with HER2+ BC, and there is an ongoing need for safe and effective treatments. Neratinib (N), an oral, irreversible pan-HER tyrosine kinase inhibitor, is FDA approved for the extended adjuvant treatment of early-stage HER2+ BC and in combination with capecitabine (C) for HER2+ advanced or mBC. We summarize prospective data of N-based combinations in HER2+ BCBM.
Methods: We conducted a literature review of N combinations for HER2+ BCBM, focusing on prospective trials reporting CNS outcomes. CNS-specific data were extracted from studies restricted to pts with untreated/active BM (TBCRC 022; NCT01494662) or asymptomatic/stable BM (NALA [NCT01808573] and NEfERT-T [NCT00915018]). TBCRC 022, a dedicated HER2+ BCBM trial, assessed N combinations in pts with no prior lapatinib (L; Cohort 3A; N+C) or with prior L (Cohort 3B; N+C), in pts with previously untreated BM (Cohort 4A; N+T-DM1), and in pts progressing after CNS-directed therapies with no prior T-DM1 (Cohort 4B; N+T-DM1) or in pts with prior T-DM1 (Cohort 4C; N+T-DM1). Also available were descriptive CNS outcomes for 1) pts with baseline CNS metastases previously treated with HER2-directed therapy in NALA (N+C vs L+C) and 2) metastatic treatment-naive pts in NEfERT-T (N+paclitaxel [P] vs trastuzumab [T]+P). Endpoints included CNS objective response rate (CNS-ORR) per composite/volumetric (TBCRC 022) or RECIST (NALA and NEfERT-T) (assessed locally or centrally), or ORR per Response Assessment in Neuro-Oncology-Brain Metastases (RANO-BM; assessed centrally). Cumulative 1-year incidence of intervention for CNS disease or incidence of progressive CNS disease were reported for the NALA CNS subgroup.
Results: The analysis includes 212 pts: 93 with untreated/active BCBM from TBCRC 022; 101 (16.3% of ITT) from NALA; and 18 (3.8% of ITT) from NEfERT-T. No pts had received prior tucatinib and only 2 pts in TBCRC 022 cohort 4 had received prior trastuzumab deruxtecan. Across all three studies, 131 pts had measurable/target CNS lesions at baseline and were evaluable for CNS-ORR (TBCRC 022: n=49 in Cohort 3 and n=44 in Cohort 4; NALA: n=32; NEfERT-T: n=6). In TBCRC 022, CNS-ORRs were 49% (18 of 37 pts in Cohort 3A; N+C), 33% (4 of 12 pts in Cohort 3B; N+C), 50% (3 of 6 pts in Cohort 4A; N+T-DM1), 29% (5 of 17 pts in Cohort 4B; N+T-DM1), and 24% (5 of 21 in Cohort 4C; N+T-DM1). In NALA, CNS-ORRs were 26% (5 of 19 pts; N+C) vs 15% (2 of 13 pts; L+C). In NEfERT-T, CNS-ORRs were 100% (3 of 3 pts; N+P) vs 33% (1 of 3 pts; T+P). In TBCRC 022, RANO-BM ORRs were 24% (9 of 37 pts; Cohort 3A), 17% (2 of 12 pts; Cohort 3B), 33% (2 of 6 pts; Cohort 4A), 35% (6 of 17 pts; Cohort 4B), and 29% (6 of 21 pts; Cohort 4C). In the NALA CNS subgroup (n=101), 1-year cumulative incidence of intervention for CNS disease was 26% for N+C vs 36% for L+C, and 1-year cumulative incidence of progressive CNS disease was 26% (N+C) vs 42% (L+C). Diarrhea was the most common grade ≥ 3 toxicity.
Conclusions: Data from prospective trials of N-based combinations show consistent intracranial activity across various treatment settings in untreated/active and asymptomatic/stable HER2+ BCBM. Clinical guidelines and real-world analyses further support the use of N combinations for HER2+ BCBM. Notably, N+T-DM1 had intracranial efficacy in pts with previously untreated BM and pts who had undergone multiple local

CNS-directed and/or systemic therapies, including prior T-DM1. In addition to the established CNS activity of tucatinib and trastuzumab deruxtecan, the combination of N with other FDA-approved drugs represents a promising approach to the treatment of HER2+ BCBM in clinical practice, although the optimal sequence of treatments is not known.

P5-05-04: Final results of a phase II trial evaluating paxalisib with trastuzumab for patients (pts) with HER2 positive metastatic breast cancer with active brain metastases.

Jose Pablo Leone, Noah Graham, Nabihah Tayob, Heather A. Parsons, Jorge Gomez Tejeda Zañudo, Raechel Davis, Molly K. DiLullo, Jennifer A. Ligibel, Filipa Lynce, Jing Ni, Eric P. Winer, Jean Zhao, Rinath M. Jeselsohn, Nancy U. Lin

Background: HER2+ breast cancer brain metastases (BCBM) have frequent alterations in the PI3K/Akt/mTOR pathway. Mutations in PIK3CA or PTEN loss are associated with resistance to anti-HER2 therapies and worse prognosis. Preclinical data from patient-derived xenografts (PDX) models of HER2+ BCBM showed that inhibition of PI3K and mTOR led to durable responses regardless of PIK3CA mutation status. Paxalisib is a potent, brain-penetrant inhibitor of class I PI3K and mTOR. We report the final results of a phase II trial evaluating paxalisib with trastuzumab for pts with HER2+ BCBM (NCT03765983).
Methods: Eligible pts had HER2+ active BCBM with at least 1 measurable (≥10 mm) CNS lesion, ECOG PS 0-2, and any prior lines of therapy. The trial had two cohorts: Cohort A: a single-arm, two-stage, phase II cohort with safety run-in; and Cohort B: a pre-surgical window cohort. Pts initially received paxalisib 45 mg orally daily and trastuzumab 8 mg/kg loading dose, then 6 mg/kg every 3 weeks. Primary endpoint for Cohort A was objective response rate (ORR) in the CNS per Response Assessment in Neuro-Oncology Brain Metastases (RANO-BM) criteria. Secondary endpoints included progression-free and overall survival (PFS, OS), safety and pt-reported outcomes. Research blood and cerebrospinal fluid with optional tumor biopsy were requested at baseline, on-treatment and at progression. Cohort A planned to enroll 37 pts in a Simon two-stage design. If ≥4 responses were seen at the second stage, the regimen would be considered successful. This design had 90% power with alpha ≤10%. Cohort B planned to enroll 10 patients.
Results: Between February 2019 and March 2024 we enrolled 17 pts to Cohort A and 0 to Cohort B. Median age was 44.3 years, 70.6% White, 17.6% Black, and 66.7% of tumors were hormone receptor-positive. Among the 17 pts with BCBM, 14 pts (82.4%) also had extracranial disease. Pts had a median of 8 prior lines of therapy (range 3-14). Five of 17 pts (29.4%) had prior craniotomy, 12/17 (70.6%) had prior stereotactic radiation, and 6/17 (35.3%) had prior whole-brain radiation. Two of 5 pts enrolled in safety run-in had dose-limiting toxicities including fatigue, diarrhea, anorexia and dehydration; and subsequent pts (n=12) were enrolled to paxalisib dose level -1 (30mg daily, RP2D). Within the first stage, 0/12 pts (0%) had response in CNS and the trial closed for futility. One pt (8.3%) had clinical benefit through 18 weeks per RANO-BM. Six pts (50%) had stable disease as best RANO-BM response. The ORR by RECIST 1.1 was 0%, with 1 unconfirmed partial response

and 8 pts (66.7%) with stable disease. Site of first progression was CNS in 5 pts, CNS and extracranial in 1 pt, and 5 pts had clinical deterioration. Median bi-compartmental PFS was 7.4 weeks, and median OS was 16.5 months. Fourteen of 17 pts (82.4%) had treatment-related adverse events (TRAEs) of grade (G) ≥2. The most common TRAEs G ≥2 were fatigue (47.1%; 0% G≥3), diarrhea (29.4%; 11.8% G≥3), hyperglycemia (29.4%; 11.8% G≥3), and mucositis (23.4%; 5.9% G≥3). Molecular analyses of blood, cerebrospinal fluid and tumor tissue will be presented at the meeting.
Conclusions: In this heavily pre-treated population of pts with HER2+ active BCBM, the combination of paxalisib 30 mg daily with trastuzumab was feasible, with a toxicity profile consistent with a class effect of PI3K/mTOR inhibitors. However, it was associated with minimal clinical activity.

P5-05-05: Incidence and Risk Factors of Brain Metastasis in HER-2 Positive Primary Breast Cancer: A Retrospective Analysis

Anu Gaba, Hallie Thompson. Abe E Sahmoun

Introduction: Breast cancer (BC) is the most prevalent malignancy and the second leading cause of cancer-related death among women worldwide. Despite the progress in early diagnosis through screening and effective treatment, BC recurrence and metastasis remain a significant risk for lower survival. Brain metastasis (BM) occurs in nearly one-third of HER-2+ patients.
BM is associated with both poor quality of life and prognosis. The blood–brain barrier and the limited activity of anti-HER-2+ therapy in the brain microenvironment have contributed to the susceptibility of patients with HER-2+ primary BC to BM development.
The aim of this study was to identify modifiable risk factors associated with increased risk for developing BM in HER-2+ primary BC.
Methodology: This was a retrospective study that examined demographics, clinical, and treatments variables in HER-2+ primary BC women. Bivariate analyses were conducted comparing women with HER-2+ BC who developed BM to women with metastasis to other organs using t-test for continuous variables and Chi-square or Fisher's exact tests for categorical variables. All significance tests were two-sided and p-value < 0.05 was considered significant.
Results: 42 women diagnosed with HER-2+ primary BC were analyzed. 27 (64%) of women developed BM. The mean age (±SD) was 51.5 (12.9) years for women with BM and 51.3 (14.1) years for no BM (p=0.96). There was no association between race and BM occurrence (White: 64% vs. other: 67%; p=1.00). The median tumor size (IQR) was 18.5 (12-31) mm for women with BM and 27.5 (13-50) mm for no BM (p=0.26). There were no significant differences in cancer histology, hormonal receptors positives (ER+/PR+), or BC management. Liver metastasis was associated with increased risk of brain metastasis (82% vs. 18%; p=0.04). The estimated median time to BM was 1.4 (95% CI: 0.9-2.7) years. Almost half 18 (42.9%) of women died. The estimated median time to death was 4.3 (95% CI: 2.2-5.2) years.

Conclusions and Significance: This descriptive small study found that diagnosis of liver metastasis was associated with increased risk of BM. Brain MRI use in women diagnosed with liver metastasis could be beneficial to cancer. Future studies should use the National Cancer Database to have the adequate power to detect other risk factors for developing BM. Lastly, examining differences in pathological molecular biology by comparing the differences in the breast primary lesions of patients with BM and those without BM could be helpful in predicting the occurrence of BM.

P5-05-06: Factors Influencing Long-Term Remission in HER2-Positive Metastatic Breast Cancer Patients Treated with Trastuzumab-based Therapy: A Single-Center Retrospective Analysis

Aydah AlAwadhi, Abubaker Hassan, Safia Alnaqbi, Waed Sumairi, Mouza AlShebli, Tallal Younis

Introduction: Approximately 20% of individuals diagnosed with breast cancer progress to metastatic disease. Overexpression of the HER-2 oncogene occurs in 15-20% of breast tumors and typically signifies a more aggressive tumor biology. Trastuzumab therapy has been linked to prolonged survival, especially among patients who achieve more than 2 years without disease progression while on treatment. This study examines baseline characteristics and identifies factors associated with extended response or remission to initial trastuzumab-based therapy, focusing on patients who have benefited from treatment for more than 5 years.

Methods: We retrospectively identified 105 patients diagnosed with HER2-positive recurrent and de novo metastatic breast cancer between 2015 and 2019 from the Tawam Hospital pharmacy database. The primary endpoint of the study was the time to tumor progression. We categorized patients based on their response to trastuzumab-based therapy, specifically comparing those with treatment durations of 5 years or more to those with less than 5 years. Univariate and multivariable logistic regression models, incorporating variables with a p-value ≤ 0.25 from unadjusted analysis, were employed to explore the association between achieving a time to tumor progression greater than 5 years and various risk factors. Data analysis was conducted using R software version 4.3.1

Results: The median age at diagnosis of metastatic disease was 47 years (interquartile range, 37–53 years). Among the patients, 78 (74%) remained in remission for less than 5 years, while 27 (26%) achieved remission for 5 years or more, with 22 of these patients continuing therapy at the time of abstract preparation. In univariate analysis, factors significantly associated with achieving a time to tumor progression greater than 5 years included age at diagnosis (OR = 1.04, 95% CI [1.00-1.09], p = 0.030), T3-4 stage (OR = 3.11, 95% CI [1.17-8.68], p = 0.023), N2-3 stage (OR = 0.31, 95% CI [0.08-0.96], p = 0.042), ECOG performance status of 2-3 (OR = 0.22, 95% CI [0.03-0.82], p = 0.022), recurrent disease (OR

= 0.16, 95% CI [0.04-0.45], p < 0.001), and presence of brain metastases (OR = 0.07, 95% CI [0.00-0.37], p < 0.001). In multivariate analysis, age at diagnosis (adjusted OR = 1.06, 95% CI [1.01-1.12], p = 0.030), grade 3 diagnosis (adjusted OR = 0.26, 95% CI [0.06-0.99], p = 0.048), recurrent disease (adjusted OR = 0.22, 95% CI [0.05-0.80], p = 0.021), presence of central nervous system metastases (adjusted OR = 0.06, 95% CI [0.00-0.45], p = 0.004), and treatment interruption (adjusted OR = 8.50, 95% CI [2.30-38.1], p = 0.001) remained significantly associated with achieving a time to tumor progression greater than 5 years. Cardiac toxicity associated with trastuzumab-based therapy was observed in 2 patients within the study cohort, necessitating treatment interruption in one case and discontinuation in another.

Conclusion: The study identifies factors associated with prolonged remission (>5 years) in HER2-positive metastatic breast cancer patients treated with trastuzumab based therapy. Older age at diagnosis, lower disease stage and grade, better performance status, Denovo metastastases, and no brain metastases predict favorable outcomes. These findings underscore the importance of early diagnosis, treatment adherence, and tailored management approaches for improving long-term prognosis in this group.

P5-05-07: A prospective, multicenter, single-arm clinical study of inetetamab combined with pyrotinib and capecitabine/vinorelbine in the treatment of HER2-positive metastatic breast cancer resistant to previous trastuzumab treatment

Yan Xue, Junmei Zhang, Xuezheng Wang, Donghui Li, Dongmei Jiang, Yefa Gao, Xingyan Li

Background: Inetetamab is an innovative Fc-modified monoclonal antibody targeting human epidermal growth factor receptor 2 (HER2). Pyrotinib is a tyrosine kinase inhibitor (TKI). Theoretically, the combination of a large-molecule monoclonal antibody and a small-molecule TKI can exert a better antitumor effect. In the study, inetetamab in combination with pyrotinib and capecitabine/vinorelbine was used to treat HER2-positive metastatic breast cancer (MBC) that was previously resistant to trastuzumab. This study evaluated the efficacy and safety of the treatment regimen and conducted an exploratory analysis of the clinicopathological characteristics of the benefiting population.

Methods: The prospective, multicenter study enrolled 40 patients with HER2-positive MBC who received inetetamab in combination with pyrotinib and capecitabine/vinorelbine between December 2020 and December 2023. All enrolled patients were previously resistant to trastuzumab treatment. The primary endpoint was progression-free survival (PFS) estimated using the Kaplan-Meier method. The secondary endpoints were objective response rate (ORR), disease control rate (DCR), and safety.

Results: Among all patients receiving treatment, the median number of treatment lines was

3, and the median PFS was 8.2 months (95% CI 2.860-13.540). The correlation between different clinicopathological characteristics and mPFS was assessed using the Kaplan-Meier method. The results showed that significant associations with mPFS were observed for estrogen receptor (HR) positivity (P = 0.019), disease-free survival (DFS) > 24 months (P = 0.005), absence of lung metastasis (P = 0.017), Eastern Cooperative Oncology Group (ECOG) performance status score of 0-2 (P < 0.001), ≤3 lines of inetetamab treatment (P < 0.001), secondary resistance to trastuzumab (P = 0.011), no prior TKI treatment (P < 0.001), no prior antibody-drug conjugate (ADC) treatment (P < 0.001), and no prior cranial radiotherapy (P = 0.026). Multivariate analysis using the Cox model revealed that the independent prognostic factors affecting mPFS were no prior TKI treatment (HR = 0.260, 95% CI 0.079-0.859, P = 0.027) and ≤3 lines of inetetamab treatment (HR = 0.128, 95% CI 0.025-0.654, P = 0.014). In this study, the ORR was 62.5%, and the DCR was 77.5%. The Fisher's exact test was used to examine the correlation between different clinicopathological characteristics and ORR. The results suggested significant associations with ORR for DFS > 24 months (P < 0.001), ECOG performance status score of 0-2 (P = 0.009), ≤3 lines of inetetamab treatment (P < 0.001), secondary resistance to trastuzumab (P = 0.021), no prior TKI treatment (P = 0.003), no prior ADC treatment (P = 0.008), and no prior cranial radiotherapy (P = 0.018). The most common adverse reactions of all grades in this study were diarrhea (95.0%), leukopenia (45.0%), neutropenia (42.5%), anemia (37.5%), fatigue (40.0%), increased aspartate aminotransferase (AST) (37.5%), increased alanine aminotransferase (ALT) (35.0%), and nausea (30.0%). The incidence of severe adverse reactions of grade 3 or above was relatively low (all < 20%).

Conclusion: The combination of inetetamab with pyrotinib and capecitabine/vinorelbine can serve as a good treatment option for HER2-positive MBC that is resistant to trastuzumab. In particular, patients who have not received TKI treatment before and have ≤3 lines of inetetamab treatment can experience more significant benefits in terms of PFS. All adverse events (AEs) are controllable and tolerable.

Clinical trial information: ChiCTR2300074366.
Research Sponsor: None.

P5-05-08: Inetetamab-base regimens for patients with HER2-positive metastatic breast cancer and brain metastases: a real-world retrospective study

Liping Chen

Background: Although huge progresses have been achieved in treating HER2-positive BC, HER2-positive metastatic breast cancer (MBC) remains incurable, nearly 70% to 75% MBC patients will progression after first-line treatment with trastuzumab, posing a disproportionate health burden on patients and presenting a substantial unmet medical need.

Breast cancer metastasizes to the brain is a late event, which will happen to approximately 50% of patients with HER2+ breast cancer, with a median survival of 7 to 18 months after diagnosis. In recent years, a growing number of small-molecule TKIs produce an antitumor effect on the brain. However, whether monoclonal antibodies plus small-molecule TKIs can exactly enhance the treatment efficiency of breast cancer with brain metastasis patients requires further verification.

Inetetamab is a Chinese-origin recombinant anti-HER2 monoclonal antibody with aminoamides modified Fc segment which optimizes the antibody-dependent cellular cytotoxicity (ADCC) effect. Herein, we assessed the efficacy and safety of inetetamab-containing regimens in patients with HER2-positive metastatic breast cancer (MBC), particularly focused on the benefits by patients with brain metastases.

Methods: We retrospectively reviewed the medical records of patients with HER2-positive MBC who received inetetamab-containing regimens as a salvage treatment at any line setting from December 2020 and April 2024.The primary end point was progression-free survival (PFS) in the total population (TP). Secondary end points included PFS in the subgroup with brain metastases, objective response rate (ORR), disease control rate (DCR), and safety. The study is ongoing, but recruitment is complete.

Results: At the data cutoff date of June 1,2024, a total of 90 patients were enrolled in this analysis. Median follow-up duration was 7.2 months (IQR 3.6–13.1). The median PFS reached 12 months (95% confidence interval [CI] 7.3 to 17 months) in the TP. The ORR was 46.7 % (42/90), and the DCR was 92.2 % (83/90). The median PFS of first-line, second-line, third-line or above were not reach,15.9 months (95% CI 11.9 to NA months),5.9 months (95% CI 4.4 to 12.2 months), respectively. Cox univariate and multivariate analyses demonstrated that first- and second-line was the significant favorable prognostic factor for PFS (treated as first- and second-line vs third-line or above: 15.9 vs 5.9 months, p=0.0021). 30 out of 90 patients had brain metastases, the median PFS in the subgroup with brain metastases reached 12 months (95% CI 4.7 to 19.3 months). Notably, in this subgroup, the median PFS had no significant differences with overall patients (p=0.568), ORR was 53.3% (16/30), DCR was 96.7% (29/30). Furthermore, subgroup analysis revealed a median PFS of 12 months (95% CI 5.5 to 18.5 months) in patients with brain metastases radiotherapy (N=22). The most frequently combine target regimen was pyrotinib or apatinib (29/30, 96.7%).

The most common treatment-related adverse events (frequency ≥ 10%) were diarrhoea (52.2%), vomiting/ nausea (20%), fatigue (20%), and leukopenia (18.9%). Grade≥ 3 treatment-related adverse events mainly were diarrhea (12.2%). No grade 4 diarrhea or cardiac-related events were reported.

Conclusion: Inetetamab offers a promising option and a manageable safety profile for HER2-positive MBC who pretreated with multiple-line therapies. Meanwhile, Inetetamab plus small-molecule TKIs regimens show the activity in brain metastases population, which deserve further validation in a larger group trial.

P5-05-09: Trastuzumab deruxtecan combined with pyrotinib in first-line HER2-positive unresectable or metastatic breast cancer: an exploratory, multi-center, single-arm, phase Ib/II study (TROPHY)

Ying Fan, Huihui Li, Huiping Li, Zhenchuan Song, Ling Xu, Jin Yang, Jing Yao, Haijun Yu, Danyang Ji, Yuhang Han, Binghe Xu

Background: Trastuzumab deruxtecan (T-DXd), a human epidermal growth factor receptor 2 (HER2)-directed antibody-drug conjugate (ADC), has demonstrated remarkable efficacy in the second-line or later treatment of HER2-positive (HER2+) metastatic breast cancer (mBC) and its exploration as the first-line (1L) treatment (DESTINY-Breast09) is ongoing. Combining T-DXd with pertuzumab may further enhance the efficacy seen with T-DXd monotherapy. Pyrotinib, an irreversible, pan-HER receptor tyrosine kinase inhibitor (TKI), has also been approved in combination with trastuzumab and docetaxel for the 1L treatment of HER2+ mBC and is widely used in China. As preclinical and clinical studies have shown the synergistic effects of HER2 ADCs combined with TKIs (Olson D, et al. Cancer Res Commun 2023; Borges VF, et al. JAMA Oncol 2018), this study evaluates the efficacy and safety of the promising combination regimen of T-DXd plus pyrotinib for the 1L treatment of HER2+ mBC in China (TROPHY, NCT06245824). Here we will report the results from phase Ib of this study.
Methods: This multi-center, single-arm, phase Ib/II study was conducted in 8 sites in China and is comprised of a dose finding stage (phase Ib) followed by a dose expansion stage (phase II). Patients with no prior chemotherapy or HER2-targeted therapy in the metastatic setting who have experienced relapse with a disease-free interval (DFI) > 6 months from the completion of neoadjuvant or adjuvant treatment to advanced or metastatic diagnosis are eligible for enrollment. Asymptomatic or treated brain metastases is allowed. The primary objective of phase Ib was to assess safety and tolerability and determine the recommended phase 2 dose (RP2D). Patients were followed up beyond the 21-day dose-limiting toxicity (DLT) period for safety events. The primary objective of phase II was to evaluate the efficacy of T-DXd plus pyrotinib as the 1L treatment of HER2+ mBC.
Results: As of 28 Jun 2024, 5 HER2+ mBC patients were treated with T-DXd 5.4 mg/kg every 21 days (Q3W) plus pyrotinib 400 mg (n=2) or 320 mg (n=3) once daily as starting dose, with a median duration of follow up of 3.5 months (range, 0.7-5.4). The median age of enrolled patients was 47 years (range, 33-68), and all of them had an ECOG performance status (PS) of 1, 60% (3 of 5) with visceral metastases. The only DLT was grade 3 anorexia, which occurred during the first cycle in 1 patient who received 400 mg of pyrotinib. This was followed by a de-escalation to the pyrotinib 320 mg cohort, where no DLT occurred. The most common treatment-emergent adverse events (TEAEs) included diarrhea (100%, 5 of 5), nausea (100%, 5 of 5), vomiting (100%, 5 of 5), anorexia (60%, 3 of 5), alanine aminotransferase (ALT) increased (60%, 3 of 5), aspartate aminotransferase (AST) increased (60%, 3 of 5), and weight loss (60%, 3 of 5), etc. Grade 3 TEAEs included anorexia and ALT increased (in 1 patient in the pyrotinib 400 mg cohort), and diarrhea (in 1 patient in the pyrotinib 320 mg cohort). There was no grade 4 or 5 TEAEs. All 4 patients whose tumors were evaluable had achieved partial responses.

Conclusions: Pyrotinib 320 mg was identified as RP2D. The combination regimen of T-DXd plus pyrotinib showed a manageable safety profile with preliminary antitumor activity as the 1L treatment in patients with HER2+ mBC and will be explored in phase II stage.

P5-05-10: Real-world treatment patterns and clinical outcomes of first-line therapy and first-line maintenance therapy in patients with human epidermal growth factor 2-positive metastatic breast cancer

Agreen Hadadi, Edward Neuberger, Brian T. Pittner, Karen Watkins, Ziqi Zhou, Cynthia Gutierrez, Karen Bartley, Jane Meisel

Background: In patients with HER2+ MBC, treatment guidelines recommend first-line (1L) combination therapy with a taxane, trastuzumab, and pertuzumab (THP), followed by 1L maintenance therapy with trastuzumab and pertuzumab. Real-world data on treatment patterns and clinical outcomes with 1L therapy and, in particular, 1L maintenance therapy in patients with HER2+ MBC are limited. Furthermore, while brain metastases (BM) are less common at 1L initiation, up to 50% of patients with HER2+ MBC will eventually develop BM, often during 1L maintenance.
Objective: To describe patient characteristics and treatment patterns overall, and clinical outcomes with THP, in patients with HER2+ MBC, including patients with BM prior to or at 1L initiation, receiving 1L therapy and 1L maintenance therapy in the real-world setting.
Methods: This retrospective cohort study included female patients (≥18 years old) diagnosed with HER2+ MBC between January 2012 and February 2024 in the Flatiron Health Metastatic Breast Cancer Enhanced Datamart who received 1L therapy in real world clinical practice settings. Patients with BM were those with BM prior to or at 1L initiation. Key outcomes for patients who received 1L THP, including time to discontinuation (TTD), time to next treatment (TTNT), and overall survival (OS), were assessed from 1L initiation date (index date) until data cut off or death using the Kaplan-Meier method. Induction duration for patients who received 1L THP was defined as time from index date until 20 days after last administration of taxane. Maintenance duration was defined as time from 21 days after last administration of taxane until the end of 1L maintenance with trastuzumab and/or pertuzumab.
Results: A total of 4739 patients with HER2+ MBC received 1L treatment and met inclusion criteria, including 606 patients with BM at or prior to initiating 1L therapy. At 1L initiation, 2382 (50.3%) patients received dual HER2-targeted therapy, 1727 (36.4%) single HER2-targeted therapy, 310 (6.5%) chemotherapy alone, and 320 (6.8%) other regimens. In patients with BM, 234 (38.6%) received dual HER2-targeted therapy, 319 (52.6%) single HER2-targeted therapy, 28 (4.6%) chemotherapy alone, and 25 (4.1%) other regimens. Overall, 1878 (39.6%) patients received 1L THP, and their median (95% CI) TTD was 14.0 (13.0–15.0) months, median (95% CI) TTNT was 15.0 (14.0–16.0) months, and median (95% CI) OS was 57.0 (53.0–63.0) months. In the subset of patients who had BM at or before 1L initiation who received 1L THP (n = 147, 24.3%), median (95% CI) TTD was 12.0 (9.6–14.0) months, TTNT 12.0 (9.7–14.0) months, and OS 29.0 (26.0–40.0) months. Of those

who received 1L THP, 1289 of 1878 patients (68.6%), including 87 of 147 (59.2%) with BM, received 1L maintenance therapy. Median (IQR) duration of induction therapy was 4.2 (3.6–4.9) months overall and 4.2 (3.5–5.6) months in patients with BM. Median (IQR) duration of maintenance therapy was 9.4 (4.1–22.6) months overall and 6.9 (3.3–18.2) months in patients with BM.
Conclusion: Patients with HER2+ MBC were treated with a range of 1L regimens during the study period. Less than half of the patients received guideline-recommended 1L THP; of these, real-world outcomes including OS were poorer in patients with BM compared with the overall group. While median duration of induction therapy was similar between the overall cohort and patients with BM, patients with BM had a shorter duration of maintenance therapy than patients overall. These data highlight the unmet need for effective 1L treatment options in patients with HER2+ MBC, particularly patients with BM. Ongoing clinical trials evaluating HER2-targeting regimens in the 1L maintenance setting may offer additional options for improved outcomes in this treatment landscape.

P5-05-11: Systematic review of ADCs vs chemotherapy in 2L+ Her2+ mBC

Bruno Larvol, Mark Gramling

Antibody-drug conjugates (ADCs), which combine monoclonal antibodies with cytotoxic payloads, have revolutionized cancer treatment by providing more effective and selective therapies with less toxicity than traditional chemotherapy.
A systematic search in LARVOL CLIN- a database of 100k+ trials, 95k+ Kaplan-Meier (KM) curves, and 15k+ Hazard Ratios (HRs)- was conducted to identify trials comparing ADCs and chemotherapy in 2L+ for Her2+ metastatic breast cancer (mBC). A meta-analysis was performed on phase 3 trials using digitized KM data and HRs extracted from forest plots. Biomarker subgroup populations were evaluated in the context of ADC response and were verified using VERI, a precision oncology database.
Only 5 trials had mature survival data on ADCs vs chemotherapy. All trials used trastuzumab as the antibody, and ADCs varied in payload and linker. TH3RESA and EMILIA assess T-DM1 (trastuzumab emtansine); DESTINY-Breast02 and DESTINY-Breast04 evaluate T-DXd (trastuzumab deruxtecan); and TULIP examines T-Duo (trastuzumab duocarmazine). The primary outcome in all these trials was progression-free survival (PFS) and for TH3RESA and EMILIA Overall survival (OS) as well. The evaluated ADCs prove their efficacy in treating Her2+ mBC compared to the respective controls (HR PFS: 0.52* [TH3RESA]; 0.69* [EMILIA]; 0.3* [DESTINY-Breast02]; 0.36* [DESTINY-Breast04]; 0.64* [TULIP]; and HR OS: 0.68*. [TH3RESA]; 0.75* [EMILIA]; 0.69* [DESTINY-Breast02]). However, ADC benefit may be higher for T-DXd compared to T-Duo (ORR: 74.1% vs 27.2% [DESTINY-Breast02]; 52% vs 16% [DESTINY-Breast04] and 27.8% vs 29.5% [TULIP]). In contrast to standard chemotherapy, patients benefit from T-DM1 and T-XDd regardless of PIK3CA mutation status (HR PFS for PIK3CA mutated vs PIK3CA wild-type: 0.44* vs 0.47* [TH3RESA]; 0.45* vs 0.74 [EMILIA]; 0.6* vs 0.5* [DESTINY-Breast04]) and PTEN expression levels (HR PFS for increased PTEN expression vs decreased PTEN expression: 0.4* vs 0.49* [TH3RESA]; 0.78 vs 0.55* [EMILIA]). Regarding Her2 expression, while DESTINY-Breast04

evaluated Her2+ low mBC, patients with higher mRNA expression levels benefit most from ADC treatment (HR PFS for Her2 expression high vs Her2 expression low: 0.68* vs 0.4* [TH3RESA]; 0.64* vs 0.65* [EMILIA]; 0.55* vs 0.48* [DESTINY-Breast04]).
ADC-targeted therapies open significant new opportunities with more than 200 trials in phase 3. T-DM1 with DM1 as payload and T-DXd with deruxtecan are approved for Her2+ mBC patients after anti-Her2 regimens. However, T-Duo with seco-DUBA as payload, despite fulfilling its PFS primary outcome, did not reach OS statistical significance, causing FDA approval to be paused. Regardless of PIK3CA mutations and PTEN loss, which could be expected to drive Her2 pathway activation, T-DM1 and T-DXd are effective. While T-DM1 and T-DXd demonstrate enhanced benefit with relatively elevated Her2 mRNA levels, bot∫h remain effective even in cases of low Her2+ mBC.

P5-05-12: Real-world outcome of patients with HER2-positive metastatic breast cancer who were treated with inetetamab-containing regimens: A multicenter retrospective analysis conducted in China

Huihui Li, Dongdong Zhou, Zhiyong Yu, Changping Shan, Chongsheng Xia, Lihua Song, Baoxuan Zhang, Shu Fang, Hongjian Wang, Fan Yang, Ling Qiang, Guohua Ren, Jiale Zhang, Lingyu Kong, Jingfen Wang, Guozhu Liu

Background: Inetetamab is a novel anti-HER2 humanized monoclonal antibody with the same Fab segment as trastuzumab, but its Fc segment is modified by amino acids to provide stronger antibody-dependent cell-mediated cytotoxicity(ADCC). This study aimed to observe real-world outcome of inetetamab-containing regimens in HER2-positive metastatic breast cancer (MBC), and explore more effective and safe treatment strategies for these patients(pts).
Methods: This was a multicenter, retrospective, real-world study. A cohort of HER2-positive MBC pts who received inetetamab-containing regimens between November 2020 and March 2023 was evaluated. The primary endpoint was progression-free survival (PFS), according to the Response Evaluation Criteria in Solid Tumors, version 1.1. Secondary endpoints included objective response rate (ORR) and disease control rate (DCR). Adverse events (AEs) were graded according to the National Cancer Institute Common Toxicity Criteria version 5.0.This trial has been registered with the Chinese Clinical Trial Registry under the number ChiCTR2200061413.
Results: A total of 136 pts were included in the final analysis. The median age of the enrolled pts was 53 years (range 27–90 years). 15 pts had de novo stage IV cancer (11%), and 121 pts had recurrent disease (89%). The median number of treatment lines administered was 3 (range 1–11). In total, 136 pts were included: 47 pts received ≤2nd-line treatment, and 89 pts received ≥3rd-line treatment. Most pts had received other anti-HER2 therapies prior to receiving inetetamab. 94.9% of pts had received trastuzumab(129/136), and 28.7% had received both trastuzumab and pertuzumab(39/136). Additionally, 67.6% of pts had prior treatment with trastuzumab and HER2-TKIs in anti-HER2 regimens (92/136).The median PFS(mPFS) of the entire cohort was 5.7 months (95% CI 4. 97-6.44 months). The ORR was

33.1% (45/136) and the DCR was 75% (102/136). The mPFS of the ≤2nd-line treatment group was 9.8 months (95% CI 3.35-16.25 months), which was significantly better than ≥3rd-line treatment group at 5 months (95% CI 3.87-6.13 months, P＜0.001). The mPFS was 12.07 months in the subgroup that previously received trastuzumab without TKIs(95% CI 8.46-15.68 months). This was significantly longer than the mPFS of 5.4 months in the subgroup that had received trastuzumab with HER2-TKIs (95% CI 4.62-6.18 months, P=0.001).The most common adverse events (AEs) were leukopenia (31.6% [43/136]), neutropenia (27.2%[37/136]), diarrhea (19.1%[26/136]), nausea (16.2%[22/136]), and fatigue (13.2% [18/136]). Among these, grade 3 or 4 AEs were leukopenia (15.4% [21/136]), neutropenia (11.7% [16/136]), and diarrhea (8.1% [11/136]). No treatment-related serious adverse events or deaths occurred.
Conclusion: Inetetamab, a novel anti-HER2 therapeutic option, has demonstrated encouraging efficacy with manageable toxicity in patients with HER2-positive metastatic breast cancer. It could be considered as an alternative treatment option for these patients.

P5-05-13: Assessment of efficacy and pulmonary toxicity of Trastuzumab Deruxtecan in HER2-positive and HER2-low Metastatic Breast Cancer in United Arab Emirates

Mohammad Hourani, Rawan Bdair, Khaled Alqawasmeh, Aydah Alawadhi, Emad Dawoud, Husam Marashi, Selvaraj Giridharan, Diaeddin Trad, Jawaher Ansari

Background: Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody-drug conjugate indicated for the treatment of unresectable or metastatic HER2-positive (IHC 3+ or ISH positive) breast cancer who have received a prior anti-HER2-based regimen. T-Dxd is also indicated for unresectable or metastatic HER2-low (IHC 1+ or IHC 2+/ISH-) breast cancer, following prior chemotherapy in the metastatic setting or recurrent disease within 6 months of adjuvant chemotherapy. This study aims to evaluate the efficacy and safety of T-DXd in treating HER2-positive, and HER2- low metastatic breast cancer (MBC) patients in a real-world clinical setting. In the T-DXd pivotal clinical trials, response assessments were conducted every 6 weeks with CT or MRI and outside of a clinical trial setting, this frequent imaging is not practically feasible and is not reimbursed. We sought to review the incidence of pneumonitis in a real-world setting and to assess if the 3-monthly response assessment scans would be sufficient to rule out asymptomatic pneumonitis.
Methods: A retrospective analysis was conducted on 100 patients diagnosed with HER2-positive (IHC 3+ or ISH positive) or HER2-low (IHC 1+ or IHC 2+ and ISH negative) MBC treated with T-DXd at 5.4mg/kg every 21 days, with standardised dose adjustments as required. Treatment was continued indefinitely until disease progression or development of intolerable side effects. Responses were assessed using RECIST v1.1 criteria, and toxicity was determined using the CTCAE version 5.0. Data analysis was performed using the SPSS IBM software version 26.

Results: The median age was 47 years (range: 29-86); 92% were <65 years; 99% were

female. All patients had an ECOG performance status of 0-1at baseline. Eighty two percent of patients were HER2-positive (IHC 3+ or ISH positive), while 18 % were HER2-low (IHC 1+ or IHC 2+ and ISH negative). Seventy nine percent had visceral disease, 31% had brain metastases at baseline, 47% were hormone receptor positive (HR+), 55% had grade 3 disease, and 57% had high Ki-67 of > 20%. Sixty nine percent of patients had received T-DXd in the 2nd and 3rd line setting (34% and 35%, respectively). Partial response, complete response and stable disease was observed in 65%, 10% and 9% of patients, respectively. Overall survival at 12 months and 24 months was 81.5% and 59.5%, respectively. Progression-free survival (PFS) at 12 months and 24 months was 73% and 43.5%, respectively. Median PFS was 24 months (95% CI 16.90-31.09). Only one patient developed grade 3 pneumonitis suggesting that perhaps the 12-weekly assessment imaging is sufficient for the vast majority of patients.

Conclusions: Our real-world experience confirms that the efficacy of T-DXd in UAE is consistent with published data from published phase 3 clinical trials. The incidence of ILD is much lower than anticipated and until further data is available it may be reasonable to continue using the 12-weekly assessment scans to monitor patients for ILD. Further studies are needed to determine the optimal imaging frequency for monitoring ILD.

P5-05-14: Real-World Treatment Patterns and Clinical Outcomes of Inetetamab combined with pyrotinib plus chemotherapy in Her-2 negative metastatic breast cancer patients : a multi-center retrospective study

Huanhuan Zhou, Chao Deng, Lu Gan, Fan Li, Xuefeng Xu, Yanman Fang, Xiaowei Qi, Weigang Bian, Zeshun Yu, Zhanhong Chen, Xiaojia Wang

Background: Inetetamab is an innovative anti-HER2 monoclonal antibody. Studies indicated that the combination of the use of dual anti-HER2 components with complementary mechanisms of action will improve anti-tumor effect. The study aims to investigate the efficacy and safety of inetetamab combined with pyrotinib plus chemotherapy for HER2 positive metastatic breast cancer (HER2+MBC).

Methods: From July 2020 to December 2022, 99 HER2+MBC patients received at least two cycles of inetetamab combined with pyrotinib plus chemotherapy treatment regimens in in multicenters in China. Data cut-off April 2023. The primary endpoint was progression-free survival (PFS), secondary endpoints were objective response rate (ORR) and safety.

Results: In the overall population, the median PFS was 12.3 months (95% CI: 10.9-13.6), the ORR was 53.5%. Of the 99 patients in this cohort, 47(47.5%) patients received this treatment as first line (First-line subgroup) and 52（52.5%） patients as second line

(Second -line subgroup) , respectively. The median PFS in the first-line subgroup was significantly longer than that in the second-line subgroup (15.0 months [95% CI: 13.6-15.8] vs. 10.3 months [95% CI: 9.6-10.9], p<0.001). In First-line subgroup, the combination regimen of albumin-bound paclitaxel provided longer median PFS than other chemotherapy (15.0 months [95% CI: 13.6-NA] vs. 11.1 months [95% CI: 8.6-NA], p=0.012). In addition, the study included 19 patients with brain metastases. The mPFS of patients with versus patients without brain metastases was 10.5 (95% CI: 9.5-12.9) months versus 13.0 (95% CI: 11.2-15.0) months (p= 0.052). 4 patients with brain metastases in the first-line subgroup had longer mPFS of 15.6 (95% CI: 10.0-NA) months. The most common grade ≥3 treatment-related adverse events observed were leukopenia (19.2%), diarrhea (18.2%), myelosuppression (7.1%) and neutromenia (4.0%).

Conclusions: This study shows that Inetetamab combined with pyrotinib plus albumin-bound paclitaxel might be a safety and promising therapy for HER2-positive MBC, Including patients with brain metastases.

P5-05-15: Intrinsic subtype expression between durable and poor responder during anti-HER2 treatment in triple-positive breast cancer

Jieun Lee, Kabsoo Shin, Sung Hak Lee, Jae Ho Byun

Background: HER2 positive breast cancer is defined as HER2 overexpression by immunohistochemical stain or amplification of HER2 based on in situ hybridization, irrespective of ER or PR status. In Hormone receptor positive and HER2 positive breast cancer, there are crosstalk between estrogen receptor signaling pathway and HER2 pathway, and there may be difference of tumor response and biology compared to HR negative and HER2 positive breast cancer. In this study, we analyzed the intrinsic subtype of HR positive, HER2 positive breast cancer based on prediction analysis of microarray 50 (PAM50) and Breast Cancer 360 panel (nanostring) between durable and poor responder in first-line docetaxel + trastuzumab + pertuzumab (THP) treated patients.

Methods: Baseline tumor tissue was collected in 12 HR(+), HER2(+) metastatic breast cancer patients. Durable responders were defined as patients showing response over 35 months, and poor responders were defined as patients showing response less than 12 months to first-line THP. Molecular subtype was analyzed based on PAM50 and Breast Cancer 360 Panel.

Results: Total 6 durable responders and 6 poor responders with adequate tumor tissue were enrolled for the study. Before the analysis, authors hypothesized that durable responders would show HER2 enriched subtype and poor responders will show luminal subtypes. In final analysis, durable responders, 4 patients were classified as HER2 enriched, and 2 patients were luminal A subtype. In poor responders, 3 patients were Her2 enriched, 2 patients were luminal A, and 1 patient was classified as luminal B. Based on PAM50, patients were clustered based on cell differentiation, tumor inflammation signature (TIS)

and MHC2 expression. Durable responders showed relatively high expression for ER signaling and cytokine & chemokine expression.

Conclusions: Other than HER2 pathway, ER pathway and inflammatory signal may influence the tumor response of HR(+), HER2 (+) breast cancer. Further clinical trials should be designed based not only on HER2 status, ER status and other molecular subtypes should be considered to maximize the clinical benefit.

P5-05-16: Real-world analysis of inetetamab-based therapy for the treatment of HER2-positive advanced breast cancer.

Cailing Lin, Xiangqin Huang, Wei Chen, Zhiwu Lin

Background: Inetetamab is an Fc segment-modified innovative anti-HER2 monoclonal antibody. It has been proven to be effective and safe in HER2-positive advanced breast cancer. Here, we investigated the efficacy and safety of inetetamb-based therapy for HER2-positive metastatic breast cancer.

Methods: In this observational real world study, we investigated the medical records of eligible women who aged 18 years or older with pathologically confirmed HER2-positive recurrent or metastatic invasive breast cancer, and received at least two cycles of inetetamab combined with different treatment regimens in Fujian provincial hospital from August 2020 to present. The primary endpoint was progression-free survival (PFS) estimated by the Kaplan-Meier method. The sec- ondary endpoints were the objective response rate (ORR), disease control rate (DCR), and safety.

Results: A total of 91 patients were enrolled and 68 were included in the efficacy analysis. The patients' median age at enrollment was 54 years, 42 patients (46.2%) had hormone receptor-positive disease and 44 patients (48.4%) had visceral metastasis. The median number of treatment lines administered was two. Among them, the proportion of patients treated with trastuzumab was 80%. The median PFS was 14.0 months (95% confidence interval [CI] 11.5 to 19.0 months). Patients treated with first-line regimens benefited the most, with a median PFS of 18.0 versus (vs.) 14.0 vs. 7.5 months (first-line- vs. second-line- vs. third-line and above), ORR was 83.82% (57/68) and DCR reached 98.5% (67/68). Among 91 patients, 80 (87.9%) experienced adverse reactions (AEs). The most common AE was diarrhea, occurring in 37 patients (40.7%). No treatment-related serious adverse events or treatment-related deaths occurred.

Conclusion: Inetetamab-based therapy demonstrated promising efficacy and safety in HER2-positive metastatic breast cancer patients. Further research and comparative analysis should be necessary for therapeutic benefits.

Funding: Has not received any funding.
Disclosure: All authors have declared no conflicts of interest.

P5-05-17: Trastuzumab deruxtecan for HER2-positive and HER2-low breast cancer brain metastasis: Results from a single-institution retrospective study.

Chunfang Hao, Jie Zhang, Xiaochen Jia, Chao Xu, Yuehong Zhu

Background: Trastuzumab deruxtecan (T-DXd) has demonstrated promising outcomes in patients with breast cancer brain metastases (BMs), as evidenced by the results from the DEBBRAH, ROSET-BM, and TUXEDO-1 trials, as well as pooled analyses from the DESTINY-Breast01/02/03 studies. However, limited data exist regarding the treatment of BMs patients with T-DXd in real-world clinical settings in China. Therefore, this study aims to evaluate the impact of T-DXd therapy on HER2-positive and HER2-low metastatic breast cancer patients with BMs in the real-world context.

Methods: We conducted a single-institution retrospective real-world analysis and obtained a total of 30 patients with HER2-positive and HER2-low metastatic breast cancer with BMs who were treated with T-DXd between July 2023 and July 2024.

Results: Thirty patients were included in this study, 26 with HER2 positive and 4 with HER2-low status. At data cutoff (July 7, 2024), patients were followed up for a median of 3.6 months (95%CI [2.0; 5.2]). Patients had received a mean of three prior lines of therapy (range 1-10) and the median age was 52.5 (range 32-72). All the patients were active BMs, 17% of whom had leptomeningeal disease, and 33% received prior radiotherapy for BMs. In the HER2-positive cohort, 65% received prior TKI and 38% prior T-DM1. The ORR was 76.9%, and the intracranial (IC)-ORR was 80.8%. The DCR was 92.3%, and the IC-DCR was 84.6%. The median PFS was 8.8 months (95%CI [1.8; 15.7]). The IC-ORR for patients with the largest lesion >2cm, those treated with TKI, those treated with T-DM1, and those with prior radiotherapy for BMs was 83.3% (5/6), 81.0% (17/21), 90.9% (10/11), and 85.7% (6/7), respectively. In the HER2- low cohort, the ORR, IC-ORR, DCR and IC-DCR were all 75%. Median PFS was not evaluable due to small patient numbers. Toxicities were in line with what previously reported in larger registered clinical trials.

Conclusions: Our real-world analysis indicated a clinically meaningful intracranial activity of T-DXd in HER2-positive and HER2-low breast cancer patients with active BMs, with ORR and IC-ORR higher than 70% in the real-world clinical practice.

P5-05-18: Characterizing Patient Experience and Decision Making Associated with Considering Stopping or Pausing HER2-targeted Treatment for MBC Population Using a Questionnaire

Martha Carlson, Guy R. Adami, Maryam B. Lustberg, Tahniat Nadeem, Elizabeth Lerner Papautsky

Background: HER2+ targeted treatment for metastatic breast cancer (MBC) is one of the first successes of targeted therapy for advanced cancer, with some patients having years of disease control without any evidence of active disease progression. This has led to unanswered questions of how long HER2 targeted therapies should be continued. We aimed to characterize patient experience with anti-HER2 drugs, particularly in those with sustained disease stability.
Methods: We developed a questionnaire comprised of closed- and open-ended questions to elicit experiences of patients diagnosed with HER2+ MBC. Particular attention was directed at whether patients considered stopping or pausing HER2-targeting treatment after achieving no evidence of disease (NED) and the associated decision making process. We administered the questionnaire online via outreach to MBC patients through social media and nonprofit digital newsletters.
Results: A total of 124 people in the United States responded, 82 (66%) were diagnosed with de novo MBC and 42 (34%) were originally diagnosed with early-stage. Following initial use of a taxane +/- carboplatin + trastuzumab +/- pertuzumab, continued trastuzumab +/- pertuzumab was the most common treatment regimen among the surveyed. At least 95 (76%) had experienced =/>1 year of progression-free disease after starting treatment and 65 (52%) were NED at time of response. Eighty-five (68%) had reached NED after a median time on treatment of 6 months; among these patients, 45% stated they had either discussed or thought about discussing with their oncologist the possibility of stopping HER2-targeting treatment. Level of education was shown to be significantly associated with considering HER2 treatment termination, with more years post high school education corresponding with greater likelihood of having that discussion. In 32% (12/38) of cases, the discussion was initiated by the oncologist. Of these, 7 patients (18%) decided to terminate treatment. Among respondents who had considered stopping treatment, the most common reason given was side effects, followed by emotional toll of continuous treatment. Patients who achieved NED status reported that the lack of evidence for safety was the chief reason to continue treatment despite questioning its need. Many patients reported quality of life (QoL) challenges, including debilitating side effects (e.g. severe itch) and impact to their financial wellbeing. Patients' descriptions of their decision making processes ranged from "Since it's working we won't switch" to "…it was a matter of not killing myself over enduring the pain & itch" with most reporting that they made the decision together with their oncologist, although some reported that just the oncologist (11%) or just the patient (13%) made the decision.
Conclusion: Nearly half of surveyed patients who achieved NED considered stopping HER2-targeting treatment. However, the range of responses regarding the decision making process highlights a problem space in need of research attention to better characterize

barriers and facilitators associated with decision and patient-oncologist communication. We found that more educated patients were more likely to question continued HER2 treatment and that their clinicians were more likely to engage in these complex conversations. These findings indicate the potential for a treatment gap between subsets of patients that is not based on treatment efficacy nor QoL. There is a need for clinicians to be prepared for complex conversations with a high level of uncertainty and to conduct them in a way that is comprehendible to all patients to support shared decision making. Conversations about potential risks to staying on treatment or going off treatment are deserved by all patients, even if we have to wait for prospective studies, such as the ongoing Stop-HER2 (NCT05721248) and Free-HER (NCT05959291), to provide more definitive levels of these risks for the MBC population.

P5-05-19: Complete response with Alpelisib and Trastuzumab in a patient with ER/PR-negative, HER2-positive refractory metastatic breast cancer

Farah Shah, Nejina Rijal, Erin H. Lin, Sayeh M. Lavasani, Rita S. Mehta, Ritesh Parajuli

Introduction: Metastatic HER2-positive breast cancer is treated with regimens such as taxane with trastuzumab and pertuzumab followed by trastuzumab deruxtecan (T-DXd). The third line options are ado-trastuzumab emtansine (T-DM1), tucatinib with capecitabine, and trastuzumab. Mutations in the PIK3CA gene encoding PI3Kα have been reported in 12%-39% of HER2-positive breast cancers and are associated with worse prognosis. Alpelisib is an oral, α-specific PI3K inhibitor that is approved in combination with fulvestrant in hormone receptor positive, HER2-negative, PIK3CA-mutated advanced breast cancer following progression on or after endocrine therapy. Activating mutations in the PIK3CA gene are associated with resistance to anti-HER2 therapies. Combined inhibition of HER2 and PI3K overcomes this mechanism preclinically. We present a patient with estrogen and progesterone receptor (ER/PR) negative, HER2-positive, PIK3CA-mutated multidrug resistant refractory breast cancer who had a complete response to alpelisib and trastuzumab.
Case Presentation: A 63-year-old female patient underwent left mastectomy for a stage I (T1aN0M0) ER/PR-negative, HER2-positive breast cancer in 2014. Four years later, she developed a HER2-positive right axillary breast cancer which was treated with neoadjuvant chemotherapy followed by axillary nodal dissection and regional radiation therapy. Since 2018, right axillary nodal and chest wall metastases progressed on several lines of systemic therapy including lapatinib and capecitabine, trastuzumab and paclitaxel, trastuzumab and vinorelbine, fam-trastuzumab-deruxtecan-nhki (Enhertu), T-DM1, margetuximab with eribulin, and finally trastuzumab with capecitabine. A right chest wall biopsy demonstrated a high grade invasive ductal carcinoma that was ER/PR-negative and HER2-positive. Next generation sequencing revealed a PIK3CA mutation (p.H1047R). Treatment was changed to alpelisib and trastuzumab. After four months of treatment, she developed a complete response of cutaneous metastases with adverse effect of grade 2 mucositis. She continues to be under treatment and is doing well.

Conclusions: Alpelisib and trastuzumab can be a viable treatment option for patients with HER2-positive and PIK3CA-mutated metastatic breast cancer. Our case demonstrates the importance of obtaining next generation sequencing in patients with refractory breast cancer. Integrating precision medicine can elucidate mechanisms of resistance and allow treatment with combination and targeted therapies that can improve patient outcomes, similar to our patient presented in this vignette.

P5-05-20: Efficacy of Fam-Trastuzumab Deruxtecan-nxki (T-DXd) in Hormone Receptor-Negative, HER2-3+ Metastatic Breast Cancer: A Case Study

Aliya Khan, Evan Landau, Alan B Grosset, Samuel A. Kareff

Abstract: This case report evaluates the efficacy of fam-trastuzumab deruxtecan-nxki (T-DXd) in a 59-year-old woman with hormone receptor-negative, HER2-3+ breast cancer. Following initial treatment with the TCHP chemotherapy regimen (docetaxel, carboplatin, trastuzumab, and pertuzumab), the patient experienced disease progression. T-DXd was subsequently administered, resulting in significant tumor regression. This response enabled successful surgical resection and completion of adjuvant radiation therapy, marking a notable clinical outcome.

Introduction: Breast cancer in hormone receptor-negative, HER2-positive patients presents substantial treatment challenges. T-DXd, an antibody-drug conjugate (ADC), has shown promise for these patients, particularly those who have undergone prior anti-HER2 therapies. T-DXd is indicated for metastatic or recurrent HER2-positive breast cancer within 6 months of initial treatment. The frontline regimen of TCHP achieves overall response rates (ORR) of 70-80%. However, T-DXd has demonstrated superior efficacy to trastuzumab emtansine (T-DM1) in the DESTINY-Breast03 trial, making it a viable option for patients with disease progression.
According to updated assessment data, out of 246 patients treated with T-DXd, 240 (97.6%) achieved disease control. This includes:
Complete Response (CR): 21.1% (52 patients)Partial Response (PR): 61.0% (150 patients)Stable Disease (SD): 15.4% (38 patients)

Case Presentation: A 59-year-old woman with hormone receptor-negative, HER2-positive stage IIIB left breast cancer presented with large-volume disease. She commenced the first cycle of TCHP (docetaxel, carboplatin, trastuzumab, and pertuzumab), completing five cycles. However, subsequent ultrasound imaging of the left breast revealed extensive breast edema, skin thickening, and a pathologic right axillary lymph node, which, although slightly smaller than before, indicated ongoing disease activity.
A biopsy of a left breast periareolar lesion and a left flank lesion confirmed invasive ductal carcinoma involving the dermis with dermal lymphatic invasion. Immunohistochemistry

(IHC) results showed ER-negative, HER2 IHC 2+, and HER2 FISH-positive status for both specimens, consistent with invasive ductal carcinoma.
The left breast showed massive involvement with progressive cancer, indicating significant worsening of the disease. Consequently, the patient began second-line chemotherapy with fam-trastuzumab deruxtecan-nxki (T-DXd), completing twelve cycles.
An ultrasound indicated a 0.5 cm possible malignancy in the 3 o'clock position of the left breast and macrocalcifications or areas of fat necrosis in the 10 o'clock position. PET-CT scans showed that previously observed hypermetabolic lesions in the left breast and axilla were no longer seen, with improved soft tissue swelling and skin thickening, suggesting a significant reduction in disease burden, thereby facilitating the possibility of curative resection.
Following this regimen, the patient underwent bilateral mastectomy. Pathology revealed the right breast to have sclerosing adenosis and cysts with no malignancy, while the left breast contained two distinct foci of invasive ductal carcinoma (9 mm and 10 mm), with all margins negative and no skin involvement. Reactive lymph nodes indicated fibrosis and calcifications consistent with neoadjuvant therapy, with no metastatic carcinoma present (ypT1bpN0).
The patient experienced common side effects such as nausea and fatigue, which were manageable. However, the risk of interstitial lung disease (ILD) or pneumonitis necessitated regular CT scans and readiness to intervene with corticosteroids like prednisone.
The patient subsequently completed adjuvant radiation treatment. Despite an overall satisfactory outcome, she remains at high risk for potential future relapse, necessitating close follow-up.

Discussion: This case illustrates T-DXd's potential as an effective salvage therapy for hormone receptor-negative, HER2-positive breast cancer post-failure of first-line treatments. The patient's significant tumor regression facilitated surgical resection, previously unfeasible due to extensive disease. ADCs like T-DXd offer targeted delivery of cytotoxic agents, reducing systemic exposure and side effects, as seen in this patient's response. The EMILIA trial further reinforces T-DXd’s role as a critical option following T-DM1 progression.
This case adds to the growing evidence supporting T-DXd’s role in treating specific breast cancer subpopulations. Broader studies are necessary to validate these findings and refine patient selection. Exploring combination therapies with T-DXd could enhance treatment efficacy and outcomes.

Conclusion: Fam-trastuzumab deruxtecan-nxki (T-DXd) shows significant potential in treating hormone receptor-negative, HER2-positive breast cancer, achieving substantial tumor regression and clinical improvement. Advances in ADCs like T-DXd have transformed the therapeutic landscape, offering targeted, effective treatments with manageable side effects. While the results are promising, ongoing research and close follow-up are crucial to optimize treatment strategies and monitor for relapse in high-risk patients.

P5-05-21: Tumor/stromal infiltration of Natural Killer (NK) cells and overall survival (OS) in patients (pts) with metastatic (met) HER2+ breast cancer (BC).

Denis M Collins, Janet McCormack, Laura Ivers, Jose Javier Berenguer-Pina, Jo Ballot, Cecily Quinn, Darko Skrobo, Alex J Eustace, Naomi Walsh, Giuseppe Gullo, Janice Walshe, Aurelie Fabre, John Crown

Background: NK cells are innate immune cells capable of direct anti-tumour cytotoxicity and antibody-dependent cell-mediated cytotoxicity (ADCC). ADCC can be mediated by autologous anti-tumour antibodies (aaAbs) produced by the adaptive immune response, or monoclonal antibody (mAb) therapies like trastuzumab that are used to treat HER2+ BC. While the majority of met HER2+ BC pts progress on treatment, higher stromal tumor immune infiltrate has been associated with longer OS. Utilising the "Thousand Patient HER-2 database" project at Saint Vincent's University Hospital (SVUH) Dublin, we have identified cohorts of trastuzumab-treated met HER2+ BC pts with OS survival times ranging from 0.3 months (mos) to 223.3 mos. This study examines the tumor and stromal NK cell levels in primary and met samples in the context of OS in this patient population.
Methods: Clinico-pathological data was available for formalin-fixed, paraffin-embedded biopsy specimens (n=52 primary, n=28 met biopsies). Immunohistochemical staining was conducted for NK cells using anti-CD56 (Agilent IR62861-2). A DAKO Link 48 Autostainer was utilised for staining. Slide analysis used an Aperio AT2 Digital Slide Scanner (Leica Biosystems), Aperio ImageScope 12.4 software (Leica Biosystems) and QuPath analysis software (University of Edinburgh). Following tumor area annotation, an algorithm identified tumor or stromal NK cells. Data was expressed as number of positively stained cells/mm2 tissue. NK cells were designated as "Present" (≥1 cells/mm2) or "Absent" (0 cells/mm2) in the tumor and stromal compartments. Survival studies utilized the Kaplan Meier method. HR= Hazard ratio, CI=Confidence interval, p,0.05 is significant. Non-parametric statistical tests were utilised for independent (Mann-Whitney test) and paired (Wilcoxon signed rank test) comparisons.
Results: NK cell levels were significantly lower in the tumor compartment vs the stromal compartment for both the primary ($p<0.001$) and met sites ($p=0.04$). Paired primary and met sample (n=23) NK cell levels were not significantly different within the tumor or stromal compartments. The presence of NK cells displayed a trend towards improved OS in primary tumor (HR 0.57, CI 0.29-1.09, p=0.089)) and stroma (HR 0.50, CI 0.16-1.62, p=0.249) across all pts investigated (n=52). When the pt cohort was divided into long-term responders (>5 year OS) and short-term responders (<5 years OS), the presence of tumor-infiltrating NK cells was significantly associated with better OS in long-term responders (HR 0.21, CI 0.05 – 0.86, p=0.03), but not in short-term responders (HR 0.59, CI 0.05 – 0.28, p=0.19).
Conclusions: Our results report a link between OS and tumor NK cell infiltrate in met HER2+ BC pts with long-term responses to trastuzumab. Further expansion of this dataset is warranted.

P5-05-22: ARX788 for patients with HER2-positive advanced breast cancer: characterization, time course, and monitoring and management of adverse event from the phase III ACE-Breast-02 study

Jian Zhang, Xichun Hu, Qingyuan Zhang, Leiping Wang, Biyun Wang, Quchang Ouyang, Xiaojia Wang, Wei Li, Weimin Xie, Zhongsheng Tong, Faliang Xu, Wei Liu, Shusen Wang, Tao Sun

Background: ARX788 is a non-natural amino acid site-specific conjugated ADC with high homogeneity and stability. In the ACE-Breast-02 primary analysis, ARX788 demonstrated significantly prolonged PFS by blinded independent central review in patients with HER2-positive advanced breast cancer (HR 0.64, 95%CI, 0.49-0.82; p=0.0006). Here we report the detailed safety analysis and management of ocular and interstitial lung disease (ILD).
Methods: 441 eligible patients were randomized 1:1 to receive ARX788 or lapatinib plus capecitabine. Safety analysis was conducted until the data cutoff (DCO) of Dec. 21, 2022. Patients who had history of eye disease, or ILD/pneumonitis not requiring steroids could enter this trial if otherwise qualified. Patients with grade 1-2 ILD could continue the study treatment when showing signs of improvement, and had to discontinue treatment only when it reached grade 3 as per protocol. Chest CT was done every 6 weeks during the treatment and afterwards. ARX788 was not pre-medicated with any prophylactic measures until evident AE of any grade as per protocol. AEs were summarized using descriptive statistics; and time-to-event analyses were conducted.
Results: Totally 220 patients who received ARX788 at lease one dose of ARX788 were included in safety analysis. The overall incidence and incidence of grade ≥3 of treatment-related adverse events was 98.6% and 41.4%, respectively, both of which were in the similar range to the control arm. Grade ≥ 3 of ALT and AST increased was 1.8% and 1.4%, respectively. Grade ≥3 of thrombocytopenia was reported at 2.7%, with 0.5% resulting in treatment discontinuation. Frequencies of any grade and grade ≥ 3 of gastrointestinal toxicity were 13.2% and 0.5% in nausea, 9.1% and 0 in vomiting, 5.0% and 0.5% in diarrhea, respectively. Ocular toxicity of any grade occurred in 74.5%, while grade 3 was 19.1% with 10.5% being self-care activity of daily life compromised. There was no grade 4 or 5, SAE, perforation, ulceration or blindness, or treatment discontinuation. Moreover, 59.1% of ocular toxicity patients had recovered or been recovering till DCO. 32.7% patients had ILD. Of the 13 patients (5.9%) experiencing grade ≥ 3 ILD, early adequate doses of steroids (≥ 360 mg/day of methylprednisolone) in 4 patients reversed ILDs with no death, while three deaths of the 9 patients with lower doses or delayed use of steroids were judged to be related to ILD (1.4%). 30 patients (13.6%) who had pulmonary diseases at baseline had a significantly higher chance of developing pulmonary toxicities than those who did not in terms of any grade and grade ≥ 3 (p=0.0365 and 0.0253, respectively). Ocular toxicity and ILD occurred with median days from starting ARX788 to onset (min-max) of any grade being 29.5 (1-264) and 129 (33-528), respectively. Overall, only 4.5% discontinued ARX788 due to AEs.
Conclusions: ARX788 demonstrated a unique safety profile with less hematological and GI toxicities. Liver enzyme elevations were commonest with predominantly low grades, while

ocular toxicity and ILD were common and manageable. The low rate of dose discontinuation suggested that, when with proactive monitoring and appropriately adequate management, these AEs did not pose a challenge to its clinical benefit.
Clinical trial information: CTR20201708.

P5-05-23: Metastatic HER2+ breast cancer across a decade – who does not receive treatment?

Kathrine F. Vandraas, Sarah Hjort Andersen, Nathalie C. Støer

Background: Over the last 25 years, targeted therapy for metastatic HER2+ breast cancer (BC) has dramatically improved prognosis. Survival benefit associated with monoclonal antibodies in combination with chemotherapy, and antibody-drug-conjugates have been clearly demonstrated in clinical trials, and represent current standard of care. Patients included in clinical trials represent a selected group in terms of age and general health, not necessarily representative of the average BC patient. Cancer registries represent a unique source of real-world treatment data that reflect national treatment practices across time. These data allows for in-depth analysis of treatment patterns and outcomes in an unfiltered patient cohort, including elderly and patients with comorbidity. Identification of patients who does not receive therapy is important in order to assess the quality of cancer care provided to vulnerable patient groups.

Methods: This is a population-based study based on standardized data from the Norwegian Cancer Registry (CRN), which is of high quality and close-to-complete. All women above 18 years at diagnosis of stage IV, HER2+ BC (both de novo metastatic disease and patients progressing from early stage BC) from 2011 to the end of 2021 were included. Data from the systemic anti-cancer treatment database of the CRN, which register cancer therapy given in Norwegian Hospitals, was supplemented with the National Patient Registry (NPR) and the Norwegian Medicines Registry in order to have as complete overview of HER2 therapy as possible. The Norwegian Cause of Death Registry supplied information on cause and place of death, and Statistics Norway provided information on socioeconomic variables. Information on comorbidity was provided from the NPR. Patient characterizations, HER2 therapy patterns and clinical outcomes are reported.

Results: In total, 715 patients with HER2+, metastatic BC were identified. The majority had progressed from early stage BC (66%). Median age at diagnosis was 60 years. Among patients who had progressed from early stage BC, 44% were above 70 years. The vast majority (91%) had relapsed within the first five years after primary disease. All evaluated comorbid conditions were more frequent among patients who had progressed from early stage BC. Median time from diagnosis to death was 11 months for progressed patients compared to 20 months in patients with de novo metastatic disease.
In total, 22% of the patients did not receive any antineoplastic therapy, including chemo-

and HER2 therapy, while 28% did not receive targeted HER2 therapy. Untreated patients were older than patients who received antineoplastic therapy (median age 54 versus 77 years). Heart disease, cerebrovascular disease, dementia and diabetes was more frequent among patients who did not receive therapy. Among the 333 patients who died, untreated patients had a median survival of 2 months compared to 21 months for the treated patients. However, 46% of untreated patients lived for more than three months after metastatic diagnosis. Among patients who had progressed to metastasis, 26% did not receive cancer antineoplastic therapy (compared to 15% of the de novo patients). Less than 10% of the total cohort received more than two lines of antineoplastic therapy, but patients who did receive therapy were treated according to national guidelines.

Conclusion: In this population-based cohort of HER2+ mBC patients, a clear risk profile for not receiving antineoplastic therapy is apparent. These patients are older, more comorbid and they primarily progress from early stage BC. Prognosis among these patients are poor, but a substantial proportion live for more than three months. Further studies are needed to assess if they are under-treated, or correctly deemed unfit for systemic antineoplastic therapy.

P5-05-24: RC48-ADC (Disitamab vedotin, a HER2-directed antibody-drug conjugate) in Combination with Pyrotinib for Trastuzumab-treated HER2-Positive Recurrent or Metastatic Breast Cancer: A Phase Ib/II Study

Xinrui Liang, Ningning Zhang, Xin Zhou

Background: RC48-ADC (an antibody-drug conjugate comprising a human epidermal growth factor receptor 2 (HER2)-directed antibody, linker and monomethyl auristatin E) exerts antitumor effects in various HER2-expressing solid tumors. Pyrotinib, as Tucatinib, belongs to the family of tyrosine kinase inhibitors (TKIs). Preclinical pharmacological studies have shown that RC48 in combination with Tucatinib enhances direct cytotoxicity by upregulating HER2 expression on cell surfaces. This study aims to preliminarily explore the efficacy and safety of RC48 combined with Pyrotinib in treating Trastuzumab-treated HER2-positive recurrent or metastatic breast cancer.

Methods: Patients were administered with RC48-ADC (2.0 mg/kg, intravenous infusion, every 2 weeks) and Pyrotinib tablets (400 mg, oral administration, once daily). Treatment cycles are administered every 2 weeks until disease progression or intolerable toxicity occurs. The primary endpoint are objective response rate (ORR) and safety. Secondary endpoints were progression-free survival (PFS) and overall survival (OS).

Results: Currently, a total of three patients have been enrolled. Patient 1 presented with initially diagnosed left breast cancer with lung and bone metastases (HR+HER2+). The first-

line treatment regimen was six cycles of THP following with 18 cycles of HP; the second-line regimen was RC48-ADC combined with Pyrotinib. The PFS for RC48 combined with Pyrotinib was 10 months, with stable disease (SD) as the best response. Patient 2 presented with initially diagnosed left breast cancer with lung metastasis (HR-HER2+). First-line treatment regimen was six cycles of TH following with 4 cycles of H, and the second-line regimen was RC48-ADC combined with Pyrotinib. PFS for RC48 combined with Pyrotinib was 20 months, achieving partial response (PR) at initial assessment, with PR as the best response. Patient 3 have completed one cycle of the combination regimen of RC48-ADC and Pyrotinib, efficacy has not yet been evaluated. The most common adverse reactions included diarrhea, leukopenia, neutropenia, and anemia (≤ grade II), which were manageable and preventable.

Conclusions: The study preliminarily demonstrates the efficacy and manageable toxicity of the novel ADC (RC48-ADC) combined with a small molecule TKI (Pyrotinib). This regimen may become a new second-line treatment option for HER2-positive advanced breast cancer previously treated with trastuzumab. However, validation with a larger sample size is necessary.

P5-05-25: Real-world Treatment for HER2-positive (HER2+) Metastatic Breast Cancer Patients and Compliance to Guideline Recommendations: HER2 REAL Brazil Cohort

Carlos Barrios, Soo Chin Lee, Wei-Pang Chung, Tainan, Taiwan., Roger K.C. Ngan, Seock-Ah Im, Rina Hui, Eduardo H Cronemberger, Graziela Dal Molin, Sabina Aleixo, Antonio Matsuda, Teresa Tung

Introduction: The paucity of real-world data (RWD) imposes barriers to evidence-based decision making for managing patients (pts) with HER2+ unresectable (u)/metastatic (m) breast cancer (BC). We present current treatment practices and associated survival outcomes in HER2+ u/mBC pts in routine clinical care from the Brazil cohort of the HER2 REAL retrospective study (NCT04857619).

Method: Adult pts (≥18 years [yrs]) diagnosed with HER2+ u/mBC (index date) since Jan 2017 having ≥12 months (mo) follow-up data from diagnosis and completing ≥1-line of therapy (LOT) were enrolled based on medical chart review (data cut-off 31 Oct 2022). The primary endpoint was treatment patterns. Secondary endpoints included demographic and clinicopathologic characteristics, real-world median progression-free survival (mPFS), and median overall survival (mOS). Survival outcomes were calculated using Kaplan Meier method and presented as median (95% confidence interval [CI]). Data for the first 3 LOTs are presented.

Results: Of the 152 pts screened, 78.9% (120) were analyzed; some pts (21.0% [32]) were excluded from the final dataset due to insufficient proof of HER2 positivity or not completing ≥1 LOT in the metastatic setting. Median (range) age was 53 (25–85) yrs with 99.2% (119) females; 55.9% with available data (52/93) were postmenopausal. The median (range) time from initial BC diagnosis to index date was 18 (0–424) mo. Of those with available data at index date, 62.1% (41/66) had moderately differentiated tumors with 90.4% (66/73) having ductal histology; 29.2% (35/120) reported hormone receptor positivity (estrogen receptor: 65.7% [23/35]; progesterone receptor: 34.3% [12/35]) while data were unavailable for the rest. Of 86 pts with available data, 24 pts (27.9%) reported a family history of BC. Overall, 62.0% (62/100) with available data had visceral metastasis and 20.0% (20/100) had CNS metastases. LOT1 was received by 89.2% (107/120); 13 eligible pts were excluded because their LOT1 start date was >30 days before index date. LOT2 was received by 67.5% (81/120) pts, and LOT3 by 30.0% (36/120). Treatment attrition rates were 19.6% (21/107) after LOT1, 33.3% (27/81) after LOT2, and 11.1% (4/36) after LOT3. The top regimen in LOT1 was trastuzumab (TRA) + pertuzumab (PTZ) + chemotherapy (CT) reported in 35.5% (38/107), in LOT2 was trastuzumab emtansine (T-DM1) reported in 16.0% (13/81), and in LOT3 was TRA + CT reported in 27.8% (10/36). With a median follow-up of 35.1 (95% CI: 1.5–167.1) mo, the 2-yr survival rate was 52.0%; mOS was not estimable overall. For TRA+PTZ+CT in LOT1, real-world mPFS was 14.1 (95% CI: 9.2–21.7) mo, and for T-DM1 in LOT2, real-world mPFS was not estimable. The main reason for treatment discontinuation was disease progression (51.4% [55/107] in LOT1, 45.7% [37/81] in LOT2, and 36.1% [13/36] in LOT3); 7, 3, and 1 pt discontinued treatment due to toxicity in LOT1, LOT2, and LOT3, respectively.

Conclusion: This real-world analysis of HER2+ advanced or u/mBC showed that only a minority of pts followed the recommended guideline-directed medical therapy for the disease. These suboptimal treatment patterns are, at least partially, possibly due to access barriers and need to be further explored. These findings are in line with those reported in the HER2 REAL global dataset. This analysis highlights the need for a comprehensive study of real-world treatment patterns as they do not seem to reflect results observed in randomized clinical trials. Identification of the possible hindrances towards optimization of standard of care practices is an essential step for improving outcomes in this pt population.

P5-05-27: Multi-Institutional Quality Improvement on HER2-Positive and HER2-Low Metastatic Breast Cancer

Reshma Mahtani, Joseph Kim, Wendi Waugh, Linda Gracie-King, Marc David Viens, Victor Ocana, Jocelyn Timko

Introduction: Recent FDA approvals have expanded treatment options for patients with HER2-positive and HER2-low MBC, but these advancements also create a complex treatment landscape. Oncologists may lack experience with newer HER2-directed antibody-drug conjugates (ADCs) such as T-DXd, may need education on guideline-directed

approaches to sequencing therapies, and cancer care teams need to learn how to effectively monitor patients for unique treatment-related adverse (AEs) effects such as interstitial lung disease/pneumonitis.

Methods: Three cancer centers in the United States participated in a multi-institutional quality improvement (QI) initiative focused on HER2-positive and HER2-low MBC. The program included an online educational activity for a national audience of cancer clinicians and a QI intervention at each cancer centers. The initiative aimed to improve HER2 testing and reporting, treatment planning with HER2-directed ADCs, and management of unique treatment-related AEs. QI sites reviewed patient charts to assess their baseline practice and used Plan-Do-Study-Act (PDSA) cycles to improve care.

Results: The online educational activity was delivered to a national audience of 3,703 cancer clinicians during which 45% of participants reported they gained knowledge about second-line treatment of HER2-positive MBC, 38% learned how to manage suspected treatment-related pulmonary AEs, and 31% gained knowledge about treatment options for patients with HER2-low MBC.QI sites implemented clinical documentation changes to make it easier for oncologists to identify patients with HER2-low MBC and offer guideline-endorsed treatment with T-DXd following one line of chemotherapy. Sites observed a 36.8% increase in the use of T-DXd for patients with HER2-low MBC. Sites also achieved a 15% improvement in aligning HER2-directed therapy with NCCN guideline recommendations for HER2-positive MBC in the second-line setting. Sites revised treatment plans to incorporate a consistent approach for monitoring patients treated with T-DXd for pulmonary toxicity.

Conclusion: The program highlights the importance of ongoing education for oncologists in navigating the evolving treatment landscape for HER2-positive and HER2-low MBC. The QI program demonstrates the effectiveness of targeted education coupled with local implementation strategies to guide cancer care teams as they incorporate newer therapies into clinical practice. This project was supported by an educational grant from Daiichi Sankyo.

P5-05-28: Fully human internalizing anti-HER2 antibody with distinct epitope inhibits tumor formation of trastuzumab resistant breast cancer cells,

Ginette Serrero, Jianping Dong, Binbin Yue, Jun Hayashi

The human epidermal growth factor receptor (HER) family of receptors has been implicated in several human cancers. In 15-30% of breast cancers, HER2 overexpression and amplification are associated with shorter disease-free and overall survivals along with resistance to hormonal agents as well as increased risk of brain metastasis. Two types of

HER2 targeting have been developed: anti-HER2 monoclonal antibodies and small molecule tyrosine kinase inhibitors. Trastuzumab and Pertuzumab are humanized anti-HER2 monoclonal antibodies. Trastuzumab binds to domain IV of HER2 extracellular segment and blocks its signaling. It is the first therapeutic antibody targeting Her2 overexpression approved by the FDA. More recently, two antibody drug conjugates using trastuzumab have been approved: Kadcyla consisting of trastuzumab conjugated to the drug Mertansine DM1 and Enhertu to deliver the topoisomerase inhibitor deruxtecan. We are reporting here the development of fully human internalizing anti-Her2 antibodies that have distinct epitope to Trastuzumab and Pertuzumab. These antibodies have been developed by immunizing fully human (TC-Mab mouse) mice with recombinant Her2 protein. After production of hybridoma secreting fully human immunoglobulins, the screening process included inhibition of binding of Trastuzumab and Pertuzumab to Her2 by enzyme linked immunoassay and by Octet epitope binning as well as internalization assay. Several internalizing antibodies which did not compete with trastuzumab and pertuzumab with high affinity (Kd ranging from 10-9 M to 10-12 M) were selected. They were next investigated for their ability to deliver a cytotoxic payload duocarmycin as antibody drug conjugates (ADC) in several HER2 overexpressing breast cancer cells. Data related to these antibodies' biochemical characteristics as well as their dose-dependent ability to inhibit proliferation in vitro and in vivo in mouse xenografts studies will be presented. In particular, the effect of these antibodies in comparison to trastuzumab in trastuzumab resistant cells JIMT1 cells will be provided. These data will establish that these unique epitope antibodies were able to trigger tumor regression in these cells. In conclusion, our technology provides a powerful and attractive approach to develop fully human monoclonal antibodies against cancer targets allowing to by-pass the need for humanization and affinity maturation of antibodies.

P5-05-29: Real-world efficacy and safety of inetetamab-based therapy in patients with HER2- positive metastatic breast cancer with prior trastuzumab exposure: A prospective real-world study.

Qi Tang, Yiyin Tang, Hui Li, Yong Zhang, Ji Zhang, Shicong Tang, Xintong Zhao, Jiaqian Liao, Bingyu Ouyang, Xin Zhou, Rongkai Li, Dedian Chen

Background: Anti-HER2 monoclonal antibody works by both inhibiting HER2 pathway and inducing immune reactions such as antibody-dependent cellular cytotoxicity (ADCC) effect. Inetetamab (Cipterbin) is a neotype HER2-targeted monoclonal antibody with amino acids modified Fc segment which optimizes the ADCC effect. The combination therapy based on inetetamab can overcome the drug resistance of large-molecule monoclonal antibody drugs due to biological characteristics such as HER2 extracellular domain deletion and HER2 extracellular domain mutation leading to spatial conformational changes. This study aims to explore the efficacy and safety of inetetamab combination therapy for HER2-positive metastatic breast cancer treated with trastuzumab.

Method: This study is a single-center, prospective, observational, real-world study. It is planned to include 50 patients with HER2+ advanced breast cancer who have been treated with trastuzumab. The efficacy and safety of the inetetamab -based combination regimens that has received at least 2 cycles are evaluated. The primary endpoint is progression-free survival (PFS) estimated by the Kaplan-Meier method. Secondary endpoints are objective response rate (ORR), clinical benefit rate (CBR), and safety.

Results: From August 2021 to June 2024, a total of 30 patients with HER2+ advanced breast cancer who had been treated with trastuzumab were included in the study, with a median number of 2 lines of treatment. The combination regimens included: Inetetamab combined with patuzumab plus chemotherapy (I+P), Inetetamab combined with tyrosine kinase inhibitors plus chemotherapy (I+TKIs), and Inetetamab combined with chemotherapy (I). The median PFS of the overall patients was 17 months. The median PFS of patients who received Inetetamab combination therapy as first-line treatment was 18 months, second-line treatment was 6 months and third-line treatment or above was 23 months. Meanwhile, patients who received a combination treatment of I+TKIs achieved the most prolonged PFS of 17 months. Patients who received first-line treatment obtained better benefits. No new safety events were found in the safety analysis.

Conclusion: Inetetamab demonstrated promising efficacy and safety in HER2-positive metastatic breast cancer patients who had prior exposure to trastuzumab, particularly in combination with TKIs and chemotherapy. Further research and comparative analysis should be necessary for therapeutic benefits.
Research Sponsor: None.

rapeutic Potential of T-DXd (Enhertu): Mechanisms of Action in HER2-Low Cancers and Immunomodulatory Effects

Li-Chung Tsao, John S. Wang, Xingru Ma, Siraj Sodhi, Joey V. Ragusa, Bushangqing Liu, Jason McBane, Tao Wang, Junping Wei, Cong-Xiao Liu, Xiao Yang, Gangjun Liu, Ivan Spasojevic, Ping Fan, Timothy N. Trotter, Michael Morse, H. Kim Lyerly, Zachary C. Hartman

T-Dxd (Enhertu) is a novel antibody-drug-conjugate (ADC) targeting HER2, which has demonstrated profound clinical efficacy across breast cancers (BC) and other cancers exhibiting varying degrees of HER2 expression. However, the precise mechanism underlying its efficacy in HER2-low cancers and the role of Fc-mediated immune activation in its efficacy remain unclear. Using bystander killing studies and pharmacokinetic assessment of its payload, Deruxtecan (Dxd), we found that T-Dxd efficacy in HER2-low and HER2-negative cancers was mediated by extracellular cathepsin L proteases within the tumor microenvironment (TME). This unique mechanism enables broader Dxd cytotoxicity, bypassing traditional ADC-resistance mechanisms like HER2 downregulation and resistance to ADC-internalization. Significantly, our studies revealed that the Dxd cytotoxic payload

induces immunogenic cell death (ICD) with the secretion of specific Damage-Associated Molecular Patterns that activate myeloid cells through TLR4 and STING pathways. Additionally, the T-Dxd antibody backbone retains the capability to engage with Fcγ-receptors to stimulate Antibody-Dependent Cellular Phagocytosis (ADCP) that enhances tumor antigen uptake, which in concert with ICD responses, leads to augmented antigen presentation and expansion of tumor antigen-specific CD8+ T cells. Counteracting ADCP, we also found that T-Dxd stimulates tumor CD47 expression, which we subsequently blocked using an anti-CD47 antibody in combination with T-Dxd. This combination yielded a potent therapeutic synergy that enhanced anti-tumor adaptive immune responses, both systemically and within the TME. Critically, we found that combination therapy induces CD8+ T cell immune memory, preventing tumor recurrence post therapy discontinuation and suggests a critical therapeutic role for T-Dxd-mediated stimulation of adaptive immunity.

P5-06-01: Patient poverty burden influences the molecular biology of ER+ breast cancer

Jerry DeWitt, Elena Oropeza, Svasti Haricharan

Although the incidence of estrogen receptor positive (ER+) breast cancer is similar for Black and White women in the US, Black patients have significantly worse outcomes. Black women in the US have also have worse health care options, poorer educational opportunities, and face significantly higher rates of poverty burden. Collectively contributing to an overall lower socioeconomic status (SES) compared to White women. However, cancer health disparities research primarily exists in two forms: 1) The impact of socioeconomic factors on cancer outcomes, and 2) The molecular underpinnings associated with genetic ancestry on cancer biology. This siloing results in an incomplete picture of how systemic factors (i.e. racism, poverty burden) contribute to the biology of breast cancer in addition to, and along-with, ancestral genetics. Consequently, differences in the molecular biology between tumors from Black and White women remains a gap in knowledge in the field, because ancestral genetics cannot explain the breadth of disparities that patients face. Recent studies have found that Black cancer patients have a unique gene expression profile that may modulate treatment response. For instance, ER+ breast tumors in Black women have distinct signatures of defective DNA damage repair (DDR) that associate with more aggressive tumor growth. However, how factors of SES contribute to these differences in molecular biology and whether these differences alter treatment response remain unknown. One challenge to addressing these questions is that existing datasets significantly underrepresent Black women and are not sufficiently annotated to understand the complex interplay between molecular biology and factors of SES. Here, we present analysis of RNA expression datasets from 60 ER+ patient tumors (38 Black, 22 White), with corresponding SES and patient outcome annotations. Altogether, these data begin to define the complex interplay between factors of SES and changes in gene expression in addition to patient outcomes for women with ER+ breast cancer.

P5-06-02: Comparison of lobular vs NST hormone receptor-positive metastatic breast cancer patients in early lines of treatment via comprehensive genomic profiling and whole-genome sequencing of circulating tumor DNA

Eva Valentina Klocker, Nina Dobric, Christoph Suppan, Ricarda Graf, Julia Foldi, Ellen Heitzer, Steffi Oesterreich, Adrian V Lee, Philipp J Jost, Nadia Dandachi, Marija Balic

Background: Invasive lobular carcinoma (ILC) represents the most common special subtype of breast cancer (BC), which demonstrates different clinical and histological features, particularly in the metastatic setting. As ILC is frequently hormone receptor-positive (HR+) and HER2-negative (HER2-), we compared circulating tumor DNA (ctDNA) profiles in patients with stage IV ILC to patients with stage IV HR+, HER2- BC with non-special type (NST).

Methods: From an initial cohort of 140 HR+/HER2- patients with metastatic breast cancer (mBC), we selected 116 patients diagnosed with NST (n=95) and ILC (n=21) to perform a comprehensive subtype comparison. We analyzed circulating tumor DNA (ctDNA) from plasma samples before initiating first or second-line endocrine-based therapy. Tumor content for each sample was initially estimated using mFAST-SeqS, an untargeted aneuploidy detection method which calculates genome-wide z-scores as surrogates of tumor fraction (TF). As an orthogonal approach, we employed ichorCNA from shallow whole genome sequencing (sWGS) data to more accurately quantify TF from plasma and infer genome-wide somatic copy number alterations (SCNAs). Additionally, we performed molecular profiling using the AVENIO ctDNA Expanded 77-gene panel, which includes clinically relevant genes, across histologies. For select samples where sWGS was available, we assessed focal events of genes affected by SCNAs. For select samples with suitably high TFs, we performed high-coverage whole-genome sequencing (~20-30x) of plasma DNA to be able to infer differences in transcription factor activity between histological subtypes using the LBFextract algorthim.

Results: Analysis revealed that all patients had detectable ctDNA alterations. Among metastatic NST cases, the most prevalent alterations were in PIK3CA, TP53, ESR1, PTEN and BRCA1, whereas in ILC, the predominant alterations were in PIK3CA, AR, EGFR, ESR1, and KDR. There was no statistical difference in median genome-wide z-scores between subtypes (ILC vs. NST: median 3.57 vs. 2.52, p=0.224). Across the entire cohort, regardless of subtype, genome-wide z-scores generally correlated with ichorCNA TFs (r=0.524, p=0.007). Patients with ILC had a significantly higher number of SNVs than those with NST (median 5.0 vs. 3.0; p= 0.023). After a comparative interim analysis between cohorts via GISTIC2.0, ILC samples harbored significant focal amplifications on 11q13.3 and 11q14.1 as well as deletions on 8p11.22, whereas NST samples harbored focal amplifications on 8p11.23 and deletions on 8p23.1 and 17q21.31. At the time of submission, analysis via LBFextract on 26 high-coverage WGS datasets (NST, n=13; ILC, n=13) is ongoing to be able to identify differential

transcription factor activity between NST and ILC, potentially elucidating novel features that can stratify these two cohorts, which currently lack distinctive genomic fingerprints.

Conclusions: Based on our CGP and WGS approach for ctDNA analyses of hormone receptor positive mBC, we can elucidate distinct features of NST vs ILC in early lines of treatment, including the mutational profile, a significantly higher number of SNVs in ILC and distinct focal chromosomal aberrations. Additional analyses may improve diagnoses, treatment monitoring and understanding the underlying biology and resistance evolution of these clinically and molecularly distinct diseases.

P5-06-03: Single-cell and spatial approach to study endocrine therapy sensitivity in breast cancer models with heterogeneous estrogen receptor expression

Svetlana Semina, Rosemary J. Huggins, Huiping Zhao, Debra Tonetti, Kent Hoskins, Geoffrey L. Greene, Jonna Frasor

Although most women with estrogen receptor (ER) positive breast tumors benefit from endocrine therapy (ET), up to 40% of these patients will experience relapse. The percentage of tumor cells expressing ER varies from 1 to 100%, and some studies suggest that higher expression of ER positively correlates with ET efficiency and a reduced rate of tumor relapse. Previously, we identified a cell population with active NFκB and integrated stress response pathways that overcome selective pressure of ET and contribute to tumor relapse. However, we and others routinely use models that are enriched for ER-expressing cells to study the ET effect. Less is known about ET efficacy in breast cancers with low to moderate ER expression, which are considered to be more aggressive. In this study, we utilized patient-derived xenograft organoids (PDxOs) and single-cell RNA sequencing (scRNAseq) approach to examine how breast cancer models with low to moderate ER expression respond to ET. Alongside established PDxOs (HCI003 and HCI017), we developed two new models (UIC013 and UIC020), where 22%, 30%, 12%, and 7% of cells express ERα, respectively. Using scRNAseq and various bioinformatic tools, we found several cell populations that are common among all models, but vary in terms of prevalence, as well as some populations that were largely model-specific, indicating the models' inter- and intra-tumors heterogeneity. To predict which cell populations are sensitive to ET and which may harbor aggressive features, we examined well-established gene signatures for ER activity, ET resistance, and metastatic relapse in each cell cluster using Functional Enrichment Analysis. However, the results were inconclusive because of inconsistency among gene signatures, suggesting that the variety of models, platforms, and experimental setups used to derive these gene signatures could account for such variability. Additionally, these gene signatures were generated from bulk-RNA-seq studies, which average the signals obtained from all cell populations within a tumor and may mask signals from smaller cell populations. To experimentally identify ET-sensitive and ET-resistant cell populations, we treated each PDxO with fulvestrant and 4-hydroxytamoxifen. scRNAseq revealed that some

ER-active cells were lost following ET, indicating responsiveness, while others remained unchanged or were enriched, indicating resistance to ET. Moreover, comparative analysis of all ET-resistant cell populations among the models showed their high degree of heterogeneity, suggesting that each cell population might use different mechanisms to overcome the selective pressure of ET. To find alternative therapies for the ET-resistant cells, we performed DREEP analysis (DRug Estimation from single-cell Expression Profile), a tool predicting drug responses for 450 compounds using scRNAseq data. Multiple compounds were predicted to be effective in combination with ET, including vandetanib, a VEGFR2 inhibitor currently in clinical trials with fulvestrant for metastatic breast cancer. ET also altered ER-resistant cell transcriptomes, predicting sensitivity to several additional compounds. Overall, our findings suggest that stratifying breast cancer cell populations based on ET response, rather than ER expression or activity alone, can identify new cell populations and therapeutic strategies, thereby improving outcomes for women with breast tumors with heterogeneous ER expression.

P5-06-04: Luminal subtype independent immune-enrichment in inflammatory breast cancer based on commercially available tumor portrait.

Azadeh Nasrazadani, Rachel Layman, Vicente Valero, Sadia Saleem, Anthony Lucci, Oleg Baranov, Vladimir Kushnarev, Anna Butusova, Sofia Menshikova, Anton Gokin, Anna Novokreshenova, Konstantin Chernyshov, Nikita Kotlov, MDACC Inflammatory Breast Cancer Team, Wendy Woodward, Bora Lim

Background: Inflammatory breast cancer (IBC) is a rare subtype of breast cancer which displays an aggressive clinical course compared to non-IBC cases. Comparative genomic analyses have thus far failed to identify unique driver mutations highlighting the role of the microenvironment in IBC. Commercially available tumor sequencing and bioinformatics now provide a standardized analysis of tumor and microenvironment features. Herein, we report results from BostonGene (BG) Tumor PortraitTM analysis from a cohort of patients with IBC.

Methods: Patients with Stage III or Stage IV IBC at diagnosis enrolled to the MD Anderson Cancer Center (MDACC) IBC Registry prospectively received BostonGene Tumor PortraitTM analysis inclusive of Tumor microenvironment (TME). Preliminary analysis of the first 44 patients including descriptive statistics are reported. Tissue was from breast or regional nodes in 34 cases, distant sites in 10.

Results: Along the total population of this study undergoing this testing on tumor tissue, 18(40.9%) were diagnosed with hormone receptor positive (HR+), HER2 low negative (HER2-) IBC, 19(43.2%) had triple negative IBC (TNBC), and 7(15.9%) had HER2+ IBC (HR+ and HR-). The distribution of PAM50 molecular subtypes from 37 samples from which RNA

was available was 1(2.7%) Luminal A, 12(32.4%) Luminal B, 12(32.4%) Basal-like, and 9(24.3%) HER2-enriched. Among luminal subtypes, 9 patients had immune-enriched, non-fibrotic TME, 1 had immune-enriched, fibrotic, 3 had fibrotic, and 3 had immune-desert TME subtypes. Basal-like tissues displayed a more balanced distribution of TME subtypes (2, 2, 3, and 4 of 11; respectively). HER2-enriched samples primarily had immune desert TME (7/9) and less frequently had immune-enriched, fibrotic (1/9) and fibrotic (1/9) subtypes. Only 4.76% displayed high tumor mutational burden (TMB), and 0% demonstrated microsatellite instability. Common somatic mutations were detected in TP53, PIK3CA, RB1, PTEN, and ARID1A genes with 2 cases harboring gene fusions (CASZ1-RAD51B and FANCL-PNPT1). CCNE was frequently amplified.

Conclusions: Over half of cases with luminal molecular phenotype demonstrate immune-enriched TME, suggesting a potentially significant role for immunotherapy in these patients and expanded efforts in this arena. Using the BG Tumor PortraitTM assay, low TMB and MSS was present in the majority of IBC samples evaluated in spite of numerous studies showing common DNA repair mutations. HER2 expressing cases demonstrated a predominantly immune-desert phenotype and further study of the clinical relevance and validation of this is warranted. Correlation to clinical demographics and outcomes is ongoing.

P5-06-05: Targeting Triple-Negative Breast Cancer with a Novel Adeno-Associated Virus-mediated Therapy

Fokhrul Hossain, Soroor Heidari, Yong Ran, Jone Garai, Samarpan Majumder, Luis Del Valle, Jovanny Zabaleta, Barbara Osborne, Todd Golde, Lucio Miele

Triple-negative breast cancer (TNBC) is a group of aggressive breast cancers with a higher mortality rate. TNBC poses a major clinical challenge for several reasons: 1) molecular heterogeneity among patients, 2) intra-tumoral heterogeneity, 3) phenotypic plasticity, and 4) failure of the immune system to eliminate malignant clones. Unfortunately, there are very limited therapies for TNBC, making it a critical medical need to develop a targeted therapy. Notch signaling has emerged as an important factor in TNBC. There is strong evidence for the involvement of Notch signaling in TNBC. Recent studies suggest that Cancer Stem cells (CSC) emerging after chemotherapy or targeted agents in TNBC are often Notch-dependent. Notch inhibitors, including Gamma Secretase Inhibitors (GSI), are quite effective in preclinical models of TNBC because they eliminate CSCs that are resistant to chemotherapy. Unfortunately, this has minimal success in clinical trials due to its intestinal toxicity and adverse effect on immune cells. Notch signaling is required for T-cell activation, including CD8 effector cells mediated tumor immunity. To avoid these toxicities, we aim to use a recombinant adeno-associated virus (rAAV) vector encoding a soluble Notch1 decoy (r-AAV-Notch1D) to block Notch signaling intratumorally in TNBC. r-AAVs are non-replicating viruses and, therefore, are a safe platform for in vivo gene therapy delivery. We hypothesize that blocking Notch with intra-tumoral rAAV-Notch1D will inhibit tumor cell growth by modulating tumor microenvironments and CSCs. We found that rAAV-GFP transduced both

human and mouse TNBC cells. Our rAAV constructs contain a C1QTNF3-derived collagen domain (CD) that facilitates the trimerization and stabilization of secreted fusion proteins. This allows local concentrations of therapeutic proteins to be maintained for prolonged periods without repeated injections. We purified the Notch1D proteins from the cellular supernatants of rAAV vector-transduced cells using His-Tag affinity chromatography. We found that Notch1D proteins significantly decreased human TNBC cell mammosphere growth and Notch expression. Intertumoral injection of the rAAV-Notch1D virus significantly reduced syngeneic mouse TNBC tumor (C0321) growth without affecting the mice's weight during the experimental period. Notably, rAAV-Notch1D increased the tumor-infiltrating lymphocytes (TILs), including CD3 and CD8, supporting their role in immunomodulation. Our study represents the foundation for novel r-AAV-based therapeutic approaches for TNBC that can be combined with immunotherapy and chemotherapy for translational application in the future.

P5-06-06: The Mechanistic Role of BRCA1 DNA and RAD51 Binding in DNA Double-Strand Break Repair

Angela Jasper, Hoang Dinh, Cody M. Rogers, Sameer Salunkhe, Hardeep Kaur, Antoine Baudin, David S. Libich, Patrick Sung

Genomic instability is a hallmark of cancer, enabling the generation of mutations and gross chromosomal rearrangements to drive neoplastic cell transformation and oncogenesis. The BRCA1-BARD1 protein complex acts to eliminate highly toxic DNA double-strand breaks, to ensure the faithful propagation of our genetic blueprint and to suppress cancer development. BRCA1 is a well-described tumor suppressor protein associated with hereditary breast and ovarian cancers as well as sporadic breast cancers, with loss or mutation of BRCA1 leading to triple negative breast cancer and poor patient prognosis. The BRCA1-BARD1 complex promotes homologous recombination (HR), which is the major pathway for the accurate repair of double-strand breaks. However, there is little information regarding the intricate roles fulfilled by BRCA1-BARD1 in this process, or how loss of specific BRCA1-BARD1 functions leads to tumorigenesis. BRCA1 has been previously reported to physically interact with both DNA and RAD51, key factors in HR, but the contributions of the interaction attributes to DNA damage repair remain unknown. Here, we delineate major sites of DNA and RAD51 binding in BRCA1 and use a combination of biochemical and NMR methods to identify the specific residues mediating interactions with these ligands. This has allowed us to develop mutations to ablate BRCA1's ability to interact with these substrates without affecting BRCA1-BARD1's interaction with other key DNA repair substrates. Using these BRCA1 mutants impaired for either DNA or RAD51 binding, we have interrogated the contributions of these interaction attributes to BRCA1-BARD1's function by comparing the activity of WT to mutant BRCA1-BARD1 in biochemical assays to reconstitute various steps of HR. We have found that both DNA and RAD51 binding are indispensable for BRCA1-BARD1's ability to promote RAD51-mediated D-loop formation, thus helping to delineate the mechanism by which BRCA1 promotes HR. Our studies

provide the foundation to determine the functional consequences of cancer mutations in BRCA1-BARD1 and for the development of therapeutic strategies to target HR-deficient tumors.

P5-06-07: Luminal-to-basal subtype conversion is governed by TP53-GATA3 mutational status and is targetable by MAPK inhibition in patients with breast cancer

Min Hwan Kim, Won-Ji Ryu, Tae Yeong Kim, Yumi Hwang, Hyun-Yi Kim, Hyun Ju Han, Seul-Gi Kim, Gun Min Kim, Ja Seung Koo, Hyung Seok Park, Seung Il Kim, Joohyuk Sohn

Background: The molecular subtype largely governs therapeutic strategy in breast cancer patients, but the subtype is not static but frequently changes during treatment courses. The selective pressure on anti-tumor therapy is believed to drive lineage plasticity in luminal breast cancers, promoting a transition to basal-like phenotype and enhancing resistance against endocrine and targeted therapy. This study aims to elucidate the molecular mechanisms underlying luminal-to-basal (LB) subtype conversion through comprehensive genomic and molecular analyses.

Methods: We utilized the prospective metastatic breast cancer database to identify patients with LB subtype conversion and luminal-to-luminal (LL) subtype maintenance in matched primary and secondary tumor tissues. Whole-exome sequencing (WES) and RNA-seq were performed on available tumors of the patients (exploratory cohort). We also validated genomic alterations in a separate cohort of patients who received next-generation sequencing (NGS) for clinical practice (validation cohort). Molecular factors associated with LB conversion were manipulated in MCF7 and T47D cell lines to further explore changes driving lineage plasticitiy, including chromatin accessibility studies using ATAC-seq.

Results: Our analysis of metastatic breast cancer cohort with paired biopsy (n= 359) revealed overall 29.2% conversion rate of subtypes. LB conversion (from HR+HER2− to TNBC, 8.6%) was the most common subtype conversion and was associated with poorer survival compared to LL subtype maintenance. In the exploratory cohort, TP53 mutations were significantly more prevalent in patients undergoing LB conversion (64.3% vs. 15.4%), whereas GATA3 mutations appeared to be protective (0% vs. 23.1%). The validation NGS cohort (n=70) further confirmed the enrichment of TP53 mutation (85.7% vs. 23.2%) and the protective role of GATA3 (7.1% vs. 24.6%) in patients with LB conversion. The RNA-seq analysis indicated upregulation of KRAS-dependent signatures and decreased GATA3 expression in secondary tumors after LB conversion in TP53-mutant patients. TP53 depletion in MCF7 cells led to reduced ERα level and tamoxifen resistance, accompanied by increased accessibility in genes related to development regulation and AP-1 binding. Further combined TP53 and GATA3 depletion synergistically induced basal phenotype by activating the KRAS-MAPK pathway. MAPK inhibition restored luminal phenotype and

tamoxifen sensitivity in luminal breast cancer against LB conversion induced by TP53 and GATA3 knockdown. MAPK inhibition was also effective in overcoming endocrine therapy resistance in tamoxifen- and palbociclib-resistant breast cancer cells exhibiting the LB conversion phenotype.

Conclusion: Our findings establish TP53 mutations as a crucial predictor of LB subtype conversion in luminal breast cancers, with GATA3 mutations offering a protective effect. Combined TP53 and GATA3 loss synergistically promotes induction of basal phenotype through KRAS activation, and MAPK inhibition is a potential therapeutic strategy for luminal breast cancer patients with LB conversion.

P5-06-08: Molecular features of Pregnancy Associated Breast Cancer from a tertiary care cancer centre in India.

Jyoti Bajpai, Rohan Chaubal, Rajiv Sarin, Venkatesh Kapu, Khushi Patel, Ankita Singh, Jaya Chitra, Shwetali Pandey, Mrudula Madhav, Aishwarya Raja, Anushree Kadam, Khusboo Gandhi, Altaf Siddiqui, Yogesh Khembhavi, Sushmita Rath, Rajendra Badwe, Sudeep Gupta

Background: Pregnancy-associated breast cancer (PABC) encompassing breast cancer diagnosed during pregnancy or one-year post-partum is a rare and challenging entity wherein oncologists need to safeguard maternal oncological and foetal outcomes simultaneously. Little is known about genomic signatures which is worth exploring to throw light on aetiopathogeneses, prognosticators and might reveal potential targets with therapeutic relevance.
Aim: The study aimed to identify the molecular signatures to identify potential pathways implicated in pathogenesis and therapeutically relevant targets and independent prognosticators for PABC.

Methods: Patients with histologically confirmed breast cancer who were pregnant or diagnosed within one year of last pregnancy were included in study during the year 2013-2020 at our tertiary care cancer centre. Bio-specimens (tumour, tumour-adjacent normal, whole blood or plasma) were collected from the patients and the samples were subjected to DNA and RNA extraction and library preparations and then were sequenced at 200 X for tumour and 100 X for blood/tumour adjacent normal on an Illumina Platform and after through check for the quality control were analysed.

Results: There was a total of 104 patients enrolled in the registry from the year 2013-2020.Of these, 55 patients contributed at least one bio-specimen (tumour, tumour-adjacent normal, whole blood or plasma) to this study. Among those,7/55 samples were paired (Tumour and blood), with 9 were only plasma. Of the remaining 48 patients, 7 had paired (tumour and normal) samples, 38 had tumours alone and 3 had germlines alone (2 whole

blood, one tumour adjacent normal).
All the samples were subjected to DNA and RNA extraction.40/48 patients had at least one analyte (DNA or RNA) available. DNA from 29/38 tumour alone, and 6/7 with paired samples and 2/3 patients with germline alone were subjected to successful library preparation and sequencing at 200 X for tumour and 100 X for blood/tumour adjacent normal on an Illumina Platform. DNA Library prep for 1 patient tumour was unsuccessful due to low DNA quantity; however, that for the total RNA succeeded. RNA from 8 patient tumour samples that passed quality control (RIN>5.0) were also subjected to a total RNA library prep specific for fragmented RNA, followed by sequencing on an Illumina Platform to generate at least 50 million PE reads (100 million total reads). There was an overlap of 7 patients with both WES and RNA-Seq data for tumour samples.
Eight out of 38 patients were HER2 positive, with four being ER and/or PR positive and four being ER and/or PR negative. Eleven out of 38 patients were ER and/or PR positive and HER2 negative. Fifteen out of 38 patients were triple negative for ER, PR, and HER2 expression. Four patients were HER2 equivocal; among them, three were ER and PR positive, and one was ER and PR negative. The median age of patients was 30 years (22-45). 32 patients were postpartum at diagnosis while 6 were antepartum at diagnosis. Six patients were node-negative, while 32 were node-positive at diagnosis. Twelve patients presented with de novo metastatic disease at diagnosis, and 19 patients experienced metastatic progression post-diagnosis.
The median coverage for WES of Tumour samples was 182X and that for germline samples was 96X. Mutations were identified in PI3KCA (17%), TP53 (4%), and 2% in both. 6 patients harboured germline BRCA mutations. Additional mutations were identified in epigenetic modifiers. Pathways involved in PI3K signalling, mTOR signalling, ECM matrix related signalling and cell cycle related processes were de-regulated

Conclusion: The molecular profiling report for pregnancy-associated breast cancer patients presented here constitutes an invaluable, ultra-rare dataset. This will help in identifying factors associated with etiopathological and prognostic significance as well as relevant potential therapeutic targets for novel targeted therapeutics. This may contribute towards finding novel avenues which may enhance treatment armamentrium in this extremely challenging situation -an unmet need!

P5-06-09: Evaluating Functional Impacts of GATA3 Mutations in Breast Cancer Using Mesenchymal-to-Epithelial Transition Model

Aerica Nagornyuk, Mika Saotome, Nobuki Hida, Alexander Samardzic, Motoki Takaku

Breast cancer pathogenesis is closely linked to the mechanisms of cellular reprogramming, the process of converting differentiated cells into undifferentiated or different cell types. This reprogramming is achieved through the orchestrated expression of transcription factors which alter the cell's existing chromatin landscape and establish a transcriptome corresponding to the reprogrammed cell state. Pioneer factors, a type of transcription

factor, initiate cell development and cell fate transition by binding to specific DNA motifs within nucleosomes. This binding leads to the recruitment of co-factors, such as nucleosome remodelers, leading to chromatin opening and subsequent activation of specific genes essential for reprogrammed cell function. Improper engagement of these factors can lead to unanticipated or harmful gene expression, potentially contributing to various human diseases, including cancer.
GATA3, a pioneer factor, is essential for normal mammary gland development and differentiation. In breast cancer cells, GATA3 has been shown to suppress tumor growth by inducing mesenchymal-to-epithelial transition (MET), the reverse process of epithelial-to-mesenchymal transition (EMT). Interestingly, although mutations in GATA3 are frequent and considered driver mutations, breast cancer patients carrying GATA3 mutations are generally associated with better patient survival. The roles of these mutations remain largely unexplored. M294R and M294K are hot spot missense mutations found in luminal breast cancer patients. These mutations occur in the DNA-binding domain of GATA3, which is crucial for its function as a transcription factor.
For functional characterization of these mutants, we utilized MDA-MB-231 mesenchymal cells, a highly aggressive and invasive breast cancer cell line to model mesenchymal-to-epithelial transition (MET). Since ectopic expression of GATA3 induces MET in this cell line, these cells provide an excellent system to observe phenotypic and molecular alterations caused by its missense mutations M294R/K. To quantitatively measure changes in GATA3 mobility and its DNA binding dynamics in living cells, we utilized Fluorescence Recovery After Photobleaching (FRAP) assay. Additionally, to further elucidate the crucial role of GATA3, genomics analyses and phenotypic assays were conducted.
Functional characterization of M294R/K mutants in MDA-MB-231 breast cancer cells demonstrated distinct phenotypic and molecular alterations compared to wild-type GATA3. While wild-type GATA3 induced MET, mutant-expressing cells exhibited differential responses. Remarkably, mutants derived from breast cancer patients displayed increased chromatin binding, leading to a tighter chromatin structure and differential gene expression of mesenchymal or epithelial markers. Altered cellular phenotypes such as cell migration are also observed in M294R/K expressed cells.
Our finding underscores the importance of precise regulation of pioneer factor-chromatin interactions in cellular reprogramming processes. Understanding the molecular mechanisms underlying GATA3 mutations and their effects on cellular reprogramming in breast cancer provides valuable insights into the roles of GATA3 in breast cancer progression.

P5-06-10: Clinical and Transcriptomic Study of Matched Primary Breast Cancer and Brain Metastasis

Ajay Dhakal, Huina Zhang, David Hicks, Nimish Mohile, Ruth O'Regan, Carey Anders, Elizabeth Pritchett, Jeffrey Malik, Jennifer Becker, Mahlon Johnson, Matthew McCall, John Ashton

Background: Some studies suggest different genomic changes in brain metastasis (BM) compared to their primary tumors. There is a paucity of data comparing the genomic and transcriptomic features among matched pairs of primary breast cancer (PBC) and their BM. This single institution study aims to describe the clinical and transcriptomic data of matched triplets of normal tissue (NT), PBC and BMs.

Methods: Patients with archival formalin fixed paraffin embedded NT, PBC and BM tissues available at University of Rochester Medical Center (URMC) were included in this retrospective study. Survival analyses were done using Kaplan Meier method. Illumina Stranded Total RNAseq was used for library preparation, Illumina NovaSeq X Plus for sequencing. DESeq2-1.28.1 within R-4.0.2 was used to perform data normalization and differential expression analysis with an adjusted p-value threshold of 0.05 on each set of raw expression measures. Significant up-regulated and down-regulated genes based on p-adj <0.05 and abs(log2FoldChange) > 0 were submitted to Enrichr to identify significantly enriched pathways and transcription factors that could contribute to the observed phenotype.

Results: 7 patients (6 tissue triplets- NT, PBC, BM; 1 pair PBC, BM) were enrolled in the study. Median (IQR) age in years of patients was 63 (44-74). 2 patients had stage I, 3 patients stage III and 2 patients stage IV tumor at primary diagnosis (AJCC 8th, Anatomical Staging). 5 PBC out of 7 were grade 3. 3 PBCs were triple negative, while 4 were ER+/HER2-. Out of 5 patients with early stage PBC, 3 were treated with adjuvant chemotherapy and 3 out of 5 were treated with endocrine therapy. Median (IQR) days between PBC and MBC diagnosis and PBC to BM diagnosis were 730 (81-1665) and 730 (249-1665). 1 of the 2 cases with stage IV at PBC diagnosis had BM diagnosed with PBC. Out of the remaining 5 cases, 4 of them developed BM at the time of MBC diagnosis. Receptor subtypes were available on 4 BM- 2 TNBC, 2 ER+/HER2-, consistent with their original PBC subtypes. 3 out of 7 cases had lung or liver metastasis at BM diagnosis. Median overall survival (days) from PBC and BM diagnoses were 2072 and 541. Top 5 differentially expressed genes (most significant p-adjusted) with log2FoldChange in BM vs NT: FGB (-0.991), MFAP4 (-5.013), AQP7 (-5.825), ADIPOQ (-4.45), DPT (-5.769); in PBC vs NT: LINC01614 (6.493), CHP2 (-1.059), MUC4 (-5.904), MMP11 (4.734), GAS2L1P1 (0.547); in BM vs PBC: FGB (-1.815), IGHGP (-6.058), ENSG00000286034 (0.853), DPT (-4.211), HAND2 (-4.306). Top 3 most significantly upregulated pathways (based on adjusted p value) in BM vs NT: DNA metabolic process, DNA replication and extracellular structure organization pathways; PBC vs NT AND BM vs PBC: no enrichments found/insufficient genes. Top 3 most significantly down regulated pathways (based on adjusted p value) in BM vs NT: negative regulation of blood vessel morphogenesis, neuronal action potential, regulation of angiogenesis; PBC vs NT: Adipogenesis WP236, Triacylglyceride Synthesis WP325, BM vs PBC: extracellular matrix organization, extracellular structure organization, external encapsulating structure organization.

Conclusion: This small study has described the clinical and transcriptomic information

among matched normal tissue, primary breast cancer and brain metastasis. This study suggests decreased expression of genes related to extracellular matrix components- DPT and MFAP4 in BM compared to NT. Compared to PBC, BM has decreased expression of DPT (Dermatopontin) and FGB (Fibrinogen Beta chain) genes. Similarly, BM have downregulated pathways related to extracellular matrix/structure compared to NT or PBC. These results are exploratory and need validation in larger study.

P5-06-11: Serine Starvation Inhibits SRSF Protein Expression and Modulates RNA Splicing in Breast Cancer Cells

Philippa Burns, Negar Tabatabaei, Laura Selfors, Aanshi Vashi, Debolanle O. Dahunsi, Patrick Murphy, Soroush Tahmasebi, Jonathan Coloff

Breast cancer is the most common cancer in women worldwide, and luminal/estrogen receptor positive (ER+) breast cancer accounts for ~50% of breast cancer deaths. Our lab has identified serine auxotrophy as a metabolic vulnerability of luminal/ER+ breast tumors due to low levels of the serine synthesis enzyme phosphoserine aminotransferase (PSAT1). Serine is critically important for cancer cell growth due to its multiple downstream functions in protein, nucleotide, and lipid biosynthesis. There is considerable interest in starving serine auxotrophic tumors of serine for therapy, including an ongoing clinical trial in pancreatic cancer. While the metabolic effects of serine starvation have been extensively investigated, our goal is to better understand how serine starvation affects protein synthesis and expression. We found that serine starvation inhibits global translation, while inducing adaptive translation of ATF4, and causes ribosome stalling and fall-off at serine TCC codons. Analysis of changes in the proteome upon serine starvation in auxotrophic luminal breast cancer cells shows that serine-rich proteins are particularly sensitive to serine starvation; this includes the serine/arginine rich splicing factor (SRSF) family that are important regulators of mRNA splicing. Accordingly, replicate multivariate analysis of transcript splicing (rMATS) on RNA-sequencing data suggests that serine starvation dramatically changes alternative mRNA splicing in multiple breast cancer cell lines, with many differential splicing events being conserved across the four cell lines tested. These results have led to our current hypothesis that serine starvation induces splicing changes due to reduced translation of serine-rich members of the SRSF family (such as SRSF6), which ultimately impacts DNA damage and cell survival. We believe that SRSF6 depletion and subsequent alteration of RNA splicing upon serine starvation may sensitize to DNA damaging agents (e.g., chemotherapy).

P5-06-12: BreastSubtypeR: Streamlining Intrinsic Molecular Subtyping in Breast Cancer Research with a User-Friendly R Package

Qiao Yang, Xinsong Chen, Johan Hartman, Emmanouil G. Sifakis

Breast cancer (BC) is characterized by significant transcriptomic heterogeneity, enabling the classification into various intrinsic molecular subtypes, each with important prognostic implications. The integration of intrinsic subtyping into clinical practice has been instrumental in guiding BC treatment decisions. However, in the research setting, the lack of standardization has led to the development of a multitude of intrinsic subtyping methods. These methods fall into two main categories: those based on the nearest-centroid (NC) approach and those employing a single-sample prediction (SSP) model. NC-based approaches face challenges stemming from the differences in the gene expression profiling (GEP) platform, preprocessing methods, and cohort composition. On the other hand, SSP model-based methods may encounter inherent limitations typical of a model-based approach. Therefore, the primary challenge for researchers lies in the careful selection of an optimal subtyping method that is tailored to their specific cohort. This selection process can be complex and tedious, especially for targeted patient cohorts. To mitigate this challenge, we have developed the R package, BreastSubtypeR. This package integrates six main intrinsic subtyping methods, along with their derivatives, enabling users to easily inspect the results. BreastSubtypeR employs standardized input and output and provides a unified framework that is highly compatible with other R packages in the GEP field. For users who are not proficient in R, we offer an R Shiny app. BreastSubtypeR is designed to streamline the process of intrinsic subtyping in BC research. We have also explored the selection criteria for different cohorts across methods, thereby simplifying the process of selecting the most suitable subtyping methods for a given cohort. Our ongoing analyses are focused on devising strategies to enhance the classification of intrinsic molecular subtypes in BC research. Given the limited availability of standardized tests in research settings, this work significantly contributes to enhancing our understanding of BC subgroups. This is crucial for advancing personalized treatment strategies in BC, emphasizing the importance of our work in this ongoing effort.

P5-06-13: ARRB1 cooperates with estrogen receptor to drive endocrine resistance in ER-positive breast cancer

Qian Xu, Afrin Sultana, Ananya Gupta, Sanjeev Gupta

Background: β-Arrestin1(ARRB1) is a member of arrestins protein family and act as a scaffold to regulate proteins through G-protein-coupled receptors signaling (1). Recent studies show that it plays an important role in different cancers. ARRB1 enhances progression of breast and prostate cancer via regulation of HIF1A activity (2, 3), promotes lung cancer by increasing E2F1 activity (4). ARRB1 associates with androgen receptor and augments its activity in prostate cancer (5) . However, a tumour-suppressor role of ARRB1 has also been observed. Overexpression of ARRB1 inhibited the growth of human neuroblastoma cells through regulating p27 transcription (6) and triple-negative breast cancer (7, 8). These reports suggest that ARRB1 exerts diverse roles in cancers.
Breast cancer is the most common cancer diagnosed in women. Around 70% of all breast cancers are estrogen receptor α (ER) positive(9). Despite advances in treatment of ER-

positive breast cancers, the development of resistance remains a major challenge necessitating the targeting novel mechanisms of endocrine resistance to improve clinical outcome (10). Indeed, Razavi et al., 2018 reported that 60% of endocrine-resistant metastatic breast cancers lacked known somatic drivers of resistance suggesting that there are yet unidentified factors that contribute to endocrine resistance (11). Here we have evaluated the role of ARRB1 in ER positive breast cancer.

Methods: ARRB1 overexpressed stable clone is generated through a lentiviral expression plasmid. ARRB1 knockout stable clone is generated using the CRISPR-Cas9 gene knockout strategy. These clones are validated using western blot. Colony formation assay and MTS assay are used to evaluate cell viability and cell proliferation. Luciferase reporter assay is used to evaluate the effect of ARRB1 on estrogen receptor. qRT-PCR and Western blot are used to identify the mRNA and protein level. CBioPortal is used to analyze genetic status. KM plotter is used for survival analysis.

Results: The expression of ARRB1 is increased in ER-positive breast cancer compared to ER-negative breast cancer. Depletion of ARRB1 decreases colony formation of ER-positive breast cancer cells. While overexpression of ARRB1 in MCF7 cells increases cell growth and amplifies the induction of estrogen-responsive genes. What's more, overexpress ARRB1 increases E2-dependent growth in MCF7 cells while absence of ARRB1 reduces E2-dependent growth in T47D cells. ARRB1 expression provides resistance against anti-estrogens. Combined with Spiperone treatment, which downregulates ARRB1, increases the effect of Tamoxifen on viability of MCF7 cells. Further, ARRB1 co-expression enhances the transactivation function of ERα WT and ER point mutation but not ESR1 fusion mutation. In contrast, estrogen downregulates mRNA and protein of ARRB1. In addition, KM Plotter analysis shows that increased expression of ARRB1 is associated with poor outcome in ER-positive breast cancer.

Conclusions: Our results suggest that ARRB1 functionally collaborates with ER to drive endocrine resistance and targeting of ARRB1 will provide a novel approach to overcome endocrine resistance.

P5-06-14: PTBP1 is associated with tumor proliferation as an oncogene that regulates breast cancer metabolism.

Manabu Futamura, Yoshihisa Tokumaru, Akira Nakakami, Mai Okawa, Ryutaro Mori, Nobuhisa Matsuhashi

Background: We previously studied cancer cell metabolism. A critical difference exists between cancer and normal cells in terms of their energy-producing mechanisms. Polypyrimidine tract-binding protein 1 (PTBP1), which is predominantly expressed in tumor cells, plays a central role in supplying energy to cancer cells. Alternative splicing of pyruvate kinase muscle (PKM) by PTBP1 results in the formation of two isoforms: PKM1 and PKM2. Normal cells are PKM1-dominant and receive energy mainly from the TCA cycle through oxidative phosphorylation. In contrast, cancer cells are PKM2-dominant and receive more energy from the glycolytic system. This is considered to be the true nature of the energy supply caused by the Warburg effect. In our previous study on gastric cancer, PTBP1 suppression inhibited tumor growth and induced autophagy, which shifted the energy supply from PKM2 to PKM1. In this study, we investigated the significance of PTBP1 in breast cancer (BC) from both basic and clinical perspectives. (Objective) To evaluate the clinical significance of PTBP1 in breast cancer, we performed the following experiments.

Subjects and Methods: We conducted in silico, in vitro, and in vivo searches to clarify the relationship between BC and PTBP1. In an in silico search, we compared PTBP1 expression in BC between cancerous and normal tissues using the global public databases TCGA (n = 1074) and METABRIC (n = 1904). In addition, the relationship between clinical characteristics (tumor grade, stage, and prognosis) and PTBP1 expression was examined for each subtype. We then performed an in vitro search to confirm the expression of PTBP1 and its target genes, PKM1 and PKM2, in nine BC cell lines using western blotting. Among these cell lines, MCF7 (luminal type), SK-BR-3 (HER2 type), and MDA-MB-231 (triple negative) were used to knock down PTBP1 using two types of siRNA. Phenotypic changes were evaluated using cell proliferation and cancer metabolism-related assays, including ATP, NAD/NADH, and lactate assays. In addition, we performed RT-PCR on BC surgical specimens (luminal: five, HER2: five, and TNBC: five) to examine the expression of PTBP1 in vivo. (Results) In a study using paired samples from TCGA, PTBP1 was significantly more highly expressed in tumor tissues than in normal tissues ($p < 0.001$). Regarding tumor grade, PTBP1 significantly increased with advancing tumor grade in both the TCGA and METABRIC ($p<0.001$) datasets. In vitro analysis of nine BC cell lines showed that PTBP1 was highly expressed, and PKM2 expression was significantly upregulated compared to PKM1. PTBP1 using MCF7, MDA-MB-231, and SK-BR-3 cells significantly increased the PKM1/PKM2 ratio. PTBP1 knockdown significantly affected the proliferation of all cells. The ATP assay showed a significant increase in ATP production in MCF7 and SK-BR-3 cells, but not in MDA-MB-231 cells. We performed NAD/NADH and lactate assays using MCF7 and MDA-MB-231 cells and observed that NAD/NADH production was significantly increased and lactate production was significantly decreased by PTBP1 knockdown in both cell types. Thus, the expression of PTBP1 in BC cells suggested a PKM2-significant metabolic state.

Examination of PTBP1 expression using surgically resected paired samples revealed that tumor tissue showed higher PTBP1 expression in 14 of 15 cases (93.3%) than in normal tissue. Finally, an in silico search of the relationship between PTBP1 expression and prognosis revealed that in the METABRIC database, the high PTBP1 expression group had significantly worse DFS and OS than that in the low expression group ($p<0.001$, $p = 0.002$). This trend was particularly significant in the luminal group ($p<0.001$).

Conclusion: This study suggests that PTBP1 is involved in metabolism, cell proliferation, and prognosis in BC. PTBP1 can be a target molecule in BC and may lead to the development of therapies that regulate cancer cell metabolism.

P5-06-15: Nucleosome binding affinity of the pioneer factor GATA3 influences chromatin reprogramming in breast cancer

Jill Goodman, Mika Saotome, Motoki Takaku

Cellular reprogramming is a fundamental process in specific developmental stages and is also invaluable for disease modeling. It involves the conversion of differentiated cells into undifferentiated or specialized cell types. This transformation relies on coordinated action of transcription factors or chemical stimuli, which reshapes the cell's chromatin structure and establishes a different gene expression profile. Among these transcription factors, pioneer factors play a critical role, initiating cellular reprogramming and guiding cell fate transitions by selectively binding to specific DNA motifs within nucleosomes at inactive chromatin. The GATA3 protein serves as a pioneer transcription factor essential in mammary gland development and is involved in breast tumor development. GATA3 facilitates the cellular reprogramming of mesenchymal breast cancer cells into epithelial breast cancer cells. Despite the established role of pioneer factors in chromatin remodeling and cell fate regulation, the precise molecular mechanisms that govern their selective binding to chromatin are still not fully understood. Using the mesenchymal-to-epithelial transition (MET) model, we aimed to understand how GATA3 selectively binds to genes that are essential for successful cellular reprogramming. Utilizing a combination of machine learning and experimental approaches, we investigated GATA3's binding affinity to DNA and nucleosome substrates. Machine learning analysis identified two distinct zinc-finger domains which are required for effective GATA3 nucleosome binding. The results of this deep learning analysis were used to design a series of GATA3 mutant cell lines and DNA substrates. The experimental approach involved two strategies: first, analyzing the binding affinity of wild-type GATA3 to DNA substrates designed based on machine learning predictions, and second, examining the nucleosome binding affinity of GATA3 mutants, including those predicted by computational modeling and those derived from breast cancer patients. Electrophoretic mobility shift assays confirmed the differential binding affinities of GATA3 mutants, indicating the importance of specific motifs and zinc finger domains. Our findings highlight the significance of DNA sequence specificity in modulating pioneer transcription factor activity and chromatin accessibility. Mutational analysis revealed distinct roles for each zinc finger domain, with mutations affecting DNA binding affinity and

chromatin accessibility. This study provides insights into the molecular mechanisms governing GATA3-mediated chromatin remodeling during MET. By characterizing the interaction between DNA/nucleosome binding affinity and chromatin accessibility, we expand our understanding of pioneer transcription factor function in breast cancer progression.

P5-06-16: Preclinical Characterization of LAE118, a Novel Allosteric Pan-mutant Selective PI3Kα Inhibitor

Ming Li, Ruipeng Zhang, Junyan Chen, Meijuan Hu, Xiaofen Lin, Justin Gu

PIK3CA is one of the most frequently mutated oncogenes in cancer, found in approximately 13% human cancers. PI3Kα mutations are prevalent in patients with breast, colorectal, lung, endometrial, and numerous other cancers. Three hotspot mutations (H1047R, E545K, E542K) on the p110α subunit of PI3Kα are recognized activating mutations accounting for approximately 1/3 of all PI3Kα mutations. Targeting PI3Kα in cancer has been validated as a therapeutic strategy, as evidenced by the approved drug Alpelisib and the positive clincal trial result of Inavolisib, demonstrating clinical efficacy either alone or in combincation with other therapies. However, treament with non-mutant selective inhibitors raises tolerability concerns such as hyperglycimea, due to the inhibition of wild type PI3Kα. Moreover, the clinical use of PI3Kα orthosteric inhibitors, such as Alpelisib and Invaolvisib, has led to the emergency of secondary mutations (e.g. Q859K & W780R) in the ATP binding pocket resulting in resistance to these drugs. Therefore, there is a pressing need to develop novel PI3Kα-targeted therapies that can minimize on-target toxicities and overcome drug ressistance.
LAE118 is a novel allosteric pan-mutant selective PI3Kα inhibitor. LAE118 demonstrates excellent in vitro anti-proliferation activities in PI3Kα mutant cell lines and remains active against cells resistant to orthosteric PI3Kα inhibitors. LAE118 shows strong anti-tumor growth effect in Xenograft models at a dose that is much lower than other allosteric inhibitors and has less effect on glucose homeostasis compared to orthosteric inhibitors. In pre-clinical toxicology studies, LAE118 also demonstrated good tolerability. These data indicate that LAE118 offers improved efficacy and larger safety window. LAE118 is currently in IND enabling stage.

P5-06-17: The addition of ribociclib, palbociclib or abemaciclib to the next generation oral SERD, camizestrant, delivers greater anti-tumour efficacy in a range of ESR1wt and ESR1m breast PDX models

Susana Ros, Andrew Waddell, Sladjana Gagrica, Mandy Lawson, Alison Peter, Sophie D'Arcy, Mahreen Adil, Pablo Morentin Gutierrez, Ana Quiroga, Teresa Klinowska, Claire Crafter

The addition of a CDK4/6 inhibitor (CDK4/6i) to endocrine therapy (ET) in patients with hormone receptor positive (HR+) advanced breast cancer (ABC) showed significant

improvement in progression free survival (PFS) in pivotal trials. Three CDK4/6i; ribociclib, palbociclib and abemaciclib, have now been approved by global regulatory authorities, including the FDA, in this setting, leading to an improvement in patient outcomes over recent years. Unfortunately, tumours are resistant or develop resistance to these combinations, demonstrating a current unmet need for treatment regimens that can delay resistance and extend the time on 1st line therapy. This is particularly important due to shorter PFS in 2nd line.
Camizestrant is a next generation oral selective estrogen receptor degrader (ngSERD) and pure ER antagonist that has demonstrated superior activity to fulvestrant both pre-clinically and clinically. A major mechanism of resistance to current ETs is the emergence of ESR1 mutations (ESR1m) which occur in ~40% of patients after 1L therapy for metastatic disease. Camizestrant can degrade and antagonize both wild type and mutant forms of ER and delivers similar PFS in patients with or without detectable ESR1m at baseline. Therefore, camizestrant has the potential to become the backbone ET of choice.
We investigated the effect of combining camizestrant with the three globally approved CDK4/6i, palbociclib, abemaciclib or ribociclib in vitro and in vivo. Addition of camizestrant enhanced the growth inhibitory effects of all three CDK4/6i in the ER+ breast cancer cell lines, MCF7 and T47D, as well as in MCF7 cells engineered to express ESR1m (Y537S). Analysis of the response of downstream signalling biomarkers to the combination revealed that camizestrant limits the induction of cyclin D1 caused by CDK4/6i monotherapy treatment and enhances the reduction of pRB, a key regulator of the cell cycle. Consistent with this, the combination with camizestrant enhanced G1 arrest at lower doses of CDK4/6i. This combination benefit was also explored in vivo across a panel of 7 ER+ breast PDX models where the combination of camizestrant plus the CDK4/6i was well tolerated. In four of these models the addition of palbociclib, abemaciclib or ribociclib significantly enhanced the tumour growth inhibition (TGI) of camizestrant. For example, in ST1799PBR, monotherapy camizestrant delivered 60% TGI whereas the addition of palbociclib, abemaciclib or ribociclib drove 78, 89 and 76% TGI, respectively. Combination benefit was achieved in ESR1wt as well as ESR1m models and with no difference in anti-tumour activity between the CDK4/6i partners.
These preclinical data demonstrate consistent activity of camizestrant in combination with all three globally approved CDK4/6i. This, together with the efficacy of camizestrant in patients with ESR1wt and ESR1m tumours, suggests camizestrant in combination with CDK4/6i has the potential to provide extended benefit for patients with ER+/HER2 metastatic breast cancer in the first line setting, a concept under clinical investigation in the ongoing SERENA-6 (NCT04964934) and SERENA-4 (NCT04711252) studies.

P5-06-18: The Role of PARP1-mediated FOXA1 ADP-ribosylation in Breast Cancer Biology

Cristel V. Camacho, Minjung Kwon, Poulami Tapadar, Aishwarya Sundaresan, Sneh Koul, Tulip Nandu, W. Lee Kraus

Breast cancer is the most common cancer diagnosed in women. At the time of diagnosis, approximately 70% of breast cancers express Estrogen Receptor alpha (ERα), a key signature of luminal subtype tumors. Equally important in these cases is the expression of FOXA1, a subtype-specific transcription factor (TF) essential for ERα-mediated cell proliferation. FOXA1 is a key pioneer TF that assists ERα with the assembly of enhancers and the transcription of estrogen (E2)-regulated target genes. Together, the FOXA1-ERα axis is a major driver of cancer cell growth. Our recently published work implicates poly(ADP-ribose) polymerase 1 (PARP1) and ADP-ribosylation (ADPRylation) in the regulation of E2-dependent transcriptional responses in ERα+ breast cancer cells.
To determine the underlying mechanisms, we identified FOXA1 as a substrate of PARP1-mediated ADPRylation. We hypothesize that (1) PARP1 elicits its effects on E2 signaling and ERα enhancer function, in part, by ADPRylating FOXA1 at specific residues and (2) Loss of these regulatory ADPRylation events alters FOXA1 activity, which in turn can alter the assembly of ERα enhancers and transform the breast cancer cell transcriptome. Indeed, the sites of FOXA1 ADPRylation are recurrently mutated in breast cancers and are highly enriched in metastatic cases. Using an integrated set of biochemical, molecular, cell based, genomic and proteomic approaches, we have validated the ADPRylation of FOXA1 by PARP1 in vitro and in vivo. We selected two FOXA1 ADPRylation sites, D226 and E255, for further analysis due to their positions in a mutation 'hot spot' region corresponding to the C-terminal forkhead DNA-binding domain. Mutation of these sites blocks FOXA1 ADPRylation and enhances cell proliferation in MCF-7 human breast cancer cells. Additionally, preliminary ChIP-seq analysis indicates that the binding of both ERα and FOXA1 are globally reduced at ERα enhancers in MCF-7 cells expressing the FOXA1 ADPRylation site mutants compared to wild-type but may also increase both at selected enhancers. While there is a global reduction in mutant FoxA1 binding near the canonical estrogen-regulated genes, interestingly, we observe an overall enhanced binding of FOXA1 D226N compared to wild-type outside of this canonical program. Collectively, these studies will (1) reveal new molecular endpoints modulated by PARP1, providing new insights about the use of PARP inhibitors to treat ERα+ breast cancers, and (2) suggest new therapeutic strategies to disrupt the aberrant signaling pathways associated with mutant FOXA1 luminal breast cancers, and more importantly metastatic cases, which is of utmost clinical significance.

P5-06-19: Single-cell transcriptional features of human breast tumors and model systems

Julia Altman, Amy L. Olex, Emily K. Zboril, Carson J. Walker, David C. Boyd, Rachel K. Myrick, Nicole S. Hairr, Jennifer E. Koblinski, Madhavi Puchalapalli, Bin Hu, Mikhail G. Dozmorov, X. Steven Chen, Yunshun Chen, Charles M. Perou, Brian D. Lehmann, Jane E. Visvader, J. Chuck Harrell

A deeper understanding of the complicated transcriptional landscape of human breast cancers are vital to identifying more efficacious treatments. Investigating genetic variations among breast cancer subtypes at a single-cell level holds the potential to enhance our

understanding of cancer formation, progression, and elucidate actionable targets. In this study, we compile single-cell RNA sequencing data from patient tumors and matched lymph metastasis, reduction mammoplasties, breast cancer patient-derived xenografts (PDXs), PDX-derived organoids (PDXOs), and cell lines, forming a diverse dataset consisting of 117 samples with a total of 506,719 cells. These samples include hormone receptor-positive (HR+), human epidermal growth factor receptor 2 positive (HER2+), and triple-negative breast cancer (TNBC) subtypes, along with isogenic model pairs. Within this study, we outline the similarities and differences across these models and patient samples, and assess therapeutic drug efficacy based on subtype proportions. Within the TNBC subtype, PDX models exhibited a closer resemblance to patient samples in terms of tumor heterogeneity and cell cycle features compared to cell lines. Acquired drug resistance in TNBC PDX tumors was linked to an increase in basal-like cell proportions, as defined by SCSubtype and TNBCtype cell typing predictors. Cell-wise subtyping revealed all patient samples comprised a mix of subtypes; notably, HR+ lymph node metastases had a lower proportion of HER2-Enriched cells compared to matched primary tumors. PDXOs displayed differences in metabolic-related transcripts relative to matched PDX tumors. Correlative analyses of cytotoxic drugs on PDX cells demonstrated that therapeutic efficacy was dependent on subtype proportions. Herein we provide an extensive multi-model dataset, a dynamic approach to cell-wise sample annotation, and a thorough examination of models within human breast cancer systems. This analysis and reference resource will support informed decision-making in preclinical research and therapeutic development by establishing model limitations, subtype-specific insights, and novel targetable pathways.

P5-06-20: Advances in Molecular Characterization and Targeted Therapeutics for Lobular Breast Cancer: Enhancing Personalized Treatment Strategies

Mohammed Imad Malki, Ibrahim Elmakaty

Lobular breast cancer (LBC), accounting for 10-15% of all breast cancer cases, is distinct in its histopathological and clinical presentation. Despite its prevalence, LBC has been historically under-researched compared to ductal breast cancer, leading to a gap in optimized therapeutic strategies. This study aims to elucidate the unique molecular and genetic landscape of LBC, offering insights into potential targeted therapies. We conducted a comprehensive analysis of 150 LBC tissue samples, employing next-generation sequencing, transcriptomic profiling, and immunohistochemical methods to identify key mutations and pathways driving LBC pathogenesis. Our findings highlight recurrent mutations in CDH1 (50% of cases), PIK3CA (35% of cases), and GATA3 (20% of cases), alongside alterations in the estrogen receptor pathway, which were prevalent in 70% of LBC cases. Additionally, we observed significant variations in the tumor microenvironment of LBC, characterized by a unique immune cell infiltration pattern, with higher levels of tumor-associated macrophages and regulatory T cells compared to ductal carcinomas. In vitro and in vivo studies were conducted to evaluate the efficacy of targeted therapies against identified

molecular aberrations. PI3K inhibitors demonstrated potent anti-tumor activity in LBC models harboring PIK3CA mutations, reducing tumor growth by 60% in murine models. CDH1-deficient models responded favorably to E-cadherin targeted approaches, showing a 50% reduction in metastatic spread. Furthermore, our data revealed that patients with GATA3 mutations exhibited increased sensitivity to estrogen receptor modulators, with a 40% improvement in progression-free survival. Our research underscores the necessity for tailored therapeutic strategies in LBC, advocating for the incorporation of molecular diagnostics in clinical practice to personalize treatment. These findings not only advance our understanding of LBC but also pave the way for developing precision medicine approaches that improve patient outcomes.

P5-06-21: Longitudinal profiling of cell-cell interactions in estrogen receptor positive breast cancer patients treated with aromatase inhibitors: insights from single cell RNA sequencing analysis

Alida van Meeteren, Melissa Hubisz, Marie Fongaard, Pål Marius Bjørnstad, Knut Selsås, Stephanie Beate Geisler, Manouchehr Seyedzadeh, Unn-Cathrin Buvarp, Torben Lüders, Diether Lambrechts, Marianne Lyngra, Arnoldo Frigessi, Vessela Kristensen, Ashley Laughney, Jürgen Geisler, Xavier Tekpli

Introduction: Postmenopausal breast cancer patients with estrogen receptor positive (ER+) tumors are frequently treated with aromatase inhibitors (AIs) to effectively reduce estrogen levels, suppress the ER signaling pathway, and inhibit tumor growth and recurrence. The NEOLETEXE trial aimed to treat postmenopausal ER+ patients with locally advanced breast cancer in the neoadjuvant setting. In this randomized, open-label, intra-patient, cross-over, phase II clinical trial, patients received either letrozole (2.5 mg daily) or exemestane (25 mg daily) for 3 months before crossing over to the alternative aromatase inhibitors for an additional 3 months.

Methods and aims: To understand the mechanisms of resistance and sensitivity to aromatase inhibitors in ER+ breast cancer, we profiled 23 patients in the NEOLETEXE trial using single-cell RNA sequencing (scRNA-seq) at baseline, after 3 months (prior to the crossover), and at the end of neoadjuvant therapy (after 6 months).
Our aim was to analyze the dynamic changes of cell type interactions under treatment pressure using two algorithms, CellPhoneDB and ContacTracing, which reliably and complementarily identify cell-cell interactions and their functional effects from scRNA-seq data.

Results: Unsupervised clustering of approximately 400,000 cells obtained from the three longitudinal biopsies of 23 patients revealed thirteen distinct cell types. CellPhoneDB was utilized to identify the significant cell type-cell type interactions for each biopsy, providing an atlas of cell type interactions in ER+ breast cancer. Further analysis of the robust interactions across longitudinal biopsies identified which cell types significantly changed

their interactive network during treatment. Additionally, we used spatial transcriptomics to investigate the importance of cell type proximity in the commitment of cell type-cell type interactions. Finally, using ContacTracing, we aimed to understand the importance of specific ligand-receptor interactions in shaping cell phenotypes and the tumor microenvironment in relation to sensitivity or resistance to aromatase inhibitors.

Conclusions: Through scRNA-seq, we uncovered the cell-cell interaction landscape of ER+ breast cancer and evaluated the significance of cell-cell spatial proximity. Furthermore, we assessed which cell types significantly changed their interactions under treatment pressure. Our goal is to gain a deeper understanding of the role of cell type interactions in breast cancer physiopathology and under treatment pressure with different classes of aromatase inhibitors.

P5-06-22: Harnessing the Power of the Variant: Breast Cancer's Strategic Incorporation of the Histone H2A.J

Rana Gbyli, Tyler Jensen, Joseph Balowski, Yao Li, Xiang Zhang, Qin Yan, Andrew Xiao

Breast cancer (BC) is the leading cause of cancer-related deaths in women. It is molecularly and clinically heterogeneous, driven by distinct genetic and epigenetic alterations, making prognosis prediction and treatment selection challenging. Identifying novel markers for BC progression and therapeutic targets remains an urgent need. Although growing research has highlighted the role of epigenetic mechanisms, particularly cancer-associated histone mutations (onco-histone), in regulating BC pathogenesis and its hallmarks, including stemness and drug resistance, the role of histone variants—the naturally derived sequence variants—remains largely unknown, with the exception of H3.3. The newly identified, mammalian-specific histone variant H2A.J has been shown to be highly enriched in human luminal BC and implicated in a stem cell signature correlated with metastatic risk in primary BC. However, it is unclear what role H2A.J plays in BC and how it may function in other BC subtypes. Using cell lines of multiple BC subtypes and patient-derived xenograft (PDX) tumor microarrays, our studies have discovered that H2A.J is present in human triple-negative BC (TNBC), with significantly elevated levels in metastatic TNBC compared to the primary counterpart.
Our unpublished results show that H2A.J is the only histone variant that strongly and specifically interacts with the tumor suppressor, retinoblastoma 1 (RB1) in metastatic TNBC cells and luminal BC. Our data also demonstrate that RB1 protein level is significantly correlated with H2A.J in estrogen receptor-positive (ER+) luminal BC PDX samples. Our preliminary results suggest that H2A.J chromatin occupancy affects RB1 recruitment to chromatin, RB1-bound chromatin targets, and ultimately RB1-dependent phenotypes. We will discuss how H2A.J regulates RB1-bound chromatin loci, and hence, the canonical and non-canonical functions of RB1 in tumorigenesis. Our bulk RNA-sequencing and western blotting data show that knocking down (KD) H2A.J interferes with G1/S cell cycle progression and results in the upregulation of estrogen response, apoptosis, and mTOR

signaling. Notably, the H2A.J KD-transcriptome signature strongly correlates with that of CDK4/6 inhibitor treatment. Our data also suggest H2A.J's role in maintaining cell lineage fidelity.

Overall, our results suggest that H2A.J regulates cellular heterogeneity, stemness, and metastasis in BC. The outcome of our research will not only advance our understanding of the underlying mechanisms leading to BC progression and metastasis but also offer new opportunities for utilizing H2A.J as a target for diagnostic and therapeutic interventions in BC.

P5-06-23: NDRG1-AKT signaling promotes tumor stemness in inflammatory breast cancer

Emilly Schlee Villodre, Xiaoding Hu, Wendy A. Woodward, Stefan Pusch, Debu Tripathy, Bisrat G. Debeb

Background: Inflammatory breast cancer (IBC) is a rare, aggressive form of breast cancer but accounts for 10% of breast cancer-related deaths. Cancer stem cells (CSCs; tumor stemness) play a key role in tumor dormancy, progression, and treatment resistance, yet mechanisms that drive CSCs remain poorly defined. We recently identified that NDRG1 promotes tumor growth and progression in IBC mouse models, and that its depletion inhibits AKT phosphorylation. We hypothesized that NDRG1 is a key regulator of tumor stemness in IBC via activating AKT signaling.

Methods: CSCs were assessed using surrogate markers including CD44+/CD24-, mammospheres, and in vivo limiting dilution assay experiments. To identify which AKT isoforms (AKT1, AKT2, or AKT3) or upstream kinases (SGK1, GSK3β) mediate NDRG1-induced CSCs, NDRG1-depleted cells were transfected with NDRG1 WT, AKT plasmids or SGK1/GSK3β phospho-site mutants or siRNA for SGK1/GSK3β.

Results: NDRG1 depletion significantly reduced CD44+/CD24- subpopulation and mammosphere formation ($p<0.001$). Limiting dilution experiments demonstrated a significant reduction in tumor incidence and stemness frequency in mice transplanted with NDRG1 knockdown cells ($p= 1 \times 10-12$). Each of the three AKT isoforms partially rescued tumor stemness in the NDRG1 knockdown IBC cells [CD44+/CD24-: NDRG1 KD vs AKT1 OE, $p=0.008$; vs AKT2 OE, $p=0.005$; vs AKT3 OE, $p=0.001$)]. Overexpression of known inactive SGK1 phospho-site mutants of NDRG1 restored tumor stemness in NDRG1-depleted cells ($p\leq0.005$). While silencing GSK3β reduced CSCs in IBC cells SGK1 did not affect this subpopulation, indicating that the tumor stemness effect of NDRG1 is independent of SGK1 and its kinase activity and is regulated by GSK3β.

Conclusions: Our findings underscore the critical role of NDRG1 as a regulator of IBC tumor stemness. We observed all three isoforms of AKT restored CSCs in NDRG1-depleted breast cancer cells, highlighting the significance of the NDRG1-AKT axis in governing stemness and tumor progression in IBC.

P5-06-25: Dose-dependent Effects of Estrogen on Genomic Regulation in Breast Cancer Cells

Hyung Bum Kim, Tulip Nandu, W. Lee Kraus

Estrogens are steroid hormones that play a key role in a wide range of physiological and pathological processes. Notably, estrogens act as the primary mitogen in estrogen receptor positive breast cancers (ER+ BC). The primary mode of action of these hormones is through estrogen receptor-alpha (ERa), which functions primarily as a nuclear transcription factor (TF) through ligand-dependent activation by 17β-estradiol (E2), the major naturally-occurring estrogen. The physiological levels of E2 are regulated by production, sequestration, and clearance, which can limit the amount of bioavailable E2. However, many studies examining the genomic effects of E2-regulated signaling in cell-based assays used supraphysiological levels of hormone. While this has allowed us to understand the extremes of E2 signaling, it has limited our ability to examine cellular functions which operate at lower hormone concentrations. In particular, the genomic actions of ligand-bound ERa through transcriptional enhancer formation and function are not understood at physiological E2 doses. Here, we present studies examining two largely overlooked aspects of E2 signaling: (1) genomic actions at physiological concentrations of E2 and (2) cellular accumulation and retention of E2. Using an integrated genomic approach with RNA-seq, PRO-seq, ChIP-seq, and ATAC-seq, we identified gene sets that express preferentially at either picomolar or nanomolar concentrations of E2. Expression of these genes is regulated mainly at the transcriptional level and is associated with distinct enhancer features, including chromatin accessibility and H3K27ac enrichment, that may play a role in determining hormone responsiveness. These have implications of functional differences between response at low and high doses of E2. Furthermore, we found that ERa positive breast cancer (ER+ BC) cells accumulate E2 from the culture medium and retain the hormone for an extended duration. Accumulated intracellular E2 supports sustained ERa chromatin binding and E2-dependent gene expression, as well as cell proliferation. We are exploring the link between intracellular steroid-binding proteins and E2 cellular retention. Taken together, our results are expanding the role of E2 dose in hormone signaling in ER+ BC.

P5-06-26: APOBEC3B And DNA Damage Repair As Synthetic Lethal Pairs

Bojana Stefanovska, Benjamin Troness, Kevin Lin, Chad Myers, Reuben S. Harris

APOBEC3 (A3) enzymes play a pivotal role in mutagenesis across various cancer types. These enzymes, which are single-stranded DNA cytosine deaminases, convert cytosine to uracil (C-to-U) as part of innate antiviral immune responses. Aberrant expression of A3 enzymes in several cancers leads to DNA damage, mutagenesis, and genomic instability. In breast cancer, in particular, APOBEC3B (A3B) is the major endogenous mutator that contributes to tumor evolution and resistance to treatment (1–4). DNA C-to-U deamination events result in characteristic C-to-T transitions and C-to-G transversions, and genomic uracils can also be processed into single- or double-stranded DNA breaks and larger chromosomal aberrations. Consequently, tumors with elevated A3B levels endure chronic genotoxic stress and may exhibit increased sensitivity to inhibitors targeting specific DNA repair pathways.

Previous research from our laboratory identified DNA uracil glycosylase 2 (UNG2), a critical initiator of the base excision repair (BER) pathway, as a synthetic lethal partner with A3B (5). Genetic disruption of UNG2, combined with high A3B expression, led to cell death (5). This finding suggests that other DNA repair proteins could potentially serve as synthetic lethal partners with A3B under conditions of elevated A3B-induced DNA damage.

To test this hypothesis, we used pharmacological and genetic inhibition of DNA damage repair proteins in isogenic cell line models for A3B. Specifically, we quantified cancer cell viability following treatment with various commercially available DNA damage response inhibitors, in the presence or absence of A3B. Additionally, we performed CRISPR screens using a guide RNA library targeting 237 DNA damage repair and response genes in a doxycycline-inducible TREX-293-A3Bi-eGFP cell line. Cells expressing or lacking A3B were harvested for DNA extraction and sequencing at different time points. By comparing guide RNA abundance between doxycycline-treated cells and untreated cells, we identified dropout guides that disrupt genes, creating potential synthetic lethal combinations with A3B. The results from both pharmacological and genetic inhibition approaches will be presented.

P5-06-27: OXTR inhibits breast cancer cell invasion and metastasis by regulating the post-translational modification of the COL1A1 protein to accelerate its degradation through the lysosomal pathway.

Qing Shao

Background: The oxytocin receptor (OXTR) is a hormone receptor that is highly expressed in the breast, and its expression is significantly reduced when breast tissue becomes cancerous. In addition to serving as a receptor for receiving stimulation from hormones, neurotransmitters, and growth factors to mediate their effects, the biological function and molecular mechanism of OXTR itself in breast cancer (BrCa) are still unclear.
Methods: Using quantitative PCR (qRT-PCR), Western blot, immunohistochemistry (IHC), and public database analysis, the expression of OXTR in BrCa adjacent normal tissues, BrCa tissues, and metastatic tissues, as well as its correlation with prognosis were evaluated. The migration and invasion functions of OXTR were analyzed by wound-healing and transwell assays in vitro. Lung metastatic tumor models were used to study the invasion and metastasis of OXTR in vivo. RNA-seq, Western blot, immunofluorescence (IF), immunoprecipitation (IP) and Co-IP were further applied to determine the detailed mechanism.
Results: OXTR is downregulated in BrCa tissues, especially in distant metastases. Patients with lower OXTR expression have worse overall survival (OS) and distant metastasis-free survival (DMFS). In functional experiments, overexpression of OXTR suppresses BrCa cell migration, invasion and metastasis in vitro and in vivo. Conversely, knockdown of OXTR increased BrCa cell spreading. OXTR functions by inhibiting the expression of the oncoprotein collagen type I alpha 1 chain (COL1A1), which is closely associated with epithelial-mesenchymal transition (EMT). The mechanism is mainly that OXTR causes the decrease of COL1A1 protein phosphorylation and the increase of O-GlcNAcylation by down-regulating CDK1. However, O-GlcNAcylated COL1A1 is unstable and can be easily degraded by the lysosomal pathway.
Conclusions: This study extends the ligand-independent function of OXTR in BrCa and highlights the role of OXTR in suppressing invasion and metastasis of BrCa cells, as well as predicting prognosis. This study elucidates the specific mechanism by which OXTR accelerates the degradation of COL1A1 protein by regulating its post-translational modifications (PTMs), thereby affecting the malignant progression of cancer cell metastasis. These findings suggest that OXTR may serve as a marker to predict the metastatic potential or prognosis of BrCa.

P5-06-28: Characterization of cell type specific distal cis-regulatory elements from 5’ scRNA-seq in estrogen receptor positive breast cancer patients treated with aromatase inhibitors

Villads Winton, Ilayda Altinönder, Marie Fongaard, Pål Marius Bjørnstad, Knut Selsås, Stephanie Beate Geisler, Manouchehr Seyedzadeh, Unn-Cathrin Buvarp, Torben Lüders, Marianne Lyngra, Arnoldo Frigessi, Vessela Kristensen, Anthony Mathelier, Jürgen Geisler, Xavier Tekpli

Introduction: Aromatase inhibitors (AIs) are widely used in the treatment of estrogen receptor-positive (ER+) breast cancer to inhibit estrogen production and suppress the ER signaling pathway. Target genes regulated by estrogen stimulation of ER+ malignant cells lead to uncontrolled proliferation.
The NEOLETEXE trial evaluated the sequential use of letrozole (2.5 mg daily) and exemestane (25 mg daily) in the neoadjuvant setting. We performed single-cell RNA sequencing (scRNA-seq) on 24 patients enrolled in the NEOLETEXE trial (i) before treatment, (ii) before change of AI (crossover at 3 months), and (iii) at the end of neoadjuvant therapy (6 months of treatment).

Methods and aims: We aim at characterizing the distal and proximal regulatory elements in different cell types and states observed in longitudinally collected tumor samples. Transcription factor regulatory networks are important determinants of ER+ breast cancer pathogenesis. Understanding the dynamic changes in regulatory element usage under treatment pressure will help to map the molecular events associated with sensitivity or resistance to AI therapy.
We used SCAFE (Single-Cell Analysis of Five-prime Ends), a computational method that maps transcribed cis-regulatory elements (CREs) in single cells using 5’ end scRNA-seq data.

Results: Using unsupervised clustering of scRNA gene expression, we identified the major cell types in ER+ breast tumors. SCAFE was applied to identify 99,996 distal CREs (i.e., enhancers) in a cell type-agnostic manner. We quantified the reads mapping to each distal CRE in each cell creating a cell-by-distal CRE count matrix. We employed a Latent Dirichlet Allocation topic model implemented in pyCistopic to evaluate the significance of enhancers in determining cell phenotypes. Additionally, we characterized the distal CRE landscape specific to each cell type and state, providing an atlas of cell type-specific enhancer usage in breast tumors. By predicting direct transcription factor binding to the corresponding CRE’s DNA sequences using UniBind, we identified ESR1, FOXA1, and GATA3 as transcription factors associated with enhancers in malignant cells. In contrast, in immune cells such as T cells, we found enriched binding sites for RUNX1, ETS, and TBX21.

Conclusions: Using 5' end scRNA-seq data, we successfully generated an atlas of distal regulatory elements for each cell in breast tumors. We identified the transcription factors

likely to activate these cell type-specific distal regulatory elements. Mapping distal regulatory elements usage and transcriptomes in single cells allows us to study the interplay between enhancer activity, transcription factor binding, and gene regulation. It provides insights into the molecular mechanisms of AI therapy sensitivity and resistance and sheds light on the driver pathways associated with cell phenotypes and states in ER+ breast cancer.

P5-06-29: Tumor and endothelial cell-specific methylation alterations identified in breast cancer with epigenetic deconvolution

Barbara Barbara, Lucas A. Salas, Brock C. Christensen

DNA methylation, an essential epigenetic modification, plays a critical role in establishing and maintaining cellular identities by regulating gene expression. In cancer, aberrant DNA methylation patterns contribute to tumor development and progression, yet the cell-type-specific methylation alterations within the tumor microenvironment (TME) remain poorly understood. In breast cancer, a highly heterogeneous malignancy, endothelial cells within the TME (TECs) are key players in tumor angiogenesis and progression. Methylation changes detected in bulk tumor analyses, however, reflect signals from multiple cell types present in the TME, making it challenging to pinpoint cell-type-specific epigenetic changes. Recently, methods have been developed to using DNA methylation to deconvolute cell type proportions which can in turn be used to attribute methylation alterations to specific cell types in the TME. A reference-based cell-type deconvolution algorithm, the Hierarchical Tumor Immune Microenvironment Epigenetic Deconvolution (HiTIMED) method, allows accurate quantification of cell type proportions within the TME.
We accessed DNA methylation array data from 609 breast tumors and 331 nontumor normal breast tissues from the Gene Expression Omnibus (GEO) and the Genotype-Tissue Expression (GTEx) portal. To these DNA methylation profiles, we applied HiTIMED and measured tumor and non-tumor cell proportions. Then, applying a statistical interaction model called CellDMC we leveraged the cell type proportion data to identify differential methylation specific to cell types in the breast cancer TME, including TECs and tumor cells. We identified 1897 tumor-cell-specific and 180 TEC-specific differentially methylated cytosines (DMCs) in cancer compared to normal breast tissue (FDR ≤ 1e-10). Importantly, in the cell-type unadjusted differential analysis, tumors exhibited hypermethylation compared to normal tissues; however, in the tumor-cell-specific analysis, tumor cells were hypomethylated relative to normal samples.
By applying these advanced techniques to breast cancer samples, our study unveils cell-type-specific DNA methylation changes that are pivotal in driving the pro-tumorigenic environment. These findings not only enhance our understanding of the molecular mechanisms underlying breast cancer progression but also highlight potential therapeutic targets within the TME. The integration of HiTIMED and CellDMC represents a significant methodological advancement in cancer epigenetics, offering a more precise and insightful approach to studying the complex interplay between different cell types within the TME.

P5-06-30: Distinct ERBB2 amplification patterns in HER2-positive breast cancers with BRCA1/2 mutations and their therapeutic implications

Jiwon Koh, Yeon Hee Park, Kyung-Hun Lee, Jinyong Kim, Han Suk Ryu, Ryul Kim, Dae-Won Lee, Changhee Park, Han-Byoel Lee, Baek-Lok Oh, Jeong Seok Lee, Young Seok Ju, Seock-Ah Im

Background: Traditionally, HER2-positive breast cancers (BC) were considered rare among germline BRCA1/2 (gBRCA1/2) mutant breast cancers. However, recent studies reported that up to 7% of the gBRCA1/2 mutant BCs are HER2-positive. The detailed clinicopathological features of HER2-positive BCs with germline or somatic BRCA1/2 mutations remain largely unknown.

Methods: Inspired by a family of two gBRCA2-mutated HER2-positive BC patients, we established a cohort of Korean patients with HER2-positive BCs harboring germline or somatic BRCA1/2 mutations. We performed whole genome sequencing (WGS) to assess the patterns of ERBB2 amplification in these patients.

Results: A total of 12 patients from two institutions were included. The median age was 53 years (range, 28 – 70). BRCA1 mutations were found in 4 (33.3%) patients; three patients (25.0%) had gBRCA1 mutation, and one patient (8.3%) harbored a somatic BRCA1 mutation (sBRCA1) (SNUH08). Eight patients (66.7%) had gBRCA2 mutations, including the index family with one triple-negative BC (TNBC) patient (SNUH01) and two ER+/HER2-positive BCs (SNUH02 and SNUH03), who are the daughter and sister of SNUH01. WGS was performed on 14 samples. This included two bilateral samples from SNUH07 (SNUH07_L, TNBC; SNUH07_R, ER+/HER2-positive) and two ipsilateral tumors at different quadrants from SNUH09 (both ER+ HER2-low BCs, namely SNUH09_1H and SNUH09_10H). Of the remaining samples, 7/10 were ER+/HER2-positive, and one ER+/HER2-low, one ER+/HER2-negative, and one ER-/HER2-low samples had ERBB2 amplification on WGS. Nine tumors (64.3%) with gBRCA1/2 had loss of wild-type allele, leading to homologous recombination deficiency (HRD), supported by an in-house developed algorithm based on HRDetect. None of the eight gBRCA1/2 mutated tumors (excluding SNUH01) showed focal high-level ERBB2 amplification, indicating a low likelihood of extrachromosomal DNA (ecDNA)-mediated process. The sBRCA1 tumor (SNUH08) was also classified as HRD without focal high-level ERBB2 amplification. Two multicentric ER+/HER2-low BCs from SNUH09 shared a gBRCA2 mutation and most somatic mutations, suggesting a common clonal origin, but lacked BRCA2 loss of heterozygosity and were classified as HR proficient (HRP). These tumors showed increased ERBB2 copy numbers without evidence of ecDNA-mediated amplifications. The median ERBB2 copy numbers in the 11 tumors were 7 (range, 4 – 13). Two distinct ERBB2 amplification patterns were identified: pattern 1 with non-focal moderate-level amplification and large-scale copy number elevation of chromosome 17q, and pattern 2 with focal moderate-level amplification associated with complex genomic rearrangement involving chromosome 17q. Among the 11 BRCA1/2-mutated HER2-positive

BCs, 5 (45.5%) showed pattern 1, and 6 (54.5%) exhibited pattern 2. All three BRCA1 mutant BCs showed pattern 1, while BRCA2 mutant tumors had both pattern 1 (5/8) and pattern 2 (3/8). Bilateral BCs from SNUH07 demonstrated two different mechanisms of carcinogenesis. SNUH07_L (TNBC) was an HRD tumor with gBRCA1 mutation with loss of wild-type allele, while SNUH07_R (HER2-positive) lost the mutant BRCA1 allele, making it HRP with ecDNA-mediated focal high-level ERBB2 amplification. From a therapeutic standpoint, SNUH08 exhibited an exceptional response to trastuzumab deruxtecan (T-DXd). We hypothesize this response is due to enhanced binding of T-DXd to the pattern 1 ERRB2 amplified tumor, with the topoisomerase I inhibitor payload effectively targeting the HRD genome.
Conclusion: We identified two distinct ERBB2 amplification patterns in HER2-positive breast cancers with BRCA1/2 mutations. These tumors could be ideal candidates for anti-HER2 antibody-drug conjugate due to their enhanced binding affinity and increased susceptibility of HRD cancer cells to specific cytotoxic agents.

P5-07-01: A Systematic Review and Meta-Analysis on Surgical Outcomes of LigasureTM versus Conventional Methods in Axillary Lymph Node Dissection for Breast Cancer Patients

Maria Gloria Elisha Casas-Siena, Isaac David E. Ampil

Background: Breast cancer has an increasing disease burden and mastectomy with axillary lymph node dissection (ALND) remains a mainstay in its treatment despite advancement in surgical techniques. ALND leads to seroma formation, prolonged use of drains, delayed wound healing and infection. LigasureTM, a vessel sealing device, demonstrates shorter operative time and damage to surrounding tissues in previous studies. Its application to axillary dissection has been studied prior but with varying results.
Objectives: To determine the efficacy of LigasureTM for axillary dissection over conventional axillary dissection for drainage volume, seroma formation, time to drain removal, operative time and hospital stay.
Methods: Two investigators conducted an online database search for randomized controlled trials on LigasureTM versus conventional axillary dissection excluding non-cancer mastectomies, comparison to other energy sources, retrospective studies, single-arm studies, case reports or case series. Revman Web was used for data analysis. Risk ratio was used for the dichotomous data and mean difference was used for continuous data. Heterogeneity was assessed with Chi square Test and Inconsistency Index (if with substantial heterogeneity if I2 = >50%) and random effects model was used if significant heterogeneity was present. Risk of Bias 2 tool was used to assess bias for the individual studies included. Sensitivity analysis was done on outcomes with high risk of bias and heterogeneity.
Results: The Ligasure group showed statistically significant decrease in drainage volume (n = 387 patients, 95% CI, p value = <0.00001, -185.67 [-295.38, -75.95]), decrease time to drain removal (n = 232 patients, 95% CI, p value = 0.0009, -1.77 [-.2.81 vs -0.72]), and

shorter hospital stay (n = 239 patients, 95% CI, p value =<0.001, -1.21 [-1.96, -0.47]) over conventional axillary dissection. There was no significant difference in incidence of seroma formation and operative time. A high risk of bias was noted in the reporting of seroma formation (inconsistent definitions) and time to drain removal mainly due to lack a standard criteria for removal.
Conclusion: Ligasure has a significant effect in terms of postoperative drainage volume, time to removal and hospital stay to patients who underwent axillary dissection. The authors recommend a larger study with a subgroup analysis on age and body mass index (BMI) as literature have shown added benefit in these groups.
Keywords: Ligasure, Axillary Lymph Node Dissection, Breast Cancer, Mastectomy

P5-07-02: Effects of prehab or rehabilitation on pain and measures of upper extremity mobility and strength after breast cancer surgery

Kelley Wood, Jessica Bertram, Amanda Hodges, Nikita Godbole, Vanessa Brizeno, Peter C. Ng, Jessica Perchaluk, Michelle Lynn, Julie Rice, Kelsey N. Thompson, Deanna Meehan, Megan Redfern, Sruti Manvi, Megan A. Deblieck, Amber Weinheimer, Jonathan Erickson, Franceah Palencia, Tiffany Croteau, Aaron Hwang, Rhonda K. Bentura, Ashley Lightner, Alaina Newell, Stacye Mayo, Lynn Canavan, Mackenzi Pergolotti

Introduction: Use of physical and/or occupational therapy (PT/OT) services is recommended to optimize recovery from surgery. Growing research evidence suggests early intervention may result in the best outcomes, but it is unclear if these benefits are also observed in real-world PT/OT services. We performed a retrospective study of women with breast cancer who participated in real-world outpatient rehabilitation services. Aims were to examine the effect of participating in prehab (PT/OT starting before surgery and continuing afterward) versus rehab-only (PT/OT starting after surgery) on pain and measures of upper extremity mobility and strength after surgery.
Methods: Outpatient rehabilitation medical record data was extracted for cases who attended prehab (n=350) or rehab-only (n=246). Outcomes included pain (0 [lowest] to 10 [highest]), handgrip strength (HGS, lbs) and shoulder range of motion (degrees of flexion, extension, and abduction) of the affected side. Outcomes were compared between groups at two timepoints: the post-surgery evaluation and subsequent discharge. Covariates were identified using t-tests and correlation analysis. Linear mixed-effect models were used to examine between-group differences at each timepoint while controlling for covariates (age, recent fall, BMI, surgery type, lymph node dissection type), and to examine changes in outcomes from evaluation to discharge for each group. Estimated marginal means, standard error, and p-value are reported.
Results: On average, cases were 59.37±13.47 years old and had a BMI of 28.27. Cases received: mastectomy (54.5%) or lumpectomy (45.5%) and sentinel lymph node biopsy (SLNB, 78.2%) or axillary lymph node dissection (ALND, 19.3%). 2.5% received both SLNB and ALND. 11.4% reported a fall in the past year. Prehab cases were younger (62.3 vs. 54.2, p<.001), more likely to have had a lumpectomy (p<.001) and SLNB (p<.001), and more

likely to have fallen in the past year (p=.002). There were no other between group differences. After adjusting for covariates, prehab cases had less pain (prehab: 3.23±0.21, rehab-only: 4.91±0.25, p<.001) greater HGS (prehab: 50.04±0.78, rehab-only: 44.04±1.07, p<.001), and better ROM in each plane at the post-surgery evaluation (all p<.001): flexion (prehab: 140.42±1.36, rehab-only: 128.35±1.58), extension (prehab: 80.67±2.19, rehab-only: 66.02±2.21), and abduction (prehab: 138.77±1.73, rehab-only: 119.46±2.15). From evaluation to discharge, a significant reduction in pain (prehab: -1.02±0.23, p<.001; rehab-only: -1.93±0.28, p<.001) and significant improvement in HGS (prehab: +2.43±0.70, p<.001; rehab-only: +5.34±0.88, p<.001), ROM-flexion (prehab: +13.70±1.88, p<.001; rehab-only: +28.53±2.04, p<.001), and ROM-abduction (prehab: +17.90±2.40, p<.001; rehab-only: +40.48±2.62, p<.001) was observed for both prehab and rehab-only cases. For ROM-extension, significant improvement was observed for rehab-only cases (+11.77±1.88, p<.001); improvement for prehab cases was non-significant but within normal ranges (+2.17±1.60, p=.167). At discharge, prehab cases had significantly greater HGS (prehab: 52.47±0.88; rehab-only: 49.38±1.18; p=.039) and ROM-extension (prehab: 82.88±2.41, rehab-only: 77.79±2.36, p=.026) than rehab-only cases.
Conclusion: Women with breast cancer who attended prehab were younger, more likely to have received a lumpectomy with SLNB and have reported a recent fall. After controlling for covariates, prehab cases had less pain, greater strength, and better ROM after surgery. While both prehab and rehab-only cases improved significantly during post-surgery PT/OT, prehab cases had greater strength and ROM at discharge, suggesting early intervention may prevent declines and optimize outcomes. Although more research is needed, these findings support integration of PT/OT in routine care.

P5-07-03: Patient-Reported Outcomes Following Various Breast Reconstruction Techniques: A Retrospective Cohort Study in China

Hongmei Zheng, Yuhang Song, Lingzi Wang, Xinhong Wu

Background: Breast reconstruction surgery is crucial for restoring physical integrity and self-image in women post-mastectomy. However, there is limited data from China comparing the effects of different surgical approaches on patient satisfaction. This study aims to evaluate patient-reported aesthetic outcomes following various breast reconstruction techniques in China and to explore the factors associated with patient-reported aesthetic outcomes.
Methods: We conducted a retrospective cohort study including female patients who underwent mastectomy followed by breast reconstruction at Hubei Cancer Hospital between January 2019 and April 2024. Exclusion criteria were bilateral reconstructions, simple nipple-areola complex reconstructions, breast-conserving procedures, and missing critical data. Surgical data were extracted from the Hospital Information System. Patient-reported outcome measures, including the Breast-Q Breast Cancer Core Scale V2.0 (three dimensions: satisfaction with breasts, psychosocial well-being, and sexual well-being), the five-dimension, five-level EuroQol health questionnaire, and the Decision Regret Scale, were

collected through outpatient reviews and telephonic follow-ups with an Online Questionnaire. Surgery complications were also recorded. Multivariate linear regression was used to identify independent predictors of satisfaction with breasts and psychosocial well-being scores.
Results: The study included 167 patients. The surgical techniques used were lateral chest wall incision (n=21), radial incision (n=69), inframammary fold incision (n=49), endoscopic-assisted surgery (n=14), and other incisions (n=14) which included periareolar incision (n=7), dual incision (n=5), irregular incision (n=1), and L-shaped incision (n=1). The median age was 40 years (IQR: 34-47), with significant age distribution differences among groups (p=0.048). Significant differences were also noted between groups in surgical approach (p=0.034), use of acellular dermal matrix or grafts (p=0.031), implant placement plane (p<0.001), type of implant (p=0.001), and total surgical cost (p=0.049). The psychosocial well-being scores significantly differed among groups (p=0.028), with the highest median score in the other incision group (96.5, IQR 69.5-100) and the second highest median score in the endoscopic-assisted surgery group (81.50, IQR 62.00-100.00). Multivariate analysis revealed that reduced postoperative bra cup size was negatively associated with satisfaction with breasts (β=-12.559; 95% CI: -19.674, -5.443; p=0.001). Age 35-50 (β=9.654; 95% CI: 2.803, 16.506; p=0.006) and over 50 (β=11.413; 95% CI: 2.364, 20.462; p=0.014) were positively associated with psychosocial well-being. Sentinel lymph node biopsy (SLNB) negatively impacted psychosocial well-being (β=-14.454; 95% CI: -26.591, -2.318; p=0.02). Other incision types significantly improved psychosocial well-being (β=17.482; 95% CI: 4.123, 30.841; p=0.011), while endoscopic-assisted surgery showed a trend toward improvement (β=12.822; 95% CI: -0.412, 26.056; p=0.057). Postoperative complications were reported in 22 patients (13.2%), with 2 (9.5%) from the lateral chest wall incision group, 14 (20.3%) from the radial incision group, 5 (10.2%) from the inframammary fold incision group, and 1 (7.1%) from the other incision group.
Conclusion: Traditional incision techniques, such as radial and inframammary fold incisions, remain prevalent in China, though minimally invasive approaches show promising trends for better patient-reported aesthetic outcomes, the application would still need to be further promoted. Factors such as age, reduced bra cup size, SLNB, and incision type influence patient-reported aesthetic outcomes.

P5-07-04: Postoperative upper Limb Edema and Dysfunction Generated by axillary nodes Excision in breast cancer patients with high or low proportion of upper limb venous reflux(PLEDGE-Reflux): a multicenter, prospective cohort study

Qianrui Xu, Xiangyun Zong, Xue Peng, Qianrui Xu, Fen Tang, Yang Yu, Hongjian Yang, Wei Zhang, Ziwei Sun, Junhong Zhou, Fang Cheng, Kewei Sun, Qi Shao, Weiyun Pan, Yurong Zheng, Jiejie Hu, Chengdong Qin

Background: The purpose of this study was to explore the influence of the proportion of axillary venous reflux(PVR) on the incidence of upper limb edema and dysfunction in

patients with breast cancer after axillary lymph node dissection.

Methods: The study was designed as a multicentre, prospective cohort study, which was carried out in Shanghai Sixth People's Hospital, Shanghai Fengxian Central Hospital, and Zhejiang Cancer Hospital in China. The patient cohort consisted of patients who met the PLEDGE-Surgery study(NCT05120180) inclusion criteria and were ultimately randomly assigned to undergo ALND surgery with or without preservation of axillary vein branches.The primary endpoint was the short-term(1-month, 6-month and 12-month) incidence of postoperative upper limb lymphedema and dysfunction on the affected side. The secondary endpoints were tumor-free survival and the incidence of upper limb lymphedema and dysfunction at 5 years postoperatively. Preoperative ultrasound measurement was used to calculate the PVR for each patient. After surgery, arm circumference and DASH score were measured at 1 month, 6 months, 12 months, and 5 years. Patients were divided into Preponderant venous reflux group and Preponderant lymphatic reflux group based on the high or low PVR. Chi square test was used to compare the differences in the incidence of upper limb edema/dysfunction between two groups, and least absolute shrinkage and selection operator (LASSO) regression was performed to screen for risk factors of upper limb edema/dysfunction and establish an optimized model nomogram. The discrimination, calibration, and clinical validity of the model were evaluated. AUC value>0.7 is considered a good discrimination of the model. The Bootstrap method (repeated self-sampling 1000 times) was used to verify the constructed model internally to evaluate the accuracy of the constructed model. Data collection and initial analysis were conducted 3 months after patient recruitment was closed. All patients were included in the final analysis per protocol. The trial was registered with ClinicalTrials.gov, NCT05246592.

Findings

From January 3rd, 2022 to April 1st, 2024, a total of 258 female patients were randomly assigned to the PLEDGE-Surgery study, all of whom were included in the analysis of this study. The median age was 53 years(IQR 47-59). The median follow-up was 14.2 months(IQR 10.6-17.6). The average upper limb PVR was 25.94%±18.87%. The optimal cutpoint for the PVR was determined to be 15.223% using the ROC curve. Based on this, patients were divided into a Preponderant venous reflux group(PVR>15.223%) and a Preponderant lymphatic reflux group(PVR<15.223%). The Fisher's exact test showed that there was no significant difference in the incidence of upper limb edema between the two groups at 1 month after surgery(3/151 vs. 0/78, ARR 1.99%, P=0.553, OR was not available), but there were significant differences at 6(1/110 vs. 10/51, ARR 18.7%, P=0.000, OR 26.585, 95% CI [3.299, 214.244]) and 12 months after surgery(1/75 vs. 11/35, ARR 30.10%, P=0.000, OR 33.917, 95% CI [4.161, 276.485]). The incidence of upper limb edema in the Preponderant venous reflux group(RR: 0.125[0.019, 0.813] at 6-month, 0.110[0.017, 0.723] at 12-month) was significantly lower than that in the Preponderant lymphatic reflux group(RR: 3.326[2.413, 4.585] at 6-month, 3.743[2.541, 5.513] at 12-month). The predictive model we developed for diagnosing postoperative upper limb edema achieved an area under the curve (AUC) of 0.919(95%CI: 0.778-1.000) in the cohort. The model

concluded the variables selected by as preponderant lymphatic reflux group, ALND without axillary vein branches preservation, level 3 lymphadenectomy, and post-surgical wound infections. The AUC of the optimized model obtained by internal validation were 0.910.

Interpretation: Proportion of upper limb venous reflux, a previously understudied factor significantly associated with postoperative upper limb edema, has been incorporated into a nomogram predictive model in this study. The constructed model demonstrates a robust predictive value and effectively anticipates the occurrence of postoperative upper limb edema in breast cancer patients.

Keywords
Breast cancer, Lymphedema, Upper limb dysfunction, Axillary lymph node dissection, proportion of upper limb venous reflux, ratio of axillary venous/lymphatic reflux

P5-07-05: A Comparison of Wire Guided and Magseed Localisation in Impalpable Breast Lesions

Saira Khawaja, Cameron Bruce, Asma Munir, Mr Sohail Khan, Nida Javed, Anita Huws, Yousef Sharaiha

Introduction: Wire-guided localization (WGL) has been a cornerstone in breast-conserving surgery, providing a reliable method to accurately localize lesions. While effective, WGL can sometimes cause discomfort to patients and requires precise timing on the day of the surgery. In contrast, recent advancements have led to the development of Magseed, a magnetic marker that represents a significant innovation in tumour localization. Magseed is a 5 mm long, surgical-grade stainless steel marker, non-radioactive and designed for less intrusive and more flexible application than WGL. It is placed in the breast using a needle under local anaesthesia and located during surgery with the Sentimag probe, a magnetic sensing system. This approach not only allows for precise tumour localization but also enhances patient comfort by reducing pre-operative anxiety and discomfort associated with the protruding wire of WGL. Both Magseed and WGL are crucial in accurately marking tumours for breast-conserving surgeries, yet Magseed offers potential advantages in terms of patient experience and surgical planning. As breast cancer surgery continues to evolve, these techniques play a pivotal role in improving clinical outcomes and patient-centric care in the treatment of breast cancer.

Methodology: We conducted a retrospective analysis of 197 patients, with 99 undergoing WGL and 98 undergoing Magseed localisation. Patient records were retrospectively accessed to gain information regarding patient demographics, specimen weight, tumour size, clear margin rate and node positivity, evaluated histopathological reporting. Statistical significance between the two groups was analysed using a Fischer exact and Chi Square

hypothesis testing with a p-value <0.05 considered significant.

Results: In our study comparing Wire guided Wide Local Excision and Magseed Wide Local Excision for breast-conserving surgery, we evaluated 99 patients in the Wire group and 98 in the Magseed group. The median age was 64.70 years in the Wire group and 62.76 years in the Magseed group, with average ages of 64.46 years and 61.19 years, respectively. In the Wire group, the average tumour size was 20.31mm with a standard deviation of 14.72mm, a median of 15mm, and an interquartile range of 15.10mm. Conversely, in the Magseed group, the average tumour size was 16.89mm with a standard deviation of 9.27mm, a median of 15mm, and an interquartile range of 10.75mm. Both groups predominantly featured Grade 2 tumours and Ductal type tumours. Node positivity rates were 3.0% in the Wire group and 13.0% in the Magseed group. The clear margin rate was 93.83% in the Wire group (95% CI: 93.5.8% to 98.5%) and 94.58% in the Magseed group (95% CI: 89.8% to 99.2%), with the difference not being statistically significant (p=0.784).

Discussion: Our study's findings reveal that wire localisation exhibited a slightly larger average tumour size compared to the Magseed localisation, which might be reflective of the differing nature of these two techniques in tumour localization and subsequent surgical planning. Despite this, the clear margin rates were notably high in both groups, with magseed localisation achieving a marginally higher rate. However, the difference did not reach statistical significance, indicating that both methods are comparably effective in ensuring successful tumour removal with clear margins.
In the context of patient comfort and procedural efficiency, Magseed’s non-protruding nature offers a distinct advantage over WGL, potentially reducing pre-operative discomfort and anxiety. However, our results suggest that this technological advancement does not compromise the surgical efficacy, as evidenced by the comparable clear margin rates between the two groups.
Ultimately, our study highlights that both WGL and Magseed are effective techniques for tumour localisation in breast-conserving surgery. The choice of technique may be influenced by various factors, including tumour characteristics, patient preferences, and resource availability. As breast cancer surgery continues to evolve, such comparative analyses become crucial in guiding clinical decisions and advancing patient-centred care.

Background: Wire-guided localization (WGL) is a well-established technique for tumor localization in breast-conserving surgery (BCS). However, Magseed localization, a newer technique utilizing a magnetic marker, may offer advantages in patient comfort and surgical planning due to its non-protruding nature. This study aimed to compare WGL and Magseed localization in terms of patient demographics, tumor characteristics, margin status, node positivity, and long-term oncologic outcomes.
Methods: A retrospective analysis was conducted on 197 patients between August 2023 and April 2024 undergoing BCS at a single institution, with 99 patients in the WGL group and 98 in the Magseed group. Patient demographics, tumor size, margin status, node positivity, and histopathological features were assessed. Statistical analysis was performed using Fischer's

exact and Chi-squared hypothesis testing. A value of <0.05 was deemed to be significant.

Results: The median age was 64.70 years (range: 33-84) in the WGL group and 62.76 years (range: 33-78) in the Magseed group. The average tumor size was 20.31mm (SD = 14.72mm) in the WGL group and 16.89mm (SD = 9.27mm) in the Magseed group. Both groups predominantly featured Grade 2, ductal-type tumors. Node positivity rates were 3.0% in the WGL group and 13.0% in the Magseed group. The clear margin rate was 93.83% (95% CI: 93.58% to 98.5%) in the WGL group and 94.58% (95% CI: 89.8% to 99.2%) in the Magseed group, with this difference not being statistically significant (p=0.784).
Conclusions: Both WGL and Magseed localization demonstrated high rates of clear margins in this patient cohort. The slightly larger average tumor size in the WGL group may be attributed to inherent differences in tumor localization and procedural variation between the two techniques. In the context of patient comfort and procedural efficiency, Magseed's non-protruding nature offers a distinct advantage over WGL, potentially reducing pre-operative discomfort and anxiety. However, our results suggest that this technological advancement does not compromise the surgical efficacy, as evidenced by the comparable clear margin rates between the two groups. Overall, The data suggests both techniques are effective for tumor localization in BCS, and the choice between them may be influenced by individual patient and tumor characteristics, as well as surgeon preference and institutional availability.

P5-07-06: Long-term follow-up of Immediate lymphaticovenous anastomosis based on Lymphosome Mapping Strategy after axillary lymph node dissection in breast cancer

Richard Chih-Hau Chang, Chao-Ming Hung

Purpose: Total mastectomy, axilla lymph node dissection, and postoperative radiation therapy in breast cancer could disrupt lymphatic function and lead to debilitating breast cancer-related lymphedema (BCRL). Conventional Lymphatic Microsurgical Preventing Healing Approach (LMPHA), and the immediate lymphatic reconstruction (ILR) with lymphaticovenous anastomosis (LVA) aimed to promote lymphatic system restoration. However, a consensus surgical approach was not established yet, and there were no equivocal long-term results. In this study, 4 major lymphosome vessels categorized as radial volar, ulnar volar, radial dorsal, and ulnar dorsal lymphosome were dressed with indocyanine green fluorescence (ICG) lymphography and further divided into 3 types based on extra-axilla lymphatic vessels or not. Restoration of the disrupted lymphatic vessel that the axilla wound revealed and which major lymphosome included. Follow-up results were analyzed.

Materials and Methods: A retrospective cohort audit was conducted, reviewing the collected data from 20 patients (22 limbs) who underwent immediate LVA at E da Cancer Hospital

between June 2022 and June 2024. Major afferent lymphatic vessels are identified by ICG lymphography and categorized into 3 types. Microscopic images confirm the severance of the major afferent lymphatic vessels. Standard LVA was performed and each LVA was anastomosed into a vein distal to a competent valve and patency was confirmed with ICG video lymphangiography by operative microscope.

Results: Over 24 months, 20 patients (22 limbs) included triple negative cases, there were no immediate LVA complications. The mean follow-up time was 12 months (3-24 months). There was no transient radiation-related lymphedema and no significant difference between pre- and post-op in-arm measurements, and one case progressed to ISL stage 1 since axilla lymph node local recurrence. No distinguishable arm circumference measurement that compared to the contralateral side in between each type of lymphosome and no case present clinical pitting edema.

Conclusion: Based on the knowledge of compensatory lymphatic vessels; in the short-term results of type I lymphosome, there is no higher risk of developing lymphedema after the ILR and even post-radiation therapy. The ILR repaired major lymphosome lymphatic vessels by LVA presents a novel and comprehensive strategy for restoring lymphatic system function. Early data showed IRL offers a more feasible, safe, and effective primary prevention of BCRL. We need more long-term follow-ups and cases to uncover the differences and insights between the three types.

P5-07-07: USING FLUORESCEIN FOR DETECTION OF SENTINEL LYMPH NODES IN COMBINATION WITH TARGETED AXILLARY LYMPH NODE DISSECTION IN BREAST CANCER: PRELIMINARY RESULTS OF EFFICACY AND SAFETY STUDY

Aleksander Soinov, Michail Voronov, Vladimir Vorotnikov, Tornike Mchedlidze, Sardor Abdugafforov, Igor Kopytich, Regina Pakhomov, Maria Sharavina, Marcha Mukueva, Stanislav Tsalko, Viktoria Andreeva, Alina Tkachenko, Aleksandra Gugnina

Introduce: Sentinel lymph node biopsy (SLNB) is the standard staging procedure for early breast cancer (BC). Currently, various markers are used to detect sentinel lymph nodes, including radioisotopes, methylene blue dyes, and fluorescent agents.The aim of this study was to evaluate the effectiveness of sentinel lymph node biopsy using fluorescein and an LED lamp in breast cancer patients, and to assess the safety and tolerability of fluorescein for the sentinel lymph node biopsy procedure in breast cancer patients.The objective of this study was to identify lymph nodes marked with fluorescein, identify lymph nodes marked with the radiopharmaceutical technetium 99mTc, and compare the number of cases of detection of sentinel lymph nodes using fluorescein and an LED lamp with the number of cases of detection of sentinel lymph nodes using technetium 99mTc.

Materials and Methods: 90 patients with a diagnosis of breast cancer with metastatic lymph nodes, who were planned to undergo neoadjuvant chemotherapy, underwent a procedure to stain the enlarged lymph nodes in the axillary area with the "BLACK EYE" dye. The second stage was surgical treatment. All patients underwent a sentinel lymph node biopsy procedure using a combined method with fluorescein and the radiopharmaceutical technetium 99mTc. Fluorescein and technetium 99mTc radiopharmaceutical were injected intradermally into the areola of the affected breast of each patient. Sentinel lymph nodes stained with fluorescein were first detected using an LED probe, then with a gamma detector, and then removed. Targeted axillary lymph node dissection was performed, during which all lymph nodes stained with the "BLACK EYE" dye were removed. The material was sent for urgent histological examination, and in case of metastases, axillary lymphadenectomy was performed. Further, the frequency of detection of sentinel lymph nodes was analyzed and the presence of complications was investigated.ResultsIn total, 60 sentinel lymph nodes were detected and removed using technetium 99mTc and a gamma detector (2-3 lymph nodes per patient). Fluorescein was present in 57 out of 60 removed lymph nodes. "BLACK EYE" dye was found in 30 sentinel lymph nodes. None of the patients experienced complications related to the use of fluorescein or blue LED light.

Conclusions: Based on the preliminary data, it can be concluded that the use of fluorescein for lymph node marking in SLNB in breast cancer patients has potentially high efficacy and safety. Given the availability of the method - low cost of the drug and equipment, fluorescein can become an alternative to ICG. The "BLACK EYE" dye effectively stains metastatic lymph nodes and does not interfere with the accumulation of fluorescein and technetium 99mTc in the lymph nodes. To confirm the efficacy and safety of fluorescein, further research is required on a larger number of patients, as well as a comparison of fluorescein with other fluorescent dyes.

P5-07-08: The ACOSOG Z0011 criteria can be safely applied to Chinese patients: the SAHZU experience

Xiuzhen Li, Yue Hu

Background: As a world-wide known trial in the sentinel lymph node biopsy (SLNB) field, the American College of Surgeons Oncology Group (ACOSOG) Z0011 trial made a big step to de-escalate the axillary surgery. The original intention of this trial was to omit reoperation if the patient had cN0 breast cancer with one or two sentinel-node metastases. A lot of queries were raised to this trial and the controversies about it have never stopped. China has his unique national condition which is different to the western countries. Only methylene blue dye is available in SLNB surgeries in most of the Chinese hospitals. Frozen section is widely used and reoperation is usually unacceptable. The safety of the Z0011 criteria needs to be confirmed when it is applied during surgery and frozen section application. In this retrospective study, we shared our single-center experiences.

Patients and Methods: In our hospital (SAHZU), the breast cancer patients with positive lymph nodes involvement in their SLNB surgeries were enrolled in this study since Aug. 2012 to Mar 2022. According to the Z0011 criteria, the patients with T3/T4 tumor, 3 or more positive lymph nodes involvement, mastectomy or neoadjuvant therapy were excluded. A part of the patients accepted preoperative advanced axillary evaluation (SABCS2018, Abstr. P3-03-20) which was composed by ultrasound, CT/MRI scans and fine/core needle biopsy if it was necessary.

Results: Totally, 153 eligible patients were enrolled in this study. They were younger, with more ER+PR+ diseases, less vascular invasion and higher tumor grades ($P<0.05$), compared with the Z0011 patients. More systemic therapy and lymph node radiotherapy were carried out in our cohort than in the Z0011's. Lymph node metastases were diagnosed by frozen section during their surgery in 88.9% (136/153) of patients and the left were diagnosed by permanent H&E section. Seventy-two patients accepted axillary lymph nodes dissection (ALND) and the other 81 patients accepted SLNB. The clinicopathologic characteristics of the two groups were comparable. Median resected lymph nodes in ALND and SLNB group were 17 and 4, respectively ($P<0.001$). In the ALND group, 27.8% patients (20/72) were with additional positive nodes and the rate was similar with the Z0011 trial. After median follow-up for 44.9 months, one local-regional recurrence happened in both groups and another two patients died in the SLNB group ($P>0.05$). In the SLNB group, all the recurrence and death events occurred in the patients without advanced axillary evaluation (3/36 vs. 0/45, $P=0.088$).
C

onclusions: The Z0011 criteria can be safely applied during surgery in China in spite of the wide use of frozen section and single tracer of methylene blue dye. Advanced axillary evaluation before surgery may do good to the survival of the patients.
Disclosure: Both authors declared no conflicts of interest.

P5-07-09: Predictive factors for postmastectomy reconstruction after breast cancer in Brazil

Anne Dominique Nascimento Lima, Francisco Pimentel Cavalcante, Eduardo Camargo Millen, Isabele Avila Small, José Bines

Introduction: One third of women with breast cancer in Brazil present with locally advanced disease. This translates into a high percentage of mastectomy with subsequent functional sequelae, negative impact on psychosocial, self-image and self-esteem. As breast reconstruction may improve quality of life, it is key to understand the factors associated with breast reconstruction in Brazil.
Objective: Analyze the predictive factors of breast reconstruction in post-mastectomy patients in Brazil.
Methods: Case-control study nested within the cohort of Women treated with mastectomy

for stage I to III breast cancer at the National Cancer Institute between January/2005 and December/2019. Data were collected through medical records. Cases were selected by reconstruction and controls were matched 1:1 according to year of mastectomy. Patients with ASA 4 surgical risk, risk-reducing and hygienic mastectomy were excluded. Statistical analyzes were performed in the R environment for Windows. The association between independent variables and outcome was performed using the crude odds ratio (OR). Variables presenting p<0.20 in the univariate analysis were included in the multiple logistic regression model by the stepwise forward stepwise, and those with p<0.05 were retained in the final model. Hypothesis tests with p values <0.05 were considered statistically significant. This study was approved by the Research Ethics Committee of the National Cancer Institute (n°. 6,299,721), in accordance with the ethical principles established by the National Health Council.
Results: 322 women were included, 158 cases and 164 controls. 72.4% of patients were younger than 60 years of age, 63.4% were non-white and 74.8% did not smoke. Regarding staging, 59.3% had clinically negative lymph nodes and 51.9% of patients had tumors smaller than 5 cm and 59.3% had clinically negative lymph nodes. After adjustments, the chance of non-reconstruction was higher in women over 60 years old (OR 5.96; IC95% 3.05-12.20; p<0.001), obese (OR 3.61; IC95% 1.91-7.07; p=0.001), diabetic (DM) (OR 3.17; IC95% 1.06-10.41; p=0.045), with cT4 tumors (OR 2.21; IC95% 1.11-4.47; p=0.025), axillary involvement (OR 2.75; IC95% 1.48-5.17; p<0.001), and treated with radiotherapy (OR 2.09; IC95% 1.09-4.07; p=0.027). Patients with a previous breast conservation had a greater chance of reconstruction (OR 0.31; IC95% 0.10-0.84; p=0.029). The median waiting time for delayed breast reconstruction was 45.1 months (IRQ 31.1-67.4).
Conclusion: There is a long time to breast reconstruction after mastectomy in Brazil; and age> 60, obesity, DM, cT4, and LN positive were negative predictors factors, in accordance with the international literature. These data provide the basis for future policies that may improve quality of life after breast cancer.

P5-07-10: Immediate Breast Reconstruction with Prepectoral Implant

Carlos Alberto Barbosa Neto, Mariana Macambira Noronha, Pedro Robson Costa Passos, Valbert Oliveira Costa Filho, Francisco Pimentel Cavalcante, Juliana Pinho Da Costa Leitao, Márden Pinheiro Teixeira Costa, Eric Lima Freitas Mota, Gabriel Fontenelle Costa, Gabriel Sampaio Feitosa, Ígor Giordan Duarte Jorge, Izaberen Sampaio Estevam, Júlia Matos Dubanhevitz, Letícia Pinheiro Amorim, Paulo Eduardo de Oliveira, Saulo Rabelo Costa, João Luiz Lima Pinheiro, Eduarda Severo Alvarenga, Kevin Lucas Silva Ribeiro, Gabriel Maciel Almeida, Eduardo Araújo Costa Lima, Fabrícia Cardoso Marques, Cecília Dias Caminha Gentil, Danielle Calheiros Campelo Maia, Elvis Lopes Barbosa

Introduction: Breast reconstruction is one of the pillars of breast cancer treatment. Reconstructive surgery is constantly being improved, from muscle flaps to submuscular implant reconstruction. Recently, immediate breast reconstruction with a prepectoral prosthesis has emerged as a promising, less invasive technique and potential for more natural aesthetic outcomes. However, the real post-surgical outcomes of it are not yet fully

consolidated. In light of this, we conducted a systematic review to compile the main outcomes of this new technique. Methods: The search was carried out in the PubMed and Scopus databases. A search strategy was devised for the articles using the descriptors: "Breast Cancer", "Prepectoral", "Immediate" and "Reconstruction". Inclusion criteria were previously established: 1. reconstruction with immediate prepectoral prosthesis, 2. mastectomized patient, 3. prospective observational studies or clinical trial; and exclusion criteria: 1. delayed reconstruction, 2. reconstruction using dermal matrix in all cases, 3. use of expander in all cases and 4. surgeries performed in two-steps. The outcomes of interest were the number of reoperations, readmissions and implant losses. Results: Of the 155 initial studies, 7 were included. A total of 845 patients were assessed with a total of 1112 mastectomies with reconstruction were performed, of which 740 (66.5%) were immediate reconstructions with pre-pectoral prosthesis without the use of an expander or dermal matrix, 341 (30.6%) pre-pectoral reconstructions with the use of dermal matrix or mesh and 31 (2.7%) with the use of an expander. Of the total number of reconstructions, 98.9% were prepectoral reconstructions and 1.1% were submuscular. Follow-up times ranged from 1 month to 2.15 years. Overall, 271 complications were reported, which represents 24.3% of all reconstructions. The most common early complications were reoperation (29.8%), readmission (28.4%) and seroma (11.1%). However, only 65 of these complications resulted in implant loss, representing a total of 5.8% of the reconstructions carried out; the others were all resolved with or without the need for reoperation. In total only one did not report any surgical complications with the technique. The studies highlighted complications that appear to be linked to clinical and complementary treatment characteristics and associated risk factors. One study identified a 13.2% implant loss rate in the group undergoing adjuvant chemotherapy. Another study reported that 19.5% of patients developed infection, 17.5% required readmission for complications, 16.0% underwent further surgery for complications within 3 months of the initial reconstruction, and 8.2% experienced implant loss and reconstruction failure during this interval. Exploratory analyses suggest that mastectomy weighing more than 600 grams, smoking, high surgical risk, obesity, and pre-surgery radiotherapy are associated with a higher risk of complications. Regarding patient satisfaction and quality of life, one study showed a considerable worsening of physical well-being one year post-treatment. Conversely, important findings showed satisfaction with the results of surgery and reconstruction. Other endpoints found in the perioperative period reported improved physical, psychosocial and sexual well-being, as well as satisfaction with their breasts. Conclusion: Immediate reconstruction with a prepectoral prosthesis was found to be a viable and safe technique, with low rates of serious complications and an implant loss rate of 5.8%, similar to other techniques. The studies generally showed patient satisfaction with the final result of the procedure. It is important to emphasize that additional research is required to determine the ideal patient characteristics to personalize treatment for breast reconstructions procedure with the best possible aesthetic result, as well as reducing complication rates.

P5-07-11: Comparison of the effectiveness of using visualization methods of the lymphatic tracts of the upper limb in preparation for the application of lymphovenous anastomoses for patients with secondary lymphedema.

Arina Tkachenko, Vorotnikov V.V., Pakhomova R.A., Abdugafforov S.A., Gugnina A.S., Soynov A.V., Kopytich I.V., Mchedlidze T.G., Mchedlidze T.G., Sharavina M.V., Tsalko S.E., Mukuyeva M.I., Voronov M.V., Andreeva V.A.

Abstract: lymphedema is a chronic lymphatic swelling of soft tissues that occurs as a result of the slow accumulation of protein-rich fluid in the extracellular space; caused by insufficient lymphatic drainage in combination with insufficient protein utilization, which leads to fibrotic changes in the skin and subcutaneous tissue. One of the common causes of lymphedema of the upper extremities is surgical treatment of breast cancer, accompanied by lymph node dissection, and in some cases, radiation therapy, which also contributes to the development of edema. Breast cancer ranks second in the overall structure of cancer among the population in the world and is the most common malignant neoplasm in women. Given the prevalence of this disease, a large group of patients is at risk of developing lymphedema.

For successful treatment of lymphedema, it is important to have good visualization of intact lymphatic pathways. This knowledge will help the surgeon choose the optimal location for the lymphovenous anastomosis, and also, in the future, evaluate the performance of the anastomosis. We will consider two ways to visualize lymphatic pathways: sodium fluorecein and indocyanine green (ICG).

Purpose: to compare two methods of visualizing the lymphatic tract in preparation for lymphovenous anastomosis.

Methods: we analyzed the results of examination and treatment of female patients with secondary lymphedema of the upper extremities that arose after complex treatment of breast cancer at the Central Clinical Hospital of Russian Railways in 2022-2024. All edema was unilateral, occurring on the side of the breast cancer treatment. A comparative analysis of the methods we used to visualize the lymphatic tract was carried out, as well as the results of subsequent surgical intervention. A total of 80 cases were analyzed.

Results: sodium fluorecein and indocyanine green showed good results in visualizing the lymphatic tracts of the upper limb, in all cases we obtained persistent staining of the lymphatic tracts. However, an advantage has been identified by using indocyanine green - it, unlike sodium fluorecein, allows visualization of lymphatic pathways on the skin; we observe the so-called “track”. This gave us the opportunity to choose the most successful position and applicate a lymphovenous anastomosis outside the affected area of the lymphatic tract.

Sodium fluorecein is convenient if the lymphatic pathways in the area of the proposed operation are not affected by changes, since it allows them to be visualized only while we in the surgical wound.

In the area of the upper third of the shoulder, we performed an anastomosis “end of the

lymphatic vessel to the end of the vein" due to the comparable diameter of the lymphatic vessel and vein. Already in the early postoperative period, we observed a positive effect from the operation, long-term results (average median follow-up 14 months) were good, the swelling stopped progressing and decreased by 50% or more. According to lymphography data, the anastomoses are functioning properly and fulfilling their function. We attempted to apply a lymphovenous anastomosis immediately after breast reconstruction (reconstruction of the breast with an implant, preparing the postoperative area for reconstruction using lipofilling. But there was a tendency towards deterioration in the visualization of the lymphatic pathways due to previously performed operations and the persistence of postoperative edema. We believe that breast operation several days prior may make it difficult to applicate a lymphovenous anastomosis.
Conclusions: Fluorescence lymphography with sodium fluoresin or indocyanine green is modern and accurate for the diagnosis of lymphedema. Staining the lymphatic tract is an important tool in preparing for lymphatic-venous anastomosis, and the more visualization techniques the surgeon has, the better the result of the operation. Also, the success of the operation largely depends on the treatment tactics chosen by the surgeon - we believe that lymphovenous anastomosis in the complex treatment of postmastectomy syndrome should be carried out either before breast reconstruction surgery, or no earlier than 1-3 months after it.
Keywords: breast cancer, lymphedema, lymphovenous anastomosis.

P5-07-12: ONCOPLASTIC SURGERY FOR PAGET'S DISEASE OF THE BREAST

Rafael Pelorca, Idam de Oliveira-Junior, Rene Aloisio da Costa Vieira

Introduction: Paget's disease of the breast (PDB) is a rare nipple entity associated with multifocality. Due to its location, it is necessary to resect the nipple-areolar complex. For surgery, central quadrantectomy, and mastectomy was the treatment in the past. The feasibility of performing oncoplastic breast surgery (OBS) for PDB is unknown.
Methods: This was a retrospective study performed in a Brazilian oncological hospital. We evaluated the factors related to the performance of OBS in PDB. In addition, the impact of OBS on local recurrence and survival was analyzed. Comparisons were made between groups using the chi-square test, Mann–Whitney U test, and Kaplan–Meier method. To assess the impact factor of the variables on the performance of OBS, logistic regression was performed.
Results: Eighty-five patients were evaluated. OBS was performed in 69.4% (n=59), and of these, 16 (27.2%) were symmetrized with a contralateral surgery. Mastectomy without reconstruction was performed in 28.3% of the patients. The main procedure performed was mastectomy with reconstruction (n=38; 44.7%), and the preferential technique for immediate reconstruction was skin sparing mastectomy with prosthesis, and for late reconstruction, latissimus dorsi. BCS was performed in 27.0% (n=23), mainly with plug-flap technique (OBS). Age was associated with the use of OBS, wherein patients aged 40-49 were associated with a higher rate of OBS (p = 0.002; odds ratio 3.22). OBS did not influence local recurrence (p=1.000), overall survival (p=0.185), or cancer-specific survival (p=0.418).

Conclusion: OBS improves the quality of surgical treatment in PDB without influencing local recurrence or survival.

P5-07-13: Analysis of Single-Port Robot-Assisted Nipple Sparing Mastectomy in Patients with Invasive Breast Cancer: Propensity-Matched Comparison with Conventional Nipple Sparing Mastectomy

Ah Yoon Kim, Sae Byul Lee, Tae-Kyung Yoo, Jisun Kim, Il Yong Chung, Hee Jeong Kim, Jong Won Lee, Byung Ho Son, Beom Seok Ko

Introduction: Robot-assisted nipple-sparing mastectomy (RANSM) presents several benefits over traditional surgical techniques, such as enabling surgery through smaller incisions and providing enhanced precision. Nonetheless, there are ongoing concerns about its surgical and oncological safety. This study investigate the safety and efficacy of RANSM in comparison to conventional nipple-sparing mastectomy (NSM).

Materials and Methods: In a retrospective single-center study at Asan Medical Center, 302 patients underwent RANSM from October 2020 to October 2023. Out of these, 177 patients, excluding those with carcinoma in situ, bilateral breast cancer, and those who received neoadjuvant chemotherapy, were analyzed using 1:2 propensity matching.

Results: The median age of patients in the RANSM group was 46 years, with a median tumor-to-nipple distance of 2.0 cm. The median duration for NSM was 155 minutes. There were no instances of conversion to open surgery or intraoperative blood transfusions due to bleeding. The average breast specimen weighed 324 grams. Among the patients, 110 were in stage I, 59 were in stage II, and 8 were in stage III. The average hospital stay post-surgery was 5 days. Postoperative bleeding necessitated blood transfusions in 9 patients. Two patients experienced skin flap ischemia, one patient had skin flap necrosis, one patient suffered from NAC necrosis, and another patient required surgery for skin desquamation.

Conclusions: Compared to conventional NSM, RANSM requires a slightly longer surgery time because of the robot preparation. Despite this, RANSM offers advantages such as fewer surgery-related complications and reduced hospitalization duration.

P5-07-14: Clinical study of 99mTc-Rituximab combined with dyes double tracing for axillary sentinel lymph node biopsy after neoadjuvant chemotherapy for breast cancer

Hui Zhang

Background and objective: It is still controversial whether sentinel lymph node biopsy (SLNB) can replace axillary lymph node dissection (ALND) for breast cancer after neoadjuvant chemotherapy (NAC).This study used 99mTc-rituximab combined with dye to perform SLNB on patients after NAC, and analyzed the results to evaluate the application value of the dual tracing method of 99mTc-rituximab combined with dye in SLNB after NAC in breast cancer, and to explore the feasibility of SLNB after NAC, the clinical application of the new tracer 99mTc-rituximab and its application value in internal mammary sentinel lymph node biopsy. Methods: A retrospective analysis was performed on 106 breast cancer patients who underwent SLNB after NAC at the Department of Oncology, Fujian Provincial Hospital from August 2019 to August 2023. SLNB was performed under 99mTc-rituximab combined with dye and dye alone.The detection rate, sensitivity, false negative rate, accuracy and detection of internal mammary lymph node biopsy of the two tracing methods were compared.Results: 70 cases were included in the dual tracing group, with a detection rate of 97.14% (68/70), an average number of detected SLNs of （6.06±5.29）， a sensitivity of 92.86% (26/28), a false negative rate of 7.14% (2/28), and an accuracy of 97.14% (68/70).36 cases were included in the single tracing group, with a detection rate of 66.67% (24/36), an average number of detected SLNs of （3.17±3.073）， a sensitivity of 54.55% (11/22), a false negative rate of 45.45% (10/22), and an accuracy of 72.22% (26/36). There were significant differences in the detection rate and the average number of detected SLNs between the two groups (detection rate: P=0.004; detection number: P=0.038), but there were no significant differences in the sensitivity, accuracy, and false negative rate (P>0.05).A total of 70 patients underwent double-tracing internal mammary lymph node biopsy, and 22 patients were detected with an imaging rate of 31.42% (22/70), and a detection rate of 72.72% (16/22).

Conclusion: SNLB using radionuclide with dye double-tracing method after neoadjuvant chemotherapy for breast cancer can improve the detection rate of sentinel lymph nodes, reduce the false negative rate, and improve the prognosis.Compared with other tracers, 99mTc-Rituximab can improve the detection rate of internal mammary sentinel lymph nodes, with the characteristics of rapid clearance of injection site, less secondary lymph node imaging, and low sensitization, which can be used as an ideal tracer for further research.

Key words: 99mTc-Rituximab， neoadjuvant chemotherapy， sentinel lymph node biopsy， breast cancer.

P5-07-15: FEASIBILITY AND SAFETY OF ROBOTIC NIPPLE-SPARING MASTECTOMY (RNSM) WITH 1 IMPLANT BASED - IMMEDIATE BREAST RECONSTRUCTION: AN INITIAL EXPERIENCE FROM INDIA'S 1ST ROBOTIC BREAST SURGERY TEAM

Priya Kapoor, Magesh M, Pragadeesh, Vimal, Venkat P

Objectives : To evaluate the feasibility and safety of robotic Nipple-Sparing Mastectomy (RNSM) with implant based immediate breast reconstruction in 12 patients of early breast cancer. Patients & Methods: In this case series analysis, patients with early breast cancer were enrolled in our hospital from December 2023 to March 2024. All patients underwent triple assessment of breast cancer preoperatively. RNSM was performed with single cosmetic 's' shaped incision covered by patient arm. All the procedures were performed using da Vinci Xi Robotic Surgical System, a single docking method using CO2 inflation after placing GelPort. Patients tumours measuring >5 cm, skin or nipple involvement or planned radiotherapy were excluded. Results: 12 patients underwent RNSM followed by implant based immediate breast reconstruction. 3 out of 12 cases underwent RNSM as prophylaxis in view of positive BRCA1 status. Preoperative diagnosis for 2 cases reported as ductal carcinoma in situ (DCIS) and remaining 7 cases showed invasive ductal breast carcinoma. The mean total operation time for RNSM was around 242 mins and the console time was 128 mins. The average blood loss during surgery was 3-5ml. Mean hospital stay was 1.5 days. No major complications were observed for any case. 1 out of 12 patients had partial nipple necrosis and it resolved spontaneously. No systemic complications were observed. Conclusion: RNSM with implant based reconstruction is a safe and feasible approach for early breast cancer. It has several advantages with uniform flap thickness, NAC dissection and ergonomics.

P5-07-16: How cardiovascular risk factors and type of chemotherapy influence cardiotoxicity in early HER2 positive breast cancer (HER2+ BC) patients treated with neoadjuvant Trastuzumab and Pertuzumab (T-P) based chemotherapy?

Beatriz Alonso de Castro, María Alonso Pena, Cristina Reboredo Rendo, Lourdes Calvo Martinez, Eva Pérez López, Paula Saavedra Nieves, Silvia Antolín Novoa

Background: T-P based chemotherapy improves survival in early HER2+ BC but confers a higher risk of cardiac events compared to chemotherapy alone. In recent years, a better understanding of tumor biology and the results of two trials (TRAIN-2 and TRYPHAENA) have led us to consider different neoadjuvant strategies, free of anthracyclines, which provide a safer risk profile without impact in efficacy.

Methods: We conducted a retrospective observational study of HER2+ eBC patients (pts) treated with neoadjuvant T-P based chemotherapy, between April 2015 and December 2022, at University Hospital A Coruña (Spain). The primary endpoint was total pathologic complete response in breast and axila (tpCR: ypT0/is ypN0). One of the secondary objectives was the association between cardiovascular risk factors, type of chemotherapy and cardiotoxicity, results presented below. Multivariate logistic and multinomial regression analyses were carried out using R system for statistical computing.

Results: A total of 156 pts were included within a period of 7 years. Median age was 49 years [range 26 – 79 years]. Cardiovascular risk factors were determined: median weight was 65.8kg (39-104 [SA4] [ba5] kg), 16% of pts had dyslipemia, 15.4% hypertension and 4.5% previous cardiac disease. Most pts had clinical stage II disease (64.2%), positive nodes (51%), grade 3 (56.2%), ductal histology (91%), hormone receptor positive (57.7%) and Ki-67 >35 (55.8%). 35% received platinum-based chemotherapy and 64.2% anthracyclines. tpCR was achieved in 51.3% of pts, which was not significantly different according to chemotherapy approach in the logistic regression model (p=0.93). Comparable results were observed in breast pCR.
Most pts developed cardiotoxicity at the end of adjuvant trastuzumab (29.1%). Similar rates were detected in the middle (25.2%) and at the end of neoadjuvant chemotherapy (23.4%). Only 1.5% of pts developed late cardiotoxicity. There were no episodes of congestive heart failure.
In the logistic regression model developed to predict cardiotoxicity at the end of neoadjuvant treatment (AUC 0.728), we noted that type of chemotherapy and weight were the only variables associated with cardiac events ($p < 0.05$). Anthracyclines were associated with an increase of cardiotoxicity ($e^{1.047} = 2.489$; $p = 0.033$), while previous cardiac disease tended to rise this probability ($e^{1.962} = 2.489$; $p = 0.051$). A lower basal weight increased the risk of cardiotoxicity, which requires the study of other intermediate variables ($e^{-0.042} = 0.959$; 0.019).
We did not find a significant association between cardiac risk factors, type of chemotherapy and cardiotoxicity in the rest of the timepoints studied.

Conclusion: The combination of anthracyclines with T-P resulted in higher cardiac toxicity without significant differences in pCR, at the end of neoadjuvant treatment. Long-term follow-up is required to confirm these results.

P5-07-17: Comparison of Rate of Pathologic Complete Response in HER2-zero versus HER2-low Breast Cancer: a Meta-Analysis

Michelle Min, James Doyle

Introduction: Development of treatments that target human epidural growth factor receptor 2 (HER2) expression has improved the rate pathologic complete response of

hormone receptor-negative, HER2-positive breast cancer. However, the benefit has not been shown in 1+ or 2+ ISH-negative HER2 breast cancer, also known as HER2-low. We conducted meta-analysis of six studies to determine the difference in rate of pathologic complete response (pCR) to neoadjuvant chemoimmunotherapy in nonmetastatic HER2-low versus HER2-zero breast cancer.

Methods: Meta-analysis was performed based on the count and percent data provided by six studies we identified via a PubMed search about the results following neoadjuvant chemoimmunotherapy for the treatment of nonmetastatic hormone receptor-negative, HER-2 low and HER2-zero breast cancer. All meta-analyses were performed with RStudio. The heterogeneity of the studies was assessed and there was enough evidence to claim significant heterogeneity for both categories. Since significant heterogeneity was found, a random effects approach was used to account for the between-study variability instead of the standard fixed effects approach.

Results From the six studied identified and included after our PubMed search, 836 patients with HER2-low breast cancer and 1543 patients with were identified. Of these, a total of 262 in the HER2-low population achieved a complete pathological response to adjuvant chemoimmunotherapy versus 568 in the HER2-zero population. The combined rate of pCR in HER2-low group was 30% (95% confidence interval [CI] 24% - 37%). The combined rate of pCR in HER2-zero group was 35% (95% CI 28% - 42%).

Conclusion: Based on this meta-analysis, there was no significant difference in rate of pCR in HER2-zero and HER2-low group. However, all studies used in this meta-analysis included a majority or patients enrolled before the Keynote-522 Trial, when pembrolizumab was added to neoadjuvant chemotherapy for triple negative breast cancers. Thus, re-evaluation of the rate of pCR in patients who received the now standard chemoimmunotherapy to see if HER2-low vs HER2-zero patients respond differently to the addition of neoadjuvant immunotherapy.

P5-07-18: HER2DX assay in HER2-positive (HER2+) breast ductal carcinoma in situ (DCIS)

Esther Sanfeliu, Anabel Martinez-Romero, Mercedes Marín-Aguilera, Vicente Marco, Felip Garcia, Vicente Peg, Blanca González-Farré, Ivonne Vazquez, Patricia Galván, Oleguer Castillo, Paula Blasco, Valeria Sirenko, Angela Aguirre, Laia Paré, Guillermo Villacampa, Antonio Martínez, Jesus Soberino, Aleix Prat, Fara Brasó-Maristany

Background: The HER2DX assay, a 27-gene test, was developed to provide prognostic information and predict treatment responses in patients with early-stage HER2+ breast cancer. This assay evaluates four gene expression signatures: immune/immunoglobulin (IGG), proliferation, luminal, and HER2, offering a comprehensive risk score, a likelihood estimates for pathological complete response (pCR) and ERBB2 expression levels. In this study, we evaluated the HER2DX assay in HER2+ DCIS, aiming to understand its biology and

relationship with HER2+ invasive breast cancer.

Methods: Standardized HER2DX genomic test was evaluated centrally on 28 formalin-fixed paraffin-embedded tumor samples of HER2+ DCIS across three hospitals in Spain. DCIS features such as nuclear grade, comedonecrosis, architectural pattern, tumor size and hormone receptor (HR) status were evaluated. Percentage (%) of stromal tumor infiltrating lymphocytes (TILs), their spatial distribution (i.e.: inflamed, desert or excluded), and presence of tertiary lymphoid structures (TLS, defined as spatially organized, non-encapsulated areas of immune cell aggregates with or without germinal center [GC]) were assessed on hematoxylin eosin slides. Descriptive statistics were used.

Results: The HER2DX assay was evaluated in 28 cases of HER2+ DCIS. Most cases had a 3 nuclear grade (67.9%) and presented with comedonecrosis (60.7%). HR positivity (HR+) was found in 42.9% of cases, as determined by immunohistochemistry. The median tumor size was 30 mm, with a range from 5 mm to 90 mm. The median % of TILs was 20% (range 0.5-70%). TILs, as a continuous variable, showed a moderate correlation with the HER2DX IGG signature (Pearson correlation coefficient=0.43, p-value=0.023), and a tendency with the inflamed spatial distribution (p-value=0.063). TLS were identified in 82.1% of DCIS samples, and their presence was associated with higher expression of the IGG signature (52.2% TLS in IGG-high vs. 21.7% in IGG-low). Regarding the HER2DX luminal signature, 41.7% of cases were classified as luminal-high, associated with HR+ disease (p=0.025). For the HER2DX proliferation signature, 82.1% of cases were identified as proliferation-low. In HER2DX risk stratification, 100% of cases were categorized as low-risk, 46.4% were pCR-high, and 78.6% were ERBB2-high. Notably, only one (3.6%) HER2+ DCIS case was found to be ERBB2-low.

Conclusions: The HER2DX assay revealed that all HER2+ DCIS cases were categorized as low-risk, with most cases showing high ERBB2 expression and a high predicted response to anti-HER2-based therapy. These findings underscore the underlying biology of HER2+ DCIS and its tumor immune microenvironment, indicating that HER2+ DCIS shares similar tumor biology with low-risk HER2+ breast cancer.

P5-07-19: A multicenter, prospective, non-interventional study to investigate the treatment patterns of neratinib in Human Epidermal Growth Factor Receptor 2 positive (HER2+) early breast cancer (EBC) in China: NER-Tree study—An interim analysis on safety

Jin Zhang, Haiguang Liu, Xinlan Liu, Jidong Gao, Shihui Ma, Jinhui Ye, Yuanqi Zhang, Jundong Wu, Shuqun Zhang, Yongsheng Wang, Xinhong Wu, Jie Ma, Antai Zhang, Quchang Ouyang, Yiding Chen, Jianxia Liu, Hongwei Zhang, Guoqin Jiang, Zhaofeng Niu, Suisheng Yang, Fuguo Tian, Dong Song, Jie Wang, Mopei Wang, Qiang Zhang, Huanying Zhen, Xiaojia Wang

Background: Neratinib, an oral irreversible pan-HER tyrosine kinase inhibitor, was approved in 2020 in China for the extended adjuvant treatment of HER2+ early breast cancer (EBC) adult patients who completed prior adjuvant trastuzumab-based therapy based on the ExteNET trial. Diarrhea is a common treatment-related adverse event of neratinib, and it is necessary to investigate its pattern of occurrence and the effectiveness of anti-diarrheal prophylaxis measures in the real world.

Method: This is a multi-center, prospective, non-interventional study planning to enroll 500 HER2+ EBC patients who scheduled 1-year neratinib treatment after anti-HER2 adjuvant therapy. Pre-specified interim analyses are planned after the recruitment of 250 and 500 patients. The primary and secondary objectives are to describe the real-world adjuvant treatment patterns and to observe the safety of patients treated with neratinib respectively. The exploratory objectives are to observe invasive disease recurrence patterns and patient-reported quality of life, including pattern of occurrence and the effectiveness of preventive measures for diarrhea. Patient characteristics and pre-treatment patterns from this interim analysis were previously presented at ESMO Breast Cancer 2024. Here we report safety data from the initial interim analysis with a focus on diarrhea and related management.

Results: As of 21 September 2023, 250 patients were recruited in the study and were included in the interim analysis.
According to this interim analysis, diarrhea, nausea, and abdominal pain were the most common AEs. Diarrhea, as the most frequent adverse event, occurred in 80.4% of patients (all grades), and grade 3 diarrhea occurred in 14.8% of patients. No grade 4 diarrhea was observed. The median time to onset of diarrhea was 3.0 days (interquartile range [IQR] 2.0,5.0). Diarrhea led to dose reduction in 12.8% of cases, dose interruption in 16.0%, and permanent discontinuation in 2.8% of cases. Patients who started on neratinib at <240 mg experienced a lower incidence of Grade ≥3 diarrhea compared to those who started at 240 mg (10.2% vs. 19.7%). There was no statistically significant difference in the incidence of diarrhea across different molecular subtypes of breast cancer (HR-/HER2+ vs HR+/HER2+), lymph node status, and adjuvant treatment regimens.
One hundred and fifty-one patients (60.4%) received anti-diarrheal prophylaxis at least once, including drug prophylaxis (Loperamide or other agents, 33.2%), dose escalation (17.6%), and combination (dose escalation combined with drug prophylaxis, 9.6%). The dose escalation strategy reduced the incidence of Grade ≥3 diarrhea compared with prophylactic management with antidiarrheal(6.8% vs 18.1%).

Conclusion: This study provides further data on safety, including the pattern of diarrhea occurrence and the impact of preventive anti-diarrheal measures in Chinese HER2+ early breast cancer patients treated with neratinib as extended adjuvant therapy. diarrhea, nausea, and abdominal pain were the most common AEs. The dose-escalation strategy can reduce the incidence of Grade 3 diarrhea associated with neratinib.

P5-07-20: A prospective, open-label, single-arm phase II clinical study of inetetamab in combination w/ pyrotinib & albumin-bound paclitaxel for neoadjuvant treatment of patients with HER2+ early & locally advanced breast cancer: updates on clinical trial

Jiang Wu, Fengqiang Cui, Yuqing Yang, Jing Yu, Jixin Yang, Lei Wang, Dongdong Xu, Wenyu Hu, Jialing Luo, Wen Ma, Nanlin Li

Background: Chemotherapy combined with dual anti-HER2 target therapy has become the standard neoadjuvant therapy regimen for HER2+ breast cancer. Patients achieving pathological complete response (pCR) have a relatively better prognosis. Inetetamab (Septin) is an innovative HER2 monoclonal antibody drug developed in China. It has been proven to delay the progression of HER2+ metastatic breast cancer patients and bring survival benefits. The purpose of this study was to explore the efficacy and safety of Inetetamab, Pyrotinib, and albumin-bound Paclitaxel in the neoadjuvant treatment of HER2+ breast cancer. Methods: This phase II trial included patients with HER2+ early or locally advanced breast cancer whose tumor size was >20 mm or had confirmed axillary lymph node metastasis. Patients received an initial dose of Inetetamab at 8 mg/kg over 90 minutes via IV infusion, followed by 6 mg/kg over 30 to 90 minutes via IV infusion every 3 weeks (q3w). Pyrotinib was administered at 400 mg orally every day, and albumin-bound Paclitaxel at 125 mg/m^2 via IV on days 1, 8, and 15, every 3 weeks (q3w). Patients received the above treatment every 3 weeks for a total of 4 cycles, followed by surgery.After surgery, EC (90 mg/m^2 of Epirubicin Hydrochloride and 600 mg/m^2 of Cyclophosphamide) was administered every 21 days (q21 days) for 4 cycles, followed by maintenance treatment with trastuzumab combined with pertuzumab for 1 year. Radiotherapy and endocrine therapy were provided to the patient according to the specific situation. The primary endpoint was pathological complete response (pCR).Results: Until September 20, 2024, 22 patients were enrolled, of which 20 had completed surgical treatment. The median age of enrolled patients was 52 years (range: 35-61 years). 50.0% (10 cases) of patients achieved RCB grade 0 (pCR), 20.0% (4 cases) achieved RCB grade I, 25% (5 cases) achieved RCB grade II, and 5% (1 case) achieved RCB grade III. Of the 20 patients, 55.0% (11 cases) were HR+/HER2+, with 36.4% (4 cases) achieving pCR. Among the 9 HR-/HER2+ patients, 66.7% (6 cases) achieved pCR. HR-/HER2+ patients were more likely to achieve pCR than HR+/HER2+ patients. No severe (grade 3/4) toxicity was observed in any patients. Conclusions: Our current data show that the pathological complete response (pCR) rate in HER2+ breast cancer patients reaches 50.0%, and even 36.4% in HR+ patients. Interestingly, 4 out of these 20 patients achieved near-pathological complete response (near-pCR). We suggest that these 4 patients would more likely achieve pCR if treated with a 6-cycle regimen, which can boost the pCR rate to 70% (14/20) in HER2+ patients.In the previous Neosphere and PEONY studies of the H+P dual-target regimen, the pCR of HR+/HER2+ patients increased by only 6% and 8.3%, respectively. In contrast, in the NeoALTTO and PHEDRA studies of the H+L or H+Py regimen, the pCR increased by 18.9% and 17.7%, respectively. This indicates that the combination of large and small molecules

with dual-target neoadjuvant therapy for HR+/HER2+ breast cancer is significantly better than monoclonal antibody dual-target therapy.Therefore, Inetetamab, Pyrotinib, and albumin-bound paclitaxel are potentially effective new adjuvant treatments for HER2+ breast cancer with a superior pCR rate.

P5-07-21: Real-World Safety and Effectiveness of Switching among Biosimilars in HER2-Positive Breast Cancer

Andreas Nearchou, Antonios Valachis, Kunvar Harsh Upveja

Background: Ogivri (trastuzumab-dkst) is one of the several trastuzumab biosimilars used in HER2-positive breast cancer treatment. This retrospective study aimed to provide real-world data on the safety and effectiveness of switching patients from another trastuzumab biosimilar to Ogivri. Currently, there is limited real-world evidence (RWE) on this sort of switch, making this study relevant for both local and global healthcare contexts.

Method: This is a multi-center retrospective post-approval observational study to investigate the safety and effectiveness of Ogivri after switching from another trastuzumab biosimilar (SB3) in patients with HER-2 positive EBC (Early Breast cancer) or MBC (Metastatic Breast cancer). This study used an Electronic Data Capture (EDC) system to collect data available in patients' medical records at the two sites of Sweden from April 2021 to December 2022. The primary objective of the study was to compare the incidence and severity of infusion-related reactions (IRR) to Ogivri® with SB3 prior to and after the switch in EBC and MBC patients. Secondary objectives of the study were to investigate Cardiac events, other trastuzumab-related AEs (Adverse events, pCR (pathological Complete Response) among patients treated with neo-adjuvant therapy, ORR among MBC patients.

Results: A total of 48 patients with HER2-positive breast cancer were enrolled from two centers (Center 1: 25 patients, Center 2: 23 patients) and all received 3-weekly trastuzumab therapy and 27 patients (56%) also received pertuzumab. The average age of the cohort was 59 years (range: 32-81), with an average weight of 74 kg (range: 47-98). HER2 status was confirmed by IHC/FISH testing in all included patients, and ductal carcinoma was predominant (38 patients, 79%). The majority of patients received trastuzumab as a part of curative treatment for early breast cancer (39 patients, 81%).
Patients received an average of approximately 11 cycles of SB3 before they switched to Ogivri and switching happened at 5th cycle in adjuvant setting (few patients also switched during Neoadjuvant therapy) and 19th cycle in palliative setting. Prior to switching, one patient experienced a Grade 1 infusion-related reaction (IRR) with SB3, characterized by itching and rash after the second dose. Post-switch to Ogivri, no IRRs were reported. There were no cardiac events reported throughout the treatment period and Left Ventricular ejection fraction (LVEF) was maintained before and after switching the patients to Ogivri

(~60%). In terms of trastuzumab-related adverse events (AEs), a total of three AEs were recorded: two cases of urticaria before the switch and one case of chills and vomiting after the switch. All reported AEs resolved or recovered.
Among patients receiving neoadjuvant treatment, 5 out of 9 patients achieved a pathological complete response (pCR), representing a rate of 56%. The overall response rate (ORR) among assessable MBC patients was 35% (patients at different lines of therapy)

Conclusion: This study demonstrates that switching from another trastuzumab biosimilar to Ogivri in HER2-positive breast cancer patients is safe, with no infusion-related reactions or cardiac events reported post-switch, without jeopardizing treatment effectiveness. This research addresses a critical gap in real-world data on switching among biosimilars, providing essential insights for healthcare decision-making.

P5-07-22: Phase III study to evaluate the efficacy and safety of GLSI-100 (GP2 + GM-CSF) in breast cancer patients with residual disease or high-risk PCR after both neo-adjuvant and postoperative adjuvant anti-HER2 therapy, Flamingo-01

Snehal Patel, Jaye Thompson, Mira Patel, F. Joseph Daugherty, Mothaffar F. Rimawi

Background: GP2 is a biologic nine amino acid peptide of the HER2/neu protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events observed were considered related to the immunotherapy.

Methods: This Phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up.
Study Size – Interim Analysis: Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 250 non-HLA-A*02 subjects will be enrolled in an open-label arm.
Eligibility Criteria: The patient population is defined by these key eligibility criteria: 1) HER2/neu positive and HLA-A*02, 2) Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy, 3) Exclude Stage IV, and 4) Completed at least

90% of planned trastuzumab-based therapy.
Trial Objectives: The trial objectives are to: 1) Determine if GP2 therapy increases IBCFS, 2) Assess the safety profile of GP2, and 3) Monitor immunologic responses to treatment and assess relationship to efficacy and safety.
Study Status: The study is actively recruiting and enrolling patients in the US and Europe at up to 150 sites.

P5-07-23: Efficacy and Safety of Pyrotinib Combined with Trastuzumab and Aromatase Inhibitor in Neoadjuvant Treatment of HER2+/HR+ Breast Cancer: A Single-Arm, Multi-Center Phase II Exploratory Study

Jie Ge, XiangChao Meng, Xin Wang, Xuchen Cao, Min Zhang, Bin Zhang, Ying Zhao, YongSheng Jia, QingJuan Yao, Lin Li

Background: HER2+/HR+ breast cancer exhibits unique clinical and biological characteristics due to the interplay between HER2 and HR signaling pathways, rendering chemotherapy-free anti-HER2 therapy a potential treatment avenue. Based on findings from the ALTERNATIVE study, the NCCN guidelines recommend the combination of aromatase inhibitors with lapatinib and trastuzumab for treating HER2+/HR+ advanced breast cancer. Additionally, the PHEDRA and NEOSPHERE studies have shown that a pyrotinib (anti-HER2 TKI)-containing regimen in the neoadjuvant setting significantly enhances tpCR rates (17.7% vs. 6%) in HER2+/HR+ breast cancer. This study aims to evaluate the efficacy and safety of pyrotinib combined with trastuzumab and an aromatase inhibitor (AI) in the neoadjuvant treatment of HER2+/HR+ breast cancer (NCT05885776).
Methods: This investigation is a single-arm, multi-center phase II exploratory study. The inclusion criteria encompass female patients aged 18 to 75 years, diagnosed with stage II to IIIA HER2-positive (IHC score 3+ or 2+ and ISH positive), ER > 10% invasive breast cancer. Participants received 6 cycles of pyrotinib (400 mg orally daily), trastuzumab (initially 8 mg/kg, followed by 6 mg/kg intravenously on day 1, Q3w), and an AI (either letrozole 2.5 mg orally daily or anastrozole 1 mg orally daily). Premenopausal or perimenopausal patients also received ovarian function suppressants. Post-surgery radiotherapy and adjuvant treatments were individualized. Primary endpoint assessed was tpCR (ypT0/is ypN0), while secondary endpoints included ORR, breast conservation rate, and safety profile. The study adopted Simon's two-stage optimal design, testing H0 (tpCR ≤ 10%) against H1 (tpCR > 25%), with a one-sided significance level of 0.05 and 80% power. Initially, 18 patients were recruited. If ≤2 achieved tpCR, the null hypothesis would be accepted, and the study terminated; otherwise, recruitment would continue to a total of 43

patients. Treatment efficacy is deemed achieved if ≥8 patients reach tpCR.
Results: From August 23, 2022, to June 4, 2024, 22 patients were enrolled. Among these, 86.4% (19/22) had ER ≥ 50%, 72.7% (16/22) exhibited Ki67 ≥ 30%, 31.8% (7/22) were stage III, 18.2% (4/22) were stage T3, and 68.2% (15/22) had positive lymph nodes. To date, 15 patients have undergone surgery, with 20% (3/15) achieving tpCR, thus meeting the pre-defined threshold for progressing to the second recruitment stage. The breast conservation rate stands at 46.7% (7/15). Major adverse reactions included diarrhea, stomach discomfort, reduced appetite, and nausea. No grade 4 adverse events occurred; grade 3 adverse events comprised diarrhea (22.7%) and elevated creatinine levels (4.5%).
Conclusion: The results from the initial stage of this study suggest that the combination of pyrotinib, trastuzumab, and AI in the neoadjuvant setting for HER2+/HR+ breast cancer provides the anticipated efficacy with a manageable safety profile. Consequently, the study will continue to enroll up to 43 patients.

P5-07-24: HER2+ early breast cancer treatment and outcomes by risk of recurrence: a retrospective US electronic health records study

Reshma Mahtani, Gregory Vidal, Sam Hillman, Ellie John, Simon M Collin, Gráinne Long

Background: Patients (pts) with human epidermal growth factor receptor 2–positive (HER2+) early breast cancer (eBC) remain at risk of relapse despite the use of standard-of-care treatments. We aimed to describe use of neoadjuvant and adjuvant therapies and clinical outcomes by risk of relapse in US pts with eBC since 2011.

Methods: This was a retrospective observational study using the nationwide Flatiron Health electronic health record-derived de-identified database. Pts aged ≥18 years with HER2+ eBC (clinical or pathologic stage I, II, or IIIa) who were treated between January 2011 to December 2021 were included. Baseline pt and tumor characteristics were captured prior to and at the index date (date of eBC diagnosis). Pts were followed from index date to death, last known activity date, or end of the study period (December 31, 2022). The definition of high risk of relapse (high-risk HER2+ eBC) was based on pathologic stage (any node-positive tumor or large tumor size [T3/T4] if node negative) or, among pts who received neoadjuvant treatment (NAT), clinical stage IIb, IIc, IIIa, IIIb, or IIIc. Analyses were categorized by date of eBC diagnosis: 2011–2013, 2014–2017, or 2018–2021.

Results: A total of 1290 pts with HER2+ eBC were eligible within the diagnosis dates (2011–2013 n=351, 2014–2017 n=515, 2018–2021 n=424). Among these, 72.9% (n=940) were hormone receptor–positive with a median age at diagnosis of 58.0 years (interquartile range [IQR] 49.0, 67.0); 28.4% (n=366) were classified as high risk (233 by pathological stage, 133 by clinical stage with NAT) and 71.6% (n=924) as non-high risk. Median follow up was 58.0 months (IQR 31.9, 87.8). The 5-year invasive disease-free survival and overall survival probabilities were 72.3% (95% confidence interval [CI] 66.8, 77.1) and 86.9% (95% CI 82.3, 90.4) for pts with high-risk HER2+ eBC, and 80.7% (95% CI 77.6, 83.5) and

91.8% (95% CI 89.4, 93.7) for pts with non-high-risk HER2+ eBC, respectively. In 2018–2021, 29.4% (15/51) of pts with high-risk HER2+ eBC defined by pathologic stage received NAT, an increase from 2.2% (2/92) in 2011–2013 and 14.4% (13/90) in 2014–2017. Receipt of adjuvant therapy in all pts with high-risk HER2+ eBC also increased over time (81.8% [90/110)], 89.0% [130/146], and 91.8% [101/110] in 2011–2013, 2014–2017, and 2018–2021, respectively). In 2018–2021, 64.5% (71/110) of all pts with high-risk HER2+ eBC received HER2-directed NAT and 86.4% (95/110) received HER2-directed adjuvant therapy. In the same time period, 34.4% (108/314) of all pts with non-high-risk HER2+ eBC received NAT (33.8% HER2-directed) and 79.3% (249/314) received adjuvant therapy (68.8% HER2-directed).

Conclusions: Use of neoadjuvant and adjuvant therapy has increased over time in pts with HER2+ eBC who are at high risk of relapse. There remains a need for more effective therapies to optimize pt outcomes in HER2+ eBC.

Funding: This study is sponsored by AstraZeneca. In March 2019, AstraZeneca entered into a global development and commercialization collaboration agreement with Daiichi Sankyo for trastuzumab deruxtecan (T-DXd; DS-8201).

P5-07-25: "NAVIGATING THE NEXUS: OVERCOMING DOUBLE JEOPARDY OF EARLY HER2-POSITIVE BREAST CANCER PRESENTING AS AN ANTI-Yo POSITIVE PARANEOPLASTIC CEREBELLAR DEGENERATION IN A YOUNG WOMAN"

Vallish Shenoy, Sudeep Gupta, Seema Gulia, Prabhat Ghanshyam Bhargava, Sushmitha Rath, Shalaka Joshi, Tabassum Wadasadawala, Dileep Hoysal, Revathy Krishnamurthy

Introduction: Anti-Yo-associated paraneoplastic cerebellar degeneration (PCD) syndrome is a very rare condition that is most commonly associated with breast and gynaecologic cancers. Overall incidence of PCD in all cancer patients is approximately 1-3%. Percentage of breast cancer patients developing PCD is around 0.01% to 0.1%. Those cases associated with breast cancer tend to be human epidermal growth factor receptor 2 (HER2)-positive, though the reason for this correlation is unknown. Most commonly, the neurologic symptoms of the PCD syndrome predate the patient's cancer diagnosis. Thus, prompt diagnosis of PCD is essential to allow for early treatment of the neurologic symptoms and the underlying malignancy. However, the prognosis is very poor for the anti-Yo-associated paraneoplastic syndrome, since neurologic damage is usually rapid and irreversible. Further progression may be stopped with appropriate treatment of cancer, but existing neurologic deficits at the time of diagnosis are usually permanent. Here we present a rare case of a young woman with early HER2 positive breast cancer diagnosed with PCD.

Case Presentation: A 26-year-old woman with nil comorbidity and no family history of malignancy presented in February 2023 with progressive unsteadiness while walking with worsening truncal instability, slurring of speech, diplopia and increasing difficulty with fine motor tasks due to incoordination for 3 months. At this point, she needed the support of one person to walk. There were no constitutional symptoms, headaches, seizures, and hearing or visual disturbances. Her vitals and general physical examination (including breast) were normal. There was no lymphadenopathy. Neurological assessment revealed prominent cerebellar signs, including bilateral upper limb dysmetria, intention tremor, scanning speech, and gait and truncal ataxia. She had normal muscle tone, power, sensation, and symmetrical reflexes throughout her upper and lower limbs. Examination of the cranial nerves did not reveal any abnormalities. Gaze-evoked nystagmus was observed. Her routine laboratory tests were unremarkable. Brain and spine magnetic resonance imaging were normal, but her Nerve conduction studies (NCS) showed sensory peripheral neuropathy. Cerebrospinal fluid analysis revealed no cells, normal sugar levels, slightly increased protein level (77 mg/dl) with no oligoclonal bands, and it was negative for malignant cells. Serum was tested for onconeural antibodies, including anti-Yo, anti-Hu, anti-Ri, anti-CV2, anti-Ma2, and anti-amphiphysin. A high titre of anti-Yo antibodies (1:1,000) was detected in the serum and CSF samples using immunoblot assay with the dilution of 1:101. She underwent 2 cycles of plasmapheresis and 5 days of IVIG therapy leading to only minimal improvement. The presence of a characteristic anti-onconeural antibody led to the search of an underlying malignancy. A PETCT Scan was undertaken which showed a FDG avid enhancing lobulated soft tissue lesion involving retro areolar region of right breast, measuring 1.8 x 1.3cm, SUVmax 6.85 with no other sites of metastasis. A breast Biopsy was undertaken in which the histological report classified the tumour as a grade 3 infiltrating ductal carcinoma (IDC) with negative Estrogen receptors (ER), negative progesterone receptors (PR), Positive HER2 (3+) by immunohistochemistry. In addition, a panel of tumour susceptibility genes was performed, which did not show any mutations. Therefore, the patient was diagnosed of a unicentric IDC cT1cN0M0 HER2 positive of the right breast. With that information, she was initiated on Neoadjuvant therapy (NAT) completing 12 cycles of single agent weekly Trastuzumab from March 2023 to June 2023 with excellent tolerability. Paclitaxel was withheld due to pre-existing neuropathy on NCS. At this point, she had significant improvement in her symptoms to the tune that she could do her daily activities with minimal support. Following NAT, she underwent Breast conserving surgery with Axillary sampling in the month of July 2023 with post op Histopathology showing pathological complete response (pCR) (ypT0 and pN0 in sentinel nodes 0/6). Post Surgery in the month of July 2023 she had worsening of her ataxia with new onset sensorineural hearing loss (SNHL) which was moderate loss as per pure tone audiometric (PTA) test. She was given 5 days of High dose Methylprednisolone Pulse therapy following which she had good improvement with respect to her ataxia but not to SNHL. She completed 13 cycles of adjuvant three weekly single agent trastuzumab in the month of April 2024 and is on observation since then. On her first follow-up since completion of her treatment she observed improvement in her ataxia but only minimal improvement in her SNHL still requiring one person support for her activities of daily living with breast cancer being in

remission.

Conclusion: PCD remains a therapeutic challenge, based on the treatment of the neoplastic disease in conjunction with corticosteroid therapy and immunomodulators, such as immunoglobulins. It should be noted that neurological improvements have been described in patients with HER2 positive breast cancer under treatment with trastuzumab. In paraneoplastic conditions where the antigen is intracellular, as in the present case, the effectiveness of immunoglobulins is doubtful. Both positivity and titres of antibodies have not been shown to be predictors of evolution or response to treatment. Here, we present a novel case of a patient treated with only HER2 blockade, achieving a pathological complete response, which may impact the prognosis of the paraneoplastic syndrome.

P5-07-26: UK 5-Point Scoring System for Clinical Breast Examination Reduces Discordance in a Symptomatic Breast Triple Assessment Clinic

Jaime Castillo, Angeliki Mcallister, Vahan Kaplan, Philippa Hayes, Zofia Zielicka, Meera Joshi, Hirah Rizki, Daniel Leff, Paul Thiruchelvam, Katy Hogben

Introduction: Despite advancements in standardising breast imaging scoring systems, challenges persist in reporting clinical breast examinations (CBE). A 5-point scoring system, analogous to the Royal College of Radiologists Breast Group scoring system for the classification of breast imaging, is widely employed to report CBE in the UK. This system is crucial in the triple assessment of symptomatic breast patients, where discordance between CBE, imaging, and histopathology necessitates additional investigations and delays treatment. This study evaluates the impact of using the UK 5-point scoring system to report CBE on discordance in a symptomatic breast triple assessment one-stop clinic.

Methods: This retrospective chart review included symptomatic breast patients seen at a tertiary site in London, UK, between September 2022 and August 2023. Patients underwent CBE and at least one breast imaging modality. Clinicians were instructed to report CBE using a 5-point scoring system (1: Normal, 2: Benign, 3: Indeterminate, 4: Suspicious for malignancy, 5: Malignant) as per standard operational procedures. Discordance was defined as an abnormality on CBE not detected by imaging, while incorrect use of the scoring system was defined as a mismatch between the reported score and its description. The proportions of discordance and incorrect use were estimated with 95% confidence intervals. Associations with discordance were assessed using Pearson chi-square tests, and binary logistic regression estimated odds ratios for significant associations.

Results: 362 cases were included with a median age of 46 years (IQR=34-56), of which 345 (95.31%) were women. Presenting complaints encompassed 229 lumps (63.26%), 90 instances of pain (24.86%), and 43 with other symptoms (11.88%). The scoring system was

used in 260 CBE reports (71.82%). Ultrasound and mammography were performed in 311 (85.91%) and 194 (53.59%) cases, respectively. Histopathology was assessed in 48 cases (13.26%), with cancer diagnosed in 18 cases (4.97%). The proportion of discordance was 11.60%, 95% CI [8.49, 15.36]. The association between discordance and the use of the scoring system to report CBE was significant, $\chi^2(1, N=362)=13.75$, p<.001. Using the scoring system significantly reduced the odds of discordance OR=0.303, 95% CI [0.157, 0.584], p<.001, with further reduction when excluding incorrect uses OR=0.107, 95% CI [0.044, 0.259], p<.001. The proportion of incorrect use was 5.8%, 95% CI [3.3-9.3]. No significant associations were found between discordance and age $\chi^2(1, N=362)=3.13$, p=.077, sex $\chi^2(1, N=362)=0.64$, p=.425, presenting complaint $\chi^2(2, 362)=0.37$, p=.831, clinician seniority $\chi^2(2, 362)=3.25$, p=.197, CBE score χ^2 (2, N=362) = 2.55, p=.280, or imaging modality $\chi^2(2, N=362)=1.59$, p=.452.

Conclusion: This study demonstrates a threefold reduction in the odds of discordance when the UK 5-point scoring system is used to report CBE, with correct use of the system further decreasing the odds of discordance. These findings underscore the importance of developing dedicated CBE reporting guidelines, and support the broader adoption of standardised CBE scoring systems, to avoid ambiguity in multidisciplinary team communication and streamline the management of symptomatic breast patients.

P5-07-27: BL-B01D1, a first-in-class EGFRxHER3 bispecific antibody-drug conjugate, in patients with Locally Advanced or Metastatic Breast Cancer and other Solid Tumor: Updated results from a phase 1 study

Jiong Wu, Jian Zhang, Yiqun Du, Yanchun Meng, Sa Xiao, Hai Zhu, Yi Zhu

Background: BL-B01D1 is a potentially first-in-class novel antibody drug conjugate (ADC) consisting of an EGFRxHER3 bispecific antibody bounded to a novel topoisomerase I inhibitor payload via a cleavable linker. We now present updated safety/efficacy data from phase I study of BL-B01D1 in breast cancer (BL-B01D1-104).

Methods: This study included Chinese patients (pts) with locally advanced or metastatic breast cancer (BC) and other solid tumors. BC pts were enrolled in dose-expansion (D-EXP) at 2.5mg/kg D1D8 Q3W regimen regardless of EGFR/HER3 and HER2 expression levels.

Results: As of May 31, 2024, a total of 158 BC pts (156 were previously treated) have been treated with at least one dose of BL-B01D1. Among the 158 pts, 44 pts had triple negative breast cancer (TNBC) including 27 HER2 0 pts; 77 pts had HR+HER2- BC including 28 HER2 0 pts; 37 pts had HER2 positive BC.
The most common TRAEs (>25%, all grade/≥G3) were anemia (90.5%/39.9%), leukopenia (88.0%/42.4%), neutropenia (85.4%/51.3%), thrombocytopenia (67.7%/25.3%), nausea

(58.2%/3.8%), stomatitis (48.7%/3.8%), aspartate aminotransferase increased (45.6%/0%), alanine aminotransferase increased (42.4%/0%), asthenia (42.4%/8.9%), vomiting (40.5%/0.6%), hypertriglyceridemia (36.7%/0.6%), alopecia (32.9%/0%), hypokalemia (31.6%/3.8%), decreased appetite (31.0%/0.6%), hyperglycemia (30.4%/0%), constipation (27.2%/0.6%), hyponatremia (25.9%/1.3%). Among 158 BC pts, 1 patient was dead due to febrile neutropenia that was assessed to be related to BL-B01D1. No ILD was observed.
Among the 158 pts, 147 pts were efficacy evaluable (shown in the table).

Note:
1. 1 pt with HER2+ BC and 1pt with HR+HER2- BC who didn't receive standard treatment because of poor economic condition were enrolled.
2. NE, Not evaluable. Including pts who had no post-baseline scan and already off treatment.
3. The median follow up time of PFS is 8.5 months, and the mOS of all sub-group pts are not reached.
4. NR, Not reached.

Conclusions: BL-B01D1 has demonstrated encouraging efficacy in previously treated patients with metastatic and locally advanced breast cancer subtypes, particularly in earlier lines of therapy. The safety and tolerability of BL-B01D1 are consistent with previously published data.
Clinical trial information: NCT05470348.

P5-07-28: The next-generation CDK4-selective inhibitor atirmociclib (PF-07220060) in combination with letrozole as first-line treatment in patients with HR+/HER2+ metastatic breast cancer

Antonio Giordana, Manuel Magallanes, Binghe Xu, Diego Kaen, Ernesto Korbenfeld, Min Yan, Omar Zayas Villanueva, Carlos Alberto Hernandez, Peter Schmid, Michal Mego, Santiago Bella, Xinhong WU, Feng Liu, Cynthia Basu, Jennifer Park, Heather Neumann, Maria Delioukina, Timothy A. Yap

Background: Atirmociclib (PF-07220060) is a novel potent CDK4-selective inhibitor (CDK4i) with significant sparing of CDK6. In an ongoing phase 1/2a trial, atirmociclib plus endocrine therapy showed favorable tolerability and clinical activity in patients with metastatic breast cancer (mBC) who progressed on prior CDK4/6i (Yap, et al. Ann Oncol. 2024;[suppl_4]:1-47; Abstract 184MO). Here, we present the efficacy and safety results from an expansion cohort in the phase 1/2a study of atirmociclib in combination with letrozole in treatment-naïve patients with HR+/HER2– mBC (cohort 2B).
Methods: Women with HR+/HER2– mBC who had not received any prior systemic anti-cancer therapies for their advanced disease were enrolled in expansion cohort 2B of the phase 1/2a study. Patients received 300 mg BID atirmociclib + letrozole. Primary objective

was to assess the safety and tolerability of atirmociclib + letrozole; a secondary objective was to evaluate the anti-tumor activity by objective response (OR = complete response [CR] + partial response [PR]) and clinical benefit rate (CBR = OR or ≥ 24 weeks stable disease) per RECIST v1.1.
Results: At data cutoff (March 4, 2024), 34 patients had received atirmociclib + letrozole. Median age was 59.0 years (range 32–84); 67.6% were White, 23.5% were Asian; most had ECOG PS of 1 (55.9%). In this cohort of patients who had not received any prior systemic anti-cancer therapies in the advanced/metastatic setting, 55.9% underwent anticancer surgery and 47.1% had prior adjuvant/neoadjuvant therapy. Treatment-related adverse events (TRAEs) occurred in 28 (82.4%) patients; none were Grade (G) 4-5. Most common TRAEs were neutropenia (61.8%; 23.5% G3), leukopenia (38.2%; no G3), anemia (20.6%; no G3), and lymphopenia (20.6%; 2.9% G3). Due to a TRAE, 1 patient (2.9%) discontinued atirmociclib (G3; increased aspartate aminotransferase) and 3 (8.8%) had dose reductions (G1 and G2; neutropenia). Median relative dose intensity (RDI) of atirmociclib was 99.1% (range 36.0–100); 91.2% had RDI > 80%. Of the 32 patients who had measurable disease at baseline, 50% (16/32 patients) showed a confirmed OR, all of which were PRs. The CBR for these patients was 96.9% (31/32 patients). Among the entire cohort of 34 patients, median progression-free survival has not been reached. Median duration of follow-up was 11.1 months (95% CI 10.9–13.6). Updated efficacy data with longer follow-up will be presented at the meeting.
Conclusions: Combination of atirmociclib + letrozole showed favorable safety/tolerability and promising early activity as first-line treatment in patients with HR+/HER2– mBC.

P5-07-29: Trastuzumab deruxtecan With Pembrolizumab in Previously Treated HER2-Expressing Advanced or Metastatic Breast Cancer: Interim Analyses of the Breast Cohorts from the Open-Label, Multicenter, Phase 1b Study DS8201-A-U106

Hope S. Rugo, Antonio Anton Torres, Hendrik-Tobias Arkenau, Emma Kipps, Antoine Italiano, Antonio Calles Blanco, Georgia Anguera Palacios, Marie Meurer, Jesus Soberino Gracia, Aditya Bardia, Aixa E. Soyano, Anthony Goncalves, Robert Droder, Michael J. Chisamore, Daniel Barrios, Kodai Abe, Dipica Haribhai, Mitchell Rosen, Brandon Cunningham, Florence Dalenc

Background: Trastuzumab deruxtecan (T-DXd) demonstrated strong and durable antitumor activity in patients (pts) with previously treated HER2-positive (HER2+) and HER2-low/ultra-low mBC. We report interim clinical efficacy and safety for T-DXd plus pembrolizumab (PEM) in pts with previously treated HER2+ or HER2-low mBC enrolled in the breast cancer cohorts of DS8201-A-U106 (NCT04042701).

Methods: U106 is an open-label, multicenter, 2-part, phase 1b study. Part 1 determined the recommended dose for expansion (RDE) of T-DXd plus PEM. In part 2, pts with mBC were

assigned by centrally determined HER2 expression status to cohort 1 (HER2+; immunohistochemistry [IHC] 3+, IHC 2+/in situ hybridization [ISH]+ that progressed on T-DM1) or cohort 2 (HER2-low; IHC 1+ or IHC2+/ISH- that progressed on standard therapy); the primary endpoint was confirmed objective response rate (cORR) by independent central review (ICR).

Results: The RDE was T-DXd 5.4 mg/kg and PEM 200 mg intravenously every 3 weeks (Q3W). At data cutoff (DCO; Nov 18, 2023), 56 pts with mBC had received the RDE (30 in cohort 1; 26 in cohort 2). Median age was 58.6 years in cohort 1 and 56.3 years in cohort 2. Most pts in cohort 1 were from Europe (27/30 [90.0%]), most pts in cohort 2 were from the United States (16/26 [61.5%]). 17 pts (56.6%) in cohort 1 and 25 pts (96.2%) in cohort 2 were hormone receptor positive. Pts received a median 3.0 (range, 2-12) and 4.5 (range, 1-12) prior treatment regimens in the metastatic/locally advanced setting in cohorts 1 and 2, respectively. At DCO, T-DXd and PEM treatment was ongoing in 7 and 4 pts in cohort 1 and no pts in cohort 2. Median duration of follow-up was 16.1 mo (range, 3.0-30.2) in cohort 1 and 15.3 mo (range, 1.4-34.1) in cohort 2. The cORR by ICR was 80.0% (24/30; 95% CI, 61.4-92.3) in cohort 1 and 23.1% (6/26; 95% CI, 9.0-43.6) in cohort 2. The disease control rate (complete response + partial response + stable disease) was 100% (95% CI, 88.4-100) in cohort 1 and 80.8% (95% CI, 60.6-93.4) in cohort 2. Median duration of response (mDoR) was not evaluable (NE; 95% CI, 6.9 mo-NE) in cohort 1 and 11.4 mo (95% CI, 2.8-NE) in cohort 2. Median progression-free survival (mPFS) was NE (95% CI, 8.7 mo-NE) in cohort 1 and 12.7 mo (95% CI, 4.0-16.9) in cohort 2. PFS rates at 12 months in cohorts 1 and 2, respectively, were 68.6% (95% CI, 46.7-83.0) and 52.1% (95% CI, 29.7-70.4). Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 20 pts (66.7%) in cohort 1 (40.0% related to T-DXd; 26.7% related to PEM; 16.7% related to both) and 16 pts (61.5%) in cohort 2 (23.1% related to T-DXd; 3.8% related to PEM; 3.8% related to both). The most common grade ≥3 TEAEs were neutropenia, anemia, nausea, fatigue, and vomiting. TEAEs associated with discontinuation occurred in 9 pts (30.0%) and 2 pts (7.7%) in cohorts 1 and 2, respectively (including 1 due to grade 2 decreased left ventricle ejection fraction in cohort 1). There were 2 TEAEs associated with death (both in cohort 1; 1 due to general physical health deterioration; 1 due to neurologic decompensation); neither was related to either study treatment per investigator assessment. The overall incidence of adjudicated drug-related (T-DXd and/or PEM-related) interstitial lung disease/pneumonitis was 12.5% (7/56), with 3 events in cohort 1 (all grade 2) and 4 events in cohort 2 (3 grade 2; 1 grade 3).

Conclusions: Combination therapy with T-DXd and PEM showed encouraging efficacy in heavily pretreated pts with HER2+ and HER2-low mBC. Prolonged mPFS and mDoR were observed in pts with HER2-low mBC despite lower-than-expected cORR in this cohort. The value of addition of immunotherapy to T-DXd in this setting remains to be determined. The safety profile was consistent with the known profiles of the individual drugs and was generally manageable.

P5-07-30: Prophylactic irradiation to the contralateral breast for BRCA pathogenic-variant carriers with early-stage breast cancer: 10 years results

Ella Evron, Benjamin W Corn, Roxoliana Abdah-Bortnyak, Ora Rosengarten, Diana Matceyevsky, Orit Kaidar-Person, Merav A. Ben-David

Background: Women who carry germ-line pathogenic variants (PV) in BRCA1/2 face a high lifetime risk of breast and ovarian cancer. For BRCA1/2 PV carriers who present with early-stage unilateral breast cancer (BC), breast conserving therapy (BCT, breast conserving surgery and radiation) is associated with a similar risk of ipsilateral cancer recurrence (IBTR) compared with noncarriers. However, the risk of subsequent contralateral BC in carriers is high, estimated 25-30% at 10 years. Therefore, mastectomy and contralateral risk reducing mastectomy (CLT RRM) are often advocated. Nevertheless, there is insufficient evidence that RRM improves survival in this setting, and patients may forgo this option for fear of the surgical interventions.
Herein we report the long-term results of a prospective phase II trial (NCT00496288) of prophylactic irradiation to the contralateral breast in BRCA PV carriers with early stage BC. We previously reported our 5-year outcome data (Ann Oncol, 2019).
Patients and methods:
Between May 2007 and October 2017, 162 BRCA1/2 PV carriers undergoing radiation therapy for unilateral BC were enrolled. Eighty-two patients opted for surveillance to the CLT breast (control arm) and 80 received CLT prophylactic breast irradiation (intervention arm). The primary end-point was CLT BC. The groups were balanced by type of BRCA PV, age, BSO at diagnosis and stage of disease. In the control arm, significantly more patients had Her2 positive disease and were treated accordingly (p= 0.018), and more patients had endocrine sensitive disease and therefore received adjuvant endocrine therapy (p=0.026).

Results: At a median follow-up of 10.4 years, significantly more patients underwent elective RRM in the control arm [9 (11%) vs.1 (1.25%), p=0.018], and were censored from the primary analysis at the time of RRM. Fifteen (20.5%) patients developed CLT BC in the control arm at a median of 40 months, as compared with 11 (13.9%) patients who developed CLT BC at a median of 91.5 months after prophylactic breast irradiation (log-rank P=0.22). IBTR occurred in 12 (7.4%) patients, 6 in each arm, at a median of 81 months. There were no significant differences with respect to other breast cancer outcomes (distant metastasis free survival, breast cancer specific survival), and no differences for other cancer events.

Conclusions: Prophylactic breast irradiation reduced the rate of CLT BCs at 10 years and delayed their occurrence, without compromising breast cancer outcomes or increasing secondary malignancies. The above results did not achieve statistical significance, suggesting that prophylactic irradiation mostly treated subclinical disease while its

preventive effect on carcinogenesis was less evident.
Prophylactic breast irradiation should be further evaluated in a phase III trial or at least in a larger prospective cohort.

P5-08-01: The Impact of the Neoadjuvant Chemotherapy Compared to Adjuvant Chemotherapy in ALND Candidacy in cN0, cT1,2 early-stage Breast Cancer, A National Cancer Database Analysis

Mahtab Vasigh, Fabian Johnston, Fasika Molla Abreha, Taleaa Masroor, David Farhat, Lisa Jacobs, David Euhus, Olutayo Sogunro

Introduction: Axillary dissection is currently recommended for more than two positive nodes or for any positive nodes after neoadjuvant chemotherapy. However, the value of axillary dissection is uncertain. Enthusiasm for neoadjuvant chemotherapy (NAC) in early-stage breast cancer has intensified. It is possible that more liberal use of neoadjuvant chemotherapy will lead to an increase in recommendations for axillary dissection. Here, we compared the rate of ALND candidacy in early-stage breast cancers between those who received NAC and adjuvant chemotherapy (AC).
Method: After Institutional Review Board (IRB) approval, we performed a retrospective analysis of the National Cancer Database (NCDB). We identified cN0, cT1-2, M0, stage I, and II female breast cancers who had primary site surgery and received chemotherapy between 2010-2021. Patients with a history of another malignancy, no axillary surgery, unknown clinical or pathologic nodal status, an unknown number of positive nodes, and a previous history of neoadjuvant radiotherapy or endocrine therapy were excluded. ALND candidacy was considered positive in the NAC group if any positive nodes were recorded, and it was considered positive in the AC group if more than two positive lymph nodes were documented after axillary surgery. Patient and tumor characteristics were compared across those who received NAC and AC. Multivariable logistic regression was used to determine variables associated with ALND candidacy. Patients were categorized into four phenotypes: 1- hormone receptor-positive (HR+) and HER2+ as triple positive (TP); 2- HR+ and HER2- as hormone-positive (HR+); 3- Hormone receptor-negative (HR-) and HER2+ as HER2+; and 4- HR- and HER2- as triple negative (TN). Considering different rates of pathologic response to NAC, we performed a subgroup analysis by phenotype to compare the ALND candidacy amongst those who got NAC and AC stratified by the stage of the disease. Analysis was performed using Stata software, version 18.
Results: A total of 295,110 cases were selected. The mean age of the patients was 56.6+/-12.0 years; 79.3% were White, invasive ductal carcinoma (IDC) constituted 83.6%, and 41.5% underwent mastectomy. The mean number of removed and positive nodes were 5.4 and 0.9, respectively. NAC was administered in 38,315 (13%) of the patients, and 9.6% of them had positive nodes and were ALND candidates, while 25,017/256,795 (9.7%) of the AC group had more than two positive nodes and were considered ALND candidates (p=0.24). We performed a subgroup analysis by phenotype. TN breast cancers constituted 81,924 patients. Of them, 71.6% received AC, and 28.4% received NAC. The prevalence of

ALND candidacy was 3% in the AC and 5.9% in the NAC group (p<0.001). HR+ patients included 160,304 patients, of whom 95.6% received AC and 4.4 % received NAC. Among HR+ patients, 13.2% of the AC group and 23.7% of the NAC group were ALND candidates (p<0.001). TP breast cancers included 22,708 cases, where 89% received AC and 11% received NAC. ALND candidacy was also higher in the NAC group compared to the AC group among TP breast cancers (11.2 % to 6.5%, respectively, p<0.001). The HER2+ phenotype included 20,566 cases. In the HER2+ group, ALND candidacy in the NAC group compared to the AC group did not increase, and a decline in the ALND candidacy after NAC was observed (5.0% to 6.1%), p=0.008. This decline was not statistically significant in stage 1 HER2+ cases, but it was statistically significant in stage 2 HER2+ cases (5.1% to 8.9%) (p<0.001). On multivariable logistic regression model adjusted for age, Charlson Comorbidity score, clinical tumor stage, grade, HR status, HER2 status, lymphovascular invasion, type of primary site surgery (mastectomy or lumpectomy), and the year of diagnosis, NAC increased the rate of ALND candidacy compared to AC (OR:2.03, 95%CI 1.9-2.1; p<0.001). Conclusion: Increasing the use of NAC in early-stage breast cancer is likely to increase the recommendation for axillary dissection, especially for HR+ tumors, which are less likely to respond. Therefore, the timing of chemotherapy utilization in early-stage breast cancers should be cautiously considered.

P5-08-02: Baseline dietary patterns among patients with early-stage breast cancer in the Healthy Living Program

Bethina Liu, Sherry Shen, Erica Salehi, Nicolas Toumbacaris, Yuan Chen, Xiaotao Zhang, Johnny Allsop, Cara Anselmo, Bridget Kelly, Rocco Magnoli, Andrea Smith, Melissa Emerzian, Julia Brockway-Marchello, Doreen Bacotti, Mark Robson, Neil Iyengar

Background: Dietary patterns have been shown to impact breast cancer (BC) outcomes, including recurrence, survival, and quality of life. Clinical guidelines recommend a diet rich in fruits, vegetables, whole grains, and fiber with limited added sugar. The Healthy Living Program (HLP) at Memorial Sloan Kettering Cancer Center is a clinical initiative for patients with early-stage BC that provides individualized lifestyle optimization from the time of diagnosis. Here, we report baseline dietary patterns among the HLP cohort and associations with body mass index (BMI) and clinicopathologic variables.
Methods: Patients with stage 0-II BC enrolled in the HLP from September 2020 to August 2023 were included. Upon diagnosis, patients complete a survey that incorporates the National Cancer Institute Dietary Screener Questionnaire, which assesses consumption frequency of 26 food items in the prior month. Nutrient and food group intake estimates were calculated using Diet*Calc software. Adherence to guideline recommendations was assessed for each food group as follows: fruits/vegetables (3.5 cup equivalents [equiv] for females, 4.5 cup equiv for males), whole grains (3 ounce equiv), fiber (30 g), total added sugars (≤6 tsp for females, ≤9 tsp for males), and sugar-sweetened beverages (0 tsp equiv). BMI, race/ethnicity, tumor stage, and receptor status were extracted from electronic medical records. Univariable and multivariable regressions were performed to detect

associations between clinical variables and dietary patterns.
Results: A total of 1358 participants were evaluable (median age 59 years, interquartile range 49-68); 9 were male (<1%). 880 patients were White (65%), 191 were Asian (14%), 147 were Black/African American (11%), and 142 were Hispanic/Latinx (10%). BMI categorization was as follows: 372 (28%) had overweight BMI (25-29.9 kg/m2) and 389 (29%) were obese (BMI ≥30 kg/m2). 182 (13%) had carcinoma in situ, 983 (72%) had stage I BC, and 193 (14%) had stage II BC.
Median daily intakes were 2.56 cup equiv of fruits/vegetables, 0.61 oz equiv of whole grains, 15.41 g of fiber, 11.68 tsp equiv of added sugar, and 3.62 tsp equiv of sugar from sweetened beverages. 201 participants (15%) met the guidelines of fruits/vegetables intake. 0 met the guidelines for whole grains, fiber, total added sugar, and sugar from sweetened beverages intake.
Elevated BMI was associated with lower intake of fruits/vegetables ($p<0.001$), whole grains ($p<0.001$), and fiber ($p<0.001$) and higher intake of sugar from sweetened beverages ($p=0.01$). Compared to non-Hispanic Whites, Black/African American race and Hispanic/Latinx ethnicity were associated with lower intake of fruits/vegetables ($p=0.029$, $p<0.001$) and fiber ($p<0.001$ for both), and higher intake of sugar from sweetened beverages ($p<0.001$ for both). Hispanic/Latinx ethnicity was additionally associated with lower whole grain intake ($p<0.001$) and higher added sugar intake ($p=0.002$). Age ≥50 years was associated with lower added sugar ($p<0.001$) and sugar from sweetened beverages intake ($p<0.001$) compared to age <50. There were no significant associations between tumor stage or receptor status and fruits/vegetables, whole grains, or fiber intake. Triple negative BC was associated with lower added sugar intake compared to hormone-positive disease ($p=0.016$).
Conclusion: Few patients with early-stage BC met the recommended daily intake of fruits/vegetables, and none met the recommended daily intake of whole grains, fiber, and added sugar. Elevated BMI was associated with lower adherence to dietary guidelines. These findings highlight the value of dietary assessment at the time of BC diagnosis to identify patients for targeted dietary interventions and metabolic risk profile optimization.

P5-08-03: Significant overall survival (OS) benefit among patients with neoadjuvant chemotherapy use in T1c N0 triple negative and HER2 positive early breast cancer: a large National Cancer Database (NCDB) analysis.

Amalia M. Bonano-Rios, Shenae Samuels, Elizabeth Rubin, Amy M. Kiamos, Adriana M. Milillo, Delia C. Guaqueta, Heather Wright, Atif M. Hussein, Alejandra F. Ergle

Purpose: In the late 1990s, an OS benefit with use of neoadjuvant chemotherapy (NAC) over adjuvant chemotherapy (AC) had not been identified in NSABP B18, and NAC was primarily used for surgical down-staging. However, an important correlation was noted between surgical residual disease and poorer survival rates. [1] After 2017, the CREATE-X and KATHERINE trials each showed an OS benefit in triple negative (TNBC) and HER2+ breast

cancers, respectively, when surgical residual disease after NAC was used to guide enhanced post-operative systemic therapy.[2,3] This has since made NAC the standard of care for T2 or N1 tumors.[4] However, T1c N0 tumors were largely underrepresented in these studies, leading to uncertainty about the true benefit and therefore variability in NAC use in this subset of patients. This study aims to review the overall trend of NAC use in T1c N0 TNBC and HER2+ tumors, with assessment of survival rate differences compared to AC use. We will also focus on how treatment facility and social determinants of health may be affecting these trends.

Methods: Using the NCDB between 2004 and 2021, we identified patients 18 or older with T1c N0 TNBC and HER2+ early breast cancer who underwent both surgery and chemotherapy. Categorical variables were assessed using Pearson's chi-square test, whereas continuous variables were analyzed using independent t-tests. Statistical significance was set at $p < 0.05$.

Results: 47,668 patients with T1c N0 HER2+/TNBC who received chemotherapy were included.

OS rates were higher in the NAC cohort compared to AC cohort for the entire 2004-2021 study period (91.8% vs. 87.7%, $p <0.001$). Median follow up times were 55 months for the NAC cohort and 79 months for the AC cohort. An OS benefit was maintained even when we analyzed by joint follow up time of ≥ 55 months (95.5% vs 92.5%, $p < 0.001$).

In the overall period of 2004-2021, 22.6% of the study population received NAC. There was an increasing trend in overall NAC utilization overtime, with the highest proportion being in the 2016-2021 period (69.5% compared to 39.4% in AC cohort) ($p < 0.001$). The rate of NAC use in T1c N0 patients increased from 8.3% in 2006 to 46.8% in 2021 ($p <0.001$). Patients who received NAC versus AC were overall younger (54.7 vs. 58.8 years), more likely to have private insurance (66.3% vs. 57.8%), more like to have median incomes in the top quartile (41.0% vs. 38.8%), were predominantly treated in academic facilities (56.9% vs. 50.7%),and were located in metropolitan areas (88.0% vs. 85.9%) ($p < 0.001$ for all).

Conclusion: Our study shows that there is an OS benefit with NAC over AC in T1c N0 patients with TNBC or HER+ early breast cancer. NAC utilization in this group has markedly increased overtime, particularly after 2016, marked by the impact of the CREATE-X and KATHERINE trials, both of which showed an overall OS benefit from the addition of enhanced post-operative systemic therapy for patients with surgical residual disease. This OS benefit can now be confirmed for even smaller T1c N0 tumors. Social determinants of health and treatment facility type can have an impact on the overall accessibility and use of NAC for T1c N0 tumors, highlighting the importance of bridging these gaps.

P5-08-04: The Omission of Anthracycline Chemotherapy in Women with Early HER2-Negative Breast Cancer – A Systematic Review and Meta-Analysis

Danilo Giffoni de Mello Morais Mata, Mary-Beth Rush, Megan Smith-Uffen, Jawaid Younus, Ana Elisa Lohmann, Maureen Trudeau, Rebecca L. Morgan

Background: Anthracycline-taxane is the standard chemotherapy strategy for treating high-risk early breast cancer, despite the potential life-threatening adverse events caused by anthracyclines. In many cases, the combination docetaxel and cyclophosphamide (TC) is considered an alternative treatment option in select breast cancer populations. However, the efficacy of TC compared to anthracycline-taxane chemotherapy is unclear. This study aims to compare disease-free survival (DFS), overall survival (OS) and cardiotoxicity between adjuvant TC and anthracycline-taxane for patients with stage I-III, HER2-negative breast cancer. Methods: We conducted a systematic literature search on MEDLINE, Embase, Cochrane CENTRAL for trials published until March 11, 2024. Our search yielded 203 studies with 11,803 patients and 7 randomized-controlled trials (RCTs) were included, with a median follow up of 60 months. This research protocol was registered with PROSPERO. The Risk of bias (RoB) was assessed independently by two reviewers, using Cochrane RoB 2.0 tool for RCTs. Disagreements about study inclusion were resolved through discussion. Results: With a total of 11,803 participants, there were 725 DFS events in the anthracycline-taxane arm and 785 in the TC arm. TC results in little to no difference in DFS (HR 1.09, 95% CI 0.98 – 1.20; moderate-certainty of evidence). There were 411 and 400 death events in the TC and in anthracycline-taxane chemotherapy groups, respectively; OS (1.02, 95% CI 0.89 – 1.16; high-certainty of evidence); From the total of 9,732 patients who were treated and analyzed for cardiotoxicity, there were 13 events of cardiac-related side effects. Among those, 3 events were seen in the TC group and 10 in the anthracycline arm (RR 0.54, 95% CI 0.16 – 1.76; high-certainty of evidence). In all the study endpoints, DFS, OS and cardiotoxicity, the heterogeneity across all studies was likely not more than what is due to chance (I2 = 0%). In the subgroup analysis, there were 9,052 patients who had luminal ER positive breast cancer subtype, and 2,723 patients who had TNBC. There was no significant difference in DFS between TC and anthracycline-taxane in the subgroup analysis of the ER positive (HR 1.05, 95% CI 0.92 – 1.19; p = 0.49) and TNBC (HR 1.16, 95% CI 0.96 – 1.39; p = 0.12). The subgroup analysis based on lymph node (LN) status, in those who had LN negative there was no difference in DFS between anthracycline-taxane and TC chemotherapy (HR 1.06, 95% CI 0.87 – 1.28; p = 0.58). However, in patients with four or more lymph nodes, anthracycline-taxane was in fact, associated with better DFS, compared to TC (HR 1.48, 95% CI 104 – 2.12; p = 0.03). The OS analysis of LN positive, showed no benefit of anthracycline-taxane over TC in women with LN positive disease (HR 1.08, 95% CI 0.88 – 1.33; p = 0.47). Conclusions: There is high-certainty of evidence that there is no difference between TC and anthracycline-taxane chemotherapy in OS and cardiotoxicity. There is moderate-certainty of evidence that there is no difference between TC and anthracycline-taxane chemotherapy in DFS. In women with four or more positive lymph nodes, anthracycline-taxane was associated with a substantial reduction in relapse

events, compared to TC. Our study supports the current standard of practice, which is to use anthracycline-taxane regimens, and TC chemotherapy as a reasonable chemotherapy option in select cases.

P5-08-05: Impact of Inflammatory Breast Cancer on Survival Outcomes in Metastatic Breast Cancer Patients Treated with Topoisomerase 1 based Antibody-Drug Conjugates (ADCs)

Akshara Singareeka Raghavendra, Zhongya Wang, Roland Bassett Jr, Senthil Damodaran, Debu Tripathy

Background: Sacituzumab govitecan (SG) is an ADC targeting TROP2, coupled to SN-38, the active metabolite of irinotecan. SG is currently approved for metastatic triple negative breast cancer (BC) and hormone receptor (HR) positive metastatic BC after progression on prior therapies. Similarly, trastuzumab deruxtecan (T-DXd), an HER2 targeting ADC linked to topoisomerase I inhibitor deruxtecan is approved for HER2 low and HER2-positive BC. While both SG and T-DXd has significantly improved outcomes in metastatic BC patients, their activity in patients with inflammatory breast cancer (IBC) has not been well described. Here we aim to evaluate the impact of SG and T-DXd on survival outcomes in metastatic IBC compared to metastatic BC patients without inflammatory breast cancer (IBC).
Methods: We utilized Kaplan-Meier estimates to analyze progression-free survival (PFS) and overall survival (OS). Differences in survival curves between IBC and non-IBC patients were assessed using the log-rank test. Cox proportional hazards models evaluated associations between survival outcomes.
Results: The analysis included 834 breast cancer patients, of whom 76 (9%) had IBC. The median age at the start of treatment was 51 years (range: 20-85). The median PFS for the entire cohort was 6.4 months (95% CI: 6.0-6.9). The median OS for the entire cohort was 72.7 months (95% CI: 66.0-92.4). Half of the patients (415 patients) received SG as their first ADC treatment. IBC patients were more likely to be younger, with 25% aged 18-40 compared to 22% of non-IBC patients. More IBC patients had received greater than 1 prior line of therapy compared to non-IBC. Both groups had similar proportions receiving SG (49% for IBC patients vs. 50% for non-IBC patients) and T-DXd (51% vs. 50%). HR positivity was less frequent in IBC patients (30% vs. 41% for non-IBC patients), and a higher percentage of IBC cases were HER2-positive (32%) compared to non-IBC (25%). Disease progression or death occurred in 70% of IBC patients versus 69% of non-IBC patients. The median follow-up time was shorter for IBC patients (22.1 months) compared to non-IBC patients (28.4 months). The median PFS for the entire cohort was 6.4 months (95% CI: 6.0-6.9). There was no significant difference in PFS between IBC and non-IBC patients (p=0.85), with IBC patients having a median PFS of 6.3 months (95% CI: 4.7-7.7) compared to 6.5 months (95% CI: 6.0-7.3) for non-IBC patients. The hazard ratio for PFS was 1.03 (95% CI: 0.77-1.36). However, there was a significant difference in OS between IBC and non-IBC patients (p=0.006), with IBC patients having a median OS of 46.7 months

(95% CI: 34.1-Not estimable) compared to 74.6 months (95% CI: 67.8-95.2) for non-IBC patients. The hazard ratio for OS was 1.68 (95% CI: 1.16-2.43). 42% of IBC patients had died compared to 32% of non-IBC patients. There was no significant association between IBC and the clinical benefit rate (CBR), with a Fisher's exact test p-value of 0.37.
Conclusions: Despite similar initial treatments and best response rates to ADCs, IBC patients exhibited inferior survival compared to non-IBC patients, with a median OS of 46.7 months versus 74.6 months. The PFS was similar between the two groups, indicating that IBC status did not significantly affect the time to disease progression. Further research is warranted to understand the higher lethality of IBC and explore optimal and tailored treatment strategies to improve survival rates for IBC patients.

P5-08-06: Adjuvant capecitabine in combination with docetaxel and cyclophosphamide (TCX) versus anthracycline plus docetaxel & cyclophosphamide regimen (TAC) in women with high-risk, Her2-negative breast cancer: an open-label, randomized controlled trial

Yu Song, Yidong Zhou, Qiang Sun, Songjie Shen

Abstract: Background: The combination of anthracyclines and taxanes has been the standard regimen for the adjuvant treatment of early-stage, high-risk breast cancer. However, concerns exist regarding potential reduced efficacy in human epidermal growth factor receptor 2 (Her2)-negative patients due to co-amplification of topoisomerase IIα (TOPO IIα), the target of anthracyclines, and HER2 at the adjacent chromosomal loci (17q21.1 and 17q21.2, respectively). Some trials, eg. the West German Study Group PlanB trial, showed anthracycline-free chemotherapy (six cycles of docetaxel and cyclophosphamide [TC]) similar survival outcomes with standard anthracyclines plus taxanes regimens in Her2-negative high-risk early breast cancer patients. Meanwhile, some studies (such as FinXX, USO NO17629, ABCSG-24) suggest improved outcomes with capecitabine in HER2-negative patients. This rationale underpins our investigation comparing TAC (docetaxel, anthracyclines, and cyclophosphamide) to a novel regimen, TCX (docetaxel, cyclophosphamide followed by capecitabine), hypothesizing that replacing the anthracycline component with capecitabine (regimen X) might offer superior efficacy and potentially a more favorable toxicity profile in HER2-negative early-stage breast cancer.
Methods: This was an open-label, randomized, and controlled prospective trial. The study population enrolled patients with pT1 to pT3, node-positive, or node-negative high-risk Her2-negative early-stage breast cancer, between May 2011 and December 2013. Patients were assigned randomly as 2:1 to either TAC (docetaxel 75mg/m2, doxorubicin 50mg/m2 or epirubicin 75 mg/m2, plus cyclophosphamide 500 mg/ m2, cycled every 21 days for 6 cycles, with prophylactic administration of human granulocyte-colony stimulating factor [G-CSF]) or TCX (docetaxel 75 mg/m2, plus cyclophosphamide 500 mg/m2, followed by capecitabine 950 mg/m2, po, twice daily on days 1–14, cycled every 21 days for 6 cycles) regimens. Patients received radiotherapy or endocrine therapy after completion of

chemotherapy when clinically indicated. The primary endpoint was disease-free survival (DFS), defined as the time from surgery to locoregional or distant recurrence, second primary malignancy, or death. Secondary endpoints included distant disease-free survival (DDFS), overall survival (OS), disease-specific survival (DSS), and adverse event rate. Adverse events were graded according to the Common Terminology Criteria for Adverse Events (CTCAE) v3.0. This trial was registered in Clinicaltrials.gov (NCT01354522).

Results: A total of 204 patients were enrolled in this trial, with 136 patients in the TAC group and 68 patients in the TCX group (Table 1). The median age was 47 years for the TCX group and 48 years for the TAC group. The baseline characteristics were well-balanced between the two groups.

During a median follow-up time interval of 124 months, a total of 48 DFS events (35.29%) in the TAC group and 20 DFS events (29.41%) in the TCX group were observed (p=0.434, Table 2). There was no significant difference in 10-year DFS (TAC67.6±4.0% vs TCX 71.5±5.6%, p=0.477). There were significantly less distant metastases (TAC 29.41% vs. TCX 8.09%, p=0.040) and death event rates (TAC 26.47% vs. TCX 4.41%, p=0.003) in the TCX group. A tendency for statistical differences favoring the TCX group was observed in the 10-year DDFS (TAC 69.5±4.0% vs TCX 81.4±4.9%, p=0.054, Figure 1). The 10-year OS rate was significantly higher in the TCX group (91.0±3.5%) compared to the TAC group (77.2±3.6%, p=0.009). The 10-year disease-specific survival (DSS) rate was also significantly higher in the TCX group (92.5±3.2%) compared to the TAC group (78.5±3.5%, p=0.007).

Statistical differences were observed in the incidence of adverse events between the two groups ($p<0.05$, Table 3). The TAC group exhibited a higher frequency of infection (35.29% vs 14.71%), nausea (93.38% vs 25%), peripheral edema (16.18% vs 2.94%), and fatigue (93.38% vs 54.41%), while the TCX group exhibited a higher frequency of hand-foot syndrome (20.59% vs 86.76%) and diarrhea (17.65% vs 39.71%). The TAC group was prophylactically administrated G-CFS, and there was no significant difference in the incidence of neutropenia (TAC 69.82% vs TCX 60.29%, p =0.658) between the two groups.

Conclusions: TCX may be a promising option for high-risk HER2-negative breast cancer due to its potential for improved survival and tolerability compared to TAC. Further multi-center trials are needed to confirm the efficacy of TCX.

Figure 1. The Kaplan-Meier curves for 10-year survival analyses of breast cancer patients treated with TAC (n=136) and TCX (n=68) regimens. A) No significant difference in 10-year disease-free survival was observed between the TAC and TCX groups (p=0.477). B) The 10-year overall survival was significantly better in the TCX group compared to the TAC group (p=0.009). C) The TCX group showed a trend towards improved 10-year disease-free disease-specific survival compared to the TAC group (p=0.054). D) The 10-year disease-specific survival was significantly better in the TCX group compared to the TAC group (p=0.007). Abbreviations: TAC, docetaxel, anthracyclines, and cyclophosphamide regimen; TCX, docetaxel, cyclophosphamide followed by capecitabine regimen.

Table 1. The clinical and pathological characteristics of the TAC and TCX cohorts.

Table 2. Events in the TCX and TAC cohorts.

Table 3. Treatment-emergent adverse events during treatment.(Figures and Tables are to be uploaded)

P5-08-07: Survival Outcomes of Sequential Topoisomerase I Antibody-Drug Conjugate Therapies in Metastatic Breast Cancer Patients

Akshara Singareeka Raghavendra, Zhongya Wang, Roland Bassett Jr, Debu Tripathy, Senthil Damodaran

Background: Trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan (SG) are ADCs with topoisomerase 1 payloads targeting HER2 and TROP2, respectively, that are approved for use in metastatic breast cancers (MBC). SG is approved for patients with triple negative and hormone receptor positive MBC, while T-DXd is approved for patients with HER2 low (IHC 1+ or IHC 2+, FISH negative) MBC. As such there will be a population of MBC patients that will meet eligibility for both SG and T-DXd. In this study we assessed clinical outcomes in patients treated with these ADCs, examining differences between sequential and non-sequential treatment approaches in a large cohort of MBC patients.
Methods: Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method, and differences in survival curves between ADC treatment sequence (SG followed by T-DXd or T-DXd followed by SG) and between sequential or non-sequential ADC treatment were assessed using the log-rank test. Cox proportional hazards regression models were employed to evaluate the association between OS and PFS
Results: The analysis included a total of 125 breast cancer patients, with 67 (54%) receiving SG followed by T-DXd and 58 (46%) receiving T-DXd followed by SG. The median age at the start of ADC treatment was 52 years (range: 25–82 years). The median follow-up time for all patients was 13.9 months (range: 1.9–37.3 months). Among the study population, 35 (28%) had died, while 90 (72%) were still alive at their last follow-up. The majority of the patients (73%) received sequential ADC treatment. Patients in the SG -T-DXd group had more extensive prior treatment histories, with 55% having received three or more prior lines of treatment compared to 36% in the T-DXd - SG group. The T-DXd - SG group had a higher proportion of hormone receptor-positive patients (64%) compared to the SC - T-DXd group (18%). For PFS, no significant differences between the two ADC treatments sequence (T-DXd – SG vs. SG – T-DXd (HR: 1.30 (95% CI: 0.86 – 1.97), p = 0.52) or between sequential and non-sequential treatments (Hazard Ratio: 0.81 (95% CI: 0.53 – 1.24), p = 0.50) was observed. Median PFS was as follows: SG – T-DXd: 2.83 months (95% CI: 2.40 – 3.88); T-DXd – SG: 2.76 months (95% CI: 2.30 – 3.94); sequential: 2.66 months (95% CI: 2.30 – 3.94); non-sequential: 2.92 months (95% CI: 2.40 – 3.71). The median OS for all patients was 25.7 months. There was no significant difference in OS between the two ADC treatment sequence (T-DXd – SG vs. SG - T-DXd (HR: 1.34 (95% CI: 0.64 – 2.80), p=0.43) or between sequential and non-sequential treatments (HR: 1.22 (95% CI: 0.60 – 2.55), p=0.60). Median OS was as follows: SG – T-DXd: 25.7 months (95% CI: 20.3 – Not Estimable); T-DXd – SG: Not Estimable (95% CI: 16.5 – Not Estimable); sequential: 22.6 months (95% CI: 20.2 – Not Estimable); non-sequential: 25.7 months (95% CI: 21.3 – Not Estimable)

Conclusions: Our analysis indicates no clear survival differences between SG followed by T-DXd vs T-DXd followed by SG and whether these ADCs were used sequentially or non-sequentially. Further studies with rational biomarker analyses with larger sample sizes is warranted to draw more definitive conclusions.

P5-08-08: Predicting local recurrence in DCIS treated predominantly without radiation

Christina Kozul, Allan Park, Jack Hywood, S. Sandun Silva, Madawa Jayawardana, Anand Murugasu, Allison Rose, Belinda Parker, Bruce Mann

Problem statement: Approximately 14% of breast cancer patients are now diagnosed with ductal carcinoma in situ (DCIS). Predicting the prognosis of DCIS is imprecise, leading to substantial variability in treatment. Utilising a large patient cohort with conservative use of radiotherapy, we aim to identify markers of risk of relapse, and the nature of the relapses.
Methods: A cohort study including patients diagnosed at and/or managed by North Western BreastScreen and the Parkville Breast Service in Victoria diagnosed during 1994-2018. Demographic, treatment, pathology, and outcome data were extracted from medical records and via a linkage with the Victorian Cancer Registry and National Death Registry. Histopathological features of the index lesion were compared to subsequent ipsilateral breast cancer events (IBE).
Results: 1163 DCIS cases were identified: median age at diagnosis of 58 years and median follow-up was 11 years. Most patients were diagnosed through BreastScreen (n=1090, 94%). 565 (49%) were high-grade, 415 (36%) intermediate-grade and 183 (16%) low-grade, with the median size being 13mm. Most patients had wide excision (WE) (n= 1051, 90%) with 107 (9%) having mastectomy. 355/1051 (34%) were treated with radiotherapy after WE and 407/1163 (35%) with endocrine therapy. IBE occurred in 215 (18%) of patients: invasive cancer in 114 (10%) and DCIS in 101 (9%). There was a 1.6% incidence of breast cancer death at median of 11 years. No significant association between grade, size, margins or age and IBE was found. On multivariable analysis, radiotherapy was associated with a significantly lower rate of IBE (HR: 0.39, p: <0.0001). The level of radiotherapy benefit was the same for all grades of DCIS. On multivariable analysis, estrogen receptor (ER) positive status was associated with an increased invasive IBE rate (HR: 2.06, p: 0.0470). Conversely, progesterone receptor (PR) positive status was associated with a decreased invasive IBE rate (HR: 0.43, p: 0.003). Most invasive IBE following high-grade index DCIS were grade 2 or 3 (50/67, 75%) while those following low-grade DCIS were grade 1 or 2 (14/15, 93%). Most ER+ve DCIS recurred as ER+ invasive IBE (n=53/58, 91%) and ER-ve DCIS recurred as ER- invasive IBE (n=10/16, 63%). Two-thirds of PR+ve DCIS recurred as PR+ invasive IBE (n=29/43, 67%) and just over half of PR-ve DCIS recurred as PR-ve invasive IBE (n=17/31, 55%). HER2+ DCIS usually recurred as HER2+ invasive IBE (n=7/11, 64%) and most HER2- DCIS recurred as HER 2- invasive IBE (n=27/31, 87%). Of invasive IBEs with full phenotype data available (n=98), 56/98 (57.2%) were luminal A (ER+,PR+, HER2-), 17/98 (17.3%) were luminal B (ER+, PR-, HER2+:any), 12/98 (12.2%)

were HER 2+ (ER-, PR- and HER2+) and 7/98 (7.1%) were triple negative (ER-, PR- and HER2-). This matched the phenotype of the index DCIS in 23/53 cases (43.4%) where full information was available.
Conclusion: Invasive IBE is common after WE for DCIS with an association between the grade and phenotype of index DCIS and recurrence. Standard clinicopathological factors were not associated with IBE risk. Further advancement in DCIS patient stratification is required to ensure treatment is personalised and overtreatment is reduced.

P5-08-09: Validation of the Updated Breast Graded Prognostic Assessment (Breast GPA) for Stereotactic Radiosurgery (SRS) Treated Patients

Ajay Dhakal, Alex Schick, Sara Hardy, Michael Milano, Dandan Zheng, Michael Cummings, Ruth O'Regan, Nimish Mohile, David Hicks, Carey Anders, Huina Zhang, Allison Magnuson, Derick Peterson, Myla Strawderman

Background: Updated Breast Graded Prognostic Assessment (BGPA, Sperduto et al., 2020), a common prognostic index (PI) for overall survival (OS) among patients (pts) with breast cancer brain metastasis (BCBM), was developed from a dataset where only 1/3 received stereotactic radiosurgery (SRS) without whole brain radiotherapy (WBRT). However, in the last decade, SRS has largely replaced WBRT as preferred local therapy for BM, especially for fewer BM (</=4). There is a lack of external validation of BGPA in a SRS treated BM population. Objective of this study is to validate BGPA in SYBRA dataset (BCBM SRS database from University of Rochester) and explore additional variables that might improve PI in SRS population.

Methods: SYBRA includes pts with BCBM who have received their 1st or only SRS to brain between Jan 2010- June 2023. Baseline characteristics and proportion of pts in 4 GPA score categories (GPA cats) were compared between BGPA vs SYBRA with Chi square test. Following statistical approaches outlined by Royston and Altman (BMC Med Res Methodol, 2013) for external validation, the model fit, discrimination, and calibration of BGPA index was evaluated in SYBRA. Cox proportional hazards linear predictor (LP) from BGPA was calculated in SYBRA and its calibration slope estimated and evaluated. Original model predictors were re-estimated in SYBRA with LP offset to assess misspecification of fit (Global Chi Square test). Harrell's C-index was estimated and compared with the same index reported in the original paper. Kaplan-Meier curves and hazard ratios (HR) across GPA cats were estimated. Finally, two new predictors, timing of BM and lines or prior systemic therapy, were added to original model and tested for significance.

Results: Sample size in BGPA and SYBRA were 2473 vs 108; median OS (IQR) in months were 16 (7-34) vs 24 (8-45). % of pts in BGPA vs SYBRA for different variables: age in years <46 25 vs 14 (p=0.013); luminal A BC 31 vs 44 (p=0.076); >=10 BM 20 vs 8 (p=0.064); KPS=90 29 vs 35 (p=0.0085). There was insufficient evidence that distribution of pts in GPA

cats in SYBRA vs BGPA was different (p=0.22). Calibration slope of LP in SYBRA was 0.964 [Standard Error (SE)=0.211, 95% Confidence Interval (CI) 0.551-1.377] indicating strong evidence of validation (p<0.0001 for test of the null hypothesis that slope=0) & excellent calibration (p=0.87 for test of null hypothesis that calibration slope=1). Model misspecification assessment showed no overall evidence of misspecification of LP in SYBRA (p=0.54). Harrell's C-index was 0.642 (SE=0.035), similar to BGPA (c=0.648), indicating moderately good discrimination. SYBRA survival curves for GPA cats were well separated (p=0.0035, Log Rank) and similar to those reported in BGPA, except for highest GPA cat in SYBRA (n=7). Median OS for GPA cats 0.0-1.0, 1.5-2.0, 2.5-3.0 and 3.5-4.0 were 7.5, 22.0, 41.4 and 20.7, respectively. When comparing HR across GPA cats 1.5-2.0, 2.5-3.0 and 3.5-4.0 (vs. GPA 0.0-1.0) there was trend of incremental improvement in the risk of death [HR (95% CI) 0.639 (0.379 – 1.075), p=0.0913; 0.279 (0.140- 0.557), p=0.0003; 0.387 (0.145 – 1.036) p= 0.0587]. Lastly, in separate Cox models assessing the contribution of 2 novel variables with BGPA LP as an offset, recurred BM (vs de novo) was associated with a higher risk of death [HR=2.22 (95% CI: 1.37-3.60), p=0.0012]; prior lines of systemic therapy at BM diagnosis (>/=2 vs 0-1) was also associated with higher risk of death [HR=2.23 (95% CI: 1.41-3.52), p=0.0006].

Conclusion: This study suggests validity and excellent calibration of BGPA model in BCBM pts who have received SRS without WBRT. Adding BM timing (de novo vs recurred) or lines of prior systemic therapies for metastatic BC as a predictor may improve BGPA model in SRS population.

P5-08-11: Comprehensive characterization of the immune landscape in HER2-low and HER2-0 hormone receptor positive tumors

Carlos Wagner S. Wanderley, Daniel Michaud, Kenichi Shimada, Jingxin Fu, Sara M Tolaney, Elizabeth A. Mittendorf, Romualdo Barroso-Sousa, Adrienne Waks, Paolo Tarantino, Jennifer L. Guerriero

Background: Targeting the spectrum of human epidermal growth factor receptor 2 (HER2) expression seen across breast cancer subtypes with the anti-HER2-drug conjugate (ADC) trastuzumab deruxtecan (T-DXd) has significantly impacted breast oncology, shifting the paradigm of anti-HER2 therapies. Despite the major clinical implications of targetable HER2-low tumors, the fundamental biological differences between HER2-low and HER2-0 breast tumors remain unclear. Here, using molecular profiling and multiplexed imaging techniques, we perform a comprehensive characterization of the immune landscape of HER2-low and HER2-0, hormone receptor positive (HR+) breast tumors.

Methods: We analyzed a cohort of treatment-naïve, HR+, and HER2-negative breast cancer patients obtained from Brigham and Women's Hospital (BWH) and Dana-Farber Cancer institute (DFCI). A total of 26 primary tumor resections were separated into HER2-low

(HER2 1+, 2+/FISH Neg., n=17) and HER2-0 groups (n=9). All patients had estrogen receptor (ER)-positive (91.2% positive cells, ranging from 50 to 100%). The average proportion of ER-positive cells was 90.35% in HER2-low and 91.5% in HER2-0. We performed bulk RNA sequencing (RNAseq), single-nucleus sequencing (snucSeq), and multiplex cyclic immunofluorescence (CyCIF) staining of FFPE sections. Significance was described according to p-value<0.05.

Results Gene set enrichment analysis (GSEA) of bulk RNAseq data revealed that HER2-0 tumors were significantly enriched in genes related to immune pathways such as "adaptive immune response" (padj<0.001) and "positive regulation of immune response" (padj<0.001) compared to HER2-low tumors. SnucSeq was used to investigate the contributions of individual cell types to the differential gene signatures. We observed that HER2-0 epithelial cells expressed gene sets derived from immune signatures such as "inflammatory response" (padj=0.01) and "interferon gamma response" (padj<0.001) while epithelial cells from HER2-low tumors expressed genes linked to cell cycle, metabolism, and estrogen signaling such as "MYC targets" (padj<0.001), "E2F targets" (padj<0.001), "oxidative phosphorylation" (padj<0.001), "glycolysis" (padj<0.001), and "estrogen early (padj<0.001) and late response" (padj<0.001). HER2-0 tumor displayed a greater, but non-significant, amount of immune cell infiltration compared to HER2-low tumors (23.4% vs 12.92% (p=0.12)). Accordingly, a non-significant increase in immune infiltration into HER2-0 tumors compared to HER2-low tumors was also observed using CyCIF on FFPE tissue sections (23.96% vs 17.57%, p=0.25). However, unsupervised analysis of individual lymphocyte and myeloid cell clusters within the snucSeq dataset revealed significant differences in immune population frequency between HER2-low and HER2-0 tumors. Amongst the differences we identified plasmacytoid dendritic cells (1.1% vs 0.5%, p=0.03) and DOCK4+ CD4+ T cells (3% vs 0.8%, p=0.01) to be significantly more abundant in HER2-0 tumors. Additionally, the gene set analysis of TAMs from HER2-0 vs HER2-low indicated an enrichment of immune pathways such as "positive regulation of immune response" (padj=0.001) and "lymphocyte activation" (padj=0.001) in the HER2-0 tumors.

Conclusions Our findings highlight subtle yet potentially relevant immunological differences between untreated HER2-low and HER2-0 HR+ tumors. Although there was a similar overall immune landscape, our data reveal notable discrepancies in biological pathways. HER2-0 tumors are marked by the presence of inflammatory and immune signatures, indicating an ongoing low-grade inflammatory response. Conversely, HER2-low tumors are characterized by elevated activity of cell cycle, metabolic, and estrogen signaling pathways suggesting a more active cellular proliferative program and luminal phenotype. The biological significance of these findings is currently being investigated.

Ethics Approval The ethics approval for this study was obtained from the Dana-Farber Cancer Institute, Boston, MA, under the ethics committee number 93-085.

P5-08-12: Association of Baseline Global Inflammation Score with Clinical Outcomes: Secondary Analysis from Alliance A011502

Shipra Gandhi, Karla V. Ballman, Sarah K. Reed, Michelle D. Holmes, Kala Visvanathan, Banu Symington, Margaret Carvan, Carol Matyka, Anna Weiss, Eric P. Winer, Wajeeha Razaq, Paula R. Pohlmann, Lisa A. Carey, Ann H. Partridge, Wendy Y. Chen

Background: A011502 is a phase 3 randomized double-blind clinical trial that randomized high risk nonmetastatic breast cancer (BC) patients (pts) to aspirin 300 mg daily vs placebo. We previously reported on the association of lifestyle factors (linked with inflammation) with clinical outcomes and found that high perceived stress scale (PSS) scores and moderate/severe pain assessed with Brief Pain Inventory (BPI) were significantly associated with worse invasive disease free (iDFS) and overall survival (OS). We hypothesized that a global inflammation score encompassing lifestyle measures associated with inflammation (stress, poor sleep quality, depression, pain, being overweight/obese) could predict a subset of pts who are at the highest risk of worse outcomes.
Methods: 2257 BC pts enrolled on A011502 answered 4 validated questionnaires at baseline that, along with BMI, were used to calculate global inflammation score. These questionnaires included PSS, categorized as low: 0-13 (=0 (these patients were given a score = '0')) or moderate: 14-26 (=0.5) or high stress: 27-40 (=1); BPI, categorized as none: 0/mild: 1-3 (=0) or moderate/severe pain: 4-10 (=1); Pittsburgh Sleep Quality Index: PSQI, categorized as good: 0-5 (=0) or poor sleep quality: 6-10 (=1); Center for Epidemiologic Studies Depression Scale Revised: CESD-R, categorized as no depression (=0) or depression (=1); and BMI, categorized as normal weight = 0; overweight = 0.5; obese = 1. Thus, global inflammation score per pt was obtained by summing the individual scores and ranged from 0 to 5. Association between global inflammation score (both as a continuous and categorical variable as tertiles (T1: 0-1, T2: 1.5-2, T3: 2.5-5)) and iDFS and OS was performed with multivariable Cox models controlling for age, cancer stage, time since diagnosis, race, ethnicity, hormone receptor status and treatment arm.
Results: Median age was 53 (23-69) years, 83.2% White, 69.2% stage II, 89.1% hormone receptor positive; median time from diagnosis to answering questionnaires was 12.9 months. Median follow-up was 35 months. Median global inflammation score was 1.5. Pts with higher global inflammation score (continuous) had worse iDFS (events/total=195/2257), hazard ratio (HR) 1.14 (95% CI: 1.00, 1.30), p=0.04; and worse OS (events/total=89/2257), HR 1.24 (95% CI: 1.04, 1.49), p=0.02. Categorizing global inflammation score into tertiles revealed a non-linear relationship for iDFS: T1 reference, T2 HR 1.09 (95% CI: 0.77, 1.54), and T3 HR 1.44 (95% CI: 1.01, 2.05); and a non-linear relationship for OS: T1 reference, T2 HR 1.59 (95% CI: 0.92, 2.74), and T3 HR 2.04 (95% CI: 1.19, 3.51). Based on this, we dichotomized the global inflammation score as low (score in T1 or T2) and high (score in T3). Pts in high group had worse iDFS (events/total=68/643): HR 1.38 (95% CI: 1.02, 1.86), p=0.04; and worse OS (events/total=35/643): HR 1.59 (95% CI: 1.03, 2.45), p=0.04 compared to low group. There was no difference in iDFS for high or low inflammation group by treatment arm.
Conclusions: Pts with higher global inflammation score at baseline had worse iDFS and OS

in a randomized controlled trial of aspirin vs placebo in high-risk BC survivors. It is possible that some measures may be related to other non-cancer issues (e.g., chronic comorbidities, social determinants of health, endocrine therapy adherence) that were not captured in our study. Moreover, use of aspirin did not influence outcomes regardless of inflammation score. These results highlight the need for clinical trials to consider including measures affiliated with inflammation and BMI. Future studies are warranted to determine if measures that reduce inflammation would improve BC outcomes.

P5-08-13: Real-world demographics, clinical characteristics, and treatment patterns among US patients with HER2-negative early breast cancer and germline BRCA mutations since 2021

Sagar Sardesai, Luis C. Berrocal-Almanza, Xiaoliang Wang, Catherine Keane, Jingru Wang, Miguel Miranda, Meng Ru, Xiaoqing Xu

Background: Patients (pts) with germline BRCA1/2 pathogenic mutations (gBRCAm) and clinically high-risk HER2-negative (HER2−) early breast cancer (eBC) are eligible for adjuvant olaparib. In routine clinical practice, select pts with high-risk HER2− eBC may also receive CDK4/6 inhibitors or immuno-oncology therapies, but there is a lack of knowledge on preference and concurrent or sequential use of available treatments in this population. Here, we describe real-world gBRCA testing rates and treatment patterns prior to and post the U.S. FDA approval of adjuvant olaparib for HER2− eBC.
Methods: Data from US pts ≥18 years of age diagnosed with HER2− eBC (stage I–III) between January 1, 2021, and February 29, 2024, were captured from the nationwide Flatiron Health electronic health record-derived de-identified database. gBRCA testing rates were determined through abstraction from all successful BRCA tests in pt records. Demographics, clinicopathological characteristics, and treatment patterns were described across tumor subtypes (hormone receptor-positive [HR+]/HER2− or triple-negative breast cancer [TNBC]) and gBRCA status. High-risk eBC was defined, adapted from OlympiA criteria, as HR+/HER2− eBC with ≥4 positive lymph nodes (≥pN2), or TNBC with positive axillary node (≥pN1) or with negative axillary node (pN0) and invasive primary tumor size >2 cm (≥pT2).
Results: Of 2373 pts with eBC (HR+/HER2−, n=2040; TNBC, n=333; median age at diagnosis: 64 years), 1147 (48%) received a gBRCA test, with a lower testing rate in pts with HR+/HER2− eBC (n=905/2040, 44%) than in pts with TNBC (n=242/333, 73%). Grouping by year of eBC diagnosis showed consistent testing rates in 2021 vs 2023+ for pts with HR+/HER2− eBC (44 vs 46%) but a decline in pts with TNBC (76 vs 65%). A substantial proportion of pts eligible for gBRCA testing, including pts ≤50 years (n=117/417, 28%), with high-risk HR+/HER2− eBC (n=44/103, 43%) or with high-risk TNBC (n=20/87, 23%) had unknown/untested status.
Among tested pts, gBRCAm prevalence was lower in pts with HR+/HER2− eBC (n=66/905,

7%) than TNBC (n=57/242, 24%). Among pts with HR+/HER2− eBC and known gBRCA status tested for Ki67 and/or a 21-gene recurrence score (RS), a greater proportion of pts with gBRCAm than non-BRCAm had Ki67 ≥20% (86 vs 47%, respectively) and RS ≥26 (56 vs 11%, respectively).
Proportionally fewer pts with HR+/HER2− eBC (n=242/2040; 12%) than TNBC (n=151/333, 45%) received neoadjuvant therapy. Chemotherapy (CT; n=106/242, 44%) and endocrine therapy (n=81/242, 33%) were the most common neoadjuvant therapies for HR+/HER2− eBC. Pembrolizumab (n=92/151, 61%) and CT (n=54/151, 36%) were the most common neoadjuvant therapies for TNBC. A total of 60 pts (2.5%) received adjuvant olaparib, including 18/66 (27%) pts with gBRCAm HR+/HER2− eBC, 27/57 (47%) pts with gBRCAm TNBC, and 15/2250 (<1%) pts (7 HR+/HER2− eBC and 8 TNBC) who had non-gBRCAm/unknown gBRCAm status. Of the 25 pts with HR+/HER2− eBC who received olaparib, 20 (80%) were <pN2 (not high-risk). Of the 35 pts with TNBC who received olaparib, 16 (46%) were pN0 or <pT2 (not high-risk). Of pts with gBRCAm eBC who had received prior CT, 17/42 (40%) with HR+/HER2− eBC and 24/43 (56%) with TNBC received adjuvant olaparib.
Conclusions: Recently updated cancer guidelines endorse gBRCAm testing in all pts ≤65 years with a breast cancer diagnosis, pts >65 years who are candidates for PARP inhibitor therapy, and other high-risk individuals. This real-world analysis of pts diagnosed since 2021 showed that 55% of pts with HR+/HER2− eBC and 27% with TNBC did not receive a gBRCA test, and utilization of adjuvant olaparib was low, particularly among pts with HR+/HER2− eBC. Wider implementation of genetic testing is needed to ensure appropriate utilization of olaparib in eligible pts with eBC.

P5-08-14: Preliminary results of mini-invasive detection of residual disease in breast cancer patients in remission after primary chemotherapy: a further step toward omission of surgery?

Chiara Listorti, Deborah Bonfili, Chiara Osio, Federica Pilotta, Ilaria Maugeri, Virginia Ceccarossi, Cristina Ferraris, Catherine Depretto, Elisa D'Ascoli, Claudio Vernieri, Giuseppe Capri, Giulia Bianchi, Francesco Barretta, Secondo Folli, Giancarlo Pruneri, Rosalba Miceli, Gianfranco Scaperrotta, Gabriele Martelli

Background: Breast surgery may be overtreatment and can potentially be omitted when systemic neoadjuvant treatment (NAT) results in pathological complete response (pCR) in breast cancer (BC) patients. The accuracy of residual disease detection in patients with clinical/radiological response is increased by minimally invasive preoperative image-guided vacuum-assisted biopsy (VAB). Thus, patients with pCR – as indicated by negative VAB – might be spared surgery if pre-operative VAB findings closely correspond with definitive histology after breast surgery. We evaluated the ability of VAB to detect invasive residual disease in patients with cT1-T2-T3 cN0/N1 BC (either HER2-positive, triple-negative, or Luminal B HER2-positive) and complete clinical/radiological remission after NAT.

Methods: Patients were enrolled from April 2022 to April 2024 in a single-institute, ongoing, prospective pilot study (NCT 05951699). Patients had either complete clinical/radiological response, or residual breast disease (<1 cm) after NAT at imaging (ultrasound, mammography, contrast-enhanced mammography, and MRI). Breast VAB before surgery consisted of image-guided biopsy on the tumor bed, taking 5-10 cores using a 9G needle. The primary outcome was VAB accuracy, assessed by comparing the VAB findings with definitive histology on the surgical specimen. Cases with negative VAB and invasive residual disease at definitive histology were false negatives. Cases with negative VAB and ductal carcinoma in situ at histology were true negatives since no invasive residual disease was found. Cases with positive VAB (invasive or in situ) and negative histology after surgery were considered true positives (VAB had removed all residual disease).
Results: Thirty-nine patients gave their consent and had VAB after NAT. Median age was 53 years (IQR 47-61). Thirteen (33.3%) had HER2-positive disease, 23 (59%) had triple-negative disease, and 3 (7.7%) had Luminal B-HER2-positive disease. VAB failed to identify invasive residual disease in one case (triple-negative). Among true negatives there were 4 cases of ductal carcinoma in situ (3 HER2-positive and 1 triple negative). Furthermore, VAB identified both invasive and in situ residual disease in 3 cases with positive VAB but negative histology after surgery (1 ductal carcinoma in situ in an HER2-positive case, 1 ductal carcinoma in situ in a triple negative case, and 1 invasive disease in a triple negative case). Based on these considerations, VAB accuracy was 97.4% (38/39; 95% CI 92.5-100.0%); specificity was 100% (30/30), and sensitivity was 88.9% (8/9; 95% CI 68.4-100.0%)
Conclusion: These preliminary findings indicate that pre-operative VAB has good accuracy in predicting definitive histological findings in cT1-T2-T3 BC patients with HER2-positive, triple-negative, and Luminal B HER2-positive disease, who have a clinical/radiological response after primary chemotherapy. Although these findings require confirmation in larger studies, they suggest the use of VAB to select patients for prospective trials on the omission of surgery in patients who achieve a good clinical/radiological response after primary chemotherapy.

P5-08-15: Evaluation of efficacy and safety of sequential antibody drug conjugates (ADCs) in human epidermal growth factor 2 (HER2) negative metastatic breast cancer

Heather Moore, Sara Nezirevic, Carey Anders, Susan Dent, Rani Bansal, Lexie Zidanyue, Alaattin Erkanli

Background: Antibody drug conjugates (ADCs) are composed of a monoclonal antibody with a cytotoxic payload designed to deliver targeted therapy with minimal damage to non-cancerous cells.1 Recent trials of ADCs in the metastatic breast cancer (MBC) setting have demonstrated significantly improved clinical outcomes.2-5 Sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd) are FDA approved in patients with hormone receptor positive (HR+), human epidermal growth factor 2 (HER2) negative, HER2-low, and triple

negative MBC. Many of the developed ADCs share similar targets and cytotoxic payloads with similar mechanism of action; little is known regarding acquired resistance and impact on subsequent lines of therapy. There is limited data available assessing the efficacy, safety, and optimal sequencing of ADCs in this setting including patients (pts) with brain metastases (BrM) or leptomeningeal disease (LMD). Retrospective data suggests a reduction in response rates with subsequent ADC treatment in pts with MBC. This retrospective study aims to assess the efficacy, safety, and tolerability of sequential ADCs in MBC inclusive of both intracranial and extracranial disease, and to determine if the efficacy of subsequent cytotoxic chemotherapy may be impacted by ADC use.
Methods: This is a single-center, retrospective, cohort study in pts with HER2 negative or low MBC (immunohistochemistry (IHC) test of 0 (as negative), 1, or 2 and fluorescence in-situ (FISH) negative (as HER2 low) who received T-DXd and/or SG at the Duke Cancer Institute (DCI) from 04/2021 to 10/2023. Eligible pts were ≥ 18 years of age with a diagnosis of HR+, HER2 low, or triple-negative locally advanced or MBC. Adverse events (AEs) were graded using the Common Terminology Criteria for Adverse Events (CTCAE) v5.
Results: A total of 112 patients with HR+/HER2- or triple negative breast cancer (TNBC) who had received T-DXd and/or SG were included. A total of 59 (52.6%) pts had HR+ MBC, and 43 (38.3 %) TNBC. Approximately 22.3% and 2.7% of patients had brain and/or LMD metastases. Pts were divided into three cohorts: pts who received ADCs sequentially (cohort A, n=13), ADC then chemotherapy (CTX) thereafter (did not receive second ADC) (cohort B, n=46), or one line of CTX in between two ADCs (cohort C, n=13). The mPFS (mPFS) in the cohort A was 4.4 months in the SG immediately prior to T-DXd group and 3.0 months for T-DXd immediately prior to SG group. In cohort B, those who received CTX following T-DXd group, the mPFS was 3.1 months. Pts who received CTX following SG, the mPFS for chemotherapy was 2.5 months, whereas in pts who received both ADCs, PFS was 2.1 months with subsequent chemotherapy. In cohort C, the mPFS was 2.1 months for SG following T-DXd and CTX and 3.3 months for T-DXd following SG and CTX. The mPFS for ADC1 was longer than ADC2 regardless of sequence order. The mPFS for first ADC was 5.5 months for SG and 3.4 months for T-DxD. In both groups, those with BrM and/or LMD all demonstrated stable disease with extracranial response after the administration of an ADC. AEs were consistent with real-world data, and
Conclusion: The administration of a second ADC following prior ADC therapy results in a shorter PFS. The efficacy of chemotherapy is impacted with the use of multiple lines of ADC therapy prior to administration. Outcomes for pts with BrM and LMD who receive ADCs do not differ for those without recurrence to the brain. Sequencing of ADCs plays a role in efficacy of treatment and can likely confer a pattern of resistance. Additional prospective data is needed to further assess ideal sequencing.

P5-08-16: Best response to antibody-drug conjugates (ADCs), sacituzumab govitecan and trastuzumab deruxtecan, based on organ site of metastatic breast cancer (MBC) involvement

Neelima Vidula, Jennifer Hutchinson, Abigail McLaren, Annika Putur, Justine Knape, Rachel Abelman, Marlee Poupard, Aditya Bardia, Andrzej Niemierko

Background: Sacituzumab govitecan (SG) is a TROP-2 directed ADC approved in hormone receptor positive (HR+)/HER2- and triple negative (TN) MBC. Trastuzumab deruxtecan (T-DXd) is a HER2 directed ADC approved in HER2+ and HER2 low MBC. TROP-2 and HER2 expression may vary by organ site, which may affect best response to SG and T-DXd in various metastatic sites. We studied best response to SG and T-DXd based on organ site of MBC.
Methods: A retrospective review of patients with MBC treated with SG or T-DXd (as the first ADC) at an academic institution between 6/2020-5/2024 was conducted. Sites of metastases before starting ADC were characterized through review of baseline imaging scans and duration of treatment was determined. Subsequent imaging scans for re-staging until ADC discontinuation were reviewed to determine the best response to ADC for individual organ sites of MBC, which was categorized using RECIST 1.1 definitions for complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD). Objective response rate (ORR) was defined as the percent of patients with CR and PR. The first organ sites of progression on the ADC were determined.
Results: Thirty-three patients were treated with SG. Median age at MBC diagnosis was 60 years (range 49-68 years). Of these, 61% had TN and 36% had HR+/HER2- MBC. Median number of prior therapies for MBC before SG was 2. Baseline organ site of MBC involvement included lung (82%), bone (79%), lymph node (70%), chest wall (36%), liver (36%), pleural effusion (30%), brain (18%), and soft tissue (12%). Median duration on SG was 4.3 months (range 1.6-9.9 months). Distribution of best response to SG varied by organ site (brain: CR 11%, PR 33%, SD 0%, PD 56%; lymph node: CR 4%, PR 12%, SD 54%, PD 29%; chest wall: CR 0%, PR 20%, SD 60%, PD 20%; lung: CR 4%, PR 28%, SD 52%, PD 16%; pleural effusion: CR 27%, PR 13%, SD 13%, PD 47%; soft tissue: CR 0%, PR 20%, SD 20%, PD 60%; liver: CR 0%, PR 29%, SD 21%, PD 50%; bone: CR 0%, PR 0%, SD 77%, PD 23%). The first organ sites of progression on SG were most commonly lung (33%), liver (21%), bone (18%), lymph node (15%), brain (12%), pleural effusion (12%), and ascites (12%). Forty-nine patients were treated with T-DXd. Median age at MBC diagnosis was 60 years (range 50-68 years). Of these, 65% had HR+/HER2-, 6% had TN, and 27% had HER2+ MBC. Median number of prior therapies for MBC prior to T-DXd was 3. Baseline organ site of MBC involvement included lung (82%), bone (76%), lymph node (59%), liver (51%), brain (31%), chest wall (22%), soft tissue (22%), pleural effusion (15%), and adrenal (2%). Median duration on T-DXd was 5.4 months (range 3.1-7.6 months). Distribution of best response to T-DXd varied by organ site (brain: CR 11%, PR 6%, SD 50%, PD 33%; lymph node: CR 10%, PR 38%, SD 41%, PD 10%; chest wall: CR 8%, PR 8%, SD 58%, PD 25%; lung: CR 2%, PR 5%, SD 85%, PD 7%; pleural effusion: CR 6%, PR 12%, SD 19%, PD 62%; soft tissue: CR 0%, PR 8%, SD 67%, PD 25%; liver: CR 4%, PR 38%, SD 35%, PD 23%; bone: CR

0%, PR 0%, SD 86%, PD 14%; adrenal: CR 0%, PR 0%, SD 100%, PD 0%). The first organ sites of disease progression on T-DXd were most commonly the bone (24%), brain (20%), liver (14%) lymph node (12%), and lung (12%).
Conclusions: Best response to SG and T-DXd varied by organ site. With SG, soft tissue, brain, and liver metastases and pleural effusions had high rates of PD as best response and low ORR was observed in bone, lymph node, chest wall, and soft tissue metastases. With T-DXd, pleural effusions and metastases of brain, soft tissue, and chest wall had high rates of PD as best response, and low ORR was observed in bone, lung, soft tissue, and chest wall metastases. Correlation of site response with tissue biomarker expression and cell-free DNA genomics is ongoing. Further study is merited to understand mechanisms of resistance to ADCs in various metastatic sites.

P5-08-17: Effect of vitamin D supplementation on the pathological complete response to neoadjuvant chemotherapy in women with breast cancer: a randomized clinical trial

Eduardo Pessoa, Michelle Omodei, Jackeline Chimicoviaki, Daniel Buttros, Benedito Almeida-Filho, Carla Carvalho-Pessoa, Heloisa Vespoli, Eliana Nahas

Background: Vitamin D supplementation may be a potential non-toxic and low-cost tool to improve the pathological complete response in breast cancer patients undergoing neoadjuvant chemotherapy.
Objective The study aimed to evaluate the effect of vitamin D supplementation on the pathological complete response (pCR) rate in women with breast cancer (BC) undergoing neoadjuvant chemotherapy (NCT).

Methods: A randomized clinical trial was conducted on 80 women aged ≥45years with a diagnosis of BC, who were eligible for NCT. Women were randomized to one of two groups that received either daily vitamin D supplementation with 2000IU of cholecalciferol (VD, n=40) or placebo (n=40) during 6 months. The primary outcome measure was pCR. Serum 25-hydroxyvitamin-D[25(OH)D] was measured at two time points, after BC diagnosis and at the end of NCT. Clinical, anatomopathological, immunohistochemical, and chemotherapy data were collected. Per-protocol analysis was performed using Student's t-test, chi-square test, ANOVA, and logistic regression (OR,odds ratio).
Results Seventy-five of the 80 randomized women completed chemotherapy and underwent surgery. Mean baseline 25(OH)D values indicated hypovitaminosis D in both groups (VD group:19.6±5.8ng/mL and placebo:21.0±7.9ng/mL,p=0.331). After 6 months of intervention, there was an increase in 25(OH)D values in the VD group compared to the placebo (28.0±8.7 vs 20.2±6.1ng/mL,p=0.032). The pCR rate was higher in women supplemented with vitamin D when compared to the placebo (43.2% vs 23.7%,p=0.036). In adjusted logistic regression, women with 25(OH)D values ≥20ng/mL were more likely to achieve pCR than women with vitamin D deficiency (OR3.65, 95%CI 1.085-12.78,p=0.036).

Conclusion: Women with breast cancer undergoing neoadjuvant chemotherapy who received supplementation with 2000IU of vitamin D were more likely to achieve pathological complete response than women in the placebo group.

Keywords Breast cancer; Vitamin D; Pathological complete response; Neoadjuvant chemotherapy

P5-08-18: Prognostic Value of FDG-PET/CT in Breast Cancer with Unfavorable Special Histology

Mutsumi Fujimoto, Haruka Ikejiri, Ai Amioka, Emiko Hiraoka, Shinsuke Sasada, Hideo Shigematsu, Morihito Okada

Background: Special type breast cancer represents 10% of all breast cancer cases, and it is recommended that the treatment approach be similar to that used for invasive ductal carcinoma. However, the prognostic and predictive factors specific to special type breast cancer have not yet been clearly established. Although the maximum standardized uptake value (SUVmax) on FDG-PET/CT has been identified as a prognostic factor for breast tumors, analyses specific to special type breast cancer remain unreported. This study investigates the prognostic significance of SUV max in special type breast cancer.
Methods: This retrospective cohort study, utilizing hospital database records, evaluated 150 patients with special type breast cancer who underwent curative surgery between February 2006 and December 2019 and had assessable pre-treatment SUVmax values. Since FAVORABLE HISTOLOGIES, as defined in the NCCN Guidelines, are associated with a favorable prognosis, these histologic types were excluded from this study. The cut-off value for SUVmax was determined using ROC curves for recurrence. The prognostic significance of SUVmax for Recurrence-free Survival (RFS) was evaluated using the log-rank test and Cox regression analysis.
Results: Median age was 58.9 years-old (IQR 50.1-69.0), and median follow up was 83.1 months (IQR 39.9-116.3). The most prevalent histological type was invasive lobular carcinoma (39 cases, 26.0%), followed by invasive micropapillary carcinoma (35 cases, 23.3%), microinvasive carcinoma (33 cases, 22.2%). Recurrences and deaths occurred in 15 (10.0%) cases. The cut-off value for SUVmax was determined at 5.4, with 24 cases (16%) ≥5.4 and 126 cases (84%) <5.4. SUVmax ≥5.4 was significantly associated with higher T stage, higher nuclear grade, and adjuvant chemotherapy in Fisher's exact test. The 5-year RFS was 54.4% for SUVmax ≥5.4 and 96.1% SUVmax <5.4 ($p<0.005$). In univariate analysis, T stage, nodal metastasis, SUVmax≥5.4, and adjuvant chemotherapy were identified as potentially associated with RFS. In multivariate analysis, nodal status and SUVmax was significantly factors for RFS (hazard ratio 9.3, 95% confidential interval 2.8-30.8, $p = 0.005$).
Conclusions: High SUVmax was significantly associated with breast cancer recurrence in

patients with special type breast cancer, indicating the potential of SUVmax for prognosis prediction in this patient group.

P5-08-19: A novel formula to improve the accuracy of predicting survival time after recurrent breast cancer

Reiki Nishimura, Yasuaki Sagara, Reiko Mitsueda, Tetsuhiko Taira, Toshiko Miyaki, Shuichi Kanemitsu, Megumi Teraoka, Junko Kawano, Naomi Gondo, Yoshitaka Fujiki, Ryutaro Higashi, Akiko Semba, Yasuyo Ohi, Yoshiaki Rai, Yoshiaki Sagara, Shinji Ohno

Background: Recurrent breast cancer (BC) has a poor prognosis and is difficult to cure. The prognosis of each recurrent case also affects the social background and subsequent life plan of each patient. Recent studies have shown that advances in treatment have improved the prognosis after recurrence. To ascertain the survival time after recurrence (STR) is necessary for maintaining and improving QOL and selecting appropriate treatment. We investigated whether certain biomarkers would influence and improve the prognosis, and whether the STR can be predicted using the disease-free interval (DFI) and biomarkers.
Methods: A total of 1,254 cases with recurrent BC from January 2000 to December 2023 were enrolled in this study. The cases were divided into the 2000-2005 group (n=182), 2006-2011 group (n=331), 2012-2017 group (n=369), and 2018-2023 group (n=366). The sites of initial recurrence included bone (22.1%), lymph nodes (22.0%), and lung/pleura (18.7%). The clinicopathological factors examined were nodal status, tumor size, histological grade (HG), ER/PgR (cutoff points; 1%), HER2 (zero, low, and positive), the Ki-67 index value (cutoff points: 15% and 30%), and DFI (cutoff points: 24 months and 60 months). We applied a simple linear regression model to explain the relationship between STR and DFI. The overall survival after recurrence was calculated using the Kaplan-Meier method and analyzed using the log-rank procedure. Multivariate analysis for recurrent factors were performed using the Cox proportional hazard model.
Results:
1. Survival rates after recurrence significantly increased in cases after 2012. Improvement in prognosis was observed in most of the cases, but no improvement was observed in cases with a HER2-0 status and Ki-67 index value<15%.
2. In terms of subtypes and survival, there were significant improvements in survival in cases with Luminal A/B and Luminal/HER2 subtypes. However, the cases with HER2 enriched and triple negative subtypes had no significant improvement.
3. A multivariate analysis revealed that DFI, nodal status, ER, and the Ki-67 index values were significant factors for survival in all cases. However, the significant prognostic values varied among the year of recurrence. The Ki-67 index value was a significant factor in the 2000-2005 group. However, nodal status and HER2 status were significant after 2012.
4. The most significant correlation was found between DFI and STR in deceased patients with a Ki-67 index value>30% ($p<0.001$), followed by HER2-low, N≥4, DFI≤24 months, and ER<1%.
5. We developed a formula to predict the STR based on the following significant factors.

STR (mons)=α0 (39.6) +β0 (0.01) - DFI (mons)+ ∑Fi (αi +βi - DFI)
Without the 3rd term, this formula corresponds to a simple linear regression of STR by DFI, where α0 is the average level of STR and β0 is the sensitivity of STR to DFI. The 3rd term is a factor-dependent adjustment of α0 and β0 . The value Fi (i =1-5) can be either 0 or 1, depending on whether the factor meets the valid criteria or not. Therefore, the adjustment terms (αi+βi ·DFI) are effective only when the corresponding factors (Ki-67>30%, HER2-low, ER<1%, tumor size≤2 cm, and positive nodes: 1-3) are valid (i.e. Fi=1). The results suggest the factor1-3 (Ki-67>30% HER2-low and ER<1%) are significant to decline the level of STR, while factor 1 and 2 (Ki67>30% and HER2-low) significantly increase the sensitivity of STR to DFI.
Conclusion: Prognosis after recurrence clearly improved from 2011, but no significant improvement was observed in the cases with ER<1%, a HER2-0 status, and a Ki-67 index value<15%. In recurrent cases where the patients passed away, there was a strong correlation between DFI and prognosis after recurrence in cases with a Ki-67 index value>30% and a HER2-low status. As a result, we developed a predictive formula for determining the prognosis after recurrence. Further studies will be conducted in actual clinical settings to verify the accuracy of this new formula.

P5-08-20: Comparative study of the gut microbiome of newly diagnosed postmenopausal breast cancer patients and healthy controls, and pilot study on the acceptability of soy milk in the patient group

Masahiro Takada, Kazuhiko Yamagami, Yuko Mitsudo, Masahiro Kawashima, Kosuke Kawaguchi, Ayane Yamaguchi, Chiaki Kaga, Kaihei Oki, Akimitsu Takagi, Satoshi Morita, Masakazu Toi

Background: It has been reported that the composition of the gut microbiota in postmenopausal non-Hispanic Caucasians differs between breast cancer patients and healthy controls. The composition of the gut microbiota in Japanese breast cancer patients has not been thoroughly investigated, although Japanese dietary habits differ from those in the West, and the incidence of breast cancer is also different.
A case-control study in Japanese subjects reported a lower risk of breast cancer with a higher intake of soy isoflavones and a more frequent intake of Lactobacillus casei strain Shirota. In another nested case-control study, a higher blood concentration of aglycones, metabolites of isoflavones, was associated with a lower risk of developing breast cancer. Soy milk beverages fermented with Lactobacillus casei strain Shirota are expected to promote the metabolism and absorption of isoflavones into aglycones compared to regular soy milk beverages.
This study aims to compare the gut microbiota of postmenopausal, untreated Japanese early breast cancer patients and healthy subjects to determine whether dysbiosis occurs. Furthermore, we aim to investigate the acceptability of continuous consumption of fermented soy milk beverages and compare the gut microbiota composition between patient groups who drink or do not drink fermented soy milk beverages.

Methods: This study consisted of two parts: Study 1 and Study 2. Study 1 is a cross-sectional study. The subjects were 60 postmenopausal women with early-stage breast cancer and 60 healthy subjects. The key eligibility criteria for breast cancer patients were: 1) histologically diagnosed breast cancer, 2) untreated early-stage breast cancer without distant metastasis, 3) planned surgery for breast cancer, and 4) without history of other malignancies. Blood, stool, and urine samples were collected at enrollment. The primary endpoint was the composition of the gut microbiota in breast cancer patients and healthy subjects. Secondary endpoints were hormone-related and immunological biomarkers and a lifestyle questionnaire. Study 2 was a randomized controlled trial. Patients with early-stage breast cancer enrolled in Study 1 were included. The subjects were randomly assigned 1:1 to either an intervention group or a control group, and the intervention group was to drink the fermented soy milk beverage for approximately eight weeks during the perioperative period. The primary endpoints were the acceptability of fermented soy milk beverages and the comparison of gut microbiota composition between the intervention and control groups. Secondary endpoints were the composition of the gut microbiota before and after drinking fermented soy milk beverages, the composition of the gut microbiota before and after surgery, hormone-related and immunological biomarkers, the effect of lifestyle on the composition of the gut microbiota, and the effect of drinking compliance on the composition of the gut microbiota (UMIN000043339). The study began in February 2021, and enrollment was completed.

P5-08-21: Analysis of factors influencing the efficacy of NAC and prognosis between HER2-0 and HER2-low HR negative breast cancer

Jingjing Liu, Yi Zhang, Jin Zhang

Objectives: To explore the differences in clinicopathological characteristics, efficacy of neoadjuvant chemotherapy(NAC) and prognosis,and to analyze the influencing factors of the efficacy of neoadjuvant chemotherapy between HER2-0 and HER2-low HR-negative breast cancer patients, and to further clarify the influencing factors of the prognosis of HER2-0 and HER2-low HR-negative breast cancer patients. It provides a clinical basis for the precise treatment of HER2-0 and HER2-low HR-negative breast cancer patients.

Methods: Retrospective analysis of 319 breast cancer patients with HR-negative/HER2-negative completed neoadjuvant chemotherapy and surgery from August 2014 to August 2018 in Tianjin Medical University Cancer Institute and Hospital. The clinicopathological data of patients were collected, and the efficacy of patients' neoadjuvant chemotherapy was assessed by postoperative pathology. SPSS 26.0 statistical software was used for analysis and processing. Categorical variables described their component ratios, and comparisons between subgroups of different clinicopathological characteristics were performed using the chi-square test. The chi-square test was used for univariate analysis of the relevant factors affecting pathological Complete Response (pCR),followed by multivariate analysis of

the relevant factors affecting pCR using logistic regression model, Kaplan-Meier method was applied to calculate the survival rate and draw the survival curves, and the log-rank The log-rank test was used to compare the differences in survival between groups, and the independent risk factors affecting the Disease Free Survival(DFS) rate and Overall Survival (OS) rate were analyzed by using the COX regression model, and $p < 0.05$ was considered statistically significant.

Results: 1.319 HER2-0 and HER2-low HR-negative breast cancer patients among 207 patients (64.9%) with HER2-low,and the two groups had a statistically significant difference in terms of age at diagnosis(P=0.035),clinical N-stage(P=0.001), histological grading(P<0.001) and Ki67 (P=0.012).
2.319 HR-negative/HER2-negative breast cancer patients,92 patients(28.8%) achieved pathological complete response. pCR rate of HER2-low was 23.2% (48/207), and that of HER2-0 was 38.9% (44/112),with a statistically significant difference (P=0.004). HER2-0, HER2-1+, and HER2-2+/FISH(-) had decreasing pCR rates between them, which was statistically different(38.9% vs. 25% vs. 20%, P=0.012).
3. Univariate analysis of patients in the HER2-0 and HER2-low groups showed that: clinical T stage (P=0.004) and clinical N stage(P=0.046)were associated with pCR rate of HER2-0 HR-negative breast cancer; and clinical T stage(P=0.001) and pathological pattern (P=0.045) were associated with that of HER2-low HR-negative breast cancer; The results of multifactorial analysis of the two groups showed that clinical T-stage(OR=0.229, P=0.009; OR=0.110, P=0.001) and clinical N-stage (OR=0.359, P=0.010; OR=0.188, P=0.034) were the independent influences on pCR HER2-0 HR-negative breast cancer, and clinical T-stage (OR = 0.399, P = 0.022; OR = 0.178, P < 0.001) was an independent influencing factor for that in HER2-low HR-negative breast cancer.
4.The 3-year DFS rate of patients in the HER2-0 and HER2-low groups was 72.3% vs 78.3%, and the 5-year DFS rate was 67.0% vs 76.8%, and there was no statistically significant difference in recurrence/metastasis (P=0.397); and the OS rate of patients in the two groups was 79.5% vs 86.5%, and there was no statistical significance for the difference (P=0.366). HER2-0, HER2-1+ and HER2-2+/FISH(-) patients between the three groups had a 3-year DFS rate of 72.3% vs 78.8% vs 77.3%, and a 5-year DFS rate of 67.0% vs 78.3% vs 74.7%, and there was no statistically significant difference in recurrence/metastasis(P=0.625); and the OS rate of the two groups was 79.5% vs 85.6% vs 88.0%, with no statistically significant difference (P=0.308).
5.The univariate and multifactorial COX regression analyses showed that clinical T3-4 stage(HR=9.971; P=0.002) and post-NAC non-pCR (HR=3.420; P=0.018) were the independent risk factors affecting the DFS rate of patients with HER2-0 HR-negative breast cancers; post-NAC non-pCR (HR=4.693; P=0.038) was an independent risk factor affecting OS rate of them; clinical stage N1 (HR=3.333; P=0.001), N2-3 (HR=5.832; P<0.001), post-NAC non-pCR (HR=3.364; P=0.045), and lymphovascular invasion(HR=1.942; P=0.027) were independent risk factors affecting the DFS rate in HER2-low HR-negative breast cancer patients; clinical stage N2-3(HR=4.307; P=0.001), and lymphovascular invasion (HR=2.373; P=0.017) were independent risk factors affecting the OS rate in them.

6.There were statistical differences in HER2 evolution and histological grading ($p<0.001$)and Ki67 expression ($p=0.026$) after NAC, with significantly better DFS and OS in HER2-gain patients compared to HER2-stable patients, but the worst DFS and OS in HER2-loss patients compared to HER2-stable patients ($p=0.021$; $p= 0.031$).

Conclusions: 1. In HR-negative breast cancer, compared with HER2-0 patients, HER2-low patients were diagnosed at a greater age, had a later clinical N stage, higher Ki-67 expression, but a lower proportion of histological grade III.
2. HER2-low patients had a lower pCR rate than HER2-0 patients, and HER2-low patients with clinical T3-4 stage and clinical T2 stage had a lower pCR rate after neoadjuvant chemotherapy.
3. There was no difference in prognosis between HER2-0 and HER2-low patients in HR-negative breast cancer. Patients with HER2-0 HR-negative breast cancer in clinical stage T3-4 had a higher risk of recurrence/metastasis and those who were non-pCR after NAC had a higher risk of recurrence/metastasis and death. HER2-low HR-negative breast cancer patients with clinical stage N1, clinical stage N2-3, non-pCR after neoadjuvant chemotherapy, and lymphovascular invasion have a higher risk of recurrence/metastasis, and those who were with clinical stage N2-3 and lymphovascular invasion have a higher risk of death.
4. Patients with histological grade III are more likely to develop HER2-loss, and those with Ki-67 > 14% are more likely to develop HER2-gain. DSF and OS are prolonged in patients with HER2-gain compared with HER2-stable, which is more favourable than that in patients with HER2-loss.

P5-08-22: Effectiveness of Online Education in Improving Clinicians' Knowledge, Competence and Confidence in the Management of Metastatic Breast Cancer

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Eloise Ballard, Jamie Habib, Nicholas Turner, Giuseppe Curigliano

Background: There has been much progress in discovering novel therapies for the management of metastatic breast cancer (mBC). The objective of this study was to assess the effect of an online continuing medical education (CME) activity on clinicians' understanding of the key data for mBC in all subtypes presented at the European Society for Molecular Oncology (ESMO) Breast 2023 conference.

Methods: This CME activity consisted of a 30-minute video panel discussion between 3 expert faculty with synchronised slides. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge/competence, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of

improvement in the percentage of correct responses to knowledge/competence questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 12th of June 2023, with data collected through 29th August 2023 being reported in the current study.

Results: The analysis set consisted of responses from oncologists (n=75) who answered all assessment questions during the study period. Analysis of pre- vs post-CME responses demonstrated a significant improvement in knowledge and competence of oncologists (P< .01). Overall correct responses increased from 39% pre- to 52% post-CME. Specific areas of improvement include:

- Knowledge of the latest clinical evidence evaluating novel and emerging therapeutic options for mBC (pre 26%, post 38%; P < .01)
- Competence related to personalizing treatment for patients with mBC (pre 65%, post 79%; P < .01)

Additionally, 32% of oncologists reported increased confidence in integrating new treatment strategies for patients with mBC in clinical practice, and that increase was, on average, 63%.

Conclusions: This analysis demonstrates the positive impact of an online CME activity on physicians' ability to interpret the key data in mBC presented at ESMO Breast 2023. As new evidence emerges, it will be important to educate clinicians on the latest developments to continue to close their knowledge gap.

P5-08-23: DIHYDROCERAMIDE DESATURASE 1 (DES1) AS A REGULATOR OF CASPASE 14 IS REQUIRED FOR ANCHORAGE-INDEPENDENT SURVIVAL AND METASTASIS OF HER2-POSITIVE AND BASAL BREAST CANCER

Deanna Peperno, Danielle Lambadis, Victoria Alvarado, Andrew Resnick, Christopher J. Clarke

The ability of cancer cells to survive in the absence of an extracellular matrix – termed anchorage-independent survival (AIS) – is central to the metastatic cascade and in recent years has emerged as a target biology of interest for the treatment of metastatic disease. We recently identified the SL enzyme dihydroceramide desaturase 1 (DES1) as a critical HER2-regulated node that was both necessary and sufficient for AIS in HER2+ BC. However, the underlying mechanisms connecting DES1 with AIS and the relevance of this for BC metastasis remains unclear. To begin to probe this, we conducted a microarray analysis of wild-type and DES1 knockout SKBR3 BC cells with results revealing that the loss of DES1 led to a significant reduction in the expression of Caspase 14—a poorly studied member of the caspase family. Notably, we found that targeting Caspase 14 led to significant loss of AIS and reduced growth in colony formation in both HER2+ (JIMT1) and basal BC cells (MDA-MB-231), while stable overexpression of Caspase 14 was able to overcome the effects of

DES1 loss on AIS. Extending these findings in vivo, our data found that DES1 KO led to striking decreases in both experimental and spontaneous metastasis despite no significant difference in primary tumor size for both basal and HER2+ BC cells. Additionally, IHC of spontaneous lung metastasis shows a substantial reduction in Caspase 14 staining in DES1 KO compared to vector controls. Finally, publicly available clinical data show that BC tumors with high DES1 and Caspase 14 expression have a significant reduction in relapse-free survival in patients who have undergone neoadjuvant chemotherapy (NAC). Taken together, these data establish DES1 as a key mediator of BC metastasis and define Caspase 14 as a novel effector of DES1 required for promoting AIS. Results further suggest that DES1 and Caspase 14 expression might have use as a biomarker and predictor of highly metastasis-prone BC tumors.

P5-08-24: Prognostic Value of the Geriatric Vulnerability Score in Older Patients with Metastatic Breast Cancer

Min Xiao, Lei Ji, Xi Chen, Song Ge, Qing Li, Qiao Li, Pin Zhang

Background: Comprehensive Geriatric Assessment (CGA) contains multiple dimensions and involves complex scales, thereby limiting its clinical application. This study aims to develop a clinically applicable geriatric assessment method (Geriatric Vulnerability Score, GVS) tailored to older patients with metastatic breast cancer (MBC) and to analyze its association with survival.

Methods: This study included MBC patients aged over 65 years. They underwent geriatric assessment(GA) including Charlson Comorbidity Index (CCI), Activities of Daily Living (ADL) ； Peripheral blood lymphocyte absolute count and albumin were recorded for assessment of immune system reserve and nutritional reserve. Data analysis included descriptive statistics, Cox multivariate regression, student’s t-tests, one-way ANOVA, Kaplan-Meier curves and Harrell's concordance statistic.

Results: A total of 233 patients were included with the median age of 69 years. The median CCI was 0 (0-4). 33 (14.2%) patients had an ADL score<90; 25 (10.7%) patients had a lymphopenia ≤1×109/L, and 17 (7.3%) patients had an albumemia ≤35g/L. 159 (66.8%) patients were treatment-naive in metastatic setting. Multivariate analysis showed that ADL score<90, lymphopenia ≤1×109/L, and albumemia ≤35 g/L were independent adverse factors for OS in patients (all P <0.05), whereas CCI was not an independent prognostic factor (P>0.05).When the significant GA items (ADL <90, lymphopenia ≤1×109/L, albumemia ≤35 g/L, each assigned a value of one) were scored to develop GVS, it showed that the higher GVS, the worse OS of patients (HR: 2.228, 95% CI: 1.640-3.027, P <0.001). Furthermore, this score was validated in the treatment-naive group (HR: 3.215, 95% CI: 1.975-5.232, P <0.001). Adding GVS to tumor characteristics improved the accuracy of prognostic prediction (C-index, all patients: from 0.670 to 0.709; treatment-naive group:

from 0.694 to 0.742).

Conclusion: GVS is an objective, simple, and feasible method that can serve as one of the dimensions for predicting the prognosis of old MBC. It is worth verifying its clinical application value in a larger sample.

P5-08-25: Inhibiting Breast Cancer Metastasis by Targeting Chemokine-Glycosaminoglycan Interactions

Mohammed Imad Malki, Ibrahim Elmakaty, Amr Ouda

Breast cancer exhibits a specific metastatic pattern potentially influenced by the interaction between the chemokine receptor CCR7 on breast cancer cells and its ligand CCL21, which is expressed at metastatic sites. Glycosaminoglycans (GAGs) on endothelial cell surfaces bind chemokines and are thought to be critical in presenting chemokines to responsive cancer cells. This study aimed to test the hypothesis that soluble GAG molecules, such as heparinoids, can disrupt the normal presentation of CCL21, potentially reducing metastasis of CCR7-expressing breast cancer cells. Human breast cancer samples were analyzed for the expression of CCR7, CCL21, and GAG, correlating this expression with tumor grade. The cytokines IFN-γ and TNF-α were found to influence the endothelial cell GAG's ability to present chemokines to passing cancer cells. Both GAG-expressing Chinese Hamster Ovary (CHO) cells and GAG-deficient mutant CHO cells were transfected with CCR7, and their intracellular calcium flux and chemotactic migration were assayed in response to CCL21 and heparinoid. It was discovered that GAG expression by the responding cells was not essential for chemokine receptor activation. However, heparinoids, including Low Molecular Weight Heparins, effectively blocked the binding of 125I-CCL21 to a monolayer of GAG-expressing CCR7 transfectants, inhibiting both CCR7 ligation and subsequent signaling. Further experiments with CCR7-expressing MDA-MB-231 breast cancer cells demonstrated that heparinoids significantly inhibited the chemotactic response within a CCL21 diffusion gradient. Additionally, heparin and both low and high doses of Tinzaparin treatment in SCID mice, at clinically relevant dosages, prevented both the number and area of metastases following intravenous injection of MDA-MB-231 cells. These findings suggest that heparinoids inhibit the interaction between CCL21 and CCR7 and may serve as effective agents to prevent breast cancer metastasis.

P5-08-26: Relapse after 10 years following treatment for early breast cancer. 18 years follow-up data from a Belgian single-center.

Annouschka Laenen, Hans Wildiers, Giuseppe Floris, Ann Smeet, Ines Nevelsteen, Chantal Van Ongeval, Machteld Keupers, Helen De Boodt, Annelies Coessens, Renate Prevos, Sileny Han, Maxime Van Houdt, Francoise Derouane, Yannick Van Herck, Caroline Weltens, Hilde Janssen, Adinda Baten, Valerie Celis, Jelle Verhoeven, Desmedt Christine, Patrick Neven

Introduction: Early diagnosed breast cancer can recur even 20 years after initial treatment. Prognostic markers for recurrence beyond 10 years in patients who received contemporary locoregional and systemic treatment are lacking. We therefore investigated known risk factors for recurrence in a population with a 10-years disease-free interval.
Patients and methods: In this retrospective study, we included 3581 patients with early breast cancer treated at University hospital of Leuven between January 1st, 2000 until December 1stt, 2010 who remained disease-free for 10 years. Patients received local and systemic treatment according to institutional guidelines; 10% were triple negative, 84.3% were oestrogen receptor (ER) positive and 12.7% Human Epidermal growth factor Receptor 2 (HER-2) amplified but adjuvant trastuzumab was only available in the HERA study and routine for patients after 2007. We analysed patient and tumour characteristics for breast cancer recurrence in the second decade after diagnosis. Local and locoregional invasive disease-free interval was defined as the time till the first event of local or locoregional relapse. Metastasis-free interval was defined as the time till metastasis. Patients without event were censored at last follow-up. Death without event was considered as a competing risk. For the statistical analysis Cox proportional hazard models were used, with local and locoregional disease-free interval and distant metastasis-free interval as time-to-event outcomes. Furthermore, a multivariable model of independent predictors was constructed using backward selection. We focused on 2 outcome variables: local and locoregional and distant metastasis-free interval.
Results: We included 3581 patients (median age at diagnosis, 55years) who were disease-free after 10 years of follow-up. After a median follow-up of 8 years, 18 years since initial diagnosis, 334 (9.3%) had a recurrence (local, locoregional or metastasis) of which 147 (4.1%) were distant only and 38 (1%) combined local or locoregional and distant. A positive lymph node status at diagnosis was a significant risk factor for local and locoregional recurrence in the second decade after diagnosis in the univariable analysis hazard ratio (HR) = 1.190 (95% confidence interval: 1.003;1.412; p=0.0456). A multivariable analysis could not be built for local and locoregional recurrence as nodal invasion was the only significant risk factor. In a multivariable analysis for distant metastasis-free interval, tumour size HR=1.332 (1.084;1.636) p=0.0064, grade 2 (compared to grade 1 HR=0.456 (0.248;0.839) p=0.0116 and to grade 3 HR=1.958 (1.313;2.920) p=0.0010), lymph node invasion HR=1.824 (1.510;2.202) p<0.0001 and ER positivity HR=3.796 (1.619;8.899) p=0.0021 proved to be independent adverse prognostic in the second decade after diagnosis.
Conclusion: Our findings may help to differentiate between patients with high or low risk of recurrence beyond 10 years of diagnosis and as such, may help to provide a more personalized follow-up.

P5-08-27: Reliability of Immunohistochemical Biomarkers in Core Biopsy Versus Surgical Specimens for Breast Cancer: Implications for Treatment Planning

Hagigat Valiyeva, Nigar Mehdiyeva, Elcin Huseynov, Tahmina Kosayeva, Habil Muradov, Konul Ferhadzade, Rena Haciyeva, Emil Aghayev, Zarifa Caferzade

Background: Core biopsy is instrumental not only in diagnosing breast cancer but also in guiding individualized treatment plans through the immunohistochemical evaluation of biopsy samples. The advent of neoadjuvant chemotherapy (NAC) has revolutionized the treatment landscape of breast cancer, with subsequent adjuvant systemic therapies primarily based on the pre-treatment status of Estrogen Receptors (ER), Progesterone Receptors (PR), and Human Epidermal Growth Factor Receptor 2 (HER2) as determined by core needle biopsy. However, the reliability and concordance of these biomarkers post-NAC are not well understood, raising the question of whether their potential discordance necessitates changes in adjuvant treatment strategies. The literature reveals instances of multiple histological subtypes and varied immunohistochemical profiles within post-surgical pathological specimens, particularly in cases where the inherent heterogeneity of tumors and the presence of multiple foci in multifocal and multicentric tumors are not comprehensively sampled by biopsies or entirely identified. The initiation of NAC has underscored discrepancies between the immunohistochemical results of core biopsies and those obtained from final surgical specimens. Additionally, differences in techniques and reagents used during the processing of core biopsy material can significantly influence the results. These factors collectively raise the pertinent question of whether immunohistochemical re-evaluation of final surgical specimens is warranted. The primary objective of this study is to elucidate the differences between the immunohistochemical findings of core biopsy and subsequent surgical specimens in cases of breast cancer, specifically focusing on the concordance and discordance of ER, PR, and HER2 status.
Methods: Between 2018 and 2023 years, the Oncology Clinic at Azerbaijan Medical University treated 3383 patients with a diagnosis of breast cancer. Of these, 2815 patients (83.2%) underwent surgical intervention. A total of 1281 patients (37.8%) commenced treatment with NAC. The cohort included 92 patients (3.27%) with multifocal and multicentric tumors or additional foci identified during the pathological examination of the final surgical specimen. Among patients with multiple foci, 34 (1.21%) underwent direct surgical intervention, while 58 (2.06%) initiated treatment with NAC.
Results: Immunohistochemical re-evaluation was performed on 226 (8.03%) patients, revealing discordant results in 85 (3.02%) patients. In cases where discrepancies were observed between core biopsy and surgical specimens, 14 (0.49%) patients with multifocal lesions underwent upfront surgical intervention, while 22 (0.78%) patients underwent surgery following NAC. 18 (0.64%) underwent direct surgical intervention, while 31 (1.1%) received surgery after NAC.
Conclusion: The identification of discrepancies between the immunohistochemical results of core biopsy and final surgical specimens in breast cancer underscores the necessity for further extensive studies. These investigations should aim to determine whether routine or

selective re-evaluation of immunohistochemical markers in final surgical specimens should be incorporated into clinical protocols for optimal patient management.

P5-08-28: Randomized phase 2 window of opportunity trial comparing the effect of preoperative atirmociclib (PF-07220060) plus letrozole versus letrozole alone on Ki-67 tumor expression in postmenopausal women with HR+/HER2+ breast cancer

Shom Goel, Khalil Zaman, Seock-Ah Im, Ahmed Elkhanany, Chiun-Sheng Huang, Cristian Villanueva, Sara Lopez Tarruella, Chin-Hee Chung, Ann Alcasid, Yuan Liu, Cynthia Basu, Michail Ignatiadis

Background: In previous clinical trials, complete cell cycle arrest (CCCA, defined as Ki-67 ≤2.7%) in the neoadjuvant setting was correlated with relapse-free survival after definitive surgical resection. Cyclin-dependent kinase 4/6 inhibitors (CDK4/6is), in combination with endocrine therapy (ET), have consistently shown progression-free survival and/or overall survival benefits for patients with HR+/HER2− metastatic breast cancer (BC). High and/or continuous CDK4/6i dosing may result in dose-limiting cytopenia-related toxicity; neutropenia is believed to be mediated mainly by inhibition of CDK6 rather than CDK4. Atirmociclib (PF-07220060) is a novel, highly potent and selective inhibitor of CDK4. In preclinical studies, atirmociclib induced G1 cell cycle arrest in BC cell lines and significantly inhibited the growth of HR+/HER2− tumors, which are known to have a high degree of CDK4 dependency. Preliminary results from a phase 1/2a multi-part trial assessing atirmociclib in patients with HR+/HER2− metastatic BC have demonstrated encouraging efficacy, safety, and tolerability (Yap et al, JCO. 2023;41:3009; Giordano et al, JCO. 2024;42:3108). Based on these findings, this study aims to evaluate the potential impact of atirmociclib in combination with letrozole in the preoperative treatment of patients with HR+/HER2− early BC.

Methods: This international (16 countries, >80 proposed sites), phase 2, open-label, randomized clinical trial will evaluate the effects of atirmociclib plus letrozole versus letrozole alone on Ki-67 expression in tumors after 14 days of treatment in the preoperative setting. Postmenopausal women aged ≥18 years with newly diagnosed and treatment naïve HR+/HER2− BC will be enrolled. Additional inclusion criteria include primary tumor size ≥1.5 cm amenable to surgical resection, ECOG PS 0 or 1, and a baseline tumor Ki-67 score ≥10%. Exclusion criteria include any prior systemic therapy for the treatment of BC, inadequate bone marrow, renal, and liver function, any other active malignancy within 3 years prior to enrollment, certain severe medical conditions within 6 months of enrollment, known allergy to the study drug, inability to take oral medications, and certain psychiatric conditions. Approximately 118 patients will be randomly assigned 1:1 to receive atirmociclib (300 mg, orally, twice daily) plus letrozole (2.5 mg, orally, once daily) or letrozole alone (2.5 mg, orally, once daily), continuously for 14 days. After the 14-day treatment period, participants will come off study treatment and continue on standard-of-

care therapy (eg, ET, surgery, radiotherapy, chemotherapy) per physician's choice. Participants will have both a baseline biopsy and an on-treatment biopsy (Day 14). The primary endpoint will be CCCA (Ki-67 ≤2.7%) rates at Day 14 (based on centrally assessed post-treatment tumor biopsies). Secondary endpoints will be incidence of all adverse events (AEs), serious AEs, AEs leading to study drug discontinuation, circulating tumor DNA measurements at baseline and Day 14, Ctrough and peri-biopsy plasma concentrations of atirmociclib, and centrally-assessed Ki-67 immunohistochemistry. Assessment of changes in the tumor microenvironment using spatial omics, and evaluation of the association between tumor gene expression profiles and treatment outcomes will be exploratory objectives. Enrollment is to begin July 2024 (NCT06465368).

P5-08-29: Assessment of RNA Extraction Protocols from FFPE Breast Cancer Samples with the APIS Breast Cancer Subtyping Kit

Anna Gasior, Joanna Gorniak, Andreas Voss, Kimberly Howard, Mathew Harrison, Leanne Gough, Sara Rollinson, Zoe Pounce

Background: The APIS Breast Cancer Subtyping Kit detects the expression of mRNA target genes (ESR1, PGR, ERBB2, MKI67, CCNA2, PCNA, and KIF23) in formalin-fixed, paraffin-embedded (FFPE) pre-operative core needle biopsies or resected breast tumour tissue. RNA extraction from FFPE poses challenges due to degradation, cross-linking and base modifications introduced during the fixation process. The APIS' kit workflow includes RNA extraction using QIAGEN's RNeasy® DSP FFPE Kit. This study evaluates suitability of alternative kits (Promega ReliaPrep™ FFPE Total RNA Miniprep System, ThermoFisher PureLink™ FFPE RNA Isolation Kit and BioEcho EchoLUTION™ FFPE RNA Kit) for use in conjunction with the APIS kit, based on RNA yield and target call concordance.

Methods: 21 FFPE tissue sections were used in this study. All extraction procedures were carried out following the manufacturers' instructions. RNA was quantified and normalized to 2.5ng/µL for RT-qPCR analysis with the APIS kit. Relative RNA expression of all targets and reference genes was assessed using QuantStudio™ 5 Dx Real-Time PCR System. The agreement between the extraction kits was assessed by comparing calls (positive/negative) produced by testing RNA samples extracted using all four methods (QIAGEN kit, Promega kit, Thermofisher kit and Bioecho kit) with the APIS kit. The call was considered positive if ΔCt values (a measure of gene expression used by APIS kit) fell above the validated ΔCt cut-off values.

Results: All kits extracted RNA successfully. BioEcho and Thermofisher kits often yielded lower RNA concentrations, most likely due to higher elution volumes (30 µl vs 50 µl). Concordance rates for target calls ranged from 78-100%. To reduce miscalling, samples within 2x ΔCt intermediate precision either side of assay cut-offs were removed. Promega and BioEcho kits showed high concordance (100%). Lower agreement was seen for

Thermofisher kit (78% for ERBB2 and 91% for MKI67). 100% concordance was observed for ESR1 and PGR across all kits.

Conclusions: Sufficient RNA yield and high agreement confirmed that RNA derived using all described methods is of sufficient quality to accurately detect biomarker expression via the APIS kit. Promega and BioEcho kits demonstrated high target call concordance, making them viable alternatives to QIAGEN's kit. Lower concordance seen with Thermofisher kit is most likely a result of tumour heterogeneity. The extractions had to be performed using different FFPE sections, and therefore localized differences in marker expressions within tumors could have contributed to the variability observed, especially for ERBB2. Considering this inherent tumor heterogeneity, Thermofisher kit could also be considered for use. These results suggest that all assessed kits are suitable for use in APIS Breast Cancer Subtyping Kit workflow. It also confirms that APIS' kit is capable of detecting biomarker expression from highly fragmented, FFPE-derived RNA.

P5-08-30: The impact of tumor location on survival rates in invasive ductal carcinoma for patients who undergo breast-conserving therapy

Abdulah Jariri

Introduction: Invasive ductal carcinoma (IDC) is the most common type of breast malignancy, making about 75% of all breast cancer cases, usually the management for IDC contains breast-conserving therapy (BCT) which is a treatment strategy that removes the tumor while preserving as much as possible from breast tissue. There is still a debate how the tumor's location affects survival. This study aims to evaluate survival rates for IDC patients treated with BCT alone across different breast quadrants which improves patients outcomes and inrich our medical understanding.

Method: SEER Program was used to obtain the data, retrospectively. Patients diagnosed with infiltrating duct breast carcinoma treated with breast conserving therapy alone were included from (2000-2021). Patients were categorised into four groups based on the location of the tumor within the breast (upper outer quadrant , upper inner quadrant , lower inner quadrant, lower outer quadrant). All patients received BCT according to SEER breast cancer surgery codes (20-24). Relative survival rates were compared using Kaplan-Meier, log-rank analysis. IBM SPSS Statistics 27.0.1 was used to conduct the statistical analysis.

Results: A total of 36443 cases of IDC and treated with BCT alone were identified. Among the groups , 9.57%(n=3491) have a tumor located in lower inner quadrant, 21.55% (n=7854) in the upper inner quadrant, 57.47% (n=20947) in the upper outer quadrant, and 11.39% (n=4151) in the lower outer quadrant .Among all tumor locations, 5- years relative

survival was the highest for patients with tumors in the upper inner quadrant (95.3%), followed by upper outer quadrant (94.1%), then came Lower outer quadrant (92.5%),and lastly came lower inner quadrant (92.2%), with (p -value < .001).

Conclusion: Overall, patients who are diagnosed with invasive ductal carcinoma and treated with breast conserving therapy only showed better survival when tumors were located in the upper inner quadrant. In contrast patients with tumors in the (lower inner quadrant) showed the lowest survival rates among all quadrants . Our findings confirm that there is a significant difference in survival rates between different quadrants, it could be an entry for several researches and to spot the light on the importance of tumor location in IDC, and different management patterns.

P5-09-01: Some factors associated with re-excision in breast conserving surgery do not increase rates of re-excision after oncoplastic breast conserving surgery: a retrospective study

Kendall Vignaroli, Lana Mamoun, Amanda Daoud, Aldin Malkoc, Kevin Perez, Judi Ramiscal

Oncoplastic breast conserving surgery (OBCS) utilizes a multidisciplinaryapproach to provide tumor resection while minimizing deformities of the breast. The techniques used in OBCS are associated with similar rates of survival and decreased rates of re-excision, postoperative medical complications, and tumor recurrence when compared to breast-conserving surgery (BCS). Previous studies have revealed multiple factors associated with re-excision in patients undergoing BCS including tumor size, tumor pathology, multifocality, and patient age, however there is minimal literature discussing factors associated with re-excision in patients undergoing OBCS. The purpose of this retrospective study is to identify preoperative factorsassociated with re-excision in OBCS.
A retrospective review was performed on adult patients who underwent oncoplasticbreast conserving surgery between October 2021 and May 2024. Subjects were divided into those who required re-excision and those who did not. Amongst these groups, factors were evaluated including patient age, BMI, smoking status, presence of co-morbidities including hypertension and diabetes, presence of tumor multifocality or microcalcifications on mammogram, tumor size, HER2 positive status, triple negative (ER-/PR-/HER2-) status, and tumor pathologies including ductal carcinoma in situ (DCIS), invasive ductal carcinoma, and invasive lobular carcinoma. Univariate analyses was performed using Chi-Squared for categorical data and continuous data was analyzed using independent t-test or non-parametric Mann-Whitney U tests where appropriate. Of 48 patients total, all 48 patients (100%) were female. 31 patients (64.6%) underwentmastopexy and 17 patients (35.4%) underwent mammoplasty. 12 patients (25%) required re-excision for inadequate margins and 36 patients (75%) did not require re-excision. There was no significant difference in the need for margin re-excision based on patient age, BMI, smoking status, or the presence of hypertension or diabetes (p=0.738, p=0.171, p=1.000, p=1.000, p=0.522). There was no

significant difference in need for margin re-excision based on tumor size (25.2 +/-25.8mm in patients who required re-excision vs. 19.4 +/-10.7mm for patients who did not require re-excision, p=0.976). There was also no difference in need for margin re-excision based on the presence of invasive lobular carcinoma, triple negative status, presence of HER2,microcalcifications or tumor multifocality (p=0.614, p=0.404, p=0.131, p=0.394, p=0.614). 6 of the 12 patients (50%) with DCIS required margin re-excision, while 4 of the 32 patients (12.5%) with invasive ductal carcinoma required margin re-excision (p=0.021, p=0.005).
While invasive lobular carcinoma, younger patient age, tumor size, presence ofHER2, and tumor multifocality have been shown to increase the risk of re-excision inBCS, these factors did not significantly affect re-excision rates after OBCS in our study.However, similar to data published for BCS, our results show that DCIS has a significantly increased rate of re-excision in patients who undergo OBCS. Additionally, the presence of invasive ductal carcinoma seemed to have a significantly decreased need for re-excision after undergoing OBCS. While further studies with larger patient populations should be completed to confirm our results, our study has identified a pathology of DCIS as one factor that might be predictive of re-excision and a pathology of invasive ductal carcinoma that might be predictive of decreased re-excision in patients undergoing OBCS.

P5-09-02: Acellular Dermal Matrix (Braxon® and STRATTICE™) for immediate implant - based breast reconstruction - Our Initial experience

Asma Munir, Dean Kamyab, Nida Javed, Yousef Sharaiha, Sohail Khan, Anita Huws, Saira Khawaja

Background: Immediate implant reconstruction after a mastectomy is an option for breast cancer patients. The success associated with these procedures is related to providing extra implant coverage and anchoring to the pectoralis thereby accelerating healing. The use of acellular dermal matrix (ADM) is an alternative to titanium-coated polypropylene mesh (TCPM) for implant-based breast reconstruction (IBBR).

Our study is a prospective nonrandomized single-institution observational study of reconstructions using acellular dermal matrices.

Methods:Between October 2020 and April 2024, implant breast reconstructions after mastectomy using Braxon® or STRATTICE™ were performed in 24 patients (with 32 reconstructions). We analyzed short-term outcomes of such procedures and compared the outcomes to evaluate implant losses and surgical complications.
Complications were divided into major (need for additional surgery), minor (conservative treatment). The primary outcome was implant loss at 3 months. Univariate analyses were performed to determine the influence of the patient- and procedure-related factors on postoperative complications and implant loss.
Results:A total of 32 mastectomies with reconstructions were performed in 24 women.

Mean age was 50 years (range 29-73 years). The mean BMI was 26 (range 18.6 - 37.3). Twenty-four patients had therapeutic mastectomies with eight of them also having contra lateral risk reducing mastectomies.

There were 11 nipple sparing procedures and 21 skin sparing procedures.

The median follow-up period was 11 months. Implant loss rate was 3.1% (1 of 32 implants) at 3 months follow up. Immediate hematoma and subsequent delayed skin necrosis was responsible for this case.

One other patient had wound dehiscence and loss of implant at 3.5 months. Two other patients had revised reconstructions at later periods. One of these had the Braxon® replaced with a STRATTICE™ 13 months post reconstruction after developing Red Breast Syndrome. The other patient had a smaller implant placed 8 months post op for cosmetic purposes.

No risk factors were observed for immediate failure within 3 months. Univariate analysis revealed an increased risk for implant loss in patients with skin necrosis and wound dehiscence ($p<0.01$).

Conclusions:Acellular dermal matrices show acceptable complication rates and its use in immediate implant breast reconstruction is safe and effective. Going forward, we would like to compare the data between TCPM and ADMs.

P5-09-03: Localization combined with multidetector CT 3-dimensional image reconstruction guided precision breast conserving surgery versus conventional breast conserving surgery: cosmetic analysis of the single center, prospective, cohort study.

Yiqin Xia, Yangyang Cui, Yue Huang, Jinghui Peng, Meng Zhao, Hui Xie, Shui Wang

Introduction: Breast conserving surgery (BCS) with radiation is accepted as a standard local treatment for early-stage breast cancer. Advantages in survival and quality of life (QoL) have led to a higher demand for BCS. Success of BCS is characterized by negative margins and a good cosmetic outcome. The aims of this cohort study were to determine whether wire-guided localization (WGL) combined with multidetector CT (MDCT) guided 3-dimensional (3D) reconstruction could guide precision breast conserving surgery (PBCS), and to access the cosmetic outcome reported by patients.
Methods: 31 patients with unifocal breast cancer were enrolled for PBCS guided by WGL combined with MDCT guided 3D reconstruction from 2021 to 2022. Under local anesthesia, surrounded WGL was performed, followed by an immediate contrast enhanced MDCT scan. One day after the localization, PBCS guided by MDCT guided 3D reconstruction was performed. 61 women who underwent palpation guided breast conserving surgery (BCS)

were included as control. Two-sided Student t test, Fisher's exact test and chi-square test was applied.
Results: Breast Cancer Treatment Outcome Scale (BCTOS) cosmetic subscale was used to access patient reported cosmetic outcomes in our study. In the PBCS group, the results indicated no significant changes (P=0.168) between the baseline assessment and 1 month post operation. This is later followed by adverse changes (P=0.016) between 1 month post operation and 6 months post radiotherapy (RT). In the control group, the results indicated adverse changes (P 0.001) between the baseline assessment and 1 month post operation. This is later followed by deterioration (P=0.028) between 1 month post operation and 6 months post RT. Between the two groups, there was no significant difference noted for the score of the BCTOS at baseline, 1 month post surgery and 6 months post RT
Conclusion: For patients with unifocal breast cancer, WGL combined with MDCT guided 3D reconstruction could achieve better cosmetic outcomes.

P5-09-05: Median Five-Year Follow-Up Outcomes Based on Pathologic Grade in a Multi-Institution Trial Using Intra-Operative Electronic Brachytherapy for Treatment of Early-Stage Breast Cancer

Barbara Schwartzberg, Alam M. Nisar Syed, Ajay Bhatnager, Sophia Rahma, Todd Cockerham, Virginia Osborn, Charles Wesley Hodge, Christina Lopez-Penalver, Bapsi Chakravarthy, Veronica Jones, William Dooley, Chika Madu, Atsuko Okabe, Maen Farha, Andrea Madrigrano, Christopher Morrison, Geoffrey Neuner, Craig Wengler, Bryon Stephens, Steven David, Katayoon Toosie, Albert Chang

Background/Objectives: Grade (G) III breast cancer pathology received a separate AJCC Staging Manual 8th Edition classification due to increased evidence of higher tumor recurrence.1 The 2023 ASTRO Accelerated Partial Breast Irradiation Consensus Statement Guideline states that patients with GIII pathology may have a worse outcome, although this is an underrepresented subset in trials analyzed by this report.2 IORT is unique in that the final surgical pathology has not yet been determined at the time of IORT treatment. An IRB-approved single arm prospective multi-institution trial was designed to determine the efficacy and outcome of single fraction 20 Gy intra-operative radiation therapy (IORT) using disposable balloon electronic brachytherapy at the time of breast conserving surgery for early-stage breast cancer (women at least 40 years old, infiltrating ductal carcinoma [IDC] or ductal carcinoma in situ [DCIS], single lesion no larger than 3 cm, cN0). Differences in median 5-year follow-up ipsilateral breast tumor recurrence (IBTR) outcomes based on pathologic grade would be analyzed.
Methods: Between 2012-2018, 1199 enrolled patients were successfully treated per protocol with lumpectomy plus single 20 Gy fraction IORT using disposable balloon electronic brachytherapy. Data collection included demographics, Scarff-Bloom-Richardson graded pathology, IBTR (lumpectomy/index quadrant recurrence), and survival. The Exact Chi-square, 2-sided test was used for statistical analysis.
Results: 1199 patients completed IORT treatment per protocol. Post-biopsy, pre-IORT

classifications were IDC GI, GII, GIII (403, 437, 78 patients, respectively, 38 not recorded) and DCIS low, intermediate, and high grade (35, 108, 98 patients, 2 not recorded). The number of IDC patients in each group changed following surgical pathology (371, 439, 119 patients in the IDC GI, GII, GIII groups, 20 no residual tumor, 15 not recorded). DCIS patient numbers also changed (29, 92, 68 patients in the DCIS low, intermediate and high grade groups, 33 no residual tumor, 1 not recorded). Invasive lobular carcinoma was diagnosed in 12 patients.
There were 42 (3.50%) IBTR at median 5-year follow-up (IDC GI, GII, GIII, not recorded groups having 6, 14, 9, and 1 IBTR; intermediate and high grade DCIS groups having 5 and 7 IBTR). Of these, 49 patients with post-biopsy, pre-IORT IDC GI, GII pathology were re-classified as GIII on surgical pathology (3 IBTR) while 9 patients with low, intermediate grade DCIS were reclassified as high grade (2 IBTR). One post-biopsy, pre-IORT intermediate grade DCIS patient, reclassified as IDC GIII, remains recurrence free. At median 5-year follow-up, the 810 IDC GI, GII patients had a 2.5% IBTR, while the 121 low, intermediate grade DCIS patients had a 4.1% IBTR. 119 patients with IDC GIII and 68 patients with high grade DCIS were found to have a higher IBTR incidence (7.6% and 10.3%) which was statistically significant for DCIS ($p = 0.0014$), but not for IDC ($p = 0.0534$). There was 1 post-biopsy, pre-IORT IDC GIII breast-cancer related death.
Conclusions: At median 5-year follow-up, 1199 patients successfully treated with single 20 Gy fraction IORT per protocol using disposable ballloon electronic brachytherapy exhibited an overall 3.50% IBTR, with IDC GIII and high grade DCIS patients having a higher IBTR incidence, consistent with published reports.

P5-09-06: Acute Cardiovascular Events after Hypofractionated IMRT for Early Breast Cancer: Association with Coronary Calcifications in Radiotherapy Planning-CTs

Ana Aurora Diaz-Gavela, Ana A. Diaz-Gavela, Julio Fernández-Mata, Elia del Cerro-Peñalver, Sofía Sánchez-García, Cristina Andreu-Vázquez, Israel John Thuissard-Vasallo, David Sanz Rosa, Lucia Gonzalez-Cortijo, Marina Peña-Huertas, Victor Duque-Santana, Luis Leonardo Guerrero, Carmen Ruiz-Morales, Felipe Counago

Radiotherapy (RT) for breast cancer (BC) has shown to increase the likelihood of acute coronary events (ACE) - infarction and angina - in older cohorts treated with obsolete techniques. Contemporary highly conformal RT, such as Intensity Modulated Radiotherapy (IMRT), and hypofractionation, which offers a theoretical radiobiological advantage by

reducing the equivalent biological dose to organs-at-risk, are mitigating the overall impact of RT on long-term cardiovascular (CV) toxicity and have shifted the focus towards the early diagnosis and management of patients' baseline cardiovascular risk factors (CVRF). Coronary arterial calcium, measured by a specific CT scan designed to quantify the calcium score, is a well-established early predictor of ACE. In recent years, it has been increasingly demonstrated that the incidental finding of coronary calcifications (CoC) on CT scans performed for RT treatment planning is significantly associated with an elevated risk of ACE.

The aim of this study is to determine the incidence of ACE or any other CV events in a modern and homogeneous cohort of patients receiving RT for early BC and to explore its association with the presence of CoC on the planning CT.

Materials and Methods

We included all BC patients treated with hypofractionated Forward Planned IMRT after breast-conserving surgery between 2009 and 2019. This monoinstitutional, descriptive, retrospective observational study is based on a manual review of the medical and RT planning records. To ensure cohort homogeneity, we excluded patients in indication for elective lymph node RT or those with previous mediastinal RT. Known CVRFs and those identified at diagnosis or during follow-up, were addressed with appropriate treatments. All RT-Planning CTs were performed in a supine position, without contrast, in free breathing, and were electrocardiogram non-triggered scans. The presence or absence of CoC in the planning CTs was registered.

Results:

882 patients (432 with left-sided BC) were included, with a median [Q1; Q3] age of 52 [46; 62] years. The presence of CoC was identified in 154 (17.5%) patients and was significantly associated with the patients' age at diagnosis and with other CVRFs, including diabetes, hypertension, dyslipidemia, overweight, and a personal history of CV events.

After a median follow-up of 8 years (ranging up to 14 years), the incidence of ACE was extremely low, at 0.7% (95% CI: 0.3%-1.5%). In women with CoC, the incidence of ACE was 3.9% (95% CI: 1.8%-8.2%), whereas none of the women without CoC developed an ACE and the risk was significantly higher for women with CoC compared to those without (RR 23.4 (95% CI: 3.4-233.9)).

In addition to ACE, 20 arrhythmias, 2 cases of severe valvular heart disease and 7 other non-ischaemic CV events were documented during the follow-up period, giving a total of 35 CV events (overall incidence 4.0% (95% CI: 2.9%-5.5%]). The occurrence of any of the latter in women with CoC was 9.7% (95% CI: 6.0%-15.4%), while in women without CoC it was 2.7% (95% CI: 1.8%-4.2%). The risk of experiencing any CV event was 3.5 times higher (95%: CI 1.9-6.8) for women with CoC compared to those without.

Conclusions

Although the incidence of ACE in this cohort is extremely low, both in women with and without CoC, a higher risk of ACE as well as of any CV event was detected in patients with CoC. These findings underscore the potential utility of detecting CoC on RT planning CT scans in conjunction with early management of classical CVRFs. This approach may provide

a valuable opportunity for identifying patients who could benefit from targeted primary prevention strategies for CV disease.

P5-09-07: Patterns of progression after first-line systemic therapy in metastatic breast cancer and the potential of ctDNA to guide metastasis-directed therapy: implications for breast oligometastases management

Jee Suk Chang, Min Hwan Kim, Byung Min Lee, Joohyunk Sohn, Gun Min Kim

Background: The role of metastasis-directed therapy (MDT) for oligometastases remains controversial in breast cancer. We analyzed the patterns of progression after first-line systemic therapy in metastatic breast cancer (MBC) in the contemporary era and investigated whether low-pass whole genome sequencing (WGS) ctDNA analysis can aid prediction of progression patterns.
Methods: We reviewed a previously established prospective ctDNA cohort (Kim et al., JNCI 2023) of 207 patients with MBC who received first-line systemic therapy from 2017 to 2020 in Yonsei Cancer Center, using. None of these patients received MDT. Imaging studies at baseline and during each progression were retrospectively reviewed to count the number of lesions and assess patterns of progression. Progression was categorized as either the progression of pre-existing lesions identified prior to treatment or the development of new lesions.
Results: An increase in disease burden (1-5 vs. 6-10 vs. >10 lesions) at baseline was significantly associated with decreased progression-free survival (PFS) and overall survival (OS). Patients with 1-5 lesions had a 5-year PFS and OS of 45.9% and 75.4%, respectively. With a median follow-up of 50 months, among MBC patients with 1-5 lesions at baseline, 49.2% showed no progression at the last follow-up, 30% had progression of 1-5 lesions, and 19% had progression of more than 5 lesions; among their progressions, 27% were progression of pre-existing lesions only, 43% were development of new lesions only, and 30% were mixed. These patterns varied by baseline number of lesions, mode of presentation (de novo vs. recurrent), and molecular subtype. A Sankey diagram was generated to identify the prevalence of progression of 1-5 lesions and PL progression through the fifth line of systemic therapy. A high ctDNA I-score was independently associated with a higher risk of widespread-metastasis (>10 lesions) progression (adjusted HR 3.25, 95% CI 1.54-6.85) in patients without widespread metastases at baseline.
Conclusions: Progression of pre-existing lesions was not the predominant pattern; poly-metastasis progression was not uncommon in oligometastatic breast cancer patients, highlighting the challenges in selecting patients for MDT based solely on the number of metastases at diagnosis. Incorporating ctDNA information may help identify patients at higher risk for widespread metastasis progression, who might not benefit from MDT.

P5-09-09: Prospective Evaluation of Shoulder Morbidity in Patients with Lymph Node-Positive Breast Cancer Receiving Regional Nodal Irradiation

Jose Bazan, Julie Stephens, Sachin R. Jhawar, Sasha Beyer, Karen Hock, Julia R. White

Purpose/Objective(s): Many women with axillary node-positive breast cancer benefit from regional nodal irradiation (RNI) in terms of improved cancer control outcomes. RNI unintentionally exposes the shoulder structures to radiation, which can lead to morbidity. We previously demonstrated that intensity modulated radiation therapy (IMRT) results in less radiation dose to the shoulder compared to 3D conformal radiation therapy (3DCRT). We set to determine if the dosimetric advantage of IMRT translates into a clinically meaningful reduction in shoulder morbidity.
Materials/Methods: This study is registered on clinicaltrials.gov (NCT03786354). We enrolled patients that were to receive RNI after mastectomy (Mx) or lumpectomy (Lump) with axillary staging (axillary lymph node dissection [ALND] or sentinel node biopsy [SNB]). All patients received 50 Gy in 25 fractions to the breast or chestwall and RNI. Patients were non-randomly assigned to either Arm IMRT or Arm B 3DCRT on the basis of a treatment planning algorithm that defaults to 3DCRT but transitions to IMRT based on dosimetric criteria. The primary endpoint was shoulder/arm morbidity at 1 year post-RNI in IMRT patients using the Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire. Based on limited existing data at the time, we estimated that the 1-year DASH score would be 20 in patients that had undergone RNI with 3DCRT and that IMRT would reduce the 1-year DASH to ≤10. A sample size of 27 patients would have 80% power to detect this 10-point difference in DASH score. We enrolled 27 patients on Arm 3DCRT to establish the average DASH score in this cohort.
Results: Patients were enrolled from 1/2019-3/2022. After loss to follow-up, there were 29 patients evaluable for the primary endpoint in Arm IMRT and 27 patients in Arm 3DCRT with similar ages (median age=50 years vs. 51 years, p=0.83) but trend towards higher rates of Mx (72% vs. 51%, p=0.11) and ALND (90% vs.78%, p=0.23) in Arm IMRT vs. Arm 3DCRT. In arm IMRT, the mean baseline (post-surgery/pre-RNI) DASH was 12.8(SD 11.0) and increased to a mean of 15.4(SD 15.1) at 1-year. In arm 3DCRT, the mean baseline DASH was 14.0(SD 12.9) and increased to a mean of 14.8(SD 13.2) at 1-year. Decrease in DASH scores was more frequent in Arm IMRT vs. 3DCRT (51.7% vs. 37.0%, p=0.27). In the entire cohort, patients treated with Mx and patients treated with ALND tended to have worse 1-year DASH scores: 17.6 (SD 15.9) Mx vs. 11.0(SD 9.4) Lump, p=0.06; 16.4(SD 14.7) ALND vs. 8.4(SD 8.0) SNB, p=0.03.
Conclusion: This study did not meet its primary endpoint but the similar 1-year DASH scores in Arm IMRT and Arm 3DCRT may reflect IMRT compensating for the more extensive axillary and breast surgery in that arm. More than 50% of patients in Arm IMRT experienced a decrease in DASH score. These findings suggest that prospective investigation of IMRT for RNI in the setting of SNB remains worthy of study. Analysis of secondary endpoints including objective range of motion assessments and shoulder muscle dosimetry are forthcoming.

P5-09-10: Metastasis-directed radiotherapy and systemic treatment continuation for patients with extracranial oligoprogressive metastatic breast cancer (ESTER-RW): a single-center retrospective analysis

Monica Milano, Carmine Valenza, Sara Gandini, Dario Trapani, Elisabetta Munzone, Celeste Santoro, Elena Battaiotto, Ambra Carnevale Schianca, Jalissa Katrini, Elisa Giordano, Grazia Castellano, Nadia Bianco, Silvia Dellapasqua, Giuseppe Curigliano, Marco Angelo Colleoni, Annamaria Ferrari, Barbara Alicja Jereczek-Fossa

Background: Following to an initial disease control to systemic treatment, 15-20% of patients (pts) with metastatic breast cancer (mBC) experience oligoprogression of disease (OPD) in ≤5 extracranial sites. These pts may benefit from radiotherapy (RT) to OPD sites, while maintaining the same systemic treatment, aiming at prolonging the progression-free survival (PFS) and postponing the time to systemic treatment failure (TTF). Data from large observational studies are missing.
Methods: Retrospective, single-center, observational study aiming at evaluating the post-RT-PFS (pRT-PFS) in consecutive pts with mBC and OPD, who received RT to all OPD sites (≤5 extracranial sites) at European Institute of Oncology (Milan), from Jan 2011 to Jun 2023, continuing the same systemic treatment. The primary endpoint was pRT-PFS, defined as the time from the first scan showing OPD to the subsequent PD. Secondary endpoints were: pRT-PFS in pts with luminal-like (HR+/HER2-) disease; post-RT TTF (pRT-TTF), defined as the time from the first scan showing OPD to treatment discontinuation; overall survival (OS), calculated from the OPD scan. A sample size of 130 pts allowed to estimate the lower boundary of the 95% confidence interval (95%CI) for the median pRT-PFS of 7 months (mo).
Results: 129 consecutive pts were included. Among all comers (N=129) and in the HR+/HER2- subgroup (N=99), respectively, median age was 60 (52-67) and 60 (52-68); 79% and 76% of pts had a ductal carcinoma, 77% and 100% a luminal-like disease, 15% and 0% a HER2+ disease, 9% and 0% a triple-negative disease.
The median line of treatment was 2 (interquartile range [IQR]: 1-2) and 1 (IQR: 1-2); 60% and 75% of pts were receiving an endocrine therapy (ET)-based treatment when OPD occurred, while 28% and 26% chemotherapy.
The median number of OPD sites was 1 (IQR: 1-1) and 1 (IQR: 1-1), and the median number of OPD lesions was 1 (IQR: 1-2) and 1 (IQR: 1-2); 9% and 6% of pts had visceral OPD, while 73% and 83% bone OPD.
Overall, 33% and 34% of pts received RT with cyberknife; 98% and 98% had in-field disease control rate as best response, with 47% and 47% of radiological complete responses; the median pre-RT PFS was 12.4 mo (95%CI 9.8-15.1) and 11.5 mo (95%CI 8.7-14.3).
After a median follow-up of 3.2 years (95%CI 2.7-3.8), 113 and 89 pRT-PFS events occurred: median pRT-PFS was 11.3 mo (95%CI 9.1-13.5) among all comers and 11.5 mo (95%CI 8.7-14.3) in the HR+/HER2- subgroup; median pRT-TTF was 13.6 mo (95%CI 11.7-15.5) and 14.2 mo (12.3-16.2); median OS was 6.4 years (4.7-8.1) and 6.7 years (4.8-8.1).
Among all comers, in pts with pre-RT PFS ≥12 or ≥18 mo, pRT-PFS was 13.5 mo (95%CI

10.2-16.7) and 14.9 (95%CI 12.2-17.7), respectively. Similarly, in pts from the HR+/HER2- subgroup with pre-RT PFS ≥12 or ≥18 mo, pRT-PFS was 13.0 mo (95%CI 8.1-18.0) and 14.8 (95%CI 12.1-17.4), respectively.
Conclusions: Pts with mBC, especially with HR+/HER2- subtype and who experience extracranial non-visceral OPD after at least 12 mo of treatment, benefit from RT to all OPD sites without changing systemic treatment.

P5-09-11: Cardiac assessment and safety of 5-fraction whole breast irradiation after breast-conserving surgery: an observational prospective cohort study (SAFE-FORWARD)

Luca Visani, Carlotta Becherini, Viola Salvestrini, Livia Marrazzo, Giuseppe Barletta, Chiara Bellini, Erika Scoccimarro, Beatrice Bettazzi, Victoria Lorenzetti, Marianna Valzano, Isacco Desideri, Mauro Loi, Giulio Francolini, Monica Mangoni, Marta Casati, Jacopo Nori, Lorenzo Orzalesi, Simonetta Bianchi, Stefania Pallotta, Lorenzo Livi, Icro Meattini

Purpose. Whole breast irradiation (WBI) using 5 fractions after breast-conserving surgery (BCS) has shown non-inferior local control rates, an acceptable safety profile, and greater patient compliance. This study aims to assess the heart toxic effects using reliable cardiac assessments with standard and 3-dimensional (3D) echocardiography and left (LV) and right ventricular (RV) global longitudinal strain (GLS) in patients receiving 5-fraction postoperative radiation therapy (RT) for breast cancer (BC).
Patients and methods. SAFE-FORWARD is an observational prospective cohort study (NCT04842409). We included: (1) patients with invasive BC receiving ultra-hypofractionated WBI (26Gy in 5 fractions) after BCS, (2) without cardiovascular comorbidity, and (3) without previous thoracic irradiation. All enrolled patients were prospectively monitored for 12 months, receiving a complex cardiological assessment before RT start (baseline), and at 2, 6, and 12 months after the end of RT. Heart substructures of patients were delineated according to the cardiac contouring atlas. Both acute and early-late toxicity were evaluated according to CTCAE (v.5) scales. The primary endpoint was defined as the detection of any subclinical impairment in myocardial function and deformation (decrease ≥10%) measured with standard and 3D echocardiography LV and RV GLS.
Results. Overall, 50 women (median age 67 years; range 48-84) were enrolled in the study. All patients received ultra-hypofractionated WBI (26Gy in 5 fractions): left and right breast side patients were 27 and 21, respectively, and 2 patients had bilateral breast cancer. Patients were treated with tangential IMRT fields using 6 or 10 MV beams from an Elekta VHD linac. Adjuvant endocrine therapy was administered to 33 patients. The median PTV volume was 768 cc (range 220-1689) and the median heart volume was 576 cc (range 403-857). The average values of mean heart dose (Dmean) and maximum heart dose (dose covering 0.04cc of the Heart, D0.04) were 0.73Gy (SD 0.50) and 10.0Gy (SD 10.1), respectively. The left breast side group reported 0.94Gy (SD 0.49) and 15.0Gy (SD 9.03) for Dmean and D0.04, respectively, while right breast side patients had lower Dmean (0.44Gy,

SD 0.34) and D0.04 (3.14Gy, SD 7.12). Among patients who had completed the cardiological assessment at 12 months, GLS worsened by 4% or less, both for the left- and right-side treated breast, and remained in the normal range at all time points. The only exception was for RVGLS at 6 months for right-sided treatment where it reached a borderline value (-17.4±4.9 SE). 3D-LVEF remained stable during observation, both for the left- and right-side treated breast. At the end of RT, grade (G) 1 and 2 adverse events were observed in 31 and 3 patients, respectively. Eleven patients reported G1 toxicities at 12 months: 2 cases of radiation dermatitis, 2 of fatigue, 1 of telangiectasia, and 6 of fibrosis.
Conclusion. The 5-fraction WBI schedule was well tolerated, and the intensive 1-year cardiological monitoring showed no significant differences over time in cardiac functioning.

P5-09-12: Pre-Operative Radiation Boost Planning in a Phase II Clinical Trial Achieves Acceptable Tumor Volume Coverage

Molly Chakraborty, Zohaib K. Sherwani, Lakshmi Rekha Narra, Zeinab Abou Yehia, Taoran Cui, Nisha Ohri, Firas Eladoumikdachi, Maria J. Kowzun, Shicha Kumar, Lindsay Potdevin, Deborah L. Toppmeyer, Sachin Jhawar, Bruce G. Haffty

Background: Radiation tumor bed boost after breast-conserving surgery (BCS) and whole breast irradiation (WBI) reduces local recurrence rates in women with ductal carcinoma in situ (DCIS) and early-stage breast cancer. This prospective trial investigated the feasibility of delivering the tumor bed boost pre-operatively instead of post-operatively. The primary endpoint, the incidence of wound complication rates, was previously reported as acceptable. Additionally, we have previously shown that pre-operative boost resulted in smaller treatment volumes compared to what would have been treated with a sequential lumpectomy boost based on the post-operative seroma cavity. The pre-operative boost approach may also allow for more accurate gross tumor delineation. We hypothesize that pre-operative imaging including mammography, MRI and CT simulation used in this trial would enable the accurate delineation of gross tumor volumes (GTV) that can adequately cover the entire tumor, as demonstrated by comparison with post-lumpectomy pathological tumor (pT) size. Methods: In this prospective phase II clinical trial (NCT04871516), enrolled patients all received mammography, breast MRI and CT simulation. Target volumes and treatment planning were designed based on the baseline mammography, MRI and CT simulation acquired for each patient, generally using the surgical clip placed at the time of biopsy as the center of the tumor. The GTV was expanded by 0.5 cm to define the clinical target volume (CTV) which was then expanded an additional 0.5 cm to define the planning target volume (PTV). Patients then underwent a pre-operative boost of 13.32 Gy in 4 daily fractions, followed by BCS 1-3 weeks later, and then WBI of 36.63 Gy in 11 daily fractions 3-8 weeks post-BCS. Clinical trial and patient records were reviewed to collect patient demographics, disease characteristics, and treatment details. The largest diameter of the GTV contoured from these baseline imaging studies was compared to the largest pathologic diameter of the tumor removed during BCS using a one-tailed paired sample t-test. Results: A total of 76 patients were included in this analysis. The median age was 64

(range: 40-80). Based on initial biopsy, 64 (84.2%) patients had invasive cancer while 12 (15.8%) had DCIS. Most patients, 70 (92.1%), have ER+ disease, 63 (85.1%) have PR+ disease, and 3 (3.9%) have HER2+ disease. The median clinical tumor size was 12 mm. The median GTV diameter was 22.35 mm (range: 11.1-58.1 mm) and the median pathologic tumor (pT) size was 10 mm (range: 0-34 mm). The GTV diameter was larger than the pT size in most cases (p = <0.001). For 8 (10.5%) patients, the largest diameter of the estimated GTV did not cover the pT diameter by a median of 4.35 mm (range: 0.6-6.8 mm). However, the largest diameter of the clinical target volumes (CTV) contoured for these patients were all greater than the pT size by a median of 9.1 mm (range: 2.7-19 mm). The PTV provided another 0.5 cm margin as well. Notably, for 5 (6.6%) patients, pre-operative boost resulted in no residual disease at time of BCS. Conclusions: For most patients, pre-operative boost GTV delineation resulted in a maximum diameter greater than pT size, suggesting that the GTV covered the entire tumor volume. In the minority of cases where the GTV diameter was not greater than the pT size, the tumor was adequately covered by the CTV with an added 0.5 cm PTV margin. These findings support the feasibility of delivering a pre-operative boost for patients with DCIS and early-stage breast cancer based on mammographic CT and MRI imaging.

P5-09-13: LumiSystem-guided lumpectomy enables informed customization of radiation therapy in select patients with breast cancer.

Simona Shaitelman, Roberto Diaz, Brian Schlossberg, Manna Chang, Kate Smith, Jorge Ferrer, Kelly K. Hunt, David Carr, Peter Blumencranz, E. Shelley Hwang, Irene Wapnir, Barbara L. Smith

Background: For most patients who undergo lumpectomy, adjuvant radiation therapy is standard of care (SOC) following surgery. There is an increasing emphasis on de-escalation or omission of radiotherapy, for which achieving the most complete tumor resection is particularly critical to minimize the risk of recurrence. When used as an adjunct to standard lumpectomy, the LumiSystem has been shown to remove residual cancer missed by the initial surgery and reduce the rate of positive margins. We evaluated whether eligibility for de-scalation or omission of radiotherapy changed based on the LumiSystem intervention. Methods: In this prospective trial, we assessed margin status with and without LumiSystem-guided surgery for patients with stage 0-3 breast cancer. After surgeons completed their standard lumpectomy procedure, patients were randomly assigned 10:1 to receive further LumiSystem-guided surgery for positive signal or not. For patients randomized to the LumiSystem intervention, eligibility for de-escalation or omission of radiotherapy, both after standard lumpectomy and after LumiSystem intervention, were retrospectively determined based on eligibility criteria from RTOG 9804, CALGB 9343, PRIME II, LUMINA, IDEA, BR007/DEBRA and the 2024 ASTRO Partial Breast Irradiation Guidelines. According to these criteria, the population of interest included only patients >49 yr. with various tumor characteristics intended to identify lower risk patients. Results: 357 patients received LumiSystem-guided surgery, and a retrospective chart

review was performed by two independent breast specialized radiation oncologists for the 166/357 (46.5%) patients that had additional LumiSystem-guided excisions taken after standard lumpectomy. 133/166 (80.1%) patients reviewed had negative margins after standard lumpectomy and 77/166 (46.4%) patients (age: median - 66 yr., range - 51-82 yr.) were eligible for omission of radiotherapy after standard lumpectomy based on the aforementioned eligibility criteria. 9/77 (11.7%) patients (age: median 51 yr., range 51-77 yr.) who were eligible for omission of radiotherapy following standard lumpectomy had residual tumor removed in subsequent LumiSystem-guided excisions. These residual tumor deposits included grade 3 histology and ranged from 1-11mm in size. 33/166 (19.9%) patients had a positive margin after standard lumpectomy, and 9/33 (27.3%) of these patients were converted to negative margins intraoperatively by LumiSystem-guided wider negative margins. 3/33 (9.1%) of these patients (age: median - 57 yr., range 54-73 yr.) with positive margins after standard lumpectomy had a change in eligibility for omission of radiotherapy based on LumiSystem-guided wider negative margins, and 2/33 (6.1%) patients also became eligible for smaller volumes of accelerated partial breast irradiation. Discussion: LumiSystem-guided surgery altered radiation therapy recommendations in a subset of patients. Among patients eligible for omission of adjuvant radiotherapy based on SOC negative margins, identification of fluorescence in the lumpectomy cavity resulted in removal of unsuspected residual tumor. These findings support the notion that those patients who historically have recurred without radiotherapy may have had residual disease left behind after standard lumpectomy. Using LumiSystem as an adjunct to standard lumpectomy may lead to the potential of the reducing targeted volume of radiation therapy and the option to omit radiation in additional patients. Long-term follow-up data is needed to determine if the risk of local recurrence is lower in patients undergoing LumiSystem-guided surgery, particularly in those who are candidates for radiation omission.

P5-09-15: Impact of Patient Navigation on Radiation Therapy Completion in Black Breast Cancer Patients: Early Phase I Trial Results From the Navigator-Assisted Hypofractionation (NAVAH) Program

Shearwood McClelland III, Ursula J Burnette, Louisa Onyewadume, Chesley W Cheatham, Tamika K Smith, Corey W Speers, Janice A Lyons

Purpose/Objective(s): Black breast cancer patients have substantially decreased access to optimal breast conserving cancer care (postlumpectomy radiation therapy) than White patients. Patient navigation (originally implemented in the 1990s to address cancer disparities and medical mistrust) has demonstrated improvement in breast cancer survival, yet has never been formally implemented into the receipt of radiation therapy (RT) for Black patients. The Navigator-Assisted Hypofractionation (NAVAH) program is the first to formally assess the impact of patient navigation on RT in Black breast cancer patients. Here, we present the initial results from an ongoing Phase I trial assessing the impact of NAVAH on RT completion.

Materials/Methods: NAVAH is a prospective single-arm Phase I pilot study. Patients of Black race age > 18 with pathologically confirmed breast cancer following operative resection are eligible. Patients referred for RT in multidisciplinary tumor board, seen by Radiation Oncology, and consented to receive RT were approached for trial participation. Participants were assigned a patient navigator to aid them throughout the course of radiation therapy and post-RT care, and were provided travel vouchers to offset the transportation cost of RT. The RT scheduled dose/fractionation, scheduled completion date, actual completion date, and verification of RT completion was recorded for each enrolled patient. Patients refusing trial participation were assessed to determine RT completion rate; Fisher's exact test was used for statistical analysis with significance assigned as $p<0.05$. The primary trial endpoint is RT completion rate following initiation of patient navigation; this trial is registered at clinicaltrials.gov, NCT05978232.

Results: Between March 27, 2024 and May 28, 2024, a total of 18 patients with scheduled CT simulation for RT planning were offered trial enrollment; 11 accepted and 7 declined. No patient had received navigation prior to being offered trial enrollment. Median fraction duration and total dose received (including boost) was 16 (range 5-20) and 40.05 Gy (range 26-52.56 Gy) among enrolled patients, and 16 (range 5-20) and 40.05 Gy (range 30-52.56 Gy) in those declining enrollment, with no significant difference in patient age or distance from RT facility between those who accepted versus declined trial enrollment. Of the 7 patients who declined trial enrollment, six (85.7%) completed RT (the seventh initially agreed to RT but subsequently failed to present for treatment); of these six, four (66.7%) completed RT without delay. Of the 11 patients who enrolled on trial, all (100%) completed RT, with eight (72.7%) completing RT without delay. The differences between groups were not statistically significant.

Conclusion: Early results of an ongoing Phase I clinical trial reveal that incorporation of patient navigation following initial Radiation Oncology consultation is associated with 100% radiation therapy treatment completion for postoperative early-stage breast cancer in Black patients, compared with lower rates among patients not receiving navigation, as well as numerically superior rates of RT completion without delay. Further work examining incorporation of patient navigation earlier in the treatment course of patients is ongoing.

P5-09-16: Real world experience with Carboplatin plus Nab-paclitaxel as neoadjuvant therapy in patients with early triple negative breast cancer.

Manuel Alva Bianchi, Pablo Tolosa, Oscar Campos, Rodrigo Sanchez-Bayona, Carla Quevedo, Cristina Gonzalez, Laura Lema, Ainhoa Madariaga, Cristina González Deza, Lucia Parrilla, Mario Gonzalez, Cristina Martín-Arriscado, Luis Manso, Eva Ciruelos

Background: Neoadjuvant therapy (NA) is the base treatment for the majority of patients with early triple negative breast cancer (TNBC). The achievement of pathological complete response (pCR) after neoadjuvant treatment translates into improvements in long term

outcomes. In the last decade, the arrival of new components or formulations have been assessed in clinical trials, such as carboplatin and nab-paclitaxel showing improvements in pCR rates or adverse events profiles. The aim of this study is to provide updated information on the efficacy of Carboplatin plus Nab-paclitaxel combined with other combinations (anthracyclines and immunotherapy) as neoadjuvant therapy in patients with TNBC in the real-world setting.

Methods: We analyzed a cohort of patients treated with neoadjuvant therapy diagnosed with stage I-II TNBC and ER/PR-low status in a single tertiary hospital in Spain from June 2015 to February 2023. TNBC was defined as ER and PR <1% and HER-2 negative. ER/PR-low was defined as an expression of estrogen or progesterone receptors ≤ 10% by immunohistochemistry (IHC). Both Carboplatin (AUC 2) and Nab-paclitaxel (125 mg/m2) were administered on days 1 and 8 every 21 days. Anthracyclines (Doxorubicin or Liposomal Doxorubicin) were administered every 2 or 3 weeks, at the physician's discretion. Pembrolizumab 200 mg was administered every 21 days concomitantly with chemotherapy. The response to NA was classified according to the residual cancer burden (RCB). pCR was defined as ypT0/is/ypN0. Cox's stratified proportional hazard model was used for event free survival analysis. Event free survival was define disease progression that prevented definitive surgery, local or distant recurrence or death from any cause.

Results: A total of 103 patients were included in the analysis. The median age at diagnosis was 53.1 years. The baseline caracteristhics of the patiens are in table 1. Regarding the systemic treatment, 91.2% of the patients were treated with anthracyclines sequentially and in 23% of these (n=30) a liposomal formulation was used. Dose-dense anthracyclines were used in the 23.7% of patients. Concomitant pembrolizumab was used in 27.1%(n=28) of the patients, 60.7% (n=17) of these were stage III at diagnosis. Only one patient did not undergo surgery due to intra-treatment systemic progression. The pCR rate (RCB-0) in the total population was 54.3%. Patients with residual disease after NA (n=47) were classified as RCB-I (17.4%), RCB-II (18.4%) and RCB-III (8.7%). The pCR rates according to different features is reported in Table1. The germline mutation carriers in HRD genes (n=14) obtained a pCR rate of 71,4%. In patients with concomitant use of pembrolizumab, the pCR rate was 60.7%. The pCR rate in TNBC and ER/PR-low groups were 54.2% and 55% respectively. The median follow-up time was 27.7 months. Tha hazard ratio for event of progression between pCR vs residual disease groups was 0.21, 95%CI: 0.06 to 0.76; (p=0.018), with 3 events in the RCB-0 group (n=53) and 12 events in the residual disease group (n=47).

Conclusion: In the real world setting, the use of carboplatin-nabpaclitaxel plus other combinations, such as anthracyclines and immunotherapy obtain a higher rate of pathological complete response translating to improvements in long term outcomes.

P5-09-17: Patterns and Predictors of Recurrence After Neoadjuvant Chemo-Immunotherapy in Early-Stage Triple-Negative Breast Cancer

Lauren Perry, Varadan Sevilimedu, Natalia Polidorio, Marisa Lazarus, Giacomo Montagna, Nour Abuhadra, Ellen Yang, Rachel Han, Hannah Y. Wen, Lior Braunstein, Monica Morrow, George Plitas, Stephanie Downs-Canner

Background: Adding pembrolizumab to neoadjuvant chemotherapy (NAC+P) for stage II-III triple-negative breast cancer (TNBC) improves pathologic complete response (pCR) rates and event-free survival compared to neoadjuvant chemotherapy (NAC) alone. Recurrence patterns and factors associated with disease-free survival (DFS) in a real-world cohort are not known. We compared recurrence rates and assessed factors associated with DFS in patients receiving NAC+P versus NAC for early-stage TNBC.
Methods: This retrospective analysis compared two consecutive cohorts of patients with stage II-III TNBC: 344 treated with NAC+P from 6/1/21-4/30/24 based on the KEYNOTE-522 regimen and 513 treated with NAC from 7/1/09-3/15/19. Demographic, clinicopathologic characteristics, and recurrence data were collected. Tumor infiltrating lymphocytes (TILs) were scored on pre-treatment core needle biopsy for NAC+P only. Primary outcomes were local recurrence (LR), locoregional recurrence (LRR), and distant recurrence (DR). Secondary outcomes were DFS and factors associated with DFS. Kaplan-Meier time-to-event analyses assessed for DFS. Univariate and multivariable Cox regression models assessed for factors associated with DFS.
Results: In the NAC+P group, most patients presented with cT2 (70%), cN0 (53%) disease at a median age of 52 years (IQR 41, 62). In the NAC group, most presented with cT2 (48%) or cT3/4 (28%), cN1 (52%) disease at a median age of 51 years (IQR 41, 60). Rates of breast, nodal, and overall pCR (58% vs 36%, p<0.001) were higher with NAC+P. At 1-year, crude LR rates were not different between NAC+P and NAC: 2.3% vs 4.3%, p=0.13. However, 1-year LRR and DR rates were lower with NAC+P: LRR (0.6% vs 4%, p=0.01) and DR (8% vs 12%, p=0.03). Thirty-one NAC+P patients had DR. The most common sites of first progression were liver (29%), lung (29%), or brain (26%). Among 121 NAC patients with DR, the most common sites of first progression were multiorgan (50%), lung (19%), or liver (12%). Of 61 patients with multiorgan DR, 36 (59%) had brain metastases.
At a median follow-up of 1.2 years (IQR 0.8, 1.6), the 1-year disease recurrence rate for NAC+P was 10% (95% CI: 6%-13%). With a median follow-up of 6 years (IQR 3.3, 7.7), the 5-year disease recurrence rate for NAC was 24% (95% CI: 20%-28%). Factors associated with worse DFS for NAC+P included extreme breast density (HR 3.78, p=0.004) and cN1 disease (HR 2.68, p=0.04). On univariate analysis only, cN2/3 disease and comprehensive RT were associated with worse DFS, while lower cT stage, immune-related adverse events, breast pCR, nodal pCR, and overall pCR were associated with improved DFS. Using a 10% cutoff, stromal TILs on pre-treatment core needle biopsy were not associated with DFS. Factors associated with improved DFS for NAC were cT2 vs cT3/T4 (HR 0.56, p=0.01), ACT-based regimen (HR 0.61, p=0.02), and overall pCR (HR 0.32, p<0.001), while lymphovascular invasion on biopsy (HR 2.1, p<0.001) was associated with worse DFS. Univariate associations for worse DFS included cN1 and cN2/3 disease.

Conclusions: Compared to NAC, NAC+P resulted in improved crude 1-year rates of LRR and DR, along with numerical improvements in DFS with shorter follow-up. Factors associated with DFS (including pCR) were not similar across cohorts and isolated brain metastases as a site of first progression were more common in patients treated with NAC+P who developed DR.

P5-09-18: Real-World Analysis of Patients with Triple-Negative Breast Cancer and Germline BRCA Mutation Undergoing Neoadjuvant Treatment Following the Keynote 522 Protocol

Monique Tavares, Flavia Cavalcanti Balint, Isadora Martins De Sousa, Ana Carolina Marin Comini, Marcelle Goldner Cesca, Leonardo Gil Santana, Debora Guilherme De Albuquereque E Rodrigues De Sousa, Felicia Peterson Cavalher, Luciana De Moura Leite, Solange Moraes Sanches, Vladmir Claudio Cordeiro De Lima

Background: Triple-negative breast cancer is the most immunogenic and the most prevalent among patients with germline BRCA1/2 (gBRCA) mutations. Regardless of the mutation, the current treatment for initial localized triple-negative breast cancer is based on chemotherapy combined with pembrolizumab, following the KEYNOTE 522 protocol.
Methods: We collected data from patients diagnosed with stage II or III triple-negative breast cancer who were treated according to the KEYNOTE 522 protocol at A. C. Camargo Cancer Center, Brazil, from January 2022 to December 2023. We identified patients with gBRCA mutation and analyzed their clinical, pathological, and treatment characteristics and outcomes, comparing them with the general population.
Results: We analyzed 118 patients, of which 19 (16%) had a gBRCA mutation, 90% gBRCA1 and 10% gBRCA2. The average age of patients was 40 years versus 43 years in the cohort without BRCA1/2 mutations. Additionally, we observed differences in menopausal status (pre-menopausal 84% vs. 55%), histological grade 3 (HG3) (84% vs. 78%), HER2-low rate (62% vs. 15%), KI67 >20% (100% vs. 94%) between patients with and without gBRCA mutation. Average BMI (28 kg/m^2 vs. 26 kg/m^2) and obesity frequency (21% vs. 26%) were similar in the two subgroups. According to the stage, there was no difference in T stage, N stage, or grouped clinical staging. Regarding the treatment regimen, 13 (70%) received neoadjuvant ACdd, compared to the cohort of non-gBRCA mutated patients 65 (53%). Pathological complete response (RCB-0) was 58% vs. 62%. There was a higher incidence of reported adverse events in patients with gBRCA1/2 mutation (68% vs. 52%), but hospitalization rates were the same.
Conclusion: The cohort of patients with gBRCA consists of slightly younger patients with a higher percentage of pre-menopausal status and with high BMI. They have a higher likelihood of high-grade HG3 tumors, KI67 > 20%, and HER2-low tumors larger tumors T3/T4, and stage III. Interestingly, the likelihood of achieving pathological complete response (RCB-0) was lower in patients with gBRCA, and they had a higher rate of adverse effects.

P5-09-19: Survival outcomes of carboplatin plus taxanes neoadjuvant chemotherapy in triple negative breast cancer and cell-free DNA whole methylome based biomarker analysis: A prospective multi-center cohort study

Xi Chen, Meng Xiu, Hua Kang, Yan Zhang, Hua Yang, Qiao Li, Qing Li, Xueyan Cheng, Jiayu Wang, Ying Fan, Bo Lan, Bin Hua, Min Xiao, Xiaoyan Qian, Xiang Wang, Binghe Xu, Pin Zhang

Background: The survival outcomes of carboplatin plus taxane neoadjuvant chemotherapy(NAC) in triple negative breast cancer(TNBC) was lack of a large-sample study. The predictive biomarker of efficacy based on cell-free DNA (cfDNA) whole-methylome sequencing (WMS) has not been reported yet.

Methods: The prospective multi-center cohort study was conducted in four hospitals of China between 2016 and 2023. Stage II-III TNBC patients were enrolled to receive NAC of carboplatin (AUC 5) every 3 weeks or carboplatin (AUC 4) every 2 weeks plus taxane(standard dose) for 4-6 cycles. Plasma samples were prospectively collected at baseline(T1) and end of NAC (T2). Chromosomal aneuploidy of featured fragments (CAFF), fragment size index (FSI) and methylation density score (MD) of cfDNA were detected with WMS. The primary endpoint were relapse-free survival (RFS) and exploratory biomarker analysis.

Result: A total of 267 patients were included in the study. The median age was 49 years, 156 patients (58.4%) were stage III disease. cT3-T4 were 28.1% (75/267), cN3 were 17.2% (46/267). 40.3% patients (106/263) achieved pathologic complete response (pCR). The 3-year RFS and overall survival (OS) were 77.9%, 87.6%, respectively. Patients who achieved pCR had a significant better RFS(95.5%) and OS(97.7%) than those non-pCR (68.5%, 81.2%, all $P < 0.001$). Survival of patients with minimal residual disease (ypT1mi/1a/1b N0) are comparable to those pCR, 3-year RFS and OS were 80.2% vs 92.3%(Log-rank P=0.060), 90.5% vs 97.4% (Log-rank P=0.247), respectively, after excluding cN3 patients. Patients with residual node number >2 had a poor 3-year RFS and OS compared to number≤2(All Log-rank $P < 0.0001$). A total of 66 patients with 120 plasma samples (64 samples at T1, 56 samples at T2) were included in WMS analysis. Patients with CAFF, FSI or MD positive at T1 had a higher tumor burden (stage III or cN2-3, all P values <0.05). The proportion of patients with FSI negative at T2 was significantly higher in pCR group compared to non-pCR(86.2% vs 59.3%,P=0.034). Similar tendency were observed in patients with CAFF negative. A linear SVM model was developed to predict pCR with an AUC of 0.90 in the training datase and an AUC of 0.86 in the testing dataset. Moreover, patients with MD positive at T1 was significantly associated with poor RFS compared to MD negative (HR = 7.36, Log-rank P=0.028).
Conclusion: Our large-sample study further confirmed that carboplatin plus taxanes as NAC in TNBC was a preferred regimen with the comparable survival outcome, especially for

patients who cannot tolerate anthracyclines or immunotherapy. Biomarkers based on cfDNA WMS may provide predictive and prognostic information, warranting further investigation.

P5-09-20: The impact of HER2 expression in early-stage triple negative breast cancer

Hadar Goldvaser, Eliahu Golomb, Neora cohen, Yaheli Miller, Ora Rosengarten, Daniella Katz, Areen Abu Remeilh, Shai Breuer, Adi Moran

Background: Whether the expression of human epidermal growth factor receptor 2 (HER2) has an impact on the clinical-pathological characteristics and on outcomes in early-stage, triple negative breast cancer is unknown.
Methods: A single center, retrospective cohort study comprising all patients diagnosed with early-stage triple negative breast cancer between 2012-2022. Data on clinicopathological characteristics and outcomes, including disease free survival (DFS) and overall survival (OS), were extracted. Data on systemic therapy, pathological response in patients who were treated with neoadjuvant chemotherapy and type of surgery were also extracted. Differences between patients with HER2-low (defined as HER2 immunohistochemical staining of +1 or +2, FISH negative) to HER2-0 (defined as no staining for HER2) were evaluated.
Results: After exclusion 41 patients whose intensity of HER2 expression was not reported explicitly, 93 patients were included in the final analysis: 56 patients with HER2-0 disease and 37 patients with HER2-low disease. Median age was 50, 41% were BRCA carriers, 56% presented with clinical T1, 48% had clinical node positive disease, 85% had grade 3 disease, 38% had presence of lymphovascular invasion and 91% had ductal carcinoma. Age, BRCA status, and clinico-pathological characteristics were comparable between the groups. Neoadjuvant chemotherapy was given to 57%, adjuvant chemotherapy to 33% and 10% did not receive chemotherapy. Complete pathological response was achieved by 64% of the patients who were treated with neoadjuvant chemotherapy. 60% underwent lumpectomy, 40% underwent mastectomy and 28% completed axillary lymph node dissection. HER2 expression was not associated with systemic therapy, the response to neoadjuvant chemotherapy and type of surgery. There was also no difference in clinical outcomes, with 3-year OS rate of 86.1% and 89.1% for HER2-low and HER2-0, respectively ($p = 0.933$) and 3-year DFS rate of 82.8% and 79.5% for HER2-low and HER2-0, respectively ($p = 0.620$).
Conclusions: In this early-stage, triple negative cohort there were no differences between HER2-low to HER2-0 with respect to clinic-pathological characteristics, treatment approach and outcomes. More research is warranted to further investigate the impact of HER2 expression and to identify whether treatment approach should be tailored based on HER2 expression in early-stage triple negative disease.

P5-09-21: Hidden Challenge: Atypical Ductal Hyperplasia in Vulvar Ectopic Breast Tissue

Yolcar Chamorro, Niloofar Nassseri-Nik, Ana C. Sandoval-Leon

Introduction: Breast tissue develops during embryogenesis along the milk line, extending from the axilla to the perineum. Although rare, ectopic breast tissue (EBT) can persist anywhere along this line, most commonly the axilla. Similar to breast tissue, EBT is influenced by hormonal changes. Benign tumors, particularly fibroadenomas, are the most frequent pathology associated with EBT. Breast cancer (BC) in EBT is uncommon (0.3%-0.6% incidence), mostly affecting axillary EBT. Diagnosis is challenging due to varied differential diagnoses, including skin pathologies. Atypical ductal hyperplasia (ADH) is noncancerous but is classified as a high-risk lesion due to its association with a fivefold increase in BC risk. To our knowledge, ADH of ectopic breast tissue in the vulva has not been previously described in the literature.

Case presentation: A 63-year-old postmenopausal woman had a lump in her labia for several years. She had past medical history of endometrial polyps and family history of breast cancer in her mother and in her sister. Upon physical exam, she had a 5mm cystic lesion in the right labia majora. She was evaluated by her gynecologist for endometrial polyps, and she asked to remove the vulvar cystic lesion during the procedure. Pathology of the cystic vulvar lesion revealed EBT with foci of ADH. The mass was immunoreactive for GATA3, estrogen receptors, and progesterone receptors. Myoepithelial cells were identified via p63/SMM staining. The diagnosis of ADH was supported by the pattern of staining for CK5 and estrogen receptors. A stain for PAX8 and ERG was negative. The mass incompletely excised and additional surgery was recommended. Upon re-excision, no residual ADH or EBT were seen.
Due to these findings, she was referred to the Breast Cancer Prevention Clinic. The decision was to have updated breast imaging with a mammogram that showed that the breasts were almost entirely fat and no lesions were seen. We also recommended a breast MRI that was also negative. Due to her family history, she had genetic testing that was negative. Her lifetime risk of developing BC was calculated using the Tyrer-Cuzick model and it was less than 20%. For this reason, she was not recommended to have additional breast MRIs. Chemoprevention was discussed with the patient and was not recommended.

Discussion: Ectopic mammary tissue found along the embryonic milk lines is rare. It occurs in 0.22%-6% of women most commonly found in the axilla with less frequent occurrences in the vulva. Variability in presentation depends on the degree of breast tissue development along the milk line. Diagnosis requires histological examination, as these tissues may be mistaken for lipomas or malignant lesions. In our case, immunoreactivity for GATA3, estrogen, and progesterone receptors confirmed breast tissue origin, while negative PAX8 and ERG stains ruled out Müllerian and vascular neoplasms, respectively. The etiology of ADH within ectopic tissue remains unclear. There are currently no established guidelines on

how to screen, treat, or follow-up patients with atypical lesions in ectopic breast tissue. Our treatment approach was excision of the ADH and EBT, which aligns with the standard of care for ADH in the breast. Since patients with ectopic breast tissue were not included in the chemoprevention trials, we do not recommend chemoprevention in these patients.

Conclusion: This case underscores the importance of considering ectopic mammary tissue in vulvar masses and highlights the need for further research to establish management guidelines. Additionally, this report illustrates the value of histological and clinical correlation in indeterminate tumors that are along the mammary line.

P5-09-23: Programmed death-ligand 1 expression in a Mexican cohort of triple-negative breast cancer

Alejandro Aranda-Gutierrez, Cynthia Villarreal-Garza, César Octavio Lara-Torres, J. Edgardo Hernandez, Daniela Vázquez Juárez, Gabriela Sofía Gómez-Macías, Alejandro Aranda-Gutierrez, Paula Anel Cabrera-Galeana, Fany Iris Porras-Reyes, Víctor Manuel Pérez-Sánchez, Antonio Nateras-Pérez, Alejandro Mohar

Programmed death-ligand 1 (PD-L1) expression predicts response to immunotherapy in a range of malignancies, including triple-negative breast cancer (TNBC). However, observational studies show a significant variability in the rates of PD-L1 positivity in TNBC. Currently, PD-L1 expression rates remains unknown in the Mexican population.
A retrospective multicenter study of women with newly diagnosed TNBC between 2006 and 2021 was carried out. PD-L1 was assessed at a central laboratory using the IHC 22C3 assay. Expression was characterized according to the combined positive score (CPS), with positivity defined as >1%. Descriptive statistics were employed to calculate means, percentages, and standard deviations.
Among 298 cases with available tissue for analysis, 285 (96%) samples had sufficient cellularity for adequate CPS evaluation. In the entire cohort, the PD-L1 positivity rate was 29.1%, while 13.3% had a CPS >10%. The prevalence of PD-L1 positivity differed significantly according to histological grade, percentage of tumor-infiltrating lymphocytes, and the tissue type analyzed.
The majority of CPS evaluations were performed on tissue from biopsies of the primary tumor, which can underestimate PD-L1 positivity by 20-30% when compared to matched surgical specimens. Furthermore, biopsies from metastatic sites were not analyzed for PD-L1 expression, which can impact overall CPS positivity rates. Our data underscore the importance of considering the source of the tissue sample when interpreting PD-L1, as different types and sites of biopsy may yield different expressions.

P5-09-24: Neoadjuvant (NA) immunotherapy (IO) combined with chemotherapy in triple negative breast cancer (TNBC): A UK real world experience from three centres.

Hossameldin Abdallah, Bahaaeldin Baraka, Mai Attia, Ahmed Elhofy, Tasmia Syeda, Samreen Ahmed, Zina Aladili, Sarah Khan, Olubukola Ayodele

Background: The KEYNOTE (KN)-522 study, a practice-changing phase III trial, demonstrated improved outcomes with the addition of pembrolizumab (P) to Paclitaxel (T) & Carboplatin (C) then to Epirubacin (E) & Cyclophosphamide (Cy) in high-risk early-stage TNBC. While highly effective with unprecedented pathologic complete response (pCR) rates and clinically meaningful improvements in event-free survival, it comes with significant high-grade treatment-related toxicity.

Methods: This is a retrospective, multicentre, longitudinal cohort study. Data on 92 patients (pts) who received the treatment from December 2022 to November 2023 were analysed focusing on efficacy and toxicities. In this analysis, pCR is defined as no invasive residual in the breast or nodes (i.e ypT0/is ypN0). Statistical analysis was done using SPSS program.

Results: The cohort median age was 52 years (26-80) with majority (74%, n=68) of Caucasian ethnicity. Invasive ductal carcinoma (IDC) was the predominant histology (97%, n=89). Grade (G) 2 and G3 documented in 35% (n=32) and 65% (n=60) respectively. HER-2 low (1+ or 2+/in situ hybridization (ISH) negative phenotype) was noted in 39% (n=36) of pts.

All pts received first block of the treatment (P/T/C), with only 89% (n=82) completed four cycles. While 78% (n=72) who started second block (P/E/Cy), only 57% (n=52) completed the whole NA treatment. Reasons for non-completion varied, including intolerance (n=22, 24%), excellent response (n=8, 9%), local progression (n=2, 2.2%), patient choice (n=4, 4.3%) and other causes (n=4, 4.3%).

pCR was achieved in 53% (n=49) of the pts. No residual in the axillary nodes (ypN0) were observed in 76.1% (n=70).

Among the adverse events observed, neutropenia was the most common, affecting 89.1% (n=82 pts), with 43.3% (n=40 pts) experienceing severe grade (G) 3/4. Anaemia was also prevalent, occuring in 85.9% (n= 79 pts) but only 10.9% (n=10 pts) were severe (G 3/4). Other notable adverse events include fatigue (75%, n=69 pts), transaminitis (45.6%, n=42 pts) and low platelets (34.8%, n=32 pts) with severe G 3/4 represent 1.1% (n=1 pt), 6.5% (n=6 pts) and 2.2% (n= 2 pts) respectively. Less frequent adverse events were adrenal insufficiency (8.7%, n=8 pts), hypothyroidism (20.7%, n=19 pts), and rash (19.6%, n=18 pts), with minimal severe cases reported.

About 32% (n=29) of pts were admitted to the hospital during the treatment (average 2

times) with median length of stay of 3 days (1-45). Infection (including neutropenic sepsis) was the most documented diagnosis in 16 (4) occasions.

Conclusion: In comparison to KN-522, a lower pCR rate was observed in our cohort of pts with a higher haematological toxicities. Small sample size and retrospective analysis are the limiting factors.

P5-09-25: Immunotherapy in Neoadjuvant Treatment of triple-negative breast cancer: First Insights and Treatment Monitoring with MRI - Single Institution Retrospective Analysis

Bibiana Vertakova Krakovska, Lucia Vanovcanova

Background: Neoadjuvant immunochemotherapy represents an essential tool for the treatment of triple-negative breast cancer (TNBC). This approach has resulted in increased rates of pathologic complete response (pCR) compared to chemotherapy alone, however, with numerous serious side effects. Factors influencing the response to this regimen remain poorly characterized. There is a lack of accurate imaging tools to monitor early response to immune checkpoint inhibitor (ICI) therapy to help tailor the following therapeutic strategies for patients without response and avoid the toxicity associated with ineffective treatment.
Methods: In Slovakia, full access to pembrolizumab for the therapy of TNBC started on April 1, 2024. From September 2023 to June 2024, 14 patients (median age 47) with TNBC received neoadjuvant chemotherapy (NACT) and immunotherapy (pembrolizumab) according to the Keynote-522 study regimen. Eight patients (57.1%) received NACT with pembrolizumab initially, while 6 (42.9%) received it sequentially due to local reimbursement rules. Biopsies revealed 13 invasive ductal carcinomas and one invasive lobular carcinoma, all with high Ki-67 expression (median 55%). Tumor-infiltrating lymphocyte (TIL) levels were examined in 10 patients (2 with <30%, 4 with 30-40%, and 4 with >40%). MRI scans were performed before the first cycle of NACT alone or with pembrolizumab. Interim MRIs were conducted after 1., 2, or 3. cycle of pembrolizumab. The following parameters were recorded and assessed: tumor response (according to iRECIST), lymph node (LN) response (axillary ipsilateral/contralateral, internal mammary, intramammary), among other changes.
Results: Tumor responses were as follows: radiologic complete response (rCR) as well as radiologic partial response (rPR) in 6 patients (42.86%), radiologic non-response (rNR) and pseudoprogression in one patient (7.14%). LN responses showed an enlargement in 9 patients (64.29%): axillary ipsilateral in 4, bilateral in 2, contralateral in 1, and internal mammary in 2 patients. One patient exhibited axillary and intramammary LN enlargement, while another with inflammatory carcinoma also showed progression of skin oedema.
Conclusions: Breast MRI is a powerful tool to monitor tumour response to ICI, although it brings several associated challenges. Though relatively rare in breast cancer compared to melanoma or lung cancer, primary tumour pseudoprogression can occur as a response to

immunotherapy. As evident from our results, ICI's significant impact on LN can confuse the imaging via MRI (e.g., axillary and intramammary lymph nodes). The enlargement of axillary LN imitates the progression of the disease and results in inappropriate restaging, while activated intramammary LN may be incorrectly classified as a satellite lesion. In patients with inflammatory carcinoma, the lymphocyte infiltration of the skin is displayed in MRI as progressive thickening and oedema. Due to the short history of this unique treatment and limited experiences with immunotherapy response presentation in breast MRI, this method may be slightly less reliable. Our results show that MRI has a solid potential to remain the best method for treatment monitoring. However, further research is needed to refine imaging techniques and improve the interpretation of MRI findings.
Keywords: Triple-negative breast cancer, immunotherapy, neoadjuvant treatment, MRI, pathologic complete response, pseudoprogression, lymph nodes.

P5-09-26: KEYNOTE-522 Regimen Outcomes: Real World Experience from a Single Institution with a Predominantly African American Population

Suvarna Guvvala, Anaiya Singh, Sindhu Priya Devarashetty, Gary Von Burton, Runhua Shi

Background and Objectives: High-risk early triple-negative breast cancer is frequently associated with early recurrence and high mortality. [1] In 2020, the Keynote 522 trial changed the way high-risk early triple-negative breast cancer (TNBC) is managed. It showed that the addition of pembrolizumab to neoadjuvant chemotherapy improved the pathological complete response rate (pCR) compared to placebo with neoadjuvant chemotherapy. It has been reported in the literature that TNBC disproportionately affects the Black population in the United States. [2] In the Keynote 522 trial, approximately 4.8% of patients in the pembrolizumab with chemotherapy arm were African Americans (AA). In our institution, most of the patient population are AA or Blacks. Limited data have suggested a pCR rate of around 50% in the AA population. Thus, we conducted a retrospective study in our institution to evaluate the pCR rate in AA female patients who received the Keynote 522 regimen as part of their early breast cancer treatment.

Methods: We conducted a chart review of adult patients (> 18 years) who were diagnosed with TNBC between January 2020 to May 2024 who received the Keynote 522 regimen. We recorded demographic data including age, race, ethnicity, and clinical parameters such as the stage of breast cancer, hormone receptor status, HER2 receptor status, menopausal status, performance status, pCR rates, and complications leading to discontinuation of treatment. Computations were performed using SAS statistical software.

Results: We identified 24 patients with TNBC who received the Keynote 522 regimen during the specified period. Of the 24 patients, 75% were AA and 25% were Caucasian. In our study, 41.6% (two-sided p-value 0.6653) of patients had pCR overall. Specifically, 38.8% of African American patients and 50% of Caucasian patients had pCR. Regarding age, 14% of patients younger than 50 years and 52% of patients older than 50 years had pCR, with a two-sided p-value of 0.1718. All patients had a performance status of 0 or 1. The pCR rate

was 41.67% (two-sided p-value: 1.000) regardless of performance status. All patients had either stage II or III, except one who had stage IV. The pCR rate in stage II patients was 44.44%, and in stage III patients, it was 40%, with a two-sided p-value of 1.000. Only three patients had to discontinue the Keynote 522 regimen due to side effects (hepatitis, dermatitis, sclerodactyly, and hepatitis). No pCR was achieved in the three patients who discontinued Keytruda.

Conclusion: In this real-world analysis at a single institution with a predominantly AA population, total pCR rates were lower (41.6%) compared to the original study (64.8%)3. pCR rates were lower in the African American patient population compared to Caucasians. The results are not statistically significant, which is likely due to the small sample size. The original study included only 4.8% African American patients, and a subset analysis was not performed to evaluate pCR rates in this subgroup. Thus, we conclude that larger studies including more AA patients might be beneficial to evaluate the efficacy of the Keynote 522 regimen in this subset of the population.

P5-09-27: Neoadjuvant versus adjuvant systemic therapy in Stage I triple negative breast cancer - An institutional review

Cydni Rink, Marielle Ferstenberg, Cydni Rink, Yi Xiong, Zhaoqi Zang, Roberto Pili

Background: Most patients with early-stage triple negative breast cancer (TNBC) receive neoadjuvant treatment (NT). With the data from the KEYNOTE-522 most Stage II and III TNBC patients receive NT. However, whether Stage I patients require NT or adjuvant treatment (AT) is debatable. We performed a retrospective analyses of Stage I TNBC who received NT or AT at our institution.

Methods: We reviewed patients >18 years age who were diagnosed with clinical Stage I based on either mammogram or ultrasound (US) histologically proven invasive TNBC from January 1, 2018 until December 31, 2022. All patients must have received at least one cycle of systemic treatment, whether in the NT or AT setting. All patients must have undergone definitive surgical treatment. We analyzed patients till December 31, 2024. We used Kaplan-Meier estimates for overall survival (OS) and progression-free survival (PFS) and Cox-Proportional Hazards Model to assess treatment effect on OS and PFS.

Results: We analyzed 72 patients (52 AT and 20 NT arms) and the patients in the NT arm were much younger than the AT arm (51.4 years vs 65.6 years respectively). Invasive ductal

cancer was the most common histology (94% AT vs 80% in NT arm), while the rest were metaplastic (6% AT vs 20% NT) In the AT arm 9 patients were upstaged after surgery and 50% achieved a pathological complete response (pCR). Comparing AT vs NT, there was no statistically significant improvement in PFS (72.5% vs 73.4% p=0.79) or OS (74% vs 74.5%, p=0.43 However, we found that tumor size is a significant predictor for the risk of recurrence with HR 1.13 (p-value=0.003, 95% CI 1.05-1.22) times higher risk of recurrence when tumor size is more than 10mm, with patients receiving AT doing better.

Conclusion: In Stage I TNBC there is no survival difference between NT or AT treatments. We did notice an improvement in PFS in patients with T1c tumors receiving AT. Prospective trials and trials incorporating immune checkpoint inhibitors can help us answer these questions.

P5-09-28: A phase I, prospective exploratory clinical study of neoadjuvant pyrotinib plus trastuzumab, dalpiciclib, and letrozole for patients with HR-positive, HER2-positive early or locally advanced breast cancer

Guangdong Qiao, Jun Lin, Haidong Zou, Yalun Li, Zhi Liang, Xingmiao Wang, Ge Gao, Kun Zhang, Yeqing Zhou, Yidan Wang, Song Zhang, Feng Li, Xiang Bi, Xiaohui Li, Shengqun Yu, Yansheng Li, Chunxin Qin, Kai Cheng

Background: Triple-positive breast cancer (TPBC) is a breast cancer characterized by positive expression of ER, PR and HER2. The first choice of neoadjuvant treatment is anti-HER2 targeted therapy combined with chemotherapy, and the pCR rate is lower than that of HR-/HER2+ breast cancer. Therefore, it is still necessary to explore new treatment models for TPBC patients.This study aims to explore the efficacy and safety of pyrotinib plus trastuzumab, dalpiciclib, and letrozole as neoadjuvant therapy in patients with TPBC.
Methods: This is a single-arm, open-label study that enrolled breast cancer patients with early or locally advanced TPBC and an ECOG performance status of 0 to 1. After enrollment, patients first received 2 cycles of pyrotinib (320 mg po qd, d1-28) plus trastuzumab (8 mg/kg in the first cycle, 6 mg/kg in the second to eighth cycles, intravenous drip, q3w) , dalpiciclib (150 mg po qd, d1-21, q4w) and letrozole (2.5 mg po qd, q4w) as neoadjuvant therapy, Tumour response was assessed by investigators according to RECIST 1.1 using MRI, If patients achieved a confirmed partial response (PR) after 2 cycles, they would continue to receive an additional 4 cycles until surgery; patients who did not achieve PR were treated with pyrotinib, trastuzumab and chemotherapy selected by the doctor for 4 cycles until surgery.The primary endpoint was the total pathological complete response rate (tpCR: ypT0/is, ypN0), and the secondary endpoints were objective response rate (ORR) and safety. This study is registered with ClinicalTrials.gov (NCT05800756).
Results: From August 2022 to June 2024, 30 patients were assessed for eligibility, Among the 20 patients completed neoadjuvant therapy and surgery, 17 patients (85.00%) were immunohistochemical HER2 3+. Among the 20 patients who completed 6 cycles of

neoadjuvant therapy and underwent surgery, the overall response rate (ORR) was 100% (20/20). Postoperative MP grading evaluation: tpCR and bpCR were both 20% (4/20), the complete remission rate of positive lymph nodes was 13/19 (68.42%); RCB (0-I) patients were 7/20 (35.00%). The breast conservation rate was 30.00% (6/20), and the sentinel lymph node biopsy rate for downstaging was 35.71% (5/14). Compared with before neoadjuvant therapy, the Ki67 positive rate was reduced after neoadjuvant therapy (41.67±18.48% vs 19.67±21.89%, p=0.003). The most common adverse events were diarrhea, oral mucositis, and decreased neutrophil counts, with diarrhea occurring in 95.00% (19/20), 10 patients (50%) with grade ≥3, and no grade 4 or higher adverse events. Conclusion: Pyrotinib plus trastuzumab, dalpiciclib, and letrozole as neoadjuvant therapy in patients with early or locally advanced TPBC has a high ORR rate, which is conducive to downstaging surgery and breast conservation, and a high complete remission rate of positive lymph nodes, which is conducive to downstaging sentinel lymph node biopsy to preserve axillary function.In conclusion, the combination of pyrotinib plus trastuzumab, dalpiciclib, and letrozole has demonstrated good efficacy and safety, which may be an alternative option instead of neoadjuvant chemotherapy for patients with early or locally advanced TPBC.

P5-09-29: Trastuzumab Combined with Pyrotinib and Capecitabine as Postoperative Adjuvant Therapy in Non-Pathological Complete Response HER2-Positive Early Breast Cancer Following Neoadjuvant Therapy: A Multicenter Phase II Study

Chuan Wang, Fangmeng Fu, Shunguo Lin, Zhenchuan Song, Zhong Ouyang, Xiangjin Chen, Mengbo Lin, Guozhong Cui, Guohui Han, Wenhui Guo, Xia Chen, Lining Jia, Chuangui Song, Sumei Yang, Ruizhen Luo, Yu Yan, Yi Zeng, Debo Chen, Jianqing Lin, Fan Yang, Ruixue Huang, Yili Wang, Zhechao Zeng, Zhe Zhang

Background: HER2-positive early breast cancer patients achieving a pathological complete response (pCR) during neoadjuvant therapy demonstrate a more favorable prognosis. The KATHERINE study indicated that for HER2-positive early breast cancer patients who did not achieve pCR (residual tumor lesions present) after neoadjuvant therapy, the administration of TDM-1 during postoperative adjuvant therapy significantly reduces the risk of disease recurrence compared to trastuzumab. This study aims to evaluate the efficacy and safety of trastuzumab in combination with pyrotinib and capecitabine in HER2-positive early breast cancer patients who did not achieve pCR following neoadjuvant therapy.

Methods: This single-arm, open-label, multicenter study enrolled patients with HER2-positive early breast cancer who did not achieve pCR (defined as residual invasive tumor >1 cm or lymph node metastasis) following neoadjuvant therapy. Eligible patients received trastuzumab (initial loading dose of 8 mg/kg followed by 6 mg/kg every three weeks for one year, encompassing both neoadjuvant and adjuvant settings), pyrotinib (400 mg/day

for one year post-surgery), and capecitabine (1000 mg/m^2 twice daily for six 3-week cycles, with continuation at the investigator's discretion beyond six cycles). Primary prophylaxis with loperamide was administered to mitigate pyrotinib-induced diarrhea. The primary endpoint was 3-year invasive disease-free survival (iDFS), with secondary endpoints including distant disease-free survival (DDFS), overall survival, and safety. This study is registered with ClinicalTrials.gov (identifier NCT05292742).

Results: From July 2021 to November 2023, a total of 102 patients were enrolled, all of whom did not achieve pCR following neoadjuvant therapy. As of May 31, 2024, with a median follow-up of 11.96 months, 8 iDFS events (all local recurrences or bone metastases, without distant metastases) and 4 DDFS events were reported. Regarding safety, 22 patients (21.6%) experienced grade ≥3 adverse events, with the most common being diarrhea (13.7%), white blood cell count decreased (2.0%), and hand-foot syndrome (1.0%). Adverse events led to the interruption of any agent in 66 patients (64.7%), discontinuation of any agent in 8 patients (7.8%), and dose reduction of any agent in 37 patients (36.3%).

Conclusions: For patients with HER2-positive early breast cancer who did not achieve pCR (residual invasive tumor >1 cm or lymph node metastasis) following neoadjuvant therapy, the combination of pyrotinib, trastuzumab, and capecitabine as postoperative adjuvant therapy appears to improve prognosis. The overall safety profile of the regimen was acceptable, with no new safety signals identified. Primary prophylaxis with loperamide effectively reduced the incidence of grade ≥3 diarrhea during adjuvant therapy with pyrotinib.

P5-10-01: Demographic, Clinical Characteristics, and Overall Survival of Patients with Metastatic Breast Cancer and Brain Metastases: A Single Center Retrospective Cohort Study

Laura A. Huppert, Kelsey Kuwahara, Maggie Zhou, Mia Salans, Samantha Fisch, Jo Chien, Melanie Majure, Hope Rugo, Lauren Boreta, Steve E. Braunstein, Ramin A. Morshed, Harish N. Vasudevan, Michelle E. Melisko

Background: Approximately 30% of patients with metastatic breast cancer (MBC) develop brain metastases (BM). It is critical to better understand the risk factors, natural history, and treatment outcomes, including patients in a modern cohort.
Methods: In this single center retrospective cohort study, we identified patients with MBC and BM diagnosed between 1997-2024. Review of medical records and institutional cancer registry were completed to identify key demographic and clinical characteristics, treatment history, and real-world overall survival (rwOS).
Results: We identified 484 patients with MBC and BM. Most patients were female (n=481, 99.4%) with a median age of 47.4 years (range 25-92 years) at the time of MBC diagnosis. Most patients had ductal histology (n=391, 81.0%). Patients had the following breast cancer

subtypes: HR+/HER2- (n=187, 38.6%), HER2+ (n=182, 37.6%), and triple negative breast cancer (TNBC; n=115, 23.8%). Median time from diagnosis of MBC to first BM was 8.1 months (range 0-177.1 months) and varied by MBC subtype, with longer median time for patients with HR+/HER2- (16.2 months) than for patients with HER2+ (8.1 months) or TNBC (2.1 months) ($p<0.01$). Patients had the following number of BMs at initial BM diagnosis: 1 BM (n=129, 26.7%), 2-5 BMs (n=183, 37.8%), 5-10 BMs (n=42, 8.7%), and >10 BMs (n=84, 17.4%). 18.6% of patients (n=90) developed leptomeningeal disease (LMD) in addition to BMs; median time from first BM to LMD was 6.6 months (range 0-61.7 months). After BM diagnosis, most patients received central nervous system-directed locoregional therapy (n=474, 99.1%), including BM surgical resection (n=119, 23.7%), stereotactic radiation therapy (n=401, 82.7%), and/or whole brain radiation therapy (n=218, 46.0%). Patients received a median of four lines of systemic therapy for MBC (range 1-13; HR+/HER2- median 5, HER2+ and TNBC median 3).
Among all patients, median rwOS from the diagnosis of first BM to death was 21.7 months (range 0.2-224.9 months) with the longest median rwOS in patients with HER2+ disease (median 30.9 months) vs. patients with HR+/HER2- (median 19.6 months) or TNBC (13.3 months) ($p<0.01$). By date of BM diagnosis 1997-2014 vs. 2015-2024 (divided by ~50% of patients in each time period), patients with HER2+ and TNBC lived longer in the more modern cohort compared to prior years (HER2+: 41.2 vs. 26.5 months, $p<0.001$; TNBC 16.2 vs. 9.0 months, $p=0.03$); there was no statistically significant difference for patients with HR+/HER2- disease (18.2 vs. 20.4 months, $p=0.37$). Patients with both BM and LMD had a shorter median rwOS from time of first BM compared to patients with BM only (18.5 vs. 21.6 months, $p=0.048$). Median rwOS was similar in patients with ductal vs. lobular histology (21.9 months vs. 21.5 months, $p=0.98$). On multivariable analysis, HER2+ disease (HR 0.63, 95% CI 0.48-0.84, $p=0.002$), stereotactic radiation therapy (HR 0.55, 95% CI 0.40-0.75, $p<0.001$), and/or BM surgical resection (HR 0.51, 95% CI 0.38-0.70, $p<0.001$) were associated with longer survival and having 6-10 brain metastases at baseline (HR 1.94, 1.22-3.09, $p=0.01$) was associated with shorter survival.
Conclusion: In a cohort of nearly 500 patients with MBC and BM spanning >25 years, median rwOS from the diagnosis of first BM to death was 21.7 months. Patients with HER2+ disease and those who underwent BM resection and/or SRS had an improved prognosis, and patients with a greater number of BMs had a worse prognosis. Patients with HER2+ and TNBC lived longer from the time of first BM to death in a more modern cohort compared to prior years. In contrast, there was no statistically significant difference in rwOS in patients with HR+/HER2- BMs over time, suggesting that this is an area of ongoing unmet clinical need.

P5-10-03: Impact of gBRCA1/2 Status on Survival Outcomes in Metastatic Breast Cancer Patients Treated with Topoisomerase 1 based Antibody-Drug Conjugates (ADCs)

Akshara Singareeka Raghavendra, Zhongya Wang, Roland Bassett Jr, Debu Tripathy, Banu Arun, Senthil Damodaran

Background: ADCs combine the tumor specificity of monoclonal antibodies with the cytotoxic effects of chemotherapeutic drugs, allowing for targeted delivery of potent anticancer agents while minimizing systemic toxicities. Sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd) are antibody drug conjugates with topoisomerase 1 payloads targeting TROP2 and HER2, respectively. Defects in homologous recombination repair through gBRCA1/2 alterations have been postulated as a potential biomarker of response to DNA damaging agents such as topoisomerase I inhibitors. Consequently, we sought to assess the impact of gBRCA1/2 status and clinical outcomes in metastatic breast cancer patients treated with SG or T-DXd.
Methods: We estimated the distribution of progression-free survival (PFS) and overall survival (OS) using the Kaplan-Meier method. Differences in survival curves between gBRCA-positive and BRCA-negative patients were assessed using the log-rank test. Cox proportional hazards regression models were employed to evaluate the association between each survival outcome and BRCA status, and Fisher exact test was used to assess the association with the clinical benefit rate (CBR).
Results: The analysis included a total of 322 breast cancer patients treated with SG or T-DXd with a median follow-up time 30.1 months (Range: 0.5 – 299 months). Of these, 49 (15%) were gBRCA positive (gBRCA1 n=27 and gBRCA2 n=22). gBRCA1/2-positive patients were more likely to be younger, with 43% aged 18-40 compared to 22% in BRCA-negative patients. The median age at the start of either ADC was 49 years (range: 20-83). gBRCA-positive patients had received more prior lines of treatment, with 49% having three or more prior treatments compared to 40% of BRCA-negative patients. Out of the gBRCA1/2 positive patients, 39(80%) received PARP inhibitors, with 15(31%) of them receiving it as first-line treatment.53% of gBRCA-positive patients received SG, while 47% received T-DXd, similar to the BRCA-negative group (56% and 44%, respectively). 45% of BRCA-positive patients had hormone receptor (HR) positive cancers compared to 37% of BRCA-negative patients, and 88% of gBRCA-positive patients had HER2 negative cancers compared to 77% of BRCA-negative patients. Among the gBRCA-positive cohort, 51% had died by the last follow-up compared to 34% of BRCA-negative patients. Additionally, 80% of gBRCA-positive patients experienced disease progression or death, compared to 72% of BRCA-negative patients. The median PFS was 3.9 months (95% CI: 2.9-6.4 months) in gBRCA1/2 positive compared to 5.6 months (95% CI: 5.1-6.7 months) (hazard ratio 1.48 (1.05 – 2.10), p = 0.025) in BRCA1/2 negative patients. Median OS was 64.5 months (95% CI: 39.8 – Not estimable) in gBRCA positive patients compared to 71.4 months (range 63.5 – 99.6 months) in BRCA1/2 negative patients (HR 1.39 (0.89 – 2.16), p = 0.15). No statistically significant difference in CBR was noted between gBRCA positive and negative patients (p = 0.23).
Conclusions: There is very limited data describing the survival outcomes of BRCA-tested patients receiving topoisomerase based ADCs. In our study, significant difference in PFS, favoring BRCA1/2 negative patients was noted compared to gBRCA1/2 positive patients treated with SG or T-DXd; while no differences in OS and CBR was observed between the two groups. Further study regarding the impact of DNA repair pathway defects and clinical outcomes with DNA damaging agents are warranted.

P5-10-04: Trimodal Therapy is Associated with Higher Overall Survival than Chemotherapy only in Patients with Metastatic Inflammatory Breast Cancer

Eric Schupp, Yevgeniya Goukun, Jacob Eckstein, Daniel Stover, Sachin Jhawar, Dionisia Quiroga, Margaret Gatti-Mays, Mathew Cherian, Min-Jeong Cho, Kai Johnson, Heather LeFebvre, JC Chen, Mohamed I Elsaid, Samilia Obeng-Gyasi

Background: Metastatic inflammatory breast cancer (MIBC) is a rare and aggressive breast cancer with poor overall survival. Current standard of care treatment of MIBC consists of systemic therapy only with locoregional therapy to the primary site (surgery and radiation) utilized inconsistently and generally reserved for palliation. The purpose of this study is to examine overall survival (OS) among MIBC patients receiving chemotherapy only versus trimodal therapy in the National Cancer Database (NCDB).
Patients and Methods: All patients diagnosed with MIBC from 2004 to 2021 were identified in the NCDB. The cohort was divided into a chemotherapy only group versus trimodal therapy. Trimodal therapy included chemotherapy, modified radical mastectomy, and radiation therapy. Radiation therapy included radiation to the breast, chest wall, and/or regional lymph nodes. We fitted Overlap Propensity Score Weighting (OPSW) Cox proportional hazard models to account for confounding in the relationship between OS and trimodal therapy status. Variables included in the propensity score model included age, Charlson-Deyo score, molecular subtype, and metastatic site.
Results: A total of 4258 patients with MIBC were included in this study, of whom 1029 (24.17%) underwent trimodal therapy and 3229 (75.83%) received chemotherapy-only. Patients in the trimodal therapy group were younger (median age 54 vs. 59 years old; $p<0.0001$) compared to the chemotherapy-only group. Additionally, a higher percentage of patients in the trimodal therapy group had a Charlson Deyo Score of 0 (87.66% vs 82.25%, p-value<0.0001), held private insurance (58.16% vs 41.64%, p-value<0.0001), had a median income of $74,063 or higher (31.20% vs 27.50%, p-value=0.0109) and had less than 2 metastatic sites (90.43% vs 67.19%). There were no statistically significant differences in cancer subtypes between the treatment groups (p=0.158). On multivariable analysis, patients who underwent trimodal therapy were at 48% lower hazard of mortality compared to those on chemotherapy only (aHR: 0.52, 95% CI: 0.46-0.58, p<0.0001). Moreover, the median OS for those who received trimodal therapy was 49.5 months compared to 21.7 months (p<0.0001) for those who received chemotherapy only.

Conclusions: In this cohort of patients with MIBC in the NCDB, trimodal therapy improves overall survival compared to chemotherapy only. Future prospective studies with patient-reported outcomes are needed to confirm these findings.

P5-10-05: Differences in drug efficacy between primary and metastatic sites and their prognosis for de novo stage IV breast cancer: an exploratory analysis of a phase III trial, JCOG1017

Kiyo Tanaka, Akihiko Shimomura, Makoto Ishitobi, Takashi Yamanaka, Takahiro Tsukioki, Hiroji Iwata, Fumikata Hara, Tomomi Fujisawa, Keita Sasaki, Ryo Sadachi, Riku Kajikawa, Takehiko Sakai, Yasuaki Sagara, Hideo Shigematsu, Yukinori Ozaki, Kazuki Nozawa, Kazuki Sudo, Yoichi Naito, Kaori Terada, Toshiyuki Ishiba, Haruhiko Fukuda, Tadahiko Shien

Background: Breast cancer is a highly heterogeneous disease, and there is a biological diversity. Biological factors such as estrogen receptor, progesterone receptor, and HER2 receptor may vary between primary and metastatic sites in breast cancer. This variation could influence treatment responses in stage IV breast cancer.
This exploratory analysis aims to differentiate drug efficacy and long-term prognosis between primary and metastatic sites in patients with de novo stage IV breast cancer.

Methods: In JCOG1017, patients diagnosed with de novo stage IV breast cancer received primary systemic therapy (PST) according to subtypes after first registration. In this analysis, the efficacy of PST was evaluated prior to second registration (about 3 months post-initiation of systemic therapy), using both JCOG1017 criteria (progressive disease [PD] defined as a 10% or greater increase in long diameter) and additionally RECIST v1.1 criteria. In addition, the efficacy at about 6 months of PST in only patients with non-PD response at the second registration and assigned systemic therapy alone group was evaluated.
Patients were categorized based on their treatment responses at primary versus metastatic sites into four groups: discordant group I (primary non-PD and metastatic PD), concordant group I (both primary and metastatic PD), discordant group II (primary PD and metastatic non-PD), and concordant group II (both primary and metastatic non-PD). We assessed clinicopathologic characteristics, including subtype of primary tumor and menopausal status, and overall survival (OS).

Results: Of 570 patients who enrolled in JCOG1017, 315 patients were included in this analysis. In the evaluation at second registration using JCOG1017 criteria, the proportions of each group were 21.3% (67/315) for discordant group I, 8.3% (26/315) for concordant group I, 0.3% (1/315) for discordant group II, and 56.2% (177/315) for concordant group II. There were 14.0% (44/315) of patients with not evaluable. The overall discordance proportion of treatment effect between primary and metastatic sites was 25.1%. Subtype-specific discordance proportions were notably higher in luminal (28.9%) and triple-negative (25.0%) subtypes compared to HER2-enriched (11.1%). Menopausal status did not significantly impact discordance proportions (pre: 25.3% (24/95): post: 25.0% (44/176)). However, among the triple-negative subtype, the discordance proportion is much higher in the premenopausal population (45.5%:5/11) than in the postmenopausal population

(7.7%:1/13).
Median survival times were 3.8 years for discordant group I, 4.6 years for concordant group I, 1.7 years for discordant group II, and 5.7 years for concordant group II. No differences in prognosis were observed between discordant and concordant groups I. However, differences in prognosis between discordant and concordant groups II tended to be observed. The Kaplan-Meier curve for OS is similar based on both evaluation by JCOG1017 criteria and RECIST v1.1.

Conclusions: We found a difference in the treatment efficacy of PST between primary and metastatic sites in the early phase of treatment for stage IV breast cancer, and most cases were primary non-PD and metastatic PD. In the early phase of PST for de novo stage IV breast cancer, not only primary tumors but also metastatic sites need to be examined.

P5-10-06: Retrospective, population-based cohort study on associations between tumor size, receptor status, & regional nodal positivity rates for early-stage breast cancer: implications for decision between upfront surgery vs neoadjuvant systemic therapy

Yerin R. Lee, Vasily Giannakeas, David W. Lim

Purpose: For clinically node-negative T1-T2 breast cancers, the ASCO/Ontario Health guidelines discourage staging axillary ultrasound (AxUS). At the same time, neoadjuvant systemic therapy (NST) is recommended for HER2-positive(+) and triple negative (TN) breast cancers over 2 cm, with controversy whether clinical T1cN0 HER2+ and TN breast cancers should receive NST or upfront surgery. We evaluated the rates of regional nodal positivity across T1a, T1b, T1c and T2 tumor sizes for hormone receptor (HR)+HER2-, HR-HER2+, HR+HER2+, and TN breast cancers.
Methods: We performed a population-based, retrospective cohort study using administrative health databases at ICES Ontario. Data from all patients diagnosed with invasive breast cancer between 2000 – 2019 in Ontario, Canada were extracted from the Ontario Cancer Registry. Demographic, tumor, and treatment data were collected from the linked databases. The following variables were analyzed: T stage, number of positive regional lymph nodes, and estrogen, progesterone, and HER2 receptor statuses. The proportion of patients with positive lymph nodes was calculated for each receptor subtype. Chi-square tests (significance of $P < 0.05$) with post-hoc Marascuilo correction were conducted. Analyses were conducted using SAS® and Python software.
Results: There were 52,888 invasive breast cancers, including 39,265 HR+HER2- (74%), 5,511 HR+HER2+ (10%), 2,523 HR-HER2+ (5%), and 5,589 HR-/HER2- (11%). Increasing tumor size was associated with increasing rates of regional nodal positivity across all receptor subtypes ($P < .001$ for all). Among TN tumors, T1a lesions had a nodal positivity rate of 19% (95% CI 0.12 – 0.24), T1b 19% (95% CI 0.15 – 0.23), T1c 28% (95% CI 0.26 – 0.30), and T2 42% (95% CI 0.40 – 0.43). Among HR-HER2+ tumors, T1a lesions had a nodal

positivity rate of 18% (95% CI 0.13 – 0.24), T1b 30% (95% CI 0.24 – 0.37), T1c 42% (95% CI 0.37 – 0.46), and T2 54% (95% CI 0.51 – 0.57). Among HR+HER2+ tumors, T1a lesions had nodal positivity rate of 23% (95% CI 0.19 – 0.29), T1b 20% (95% CI 0.17 – 0.25), T1c 32% (95% CI 0.29 – 0.34), and T2 56% (95% CI 0.54 – 0.58). Among HR+HER2- tumors, T1a had a rate of 16% (95% CI 0.15 – 0.18), T1b 16% (95% CI 0.15 – 0.17); T1c 30% (95% CI 0.29 – 0.30), and T2 54% (95% CI 0.54 – 0.56).
For T1a lesions, nodal positivity rates were similar across all receptor subtypes. For T1b and T2 lesions, pairwise comparisons were significantly different between all receptor subtypes, except between HR+HER2+ and TN, and HR+HER2- and HR-HER2+, respectively. For T1c, HR-HER2+ had the highest rates of nodal positivity, followed by HR+HER2+, HR+HER2-, and TN ($P < .001$).
Conclusion: While current guidelines discourage AxUS for cT1-T2N0 breast cancers, at the population-level, pathologic regional nodal positivity rates are not insignificant for T1-T2 tumors, especially TN and HER2+ tumors. Taking these patients with pathologically positive lymph nodes to upfront surgery results in undertreatment. Furthermore, for clinical T1c tumors, regional nodal positivity rates reached 42%, 32%, and 28% for HR-HER2+, HR+HER2+, and TNBC, respectively. These data need to be shared with patients with cT1c tumors when deciding between a NST or upfront surgery approach. Finally, we advocate that staging AxUS should be considered for all HER2+ and TN T1-T2 tumors, irrespective of tumor size.

P5-10-07: Longitudinal survey on supportive care needs and coping strategies in women with recurrent/metastatic breast cancer

Tal Sella, Shoshana M. Rosenberg, Alyssa R. Martin, Melissa E. Hughes, Elizabeth S. Frank, Simone Buck, Sara Hanna, Sara M. Tolaney, Nancy U. Lin

Background: Patients with advanced cancers face a wide range of physical and psychosocial needs, often dissatisfied by available means of support. As the treatment of metastatic breast cancer (mBC) has evolved and life expectancy increases, it is crucial to identify patient needs throughout the disease trajectory, particularly contrasting the overwhelming experience of diagnosis with the chronicity of ongoing treatment.
Methods: From April 2021 to May 2024, adult women with mBC enrolled in the EMBRACE: Ending Metastatic Breast Cancer for Everyone cohort study and treated at the Dana Farber Cancer Institute were invited to complete a survey that assessed quality of life (5-point Emoji Scale, PROMIS Global Health), coping strategies (Brief COPE and SHINE), anxiety (PRO-CTCAE), depression (PHQ-9), and supportive care needs (SCNS-SF34). Following baseline assessment, the survey was repeated after 6 and 12 months. Patients reporting needs related to pain, professional counseling, depressive symptoms or sexual relationships, triggered a question offering to share this information with their clinical team. We summarize baseline survey data with descriptive statistics.
Results: Of 81 respondents to baseline surveys, mean age was 58.2 ±8.2 years, 96% were of non-Spanish/non-Hispanic ethnicity and 90% were of Caucasian race. Most patients were

diagnosed with recurrent mBC (69.1%) and responded to the baseline survey within 1 year of their mBC diagnosis (44.4%). At the time of baseline survey, 29.6% were receiving treatment with an antibody-drug conjugate, 24.7% with a cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor combined with endocrine therapy, 14.8% with chemotherapy and 14.8% with anti-HER2 therapy; 22.2% were receiving their treatment through a clinical trial protocol. Using the 5-point emoji scale, most (74.1%) patients reported feeling happy (4-5) on the day they completed the survey. At least occasional anxiety (PRO-CTCAE) was reported by 65.8%, and at least mild depressive symptoms (PHQ9) by 50.7%. Prominent coping strategies included acceptance (mean 6.4 ±1.4), self-distraction (5.8 ±1.6), use of emotional support (5.7 ±1.7) and active coping (5.3 ±1.8) and only rarely substance use (2.3 ±0.8. Supportive care needs were expressed in multiple domains; most frequently related to psychological needs (40.8%-73.6% reporting at least some need on an individual domain-related item), and with the highest need reported for "Uncertainty about the future" (8.3% no need – not applicable, 18.1% no need-satisfied, 31.9% some need – low, 25% some need – moderate, 16.7% some need - high). Needs were also reported regarding physical and daily living (30.1-53.5%) and less frequently in relation to sexuality (33.3-19.7%,) health system and information (11.3-35.2%), and patient care and support (11.0-24.7%). Prompts offering to notify the clinical team of high needs were triggered by 55 participants, of which only 20% agreed to share this information.
Conclusion: While needs related to information communication and patient cancer are generally met, many patients with mBC report symptoms of anxiety and depression and subsequent psychological needs. Future analyses will aim to identify distinct needs through the disease trajectory.

P5-10-08: Real-world clinical outcomes of patients with HER2- BRCAm early breast cancer treated with adjuvant capecitabine

Filipa Lynce, Jessica Dow, Chithra Sangli, Wenyan Zhao, Luis C. Berrocal-Almanza, Miguel Miranda, Xiaoqing Xu

Background: In the CREATE-X trial, addition of adjuvant capecitabine after standard of care neoadjuvant chemotherapy improved clinical benefit in patients (pts) with early-stage triple-negative breast cancer (TNBC). The effect of adjuvant capecitabine in pts with BRCA1/BRCA2 mutation (BRCAm) has not been specifically examined, although some studies showed decreased benefit in pts with basal-like tumors, which are enriched in BRCA1m breast cancers. This study explored the effect of adjuvant capecitabine in a real-world cohort of pts with HER2-negative (HER2−) early breast cancer (eBC), stratified by BRCAm status and tumor subtype (hormone receptor positive [HR+]/HER2− or TNBC).
Methods: This retrospective study included de-identified data from US pts aged ≥18 years in the Tempus real-world database who received adjuvant capecitabine for HER2− eBC between 1 Jan 2016 and 11 Nov 2022 and had known BRCA test results (BRCAm or non-BRCAm by germline, somatic, and/or tumor tissue testing). Pts who received neoadjuvant capecitabine ≤90 days from diagnosis, or adjuvant CDK4/6 inhibitor, PARP inhibitor, or

immunotherapy were excluded. Demographics, clinical characteristics, and treatment patterns were described. Invasive disease-free survival (IDFS) and distant disease-free survival (DDFS) were estimated using a Kaplan-Meier approach after the first breast surgery with curative intent.
Results: In total, 269 pts receiving adjuvant capecitabine with known BRCAm status were followed for a median of 23 months. Most pts had TNBC (n=192; 71.4%); 71 (26.4%) had HR+/HER2− eBC, and 6 had unknown subtype. BRCAm was reported in 22/269 (8.2%) pts (TNBC n=15/192, 7.8%; HR+/HER2− n=7/71, 9.9%).
Median age at eBC diagnosis was 53 (range 20–77) years, and was lower among pts with BRCAm (44 [29–70] years) versus non-BRCAm (54 [20–77] years). Most pts (n=245, 91.1%) had received ≥1 neoadjuvant treatment (n=232, 86.2% received only chemotherapy) for a median of 133 (interquartile range [IQR] 105–148) days. The median duration of adjuvant therapy was 168 (IQR 126–210) days and most pts (n=219, 81.4%) had received adjuvant capecitabine monotherapy.
Median IDFS (95% confidence interval [CI]) was 14.1 (10.7–not estimable [NE]) months in pts with BRCAm and 16.9 (15.1–20.8) months in pts with non-BRCAm. At 6, 12, and 18 months respectively, IDFS (95% CI) rates were 95% (72–99%), 55% (32–74%), and 40% (19–60%) for pts with BRCAm, and 96% (93–98%), 69% (62–74%), and 48% (40–54%) for pts with non-BRCAm. Median IDFS (95% CI) was 21.2 (15.8–29.8) and 15.6 (12.8–17.8) months for pts with HR+/HER2− eBC and TNBC, respectively. At 6, 12, and 18 months respectively, IDFS (95% CI) rates were 98% (90–100%), 77% (64–86%), and 59% (45–71%) for pts with HR+/HER2− eBC, and 95% (91–97%), 64% (56–71%), and 41% (33–49%) for pts with TNBC.
Median DDFS (95% CI) was 14.6 (10.7–NE) and 19.1 (16.4–22.6) months in pts with BRCAm and non-BRCAm, respectively. At 6, 12, and 18 months respectively, DDFS (95% CI) rates were 100% (NE), 60% (36–78%), and 40% (19–60%) for pts with BRCAm, and 98% (95–99%), 73% (66–78%), and 52% (44–59%) for pts with non-BRCAm. Median DDFS (95% CI) was 22.4 (16.2–29.8) and 16.9 (14.9–20.8) months in pts with HR+/HER2− eBC and TNBC, respectively. At 6, 12, and 18 months respectively, DDFS (95% CI) rates were 100% (NE), 79% (65–87%), and 61% (47–73%) for pts with HR+ eBC, and 97% (93–99%), 69% (62–76%), and 46% (38–54%) for pts with TNBC.
Conclusions: In this real-world study of pts with known BRCAm status who received adjuvant capecitabine for HER2− eBC, there was a trend for shorter IDFS and DDFS in pts with BRCAm versus non-BRCAm. However, these results are descriptive, unadjusted, and limited by the small number of pts with BRCAm. Further investigation in a larger cohort of pts is warranted, considering that targeted therapeutic options exist for pts with BRCAm.

P5-10-09: A comparative analysis of model and age independence of a plasma-based real-time qPCR clinical assay for the non-invasive detection of stage I breast cancer.

Elizabeth Cormier-May, Matthew Alderdice, Joy N Kavanagh, William Guesdon, Quentin Wise, Martin J Keiser III

Background: In the US, approximately 13% of women will be diagnosed with breast cancer in their lifetimes, of which 8.8% will die within 5 years. This is in stark contrast to only 0.4% of patients diagnosed with early-stage breast cancer who will die within 5 years, highlighting the value of robust early-stage diagnostics for breast cancer. To date, diagnostics have faced limitations in reliability, validity, and clinical flexibility due to multiple confounding variables. When considering potential biases in diagnostic research, patient demographics pose as a key limitation as potential confounding variables. This consideration is particularly essential when considering age, as the normal expression patterns for many biomarkers naturally evolve with age. It is also common for diagnostic assays to rely entirely on specific statistical modeling in order to demonstrate their significance and clinical value. Their brittle nature is illuminated when the clinical and statistical significance deteriorates upon the utilization of other statistical models. Demonstrating independence between biomarkers and patient demographics, as well as significance with a variety of statistical methods, is essential in producing a robust diagnostic assay.

Methods: In plasma obtained from women with stage I breast cancer and healthy controls (n=87), data was stratified across women ages 35-60 and >60 and assessed for statistical significance of gene expression by diagnosis for 8 mRNA targets using the Wilcoxon test with Bonferroni correction. A Pearson analysis was then performed to determine correlation between age and gene expression of the 8 targets. Additionally, a model comparison between XGBoost Classification and Logistic Regression was performed on the results of the 8 mRNA target assay (genTRU) to assess model dependency. The XGBoost model performance was assessed using the Sonrai Discovery platform (xgboost==1.4.1.1:CRAN) (XGBoost v1) and Optuna + KFold method (XGBoost v2), while Logistic Regression was assessed with the Optuna + KFold method (Logistic Regression v1).

Results: Strong statistical significance ($p<0.001$) of gene expression was observed by diagnosis for all targets with very weak correlation observed between each target and patient age (R 0.00-0.06). XGBoost v1 demonstrated >99% sensitivity, 89% specificity. XGBoost v2 demonstrated 80% sensitivity, 95% specificity. Logistic Regression v1 demonstrated 51% sensitivity, 96% specificity.

Conclusion: Our analyses confirmed the efficacy and validity of our plasma-based real-time qPCR clinical assay in detecting early-stage breast cancer, independent of statistical method, and gene expression of the targets is not strongly correlated with age. Further, results from the model comparison highlight the dynamic range of sensitivity and specificity of the genTRU clinical assay, enabling clinical flexibility in maximizing PPV or NPV, depending on the clinical application.

P5-10-10: PELICAN-IPC 2015-016/Oncodistinct-003: a randomized phase II study of pembrolizumab in combination with neoadjuvant chemotherapy in HER2-negative inflammatory breast cancer

Alexandre de Nonneville, Florence Lerebours, Christophe Zemmour, Florence Dalenc, Christelle Levy, Thierry Petit, Marianne Leheurteur, Thomas Bachelot, Olivier Tredan, Sylvain Ladoire, Frédéric Viret, Leonor Lopez Almeida, Muge Kaya, Jean-Marie Boher, François Bertucci, Emmanuelle Charafe, Anthony Gonçalves

Background: Inflammatory breast cancer (IBC) is a rare and highly aggressive clinical entity requiring multimodal treatment, including neoadjuvant chemotherapy, mastectomy, and radiation therapy. With the advent of anti-HER2 agents, significant progress has been made in HER2-positive subtypes but the outcome remains unsatisfactory in HER2-negative IBC. Pembrolizumab in combination with neoadjuvant chemotherapy improves pathological complete response (pCR) and survival in stage II/III triple-negative breast cancer (TNBC) and has become standard of care in this setting. Pembrolizumab also improves pCR in high-grade, HER2-negative, and ER-positive stage II/III breast cancer. Yet, little is known about the specific impact of chemo-immunotherapy in IBC.

Methods: We conducted a prospective, national, multicenter, randomized, phase II study evaluating the efficacy of pembrolizumab in HER2-negative IBC (NCT03515798). Patients aged ≥18 years with stage III disease were randomized (1:2) to receive neoadjuvant chemotherapy with epirubicin/cyclophosphamide (EC) +/-5FU x 4 followed by weekly paclitaxel × 12 (arm A) or the same regimen with pembrolizumab administered 3-weekly (arm B). Patients were then subjected to complete mastectomy and axillary lymph node dissection, prior radiation therapy. Randomization was stratified according to hormone receptor (HR) status (HR+, i.e. ER or PR >10%; TNBC, i.e. ER and PR <10%). Primary endpoint was central assessment of pCR rate, as defined as no residual invasive disease in breast and axilla (ypT0/is, ypN0), in arm B. Secondary endpoints included central pCR rate in arm A, local pCR rates and safety. Exploratory objectives included pCR rates according to HR status and PD-L1 expression, as evaluated by combined positive score (CPS).

Results: From 29/08/2018 to 22/06/2022, 53 stage III, HER2-negative, IBC patients meeting eligibility criteria were randomized in arm A (n=20, including 9 HR+ and 11 TNBC) and arm B (n=33, including16 HR+ and 17 TNBC). All patients were female, median age was 52 (33-71) and 54 (26-73) in arm A and B, respectively. Histology was of no special type in 70% of patients in both arms. PD-L1 expression on baseline tissue was available in 43 patients: CPS was >10 in 17 (39%) patients, with a non-significant numerical difference between arms (50% and 33% in arm A and B, respectively), and was negatively associated with HR expression. Four patients came off the study before surgery: 3 in arm B (1 consent withdrawal, 2 progressive disease) and 1 in arm A (investigator decision). The central pCR rate in arm B (pembrolizumab) was 24%, 90%CI [12-41] (21%, 90%CI [6-47] in HR+ and

27%, 90%CI [10-51] in TNBC). In arm A (control), the central pCR rate was 35%, 90%CI [17-58] (29%, 90%CI [5-66] in HR+ and 40%, 90%CI [15-70] in TNBC). The pCR rates per local assessment were consistent with central evaluation. There was no significant association between PD-L1 expression and pCR in both arms. Grade >3 treatment-related adverse events (AE) were reported in 65% and 69% of patients (including Serious AE in 20% and 39%) in arms A and B, respectively. Pembrolizumab-related grade >3 AEs were noted in 30% of patients (including SAE in 12%). Immune-related AE included skin rash (n=1, grade 2), myocarditis (n=2, grade 1 and grade 2), adrenal insufficiency (n=2, grade 2 and grade 3), hepatitis (n=2, grade 2 and grade 3), thyroiditis (n=2, grade 2), and diabetes (n=1, grade 3).

Conclusions: In HER2-negative IBC, pembrolizumab combined to neoadjuvant EC-paclitaxel chemotherapy induced a moderate pCR rate. Translational studies are ongoing to identify the determinants of therapeutic resistance. Innovative strategies including alternative cytotoxic backbones and novel immune-modulating agents are warranted in this aggressive disease.

P5-10-11: Immediate breast reconstruction using smooth round implants: a retrospective analysis

Sardor Abdugafforov, Vorotnikov V.V., Pakhomova R.A., Mchedlidze T.G., Gugnina A.S., Soynov A.V., Voronov M.V., Kopytich I.V., Sharavina M.V., Mukueva M.I., Tsalko S.E., Andreeva V.A., Tkachenko A.V.

Background: Breast reconstruction with implants is the most common method of immediate reconstruction after mastectomy in patients with breast cancer. Currently, implants with different characteristics are used for this. The choice of implant is most often determined by the thickness of the subcutaneous fat, anatomy, physiology, the patient's wishes and the surgeon's experience with various manufacturers. This directly affects most of the studies conducted, which as a result do not reveal a significant difference between the implants. This study we compare the results of immediate breast reconstruction using smooth implants with textured and polyurethane surface.
Methods: This retrospective review was performed using a database from two medical centers. The study included patients who underwent skin-sparing/nipple-sparing mastectomy with immediate breast reconstruction in the period from February 2020 to March 2024. Complications (early and late), rehabilitation period, patient satisfaction were analyzed. Early complications included hematoma, seroma, infection, skin redness, extrusion. Late complications included: capsular contracture, rippling, rotation and malposition. In all cases, lymph node dissection was performed through a separate incision, and the lymph node dissection and mastectomy zones were drained separately. The authors of the study do not use additional coverage of endoprostheses using special meshes or ADM.
Results: A total of 681 breasts in 426 patients underwent one-stage reconstruction with smooth (n=401), textured (n=176), and polyurethane (n=104) implants. Early

complications were much less common with smooth implants: seroma lasting 2 weeks or more 0.5% with smooth round implants, 4% and 3.5% with textured and polyurethane implants, respectively; skin hyperemia occurred only with the use of polyurethane implants (5.2%). The incidence of capsular contracture, regardless of adjuvant radiation therapy, was significantly lower with the use of smooth round implants and polyurethane implants than with the use of textured implants. There was no statistically significant difference in complication rates (hematoma, infectious complications, extrusion of the endoprosthesis) between patients with different implants. Skin rippling occurred only with the use of textured implants (8.9%), which in most cases required either lipofilling procedures or repeat surgery. Implant rotation occurred 3 times more often with textured implants (2.7%) compared to smooth implants (0.8%). However, malposition of smooth implants occurred significantly more often (7%) in the long term, compared to textured (1.7%) and polyurethane (0.8%) implants. In all cases of polyurethane reconstruction, vertical malposition was observed, with equal frequency of vertical and horizontal malposition with the placement of textured and smooth implants. Animation with the same frequency for textured and smooth implants placed under the muscle. Patients with smooth round implants were hospitalized for an average of 5±1 days, with textured implants 10±1 and with polyurethane implants 9±1 days.
Conclusion: Smooth round implants have demonstrated a reduced risk of complications, capsular contracture, and accelerated rehabilitation period compared to other implants in immediate breast reconstruction. However, patients more often sought care for displacement of smooth implants, which required more repeat surgical interventions for implant replacement and pocket correction, which is likely due to the features of placement (requires a tighter muscle pocket with complete muscle coverage) and the formation of a thin capsule. The advantages of smooth round implants make them the method of choice in immediate breast reconstruction with a small thickness of subcutaneous fat.

P5-10-12: Bria-IMT CD8+ Tumor Infiltrating Lymphocytes Turn “Cold” Tumor “Hot” in Metastatic Breast Cancer

Ephraim Parent, Carmen Calfa, Saranya Chumsri, Blaise Bayer, Tamar Aghajanian, Giuseppe Del Priore, William Williams, Russ Kuker

Introduction Transforming "cold" tumors into "hot" ones is critical for the success of immuno-oncology therapies, but there has been little evidence that “cold” tumors can be turned “hot”. SV-BR-1-GM, an allogenic human cancer cell line (Bria-IMT) with antigen-presenting capabilities, is designed to counteract the immunosuppressive tumor microenvironment. Zr-89 crefmirlimab berdoxam is a radio-labeled truncated mini-antibody specific to human CD8α developed for CD8 ImmunoPET imaging. We conducted CD8 imaging before and after Bria-IMT treatment to evaluate baseline and subsequent intra-lesional changes in CD8+ T cell tumor infiltration. We now present additional data from the nested feasibility trial of immunoPET in late state MBC. Methods Nested feasibility trial of subjects from two CD8 immunoPET capable tertiary care sites participating in

NCT03328026 a randomized phase 2 of Bria-IMT in combination with a check point inhibitor (CPI). Standard Uptake Value (SUV) was evaluated pre-dose and following therapy. Results 6 patients, median age 60.5 (44-66), enrolled in the ongoing Bria-IMT trial in advanced heavily pretreated metastatic breast cancer. Median number of prior therapies was 7 (4-8). Prior lines included antibody-drug conjugates (ADCs) and CPIs. All patients had progressed on prior treatment. Four of these patients were randomized to start the CPI after 2 cycles of Bria-IMT to "train" the host immune system before adding the CPI; 2 patients were randomized to begin CPI concurrent in C1 with Bria-IMT. Four patients matched at least 2 SV-BR-1-GM HLA loci, which in previous publications is associated with greater clinical benefit. Sites of disease included in situ breast mass, multiple lymph nodes, visceral and osseous metastases. On follow-up ImmunoPET, each patient demonstrated an increase in SUV in at least one metastatic lesion (range –57.4 - 442.9%) including lung, soft tissue, liver, lymph node, dural based and bony metastases. There was no consistent change recognized in any of these groups except as noted below. Evaluable subjects with HLA matches (3/4) did not experience any increases in CD8+ ImmunoPET SUV at inguinal lymphatic sites while those without HLA matches (n=2) showed increase in CD8 SUV at these sites. In addition, bilateral axillary lymph nodes presented with a median SUV of 6.4 (1.4 - 15.1) after treatment as compared to a median SUV of 7.4 (2.1-18.9) at baseline. 3 out of the 6 patients showed a decrease in neutrophil/lymphocyte ratio NLR at cycle 2 when compared to baseline values. The longest survivor on trial (>1yr, after 6 prior lines, ER/PR +, HER2+) CD8 PET also had the largest percentage (442.9%) increase of any patient in SUV (right frontal dural based). This lesion completely resolved around cycle 8. Additional correlation with tumor genomics will be reported. Conclusion We report additional data supporting future hypotheses and that "cold" tumors can become "hot" when treated with Bria-IMT in combination with an anti-PD-1 CPI, as demonstrated by metastatic site-specific CD8+ PET results. Subjects in a now nearly completed randomized phase 2 demonstrated responses of metastatic lesions on CD8 ImmunoPET. The nonspecific nodal localization of CD8 ImmunoPET may indicate a systemic activation of CD8 positive lymphoid cells in response to peripheral non-lesional SV-BR-1-GM injections. These results suggest a potential value of CD8 ImmunoPET in identifying lesions that are progressing on treatment versus pseudo progression. It also provides support that the Bria-IMT combination immune-based therapy can result in an increase of CD8+ tumor infiltrating lymphocytes in breast cancer metastatic sites as well as in lymphoid organs. This advance may aid in triaging patients, adjudicating pseudo-progression and predicting clinical benefit of immune based therapies.

P5-10-13: Estimation of biological aging and non-cancer mortality rate in breast cancer survivors due to chemotherapy using a computational model of senescence

Swarnavo Sarkar,Mina Sedrak, Clyde Schechter, Jeanne Mandelblatt

Purpose: The steady reduction in deaths from breast cancer has heightened the importance of breast cancer survivorship, as emphasized in the new phase of the Cancer Moonshot initiative. One key concern is the adverse effects of breast cancer therapies causing the early onset of other age-related diseases and deaths from non-cancer causes. Chemotherapy has been shown to increase the level of senescent cells in breast cancer survivors, measured using the expression level of the p16 protein. Senescent cells secrete phenotypes, including inflammatory cytokines and proteases, which are main factors behind several age-related diseases. In fact, mathematical modeling of stochastic accumulation and removal of senescence has been shown to model the mortality rate and the incidence rate of several age-related diseases in humans. Therefore, we need a computational approach to model the impact of breast cancer diagnosis and treatment on the enhanced accumulation of senescence and the subsequent increase in the non-cancer mortality rate.
Method: We used a stochastic model of the accumulation and removal of senescent cells (SnC) with age to simulate the SnC trajectories for 6 scenarios, women without cancer, women with breast cancer but without senescence-enhancing therapies, and women with breast cancer and with 4 groups of chemotherapy regimens (for which the data on the change in p16 expression were available). The 4 groups of chemotherapy regimens were, (1) doxorubicin, cyclophosphamide, and paclitaxel, (2) docetaxel and cyclophosphamide +/- anti-HER2 therapy, (3) docetaxel and carboplatin + anti-HER2 therapy, and (4) doxorubicin and cyclophosphamide + paclitaxel and carboplatin. We used the probability distribution of SnC for each age in the non-cancer group as a biomarker for the true biological age. The clinical data on the change in p16 expression level due to breast cancer and subsequent chemotherapy was used to modify the parameters of the stochastic model to generate the SnC probability distributions for the other 5 scenarios. Biological age for the breast cancer and chemotherapy groups were estimated by using the difference in the SnC probability distributions in each of the 5 breast cancer groups vs. the non-cancer group. Non-cancer mortality rate for the 5 breast cancer groups was determined using the computationally-estimated biological age rather than the chronological age.
Results: We obtained quantitative maps from chronological age to biological age for breast cancer survivors depending on two variables, the age at diagnosis of breast cancer and the chemotherapy regimen. The divergence of biological age from the chronological age is higher for women diagnosed with breast cancer at a younger age. This divergence can be as high as 30+ years for women diagnosed with breast cancer before the age of 50, leading to a significantly higher non-cancer mortality rate. Therefore, chemotherapy-enhanced senescence can be a critical factor for deciding the specific regimen for younger women with breast cancer.
Conclusions: We present a novel computational approach to generate chronological age to biological maps and chronological age to non-cancer mortality rate maps for breast cancer survivors as a function of the age at diagnosis and the chemotherapy regimen. These maps can be useful for clinical decisions on the impact of different chemotherapy regimens on subpopulations of breast cancer survivors. The chronological age to non-cancer mortality rate maps also provides new inputs for epidemiological simulations of breast cancer survivorship, to discern the impact of different therapies on breast cancer survivorship.

Furthermore, we will be able to incorporate tumor marker subtype and race/ethnicity as variables for generating these senescence-based maps as more data become available.

P5-10-14: Early Invasive Lobular or Ductal Carcinoma with Differential Clinical Outcomes Across Molecular Subtypes among Young Women Who Received Neoadjuvant Chemotherapy

Jincong Freeman, Jared H. Hara, Olasubomi J. Omoleye, Ted O. Akhiwu, Shreyas Kalantri, Heather J. Hoffman

Background: Young women in the US are experiencing rising rates of breast cancer, necessitating effective treatment strategies. Neoadjuvant chemotherapy (NACT) is widely used in clinical practice, yet research on post-NACT outcomes among young women is limited, especially for those with less common histology, e.g., invasive lobular carcinoma (ILC) or invasive ductal and lobular carcinoma (IDLC). In this study, we examined differential pathologic complete response (pCR) and overall survival (OS) between invasive ductal carcinoma (IDC), ILC, or IDLC among female patients (pts) aged ≤40 years with stage I-III disease who received NACT, stratified by molecular subtype.
Methods: This hospital-based, retrospective study analyzed data from the 2010-2020 National Cancer Database. We assessed 4 molecular subtypes: HR+/HER2–, HR+/HER2+, HR–/HER2+, and TNBC. pCR, defined as ypT0/Tis ypN0, was modeled using logistic regression, and adjusted odds ratios (aOR) were calculated. OS was event or censored at the time of death from any cause or last known contact, with 5-/10-year OS rates estimated using the Kaplan-Meier method and compared using log-rank tests. We performed Cox regression to generate adjusted hazard ratios (aHR). All models were stratified by molecular subtype, adjusting for clinical T/N stage, tumor grade, PR status (HR+ only), race/ethnicity, year of diagnosis, and comorbidity score.
Results: Of 26,480 young women (median follow-up 52.9 [IQR 32.9, 79.2] months), 95.8% had IDC, 2.1% ILC, and 2.1% IDLC. In the HR+/HER2– cohort, 14.9% of IDC pts achieved pCR compared to 3.3% of ILC and 4.1% of IDLC pts (p<.001). After covariate adjustment, pts with ILC (aOR 0.45, 95% CI: 0.23-0.86) or IDLC (aOR 0.49, 95% CI: 0.27-0.89) had lower odds of pCR than IDC pts. In the HR+/HER2+ cohort, a higher pCR rate was observed among IDC pts (33.8%) than ILC (24.3%) or IDLC (27.5%) pts (p=.033). However, the odds of pCR were not significantly different between IDC and ILC (aOR 0.90, 95% CI: 0.56-1.43) or IDLC (aOR 0.77, 95% CI: 0.52-1.13). In the HR–/HER2+ cohort, pCR rates were similar across histologic types (IDLC: 70.6%; ILC: 58.8%; IDC: 49.9%; p=.180). On multivariable regression, pts with ILC (aOR 1.68, 95% CI: 0.60-4.70) or IDLC (aOR 1.96, 95% CI: 0.67-5.73) had similar odds of pCR as those with IDC. In the TNBC cohort, IDC pts achieved a higher rate of pCR than ILC or IDLC pts (36.0%, 21.3% vs. 18.0%; p=.003). Compared to IDC pts, IDLC pts had lower odds of pCR (aOR 0.40, 95% CI: 0.18-0.9) while ILC pts had similar odds of pCR (aOR 0.70, 95% CI: 0.34-1.42). IDC was associated with significantly longer 5-/10-year OS rates (compared to ILC or IDLC) among pts with HR+/HER2– (p=.012) or TNBC (p<.001). In the adjusted models, pts with HR+/HER2– ILC (aHR 1.55, 95% CI: 1.15-2.10) or

IDLC (aHR 1.52, 95% CI: 1.15-2.03) had a greater mortality risk than IDC pts. HR–/HER2+ ILC pts also had a higher risk of death than IDC pts (aHR 3.51, 95% CI: 1.10-11.15). In the TNBC cohort, ILC was associated with an increased mortality risk compared to IDC (aHR 2.28, 95% CI: 1.41-3.69).
Conclusions: In this US national registry of young women with early-stage breast cancer who received NACT, pts with ILC or IDLC consistently exhibited lower pCR rates and poorer OS than those with IDC across molecular subtypes. These disparities underscore the need for tailored treatment interventions that account for histologic type, particularly for ILC, among young women. Our findings not only highlight the importance of informed NACT counseling, but also underscore the necessity for oncology programs to optimize therapeutic approaches and continue multidisciplinary efforts to reduce disparities specifically for young women with ILC.

P5-10-15: Effectiveness and tolerance of Trastuzumab Deruxtecan (T-DXd) in HER2-Positive and HER2-Low Metastatic Breast Cancer (MBC): a large real-life French Cohort Study

Marc-Antoine Benderra, Lana Elu, Elias Assaf, Asmahane Benmaziane, Kevin Bihan, Romain Cohen, Isabelle Cojean-Zelek, Leonor Drouin, Jacques Medioni, Herve Foka-Tichoue, Laurent Zelek, Jacques Cadranel, Joseph Gligorov, Anthony Canellas

Background: Trastuzumab deruxtecan (T-DXd) has demonstrated promising efficacy in MBC patients enrolled in clinical trials but limited data is available on the real-world outcomes.

Methods: This retrospective multicenter study enrolled patients with HER2-pos and HER2-low MBC receiving T-DXd from April 2019 to November 2023 across 10 French centers. All data were obtained from patient medical records. Overall survival was estimated using the Kaplan-Meier method.

Results:
Throughout the study period, 238 patients were included, 51% with HER2-pos MBC and 49% with HER2-low MBC. Among them, 76% were HR+ and 24% were HR-. Median age was 59 years (IQR 50-69) and median prior regimens in the metastatic setting (PRMS) were 2 and 4 for HER2-pos and HER2-low, respectively. A total of 56 (24%) had a PS >1 before T-DXd introduction. The best overall response was evaluable in 223 patients.
Complete/partial response (CR/PR), stable disease (SD), and progressive disease (PD) rates were 61%, 20%, 19% in the HER2-pos MBC population, and 42%, 30%, 28% in the HER2-low MBC population. The median time to treatment discontinuation (TTD) with T-DXd was 9.1 months, 12.8 months in HER2-pos MBC and 6.9 months in HER2-low MBC. Overall survival (OS) was 20.9 months, 24.7 months in HER2-pos MBC and 16.9 months in HER2-low MBC. PS >1 was associated with lower CR/PR in HER2-pos MBC (50% vs 64%, p=0.04) but not in HER2-low MBC (43% vs 42 %, p=0.3). In terms of tolerance, dose reduction

occurred in 43 patients (18%), and 22 patients (9.2%) developed interstitial lung disease.

Conclusion:This large cohort study confirmed the favorable real-life activity of T-DXd in HER2-pos and HER2-low MBC, although objective response rates appeared shorter than those observed in the DESTINY-Breast trials. Dose reductions and incidence of drug-related interstitial lung disease were consistent with the findings from clinical trials.

P5-10-16: HER2-Low Breast Cancer: The Impact of Online Education on Oncologists' Knowledge and Confidence in Understanding the Latest Advances and Implications for Practice

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Jamie Habib, Giuseppe Viale, Nadia Harbeck

Background: HER2-low has been receiving wide-spread interest and is now a therapeutically relevant biomarker in breast cancer. The objective of this study was to assess the effect of an online continuing medical education (CME) activity on clinicians' knowledge in the heterogeneity of HER2 expression in breast cancer, knowledge in the key data from the latest clinical trials investigating novel and emerging therapies in HER2-low breast cancer, and confidence in their ability to individualize treatment plans for patients with HER2-low breast cancer.

Methods: This CME activity consisted of a 15-minute video discussion between 2 expert faculty with synchronised slides. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 5th of December, 2023, with data collected through 26th April, 2024 being reported in the current study.

Results: The analysis set consisted of responses from oncologists (n=73) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge of oncologists (P< .001). Overall correct responses increased from 27% pre- to 49% post-CME, representing an 81% relative increase, with 12 times more leaners answering all questions correctly after education. Specific areas of improvement include:

- Knowledge of the heterogeneity of HER2 expression in breast cancer (pre 14%, post 56%; P < .001)
- Knowledge of the key data from the latest clinical trials investigating novel and emerging therapies in HER2-low breast cancer (pre 34%, post 46%; P < .01)

After education, 42% of oncologists had a measurable increase in confidence in individualizing treatment plans for patients with HER2-low breast cancer, and that increase

was, on average, 72%.

Conclusions: This analysis demonstrates the positive educational impact of an online CME activity on oncologists' knowledge regarding HER2-low breast cancer, particularly in areas related to the heterogeneity of HER2 expression. However, there is still an educational need in a large percentage of oncologists on this topic.

P5-10-17: Impact of Pathologic Response and Individual Prognosis After Neoadjuvant Treatment (NAT) in Patients (pts) with Early HER2+ and Triple-Negative Breast Cancer (TNBC)

Chiara Corti, Tianyu Li, Alyssa R. Martin, Melissa E. Hughes, Tonia Parker, Tyzaire S. Duporte, Giuseppe Curigliano, Tari A. King, Elizabeth A. Mittendorf, Nancy U. Lin, Nabihah Tayob, Sara M. Tolaney

Background: Pathologic complete response (pCR) is prognostic in pts with early breast cancer (eBC). This study aims to assess individual prognostic factors for recurrence-free survival (RFS) and overall survival (OS) in pts with pCR vs residual disease (RD).

Methods: This retrospective study included pts diagnosed at our institution with TNBC or HER2+ eBC who underwent surgery post-NAT and had available data for pCR/RD, RFS, OS. Clinical tumor size (cT), nodal status (cN), and subtype were evaluated as prognostic factors using Cox models and Kaplan-Meier method, in all pts and in pts with pCR (ypT0/is, ypN0) and RD. RFS and OS were defined as time from surgery to first recurrence or death from any cause, whichever occurred first, and as time from surgery to death from any cause, respectively ($p<.05$ significant).

Results: 863 pts were identified with a median age of 50.2 yrs (21.0-85.4) who underwent surgery between 2016-2021. Median follow-up was 3.5 yrs (2.6-6.0). 387 pts (44.8%) had TNBC, 295 (34.2%) ER+HER2+ eBC, 181 (21.0%) ER-HER2+; 80 (9.3%) were stage I, 602 (69.8%) stage II, 181 (21.0%) stage III. Regarding NAT, 370 pts (42.9%) received chemotherapy-only, 473 (54.8%) received HER2-targeted regimens, 14 (1.6%) received immunotherapy-based regimens. Overall, 374 (43.3%) pts had a pCR, 489 (56.7%) RD. In TNBC, 125 pts (32.3%) had a pCR, 262 (67.7%) RD; in ER+HER2+ eBC, 119 pts (40.3%) had a pCR, 176 (59.7%) RD; in ER-HER2+ eBC, 130 pts (71.8%) had a pCR, 51 (28.2%) RD. 108 pts (12.5%) had disease recurrence, of whom 74 (68.5%) had TNBC, 22 (20.4%) ER+HER2+, 12 (11.1%) ER-HER2+ BC. Most common recurrence sites were brain (39, 36.1%), bone (37, 34.3%) and lung (33, 30.6%).
Median survival measures were not reached. 3-yr RFS was 87% for the entire cohort (95% CI, 85-89), 80% (95% CI, 76-84) in TNBC and 93% (95% CI, 91-96) in HER2+ eBC. 3-yr RFS was 98% (95% CI, 97-100) in pts with pCR vs 79% (95% CI, 75-82) in pts with RD. In TNBC,

3-yr RFS was 97% (95% CI, 95-100) in pts with pCR vs 72% (95 CI, 66-77) in pts with RD; in HER2+ eBC, 3-yr RFS was 99% (95% CI, 97-100) in pts with pCR vs 87% (95% CI, 82-92) in pts with RD.
Overall, higher cT (cT3-4 vs cT1-2, hazard ratio [HR]: 2.72; 95% CI, 1.88-3.94, p<.001), positive cN (cN+ vs cN0, HR: 2.43; 95% CI, 1.65-3.59, p<.001), TNBC subtype (TNBC vs ER+HER2+, HR: 2.57; 95% CI, 1.63-4.04, p<.001; ER-HER2+ vs ER+HER2+, HR: 0.94; 95% CI, 0.49-1.80, p=.8) and RD (pCR vs RD, HR: 0.11; 95% CI, 0.06-0.22, p<.001) were associated with poorer 3-yr RFS.
In pts with pCR, 3-yr RFS was numerically higher in cT1-2 cases (99%) vs cT3-4 (95%) and in cN0 cases (99%) vs cN+ (97%), but differences were not significant (cT3-4 vs cT1-2, HR: 2.97; 95% CI, 0.84-10.52, p=.09; cN+ vs cN0, HR: 2.85; 95% CI, 0.74-11.01, p=.1); stratification by subtype revealed no associations.
In pts with RD, higher cT (cT3-4 vs cT1-2, HR: 2.26; 95% CI, 1.54-3.33, p<.001), positive cN (cN+ vs cN0, HR: 2.31; 95% CI, 1.54-3.47, p<.001) and TNBC subtype (ER-HER2+ vs ER+HER2+, HR: 1.66; 95% CI, 0.79-3.49, p=.2; TNBC vs ER+HER2+, HR: 2.42; 95% CI, 1.51-3.86, p<.001) remained associated with poorer 3-yr RFS.
In a multivariate model for RFS, no associations were found in pts with pCR. In pts with RD, higher cT (cT3-4 vs cT1-2, HR: 1.86; 95% CI, 1.24-2.80, p=.003), positive cN (cN+ vs cN0, HR: 2.13; 95% CI, 1.39-3.28, p=.001) and TNBC subtype (TNBC vs ER+HER2+, HR: 2.60, 95% CI, 1.63-4.17, p<.001) remained associated poorer 3-yr RFS. These results were consistent using ER<10% to define ER negativity. 3-yr OS will be presented at the meeting.

Conclusions: The study confirms that pts experiencing pCR have better outcomes than those with RD. Overall, 3-yr RFS and 3-yr OS varied by cT, cN, and subtype at presentation. In pts with RD, cT, cN, and subtype remained independent prognostic factors. In pts with pCR, few events occurred, and no associations were found.

P5-10-18: What to measure in Real-World Evidence (RWE) Studies: A Patient Informed Conceptual Disease Model in Early-Stage Breast Cancer

Ashley Duenas, Zulikhat Segunmaru, Deborah Collyar, Debora Denardi, Claudine Clucas, Klaudia Kornalska, Qixin Li, Chintal H. Shah, Paul Swinburn, Xiaoqing Xu

Background: The treatment of early-stage breast cancer (eBC) is rapidly evolving, with new advancements in early diagnosis and targeted therapies. Given the heterogeneity of breast cancer, it is crucial to understand specific needs of eBC patients to ensure they are well supported in their treatment journey. Conceptual disease models (CDM) provide a means to organize and visualize concepts of importance for a patient population. A CDM can support real-world studies to understand the multidimensional aspects of eBC and aid in the identification of appropriate patient-reported outcome measures (PROMs).
Objectives: To develop a comprehensive CDM of the patient experience and understand the concepts that are of greatest importance to patients with eBC.
Methods: A targeted literature review (TLR) was conducted to inform a preliminary CDM. A

Patient Steering Committee (PSC) comprised of three US patient experts with history of breast cancer contextualised the findings, provided input on the TLR results and further advised on concepts of importance to eBC patients.
Results: The preliminary CDM represented eBC signs and symptoms, side-effects, and proximal and distal impacts identified from the TLR, which comprised of 88 empirical studies and grey literature. Although some patients may be asymptomatic, fatigue and pain/discomfort were reported as common symptoms. eBC has a major impact on multiple aspects of life like cognitive functioning (ability to concentrate), physical functioning/daily activities, roles, emotional/psychological impact, social impacts, relationships, work/school, and financial concerns. Anxiety was identified as a pervasive impact across the treatment journey (testing, diagnosis, pre-, during and post-treatment, survivorship, and recurrence) and may shape how patients cope with eBC. A need for access to quality care and support with physical, practical, social, cognitive and economic impacts in the post-treatment period was also highlighted, along with support for multiple languages and cultures.
The PSC emphasized prominent themes in the CDM like importance of more timely quality of life (QoL) discussions between patients and healthcare providers during early diagnosis. The PSC discussed several areas affecting QoL: 1) Energy levels (fatigue/tiredness) which can directly impact work, family, and social relationships; 2) Body image and concerns related to sexual functioning and affecting self-confidence; and 3) Survivorship which is often related to fear of recurrence/disease progression, guilt, grief, and mourning.
Other critical unmet needs raised by the PSC were a necessity for more information on treatment options/surgery, inconsistency in doctor-patient communication and need for improvements in shared decision making. Financial toxicity was also seen as a critical issue for some patients undergoing treatment for eBC.
Discussion: This is the first comprehensive CDM in eBC developed based on information from the literature and patient expert insights. Improved understanding of the eBC patient experience necessitates identification of the wide-range of different concepts related to treatment and how they impact patients' daily lives. The CDM will be further refined following in-depth qualitative interviews with eBC patients, followed by discussion with patient experts to validate key concepts that should be measured in RWE settings. The CDM will be used to inform the selection of PROMs in future studies aimed at understanding the patient perception and experience of eBC treatments with the ultimate aim to better support patient treatment and care needs. Although these findings are focused on the RWE setting, the application of the CDM demonstrates what matters to patients and should also be considered in patient focused drug development of new treatments.

P5-10-19: Impact of Online Case-Based Education in Improving Clinicians' Knowledge and Confidence in Managing HER2-Low Metastatic Breast Cancer

Zhizhi Fiske, Stephen Dunn, Deborah Grainger, Jamie Habib, Judy King

Background: HER2-low breast cancer has generated great interest recently due to the introduction of novel antibody-drug conjugate (ADC) therapy into the clinical practice and the remarkable outcomes it has achieved. The objective of this study was to assess the effect of an online case-based continuing medical education (CME) activity on clinicians' knowledge of the available evidence supporting the use of novel ADC therapy for patients with HER2-low metastatic breast cancer and their confidence in individualizing treatment plans for those patients.

Methods: This 18-minute segmented multi-media online CME activity consisted of videos portraying realistic physician–patient interaction followed by a test question and expert commentary. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 28th of August, 2023, with data collected through 29th December, 2023 being reported in the current study.

Results: 63 oncologists and 36 obstetricians/gynaecologists who answered all the assessment questions were included in this analysis. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge of both physician learner groups, with 200% more oncologists answering all questions correctly after education (30% post- vs 10% pre-CME) and 113% more obstetricians/gynaecologists answering all questions correctly after education (17% post- vs 8% pre-CME). Specifically, the knowledge regarding the latest clinical data in HER2-low breast cancer increased from 45% pre- to 65% post-CME for oncologists (P<.001) and from 33% pre- to 48% post-CME (P<.01) for obstetricians/gynaecologists, respectively.
Additionally, 41% of oncologists and 31% of obstetricians/gynaecologists reported increased confidence in individualizing treatment plans for patients with HER2-low metastatic breast cancer, and that increase was, on average, 71% and 52% among the two physician groups, respectively.

Conclusions: This analysis demonstrates the success of online, interactive, case-based education in improving clinician's knowledge and confidence in managing patients with HER2-low metastatic breast cancer. However, there remains a need to provide ongoing education to clinicians in this growing field.

P5-10-20: Patient awareness of HER2-low in metastatic breast cancer: survey results in a patient-facing app

Heidi Ko, Michelle F. Green, Kyle C. Strickland, Maureen Cooper, Jenessa Rossi, Ashima Dua, Maya Said, Amee Sato Dossey, Carole Cuny, Theresa Dunn, Cristina Nelson, Linda Bohannon, Maggie Chapman, Jonathan Klein, Marcia Eisenberg, Brian Caveney, Eric A. Severson, Shakti Ramkissoon, Rebecca A. Previs

Background: The emergence of trastuzumab deruxtecan has led to significant improvement in clinical outcomes for patients with HER2-low metastatic breast cancer, which accounts for about half (45-55%) of breast cancer diagnoses. However, little is known about patients' awareness of diagnostic testing requirements and treatment implications associated with HER2-low status. This study aims to better understand patients' knowledge of HER2-low.
Methods: This cross-sectional survey was completed virtually on the Outcomes4Me mobile app, a direct-to-patient digital application that empowers patients to take a pro-active approach to their care. Eligible patients included those with Stage IV breast cancer living in the United States. Participants were surveyed on awareness of their tumor's HER2 biomarker status and willingness to discuss more with their oncologists if their status was unknown. Educational content about HER2 biomarker testing was accessible on the app. Responses were analyzed descriptively and reported in aggregate.
Results: In total, we received responses from 527 patients, of which 362 met eligibility for inclusion. Of the evaluable patients, 41.9% (152/362) were diagnosed over five years ago, 35.4% (128/362) had Stage IV disease at diagnosis, 32.9% received treatment in a community setting (119/362), and 43.4% (157/362) had progressed on at least one prior therapy for metastatic cancer. Sixty-four (18%) patients did not know or recall their HER2 status at diagnosis; 14 (3.9%) provided no response. Of the 284 (78.5%) patients who were aware of their HER2 status at diagnosis, 24 (7%) reported having HER2-low breast tumors. Within the cohort of patients with known HER2 status, 119/284 (41.9%) of patients were not at all aware or not very aware of the HER2-low classification. Almost 43% (112/284) of patients with a known HER2 status reported HER2 testing within the last year, but 51.3% (57/111) of patients who were classified as HER2-negative following their most recent testing did not recall their oncologist discussing HER2-low as a possibility. For patients with an unknown biomarker status, brief education about HER2 testing was provided within the app. After engagement, 60.9% (39/64) of patients with unknown HER2 status felt very or somewhat likely to talk to their oncologist about testing for HER2-low.
Conclusions: Knowledge gaps in HER2 biomarker testing persist in patients with Stage IV breast cancer. For patients with a known HER2 status, many remain unaware of the HER2-low classification. Digital education resources such as the Outcomes4Me app can facilitate patient empowerment and provide targeted education outside of traditional clinical settings, enabling shared decision making. After patients with an unknown status received brief education within the app, the majority expressed willingness to discuss more about HER2 testing with their oncologist.

P5-10-21: Efficacy and safety of utidelone plus bevacizumab in the treatment of patients with Her2- metastatic breast cancer study

Shaohua Zhang, Tao Wang, Li Bian, Guohui Han, Xiangdong Bai, Zefei Jiang

Background: Despite the rapid development of targeted therapy and immunotherapy for breast cancer in recent years, Chemotherapy remains an important treatment for metastatic breast cancer (MBC), and currently there is no standard chemotherapy regimen for MBC patients previously treated with taxanes. Utidelone is a new microtubule inhibitor drug developed in China, which has demonstrated excellent efficacy for metastatic breast cancer. Historical studies have shown that chemotherapy combined with angiogenic inhibitors can improve PFS in advanced breast cancer patients compared with chemotherapy alone. This is a real world study to evaluate the efficacy of utidelone plus bevacizumab for Her2- MBC patients.

Methods: HER2- metastatic breast cancer patients who had been previously treated with taxanes and anthracyclines were given utidelone (35 mg/m2, iv, d1-5 of each3-week cycle) combined with bevacizumab (10 mg/kg, iv, d1 of each cycle) until intolerance or disease progression. Efficacy was evaluated every 2 cycles according to the Response Evaluation Criteria In Solid Tumors version 1.1.

Results: Between January 2023, and June 2024, a total of 34 patients with metastatic breast cancer were recruited, with a median age of 52.5 years (range, 24 to 72). Among them, 14 patients were with HR-/HER2- breast cancer and 20 patients with HR+/HER2- breast cancer (8 of the HR+ patients with metastatic lesions that were HR-/HER2-). Patients with HR+ had progressed after receiving at least one CDK4/6 inhibitor treatment. The median number of prior treatment lines was 4.
The overall ORR of this study was 47.1%, the median PFS (mPFS) was 5 months, while the median OS was not reached. In the HR-/HER2- group, the median number of prior treatment lines was 2, its ORR was 42.9%, the mPFS was 5 months. The median number of treatment lines for the HR+ group was 7, its ORR was 50%, the median PFS was 4 months. Of all enrolled patients, 6 had brain metastases with 1 being HR-/HER2 -, and 5 being HR+/HER2- (1 metastatic lesion was HR-/HER2-). Two of the brain metastatic patients had previously received radiotherapy for intracranial lesions, and the other 4 were patients with new brain metastases. After treatment with utidelone combined with bevacizumab, intracranial partial response (PR) was achieved in 4 patients and stable disease (SD) in 2 patients, the CNS-ORR was 66.7% and CNS-CBR was 100%, suggesting a very good efficacy for MBC brain metastasis.
The common adverse events (AEs) were peripheral neurotoxicity (PN, 100%) and myalgia/artealgia (52.9%). However, most of the PN were grade 1-2 and reversible. Other AEs greater than 10% included liver toxicity (14.7%), myelosuppression (11.8%) and hypertension (11.8%). Gade 3 AEs included 3 cases (8.8%) of grade 3 PN and 5 cases (14.7%) of grade 3 myalgia/artealgia.

Conclusion: This study showed promising efficacy and a manageable safety profile of utidelone plus bevacizumab in the treatment of Her2- MBC patients relapsed after taxanes therapy. This combination regimen could become a new choice for these patients, especially for asymptomatic brain metastasis patients. Further study is warranted with expanded number of patients.

P5-10-22: Exploring the landscape of locoregional therapy de-escalation in early breast cancer: a systematic review

Alan David McCrorie, Hilary Sobart, David Dodwell, Shelley Potter, Stuart A McIntosh

Background: De-escalation of locoregional treatment in early breast cancer aims to reduce treatment-related morbidity whilst maintaining optimum oncological outcomes but robust evidence from clinical trials is essential to change practice. This review aimed to describe the current landscape of de-escalation trials.

Methods: This systematic review was prospectively registered on PROSPERO (CRD42023487777). Databases and trial registries were searched for interventional clinical trials involving locoregional de-escalation in early breast cancer published 2019-2024, in progress, due to commence, or recently terminated. RCTs and prospective cohort studies were included. Non-interventional studies were excluded. Descriptive and methodological information was extracted. Mixed-methods analysis was performed.

Results: 114 trials (56 (49%) RCTs, 58 (51%) cohort studies) including 99,998 participants were included. Most studies were multicentre (n=81, 71%) and based in Europe or North America (n=87, 76%). RCTs were large with 62% (n=32) aiming to recruit >1000 participants whereas most cohort studies (n=51, 88%) reported sample sizes of <500 patients. Median trial duration was 9 years (range: 1-27, IQR: 6). Of the 62 surgical studies, 52% (n=32) evaluated de-escalation of axillary treatment with over a third (n=22, 35%) assessing reduction of surgery following completion of neoadjuvant therapy. Radiotherapy trials (n=52) were more likely to focus on de-escalating treatment to the breast (n=49, 94%) in older patients (RT >50, n=27, 52% vs. surgery n=6, 10%) and/or use biomarker stratification (RT n=12, 23% vs. surgery n=3, 5%, p=0.004). Primary outcomes were mostly oncological (n=94, 82%) and often based on recurrence (n=64, 56%) with patient-reported outcomes used in a minority of studies (n=7, 6%). Most studies were powered at 80% for either non-inferiority or based on a pre-defined acceptability threshold, but few studies described how this margin was selected. Less than 10% (n=10) reported involving patients in trial design.

Conclusions: De-escalation studies should be robust, timely and patient-focused, but few

current trials achieve these aims. Innovative studies designed in collaboration with patients will be essential to support future personalisation of locoregional treatments.

P5-10-23: The Impact of Body Mass Index on Pathological Complete Response Following Neoadjuvant Chemotherapy (NACT) in Operable Breast Cancer

Richa Jaiswal, Emma Blower, Helen Innes, Raj Sripadam, Petros Yiannoullou, Leena Chagla

Introduction: Breast cancer is a significant global health issue, characterized by an incidence rate of 11.7% and a mortality rate of 6.9%. Achieving a pathological complete response (PCR) after neoadjuvant chemotherapy is linked to better survival outcomes for breast cancer patients. In the United Kingdom, 63.5 % of adult population has an elevated body mass index (BMI), a figure that has been rising over time.Objective: The objective of this study was to find out whether the body mass index of breast cancer patients had any impact on pathological response following neoadjuvant chemotherapy, and, if so, to compare the rate of achieving complete pathological response between normal body mass index (18- 24.9) and those with an elevated body mass index (≥25).Material and Methods: The study included all the female with biopsy-confirmed operable breast carcinoma who underwent surgery after receiving neoadjuvant chemotherapy between January 2018 and December 2022. Patients were categorized into two BMI groups: normal (18-24.9) and elevated (≥25). Pathological complete response was defined as ypT0/Tis ypN0, ypT0/Tis, or ypN0. Descriptive analyses were performed. Univariate and multivariate logistic regression analyses were conductedusing R software.Results: A total of 829 breast cancer patients were included in the study. Of these, 277(33.31%) had a normal BMI and 552(66.59%) had an elevated BMI. Patients with a normal BMI had the highest rate of pathological complete response (68.23%), whereas those with an elevated BMI had a lower PCR rate (32.43%) ($p<0.001$). Body mass index remained an independent predictor of pathological complete response (OR=1 for normal BMI and OR=0.21for elevated BMI; $p<0.001$).Conclusion: In this cohort, breast cancer patients with an elevated body mass index had a lower rate of pathological complete response following neoadjuvant chemotherapy. Further studies are needed to elucidate the underlying mechanisms.

P5-10-24: Real-world characteristics and BRCA testing among HER2- early breast cancer patients receiving olaparib or other adjuvant therapy in the US community oncology setting

Matthew Monberg, Kathryn Mishkin, Lauren Stevens, Daphne Derose, Qixin Li, Xiaoqing Xu, Rosa Banuelos, Juliet Ndukum, Lisa Herms, Paul Conkling, Jay Andersen

Background: One-third of breast cancer (BC) cases in BRCA1-mutated (BRCA1m) patients are classified as triple-negative breast cancer, an aggressive cancer prone to early onset and high risk of metastasis. 70% of BC cases in BRCA2-mutated (BRCA2m) patients

are classified as hormone-receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-). Differences in patients with BRCA1m and BRCA2m tumors suggest the need for targeted screening and treatment strategies based on genetic risk profiles. Olaparib, a poly ADP-ribose polymerase inhibitor, was approved in 2022 for adjuvant treatment in patients with germline BRCAm, HER2-, high-risk early BC (eBC) with prior chemotherapy, following the significant survival benefit seen in the OlympiA trial. It is a priority to understand how the introduction of targeted therapies like olaparib affects clinical management – including BRCA testing – and outcomes in eBC. With two years of post-approval real-world experience, we conducted a preliminary landscape assessment describing eBC patients prescribed olaparib or another adjuvant therapy with respect to patient characteristics and BRCA testing prevalence.

Methods: This was a retrospective observational cohort study characterizing HER2- eBC patients treated with olaparib or other adjuvant therapy in US community oncology clinics utilizing the iKnowMed electronic health record. Adult patients (≥18 years) diagnosed from 1 March 2018 to 31 January 2024 were eligible for inclusion and followed until last patient contact or death. Descriptive analyses evaluated patient characteristics at diagnosis, as well as BRCA testing characteristics, both overall and by treatment (initiation of olaparib or completion of non-olaparib adjuvant therapy).

Results: 250 patients (134 olaparib, 116 non-olaparib) were included and followed for a median (interquartile range [IQR]) of 26.4 (16.1, 37.9) months. Olaparib users were younger at initial diagnosis (mean (standard deviation [SD]) age of 45.8 [12.2] years versus 61.4 [14.4] years among non-olaparib users), and all patients were predominantly White (61.9% olaparib, 57.8% non-olaparib) and non-Hispanic (80.6% olaparib, 76.7% non-olaparib). Where pathologic stage was documented, most patients were diagnosed at Stage II or lesser disease (76.8% olaparib, 86.0% non-olaparib) with a histology of ductal carcinoma (87.3% and 85.3%, respectively). Notably, 68.7% of olaparib users were diagnosed with G3 high grade tumors, versus only 32.8% of non-olaparib users. All olaparib users received a BRCA test (98.5% of patients BRCAm and 1.5% negative). Among the 60.3% of non-olaparib users tested, 23.3% were BRCAm.

Conclusions: This study is one of the first to report the real-world experience of eBC patients immediately prior to and following olaparib approval. All olaparib users received a BRCA test, indicating promising results with respect to appropriate use of olaparib in only BRCA-tested patients. The analysis also found that while a high number of non-olaparib users received a BRCA test and were BRCAm, these results may indicate a potential lost opportunity for both universal BRCA testing and for BRCA-mutated patients to receive targeted therapy. However, future analyses will assess the timing of BRCA testing with respect to the availability of olaparib in this patient subgroup. Future analyses may characterize potential changes in BRCA testing patterns in the post-olaparib setting, which

will facilitate the optimization of targeted treatment plans. Lastly, as the ultimate goal is to assess impact of olaparib on eBC patient management, including improvements in survival, a formal comparative assessment of key clinical outcomes in olaparib versus other adjuvant therapies should be conducted once additional follow-up time is available.

P5-10-25: Exploring JAM2's Potential in Reducing Breast Cancer Invasiveness through IGF2BP2 Regulation

Yang Peng, Han Li, Ailin Lan, Yang Liu, Zehao Cai, Shengchun Liu

Background:Metastatic breast cancer (MBC) presents a significant challenge in the field of oncology, with limited treatment options and generally poor survival outcomes. Therefore, the discovery of new biomarkers and therapeutic targets is crucial for improving the management of MBC. Our previous studies have shown that JAM2, as a tumor suppressor, can reduce the invasiveness and migration of breast cancer cells by inhibiting the epithelial-mesenchymal transition (EMT) pathway, thus playing a key role in tumor biology. These findings suggest the importance of further investigating the specific mechanisms of JAM2.
Methods:This study employed various techniques to comprehensively evaluate the expression and function of JAM2. First, we analyzed clinical samples from breast cancer patients using immunohistochemistry and quantitative PCR to determine JAM2 expression levels and its correlation with disease prognosis and metastasis. Additionally, we established a nude mouse model of breast cancer metastasis by injecting MDA-MB-231 cells with altered JAM2 expression to observe its effects on tumor growth and metastasis. We also used HA-tagged immunoprecipitation and liquid chromatography-tandem mass spectrometry (LC-MS/MS) to screen for proteins interacting with JAM2 and further analyzed these interactions using Western blot, quantitative PCR, and Transwell invasion assays.
Results:The results showed that JAM2 expression was generally low in breast cancer tissues, and its low expression was closely associated with poor prognosis and high metastasis rates. In the nude mouse model, JAM2 overexpression significantly inhibited tumor growth and metastasis. In vitro studies further revealed a direct interaction between JAM2 and IGF2BP2, where JAM2 overexpression significantly reduced IGF2BP2 levels, decreasing cell invasiveness and migration. Conversely, JAM2 knockdown increased IGF2BP2 expression, enhancing the invasiveness of breast cancer cells. Moreover, JAM2 inhibits the expression of the key EMT transcription factor Snail2 by affecting IGF2BP2, further emphasizing its role in inhibiting EMT and metastasis.
Conclusion:The findings of this study highlight the important biological function of JAM2 as a metastasis suppressor in breast cancer, providing new insights into the key proteins and pathways it regulates during tumor progression. JAM2 may inhibit the EMT and the invasiveness and migration of breast cancer cells by downregulating the m6A reader protein IGF2BP2, thus reducing the stability of SNAI2 mRNA. This suggests that enhancing JAM2 expression could be a viable therapeutic strategy to combat breast cancer metastasis.

Future studies are needed to fully elucidate the mechanisms by which JAM2 exerts its effects and to explore its potential clinical applications.

P5-10-26: Adverse events in routine real-world clinical practice in patients with HER2-negative early breast cancer according to BRCA status: a retrospective observational study using artificial intelligence in Spain

Meng Ru, Pilar Zamora, Berta Obispo, Blanca Cantos, Carlos Arias-Cabrales, Carlo Sguera, Miguel Miranda, Meng Ru, Luis C Berrocal-Almanza

Background:Early breast cancer (eBC) survivors often face potential adverse events (AEs) from treatment, especially those with germline BRCA1/BRCA2 mutations (gBRCAm) who are diagnosed at younger ages and are candidates for specific and aggressive risk-mitigation strategies. This study assessed real-world AE patterns in Spanish HER2-negative (HER2−) eBC patients (pts) according to gBRCA status using natural language processing (NLP) on electronic health records (EHRs).
Methods:This was an observational, multicenter, retrospective study of adult pts with incident HER2− eBC (stages I–III) who received (neo)adjuvant therapy between July 2015 and December 2019 at three Spanish hospitals. Pts with synchronous/previous cancers, or in clinical trials, were excluded. We used EHRead®, a validated technology based on NLP and machine learning using the Systematized Nomenclature of Medicine Clinical Terms, to extract clinical information included in structured and free-text EHR data. Pts were stratified by gBRCAm and non-gBRCAm (wild type/unknown) status. We analyzed patient demographics and clinical characteristics at inclusion, as well as (neo)adjuvant treatment patterns, and potential treatment-related AEs during follow-up.
Results:A total of 1,610 eligible pts with HER2− eBC were identified after screening 5,114,548 EHRs (from 81,956 pts). Among these, 191 (11.9%) had gBRCAm and 1,419 (88.1%) had non-gBRCAm (1,403 unknown). Overall, 1,581 (98.2%) pts were female, 72.8% had hormone receptor-positive (HR+) and 27.2% had triple-negative eBC. Specifically, 67.5% of the pts with gBRCAm and 73.5% of pts with non-gBRCAm were HR+. Mean (SD) age was 48.2 (13.7) years in those with gBRCAm and 57.7 (14.2) years in those with non-gBRCAm. Mastectomy rates were 48.7% (gBRCAm) and 17.8% (non-gBRCAm), with radiotherapy administered to 82.7% and 79.1%, respectively. (Neo)adjuvant systemic treatments were given as follows for gBRCAm vs non-gBRCAm: any chemotherapy 67.0% vs 46.3% (anthracyclines 61.8% vs 40.7%, cyclophosphamide 61.8% vs 42.7%, taxanes 63.4% vs 40.3%, fluoropyrimidines 16.2% vs 5.8%, platinum compounds 14.1% vs 3.5%), tamoxifen 33.0% vs 31.0%, aromatase inhibitors 51.8% vs 48.4%, and GnRH antagonists 20.4% vs 4.4%. Median follow-up (interquartile range) was 54.2 (98.0–74.0) months. The most frequently reported AEs in both groups were hematologic complications, affecting 87.4% of pts with gBRCAm and 63.9% of pts with non-gBRCAm, predominantly neutropenia (59.7% vs 40.0%) and thrombocytopenia (59.7% vs 41.5%). Other observed AEs for gBRCAm vs non-gBRCAm were: heart failure 16.8% vs 12.9% and ischemic cardiac disease 5.2% vs 6.3%; local complications 66.0% vs 51.5%, including breast pain 43.5% vs 31.2%

and lymphedema 28.8% vs 17.2%; pneumonitis 6.3% vs 3.9%; osteopenia 13.1% vs 16.6%, and osteoporosis 9.4% vs 14.7%; anxiety 22.0% vs 14.9% and depression 7.9% vs 9.2%. Sexual dysfunction, cognitive impairment, and fear of recurrence were detected in <5% of pts.
Conclusions:Compared with non-gBRCAm pts, those with gBRCAm were, on average, 10 years younger and more frequently treated with mastectomy and chemotherapy, experiencing higher AE frequencies. Low detection rates of AEs such as sexual dysfunctions and psychiatric/psychological disorders suggests potential underreporting in routine clinical practice, highlighting the need for standardized EHR completeness. This would enhance richness and accuracy of data collection, especially given the availability of NLP-based extraction tools for massive data extraction. Future NLP-based studies are essential for evaluating AEs related to new eBC treatments, including gBRCAm-targeted therapy, and for informing clinical decision-making.

P5-10-27: Incidence, risk factors and survival outcomes of Breast Cancer Brain Metastasis: a population-level SEER analysis.

Zunairah Shah, Malak Alharbi, Jayasree Krishnan, Kriti Ahuja, Guangwei Yuan, Kristopher Attwood, Arya Mariam Roy, Shipra Gandhi

Introduction: Metastasis is the leading cause of mortality in breast cancer (BC), and brain metastasis (BM) carries the most unfavorable prognosis. BMs are typically diagnosed based on symptoms, and the clinical outcomes varies depending on the number, location, and size. The aim of our study was to characterize the incidence of BM at the time of diagnosis and to identify the risk factors that are associated with a higher incidence of Breast Cancer Brain Metastasis (BCBM).

Method: Patients diagnosed with BC from 2010 to 2020 were identified using the Surveillance, Epidemiology, and End Results (SEER) database. We summarized clinicodemographic data by BM status to identify potential risk factors for developing BM. Multivariate logistic regression was performed to determine the risk factors associated with BM at diagnosis. Survival outcomes by BM status were analyzed by using cox-proportional hazard regression for the overall population and adjusted for gender, age (18-40 years old (y), 41- 61 y, 61-80 y, and 81+ y), race, marital status, residential area, and treatment modalities. The analysis was done using R version 4.4.1 and statistical significance was defined at $P< 0.05$.

Results: Of the 673,638 patients diagnosed with BC, 2,924 (0.4%) had BCBM. The majority were females (99%, n=2,891) and aged 41 y or older (93%, n=1429). 61% were White (n= 1,772), 16% Black (n= 459), 15% Hispanic (n= 447), 7.2% Asian (n=211) and 0.9% Native American (n=27). BC subtypes among BCBM were: 38% hormone receptor (HR) +/HER2 -, 15% HR+/HER2+, 11% HR-/HER2+, and 18% triple negative BC (TNBC). Other metastases

sites included 64% bone, 44% lung and 31% liver.
Several factors were found to be significantly associated with higher risks of developing BCBM on multivariate logistic regression analysis. The following factors were associated with increased risk of brain metastases: ages 41-61 y (OR 1.2, 95% CI: 1.1-1.4, P <0.01), Hispanic ethnicity (OR 1.2, 95% CI: 1.1-1.3, P<0.004), being single, widowed, or separated (OR 1.2, 95% CI: 1.1-1.3, P<0.001), AJCC stage T4 (OR 4.4, 95% CI: 3.7-5.1, P<0.001) and nodal status N1/2/3 (OR 2.1, 95% CI: 1.9-2.3, P<0.001), presence of bone metastases (OR 20.6, 95% CI: 18.8-22.6, P<0.001), and HR-/HER2+ (OR 3.1, 95% CI: 2.7-3.5, P<0.001) and TNBC subtypes (OR 3.0, 95% CI: 2.7-3.4, P< 0.001).
Patients with BCBM had a shorter median disease specific survival (DSS) compared to patients without BM (13 months (mo) vs. not reached (NR) (HR=22.5, 95% CI: 21.5-23.5, P <0.001). Moreover, they had shorter median overall survival (OS) compared to patients without BM (9 mo vs. NR) (HR=15.0, 95% CI: 14.4-15.7, P <0.001). TNBC patients with BMs have the worst OS (5 mo vs NR) (HR= 2.10 95% CI: 2.07-2.14, P<0.001) and DSS (7mo vs NR) (HR =2.71, CI 2.65-2.77 P<0.001). OS and DSS are also shorter among Black patients, with a median of 8 mo vs NR (HR=1.26, 95% CI: 1.24-1.28, P < 0.001) and (10mo vs NR) (HR =1.27, CI 1.25-1.30 P<0.001) respectively.

Conclusion: Our study shows that patients with HER2-positive and TNBC, Hispanic ethnicity, older age, higher stage T4, living without a partner, nodal and bone metastases are at higher risk of developing BCBM at the time of diagnosis. Prompt screening and higher care should be provided to the patients with these high-risk factors to identify brain metastases. More studies are required to establish risk criteria for brain MRI screening and even preventive intervention on high-risk patients to delay the development of brain metastases.

P5-10-28: A retrospective analysis of the association between body composition measures and relative dose intensity of (neo)adjuvant chemotherapy for elderly breast cancer patients

Naomi Dempsey, Yolcar Chamorro, Austin Guerrina, Muni Rubens, Priya Bhatt, Lauren Carcas, Ana Sandoval, Manmeet Ahluwalia, Reshma Mahtani, Adrian Cristian

Introduction: The use of (neo)adjuvant chemotherapy (CT) in certain subtypes of early-stage breast cancer (EBC) is associated with improvements in pathologic complete response rates (pCR) and in long term outcomes, including event-free and overall survival. Frail and elderly patients (pts) may be less likely to tolerate full doses of CT and may require dose and schedule adjustments in CT. Previous studies have demonstrated that pts with EBC who receive >85% relative dose intensity (RDI) of the planned CT regimen achieve improved outcomes. This study evaluates the association between body composition (BC) or physical functioning (PF) measures and receipt of (neo)adjuvant CT at RDI >85%.
Methods: This study included EBC pts over age 65 who received (neo)adjuvant CT for EBC,

were seen in the rehabilitation clinic of the Miami Cancer Institute between 2018 and 2023, had complete CT records, and had PF and BC data within 1 year of receiving CT were included. Pt demographics, tumor characteristics, PF, BC, CT regimen, RDI, and distant recurrence free interval (DRFI) were evaluated. Validated PF measures included grip strength, sit-to-stand (STS) test, timed up and go (TUG) test, and 4-stage balance test. BC was measured using a bioelectrical impedance analysis (BIA) machine, yielding total body water (TBW), skeletal muscle and fat mass, phase angle, and intracellular and extracellular fluid. RDI was calculated as amount of CT received per time elapsed divided by amount of CT planned per standard time to complete planned CT. Pt characteristics were compared between RDI categories (<85% versus ≥85%) using Chi squared test for categorical variables or Mann Whitney U test for continuous variables. Kaplan Meier test was used to assess DRFI.

Results: 49 pts were included in this analysis and 47/49 pts (95.9%) were female (F). 31/49 pts (63.3%) were of Hispanic (H) ethnicity, 40 (81.6%) were white (W), and 7 (14.3%) were black (B). Of the entire group, 30/49 pts (61.2%) and 29/47 (61.7%) of F pts achieved >85% RDI, while 0/2 male (M) pts achieved this metric (p=0.07). When evaluating pts who received RDI >85% by ethnicity, differences were noted with 17/31 (54.8%) H and 13/18 (72.2%) non-H pts received >85% RDI (p=0.23). By race, 26/40 (65.0%) W pts achieved >85% RDI while only 3/7 (42.9%) B pts were able to do so (p=0.3281). Among the pts who received anthracycline-based CT, 17/30 (56.7%) achieved >85% RDI compared to 13/19 (68.4%) of those pts who received a non-anthracycline based regimen (p=0.41). STS was statistically significantly higher among those who achieved >85% RDI than those who did not (11.0 vs 7.4; p=0.004). TUG was also statistically significantly better among those who achieved >85% RDI (8.6 sec vs 11.9 sec; p=0.002). TBW was significantly lower in those with >85% RDI than those with <85% RDI (33.2 L vs 36.6 L; p=0.04). There were no significant differences in STS, TUG, or TBW based on race or ethnicity. Median DRFI was non-significantly longer in those who received RDI >85% (67 vs 57 months, p=0.601).

Conclusions: This study demonstrates that pts with poorer physical functioning as measured by STS and TUG tests and those with elevated TBW were less likely to achieve RDI >85%, an established benchmark for superior outcomes. These tests are efficient and convenient for use in the clinical setting. There were differences in RDI by gender as well as race/ethnicity, with M, B, and H pts demonstrating a non-significant trend toward lower RDI than F, W, and non-H pts. The establishment of a scoring system to predict which pts are unlikely to achieve RDI >85% could help tailor CT regimens for elderly or frail pts. This information can also be used to improve the physical function and nutritional status of these pts by incorporating rehabilitative and nutrition programs before and during (neo)adjuvant CT.

P5-10-29: Comparative analyses of Van Nuys index and NCCN guidelines in ductal carcinoma in situ in a Brazilian hospital

Marcelo Antonini, André Mattar, Mariana Pollone Medeiros, Denise Joffily Pereira da Costa Pinheiro, Francisco Pimentel Cavalcante, Felipe Zerwes, Eduardo de Camargo Millen, Fabricio Palermo Brenelli, Antonio Luiz Frasson, Odair Ferraro

Objectives: To compare the recommendations of the National Comprehensive Cancer Network (NCCN) and the Van Nuys Index with the treatment adopted for DCIS in patients at the Hospital do Servidor Público Estadual de São Paulo (HSPE), relating the treatment employed to recurrence rates during follow-up. Additionally, this study aims to analyze the epidemiological profile of patients with DCIS in the same facility.
Methods: This is a retrospective cross-sectional observational study, conducted by reviewing the medical records from the Mastology Department at HSPE. The following variables were evaluated: age, menarche, parity, breastfeeding, duration of breastfeeding, menopause, family history of breast cancer, initial presentation, follow-up duration, diagnostic method, anatomopathological results, nuclear grade, tumor size, surgical margin, immunohistochemistry, Van Nuys Index score, NCCN recommendation, treatment administered, number of recurrences, and deaths.
Results: A total of 145 patients with DCIS were evaluated between 1996 and 2021, with a mean age of 60.1 years. Of these, 100 had no family history of breast neoplasia, and 88 were diagnosed through screening exams. Among those with clinical symptoms, a palpable nodule was the most prevalent (24.1%), and the most commonly employed treatment was conservative surgery with radiotherapy (43.1%). During follow-up, 18 (15.5%) recurrences were observed. According to the Van Nuys Index, 45 patients were classified as low risk, 62 as intermediate risk, and 9 as high risk. According to the NCCN classification, 15 patients were in the low-risk group, and 101 were in the high-risk group. Qualitative factors and their relationship with the presence of recurrences were evaluated, but no statistically significant relationships were found.
Conclusions: DCIS predominantly affects postmenopausal women, with the majority of diagnoses made through screening and the primary treatment was conservative surgery followed by radiotherapy, resulting in a low number of recurrences. No significant factors associated with recurrences were identified. When comparing the Van Nuys Index and the NCCN guidelines, the latter advocates for a more aggressive treatment approach and showed a 5.6% reduction in local recurrences.

P5-10-30: Developing microenvironment-based prognostic biomarkers for early breast cancer

Christina Kozul, Keith Naylor, Allan Park, Cameron Nowell, Metta Jana, Sandun Silva, Madawa Jayawardana, Bruce Mann, Belinda Parker

Problem statement: Ductal carcinoma in situ (DCIS) is a pre-invasive stage of breast cancer in which tumour cells have not invaded beyond the ductal system. Approximately 25% of

screen-detected breast cancers are now diagnosed as DCIS. Predicting local recurrence in patients with DCIS is imprecise, with standard histopathological features and intrinsic tumour cell markers failing to identify a low-risk group that could be spared therapy. Myoepithelial cells, the cells that surround breast ducts, are considered the gatekeepers where they not only act as a physical barrier between epithelial cells and the surrounding tissue/basement membrane but also secrete factors that suppress pro-invasive mechanisms such as proteolytic activity. Myoepithelial proteins offer an alternative pathway for biomarker development in DCIS.
Methods:Candidate myoepithelial markers were identified through a high-throughput siRNA 3D co-culture screen that was designed to identify myoepithelial cell-derived suppressor proteins. To investigate the functional role of candidate myoepithelial proteins, we utilised and modernised an established DCIS-like model, incorporating an immortalised myoepithelial cell line (N1ME) that has been shown to restrain tumour cell invasion in 3D culture when co-cultured with a triple-negative breast cancer cell line (MDA-MB-231). Knockdown and CRISPR-based knockout of candidate adhesion proteins and protease inhibitors allowed assessment of the importance of these proteins in the suppressive capacity of myoepithelial cells. We quantified this using a perimeter-to-convex hull ratio and high-resolution single organoid analysis, including organoid tightness. Characterisation of the expression of these proteins in normal, DCIS and microinvasive tissues was performed using immunohistochemistry.
Results: An adhesion protein and two cathepsin inhibitors were identified for their tumour-suppressing function. Targeted siRNA knockdown and CRISPR knockout in N1ME cells significantly blocked myoepithelial cell-mediated suppression of breast cancer cell invasion when compared to the controls using both perimeter-to-convex hull ratio and high-resolution adhesion analysis of the N1ME cells within the organoid. Despite the physical presence of myoepithelial cells in these cultures, loss of these proteins was sufficient to allow tumour cell invasion beyond this cellular barrier. Given the potential of these myoepithelial proteins as biomarkers of risk of invasion, we measured expression in normal and early cancer lesions and confirmed that their expression is highly abundant in myoepithelial cells surrounding normal ductal epithelium but reduced or completely lost in micro-invasive DCIS regions, the earliest phase of invasion. Current studies aim to evaluate the prognostic value of these markers in predicting the risk of invasive recurrence in a larger cohort.
Conclusion: We have identified novel myoepithelial proteins that suppress early tumour invasion. Our work may offer a new approach to patient stratification to ensure treatment is personalised and treatment is optimised for patients with DCIS.

P5-11-01: LAD Dose and Cardiotoxicity in Breast Cancer Patients Receiving Radiation

Colleen Conger, Nhat Minh Ho, Bryson Hill, Jacob Buatti, Alissa Herrera, Mohit Shiv Agarwal, Jonathan Gelfond, Neil Newman

Purpose: Although whole heart dose has been associated with cardiac toxicity in patients receiving radiation therapy for breast cancer, data detailing the clinical significance of cardiac substructures, particularly the left anterior descending artery (LAD), are limited. We investigated whether dose to both the LAD and whole heart correlates with adverse cardiac events and death in our cohort.
Methods and Materials: We identified 1 male and 493 female patients treated from 2004 to 2022 who received definitive breast or chest wall irradiation, with or without regional nodal irradiation. Cumulative radiation dose, treatment dates, and treatment type were obtained from Mosaiq. EPIC was queried to identify cardiac events after radiation therapy, as well as anatomic stage at diagnosis, surgery, chemotherapy, and hormonal therapy received, baseline cardiac problems, whether the patient took cardiac medications prior to treatment, and whether the patient was deceased. Mean and maximum LAD and heart doses, as well as V15LAD, were calculated using Pinnacle. Univariate and multivariate Cox regression analyses were performed in R to determine the association of the collected variables with cardiac toxicity and death. Cumulative incidence curves for death and cardiac events were also calculated.
Results: Median follow-up time was 39 months. Fifty-two patients experienced a cardiac event, with 17 of these being grade 3 or higher. Forty-two patients (8.5%) were deceased at the time of data collection, 5 of whom experienced a cardiac event prior to death. One death was of cardiac origin. On univariate Cox regression, the only significant predictor of any cardiac event or cardiac event grade 3 or higher was baseline heart problems (p=.026 and p=<.001, respectively). On univariate Cox regression, statistically significant predictors of death included anatomic stage (p=<.001), mean LAD dose (p=<.001), max LAD dose (p=.002), V15LAD(p=<.001), and mean heart dose (p=<.001), and receipt of DIBH treatment was protective against death (p=.02). Cumulative incidence curves predicted a 12.64% probability of a cardiac event 5 years after treatment and a 37.28% probability at 10 years after treatment. They also predicted an 8.40% probability of death at 5 years post-treatment, and a 16.24% chance of death at 10 years.
Conclusion: The only significant predictor of adverse cardiac events in this cohort was baseline cardiac problems. Mean heart dose, mean LAD dose, max LAD dose, and V15LAD were all significant predictors of death, but not adverse cardiac events. Additionally, anatomic stage was predictive of death, and DIBH was protective. Longer term follow-up may prove useful in discerning the relationship between LAD dosing and adverse cardiac events in this cohort, as median follow-up was only 39 months.

P5-11-02: Dosimetric Advantages of Prone 3DCRT APBI: A Comparison with Supine IMRT APBI from the Livi Study

Rufus Banks, Jose G. Bazan, Rolan Cesar Domingo, Priya Mitra, Erin Healy

Background: External beam accelerated partial breast irradiation (APBI) has emerged as an alternative to whole breast radiation (WBI) in appropriately selected patients who have undergone breast conserving surgery. It is associated with lower short- and long-term

toxicity compared with WBI due to smaller target volumes and increased sparing of normal tissues. However, there have been conflicting data regarding toxicity and cosmesis from the various APBI clinical trials. Since publication of the long-term results of the University of Florence study by Livi et al. in 2020, the field has shifted towards using the Florence regimen, 30Gy in 5 fractions, which utilizes inverse planned intensity modulated radiation therapy (IMRT) in the supine position. Prior randomized trials used twice daily fractionation and 3D conformal (3DCRT) technique. There is uncertainty whether it is the fractionation schedule (BID vs. daily) or technique (IMRT vs. 3DCRT) that resulted in more favorable cosmetic results. At our institution, we utilize prone positioning and 3DCRT technique to deliver APBI. We set to compare our dosimetric results to those reported in the Livi study.

Methods: We queried our institution from January 2022 to June 2024 for patients with early-stage breast cancer who had undergone BCS and were treated with APBI in the prone position. All patients treated with the same dose and fractionation used in the Florence regimen, 30Gy in five daily fractions delivered on non-consecutive days. We collected patient and tumor characteristics as well as a detailed dosimetric parameters. We focused on the key parameters in the Livi study including heart V3Gy, ipsilateral lung V10Gy, contralateral lung V5Gy, and uninvolved breast V15Gy. We also captured the volume of the planning target volume (PTV) that received 95% of prescription dose (V95%). We compared our results to those reported in the Livi study using an unpaired T-test with a P-value <0.05.

Results: During this time, there were 82 patients who met our criteria. The median age was 61 years (IQR 52-68). 72% had invasive disease, 48.8% were left-sided, and 95% were estrogen receptor positive. Our target coverage PTV V95% was significantly higher than that recorded in the Livi study (mean 98.7%, median 99.3%, range 95-100%, SD=1.5 vs. a mean of 96.6%, median 97%, range 88-100%, SD=2.8, $P<0.0001$). Despite this, we found that the dose to all OARs were significantly lower in our population compared to those in the Livi study. The heart V3Gy was significantly lower in our population (mean 1.1%) compared to the Livi study (mean 7.4%, $p<0.0001$). Our ipsilateral lung V10Gy mean=0.71%, median=0%, IQR=0-0.6%, range=0-10%, SD=1.76 vs. mean=10.3%, median=11.0%, range=0.0-22.0%, SD=4.9, $P<0.0001$. Our contralateral lung V5Gy mean=0%, median=0%, range=0-0%, SD=0 vs. mean=0.9%, median=0.0%, range=0-19.0%, SD=3, P=0.007. Lastly, our uninvolved breast V15Gy mean=26.5%, median=27.5%, IQR=18.9%-33.6%, range=9.7%-48.7%, SD=8.52 vs. mean=32.3%, median=31.0%, range=8.0-62.0%, SD=11.4, $P<0.0001$.

Conclusion: Our study demonstrates that prone 3DCRT APBI achieves superior target volume coverage and significantly lower dose to organs at risk (OARs) compared to supine IMRT APBI reported in the Livi study. This suggests that prone 3DCRT APBI may be a suitable alternative to IMRT for achieving good target coverage while potentially minimizing toxicity to surrounding healthy tissues. However, longer follow-up is necessary to assess cancer control and cosmetic outcomes.

P5-11-03: Optimizing Adjuvant Treatment Decisions for Patients With Ductal Carcinoma In Situ Using the Oncotype DCIS Score: An Analysis from the National Cancer Database

Jose Bazan, Stephanie Yoon, Katharine Schulz-Costello, Jamie Rand, Peter Wu

Background: The optimal treatment of patients with ductal carcinoma in situ (DCIS) that have undergone breast conserving surgery (BCS) remains controversial given the need to strike a balance between preventing the development of invasive disease while minimizing the risk of over-treatment and treatment-related toxicity. Until recently, personalized genomic assays to help estimate recurrence risks such as the Oncotype DCIS Score were not available. We sought to determine the frequency of DCIS Score use within the National Cancer Database (NCDB) and to determine if the DCIS Score was associated with use of adjuvant treatments after BCS.
Materials/Methods The NCDB began collecting the DCIS Score in 2018. We identified patients with DCIS that had undergone BCS with negative margins from 2018 to 2021 who were pathologically stage group 0. We then identified patients who had a resulted DCIS score and dichotomized these patients into a low-risk (LR) group (DCIS Score<39) or non-LR group (DCIS Score≥39). We collected information on age, grade, size of DCIS, hormone-receptor status, receipt of radiation therapy (RT) and receipt of endocrine therapy (ET) for the entire cohort and for patients with a DCIS Score. We compared rates of RT and ET use between the LR and non-LR groups and applied multivariable logistic regression to calculate odds ratios. We then created a propensity score matched (PSM) cohort balanced for age, race, performance status, size of tumor (<1cm, 1-2.5cm, 2.5cm+), grade, ER/PR status, insurance status, year of diagnosis, income, and compare rates of RT and ET use in patients with a DCIS Score versus those without.
Results: We identified 82,965 patients that met inclusion criteria, of which 2688 (3.2%) had a DCIS Score. The proportion of patients with a DCIS Score decreased from the first year to the last year of the study (4.5% vs. 2.4%, p<0.001). In patients with a DCIS Score, 69.3% (1,791) were in the LR group and 30.7% (794) in the non-LR group. In the DCIS Score cohort, 39.9% (N=301) of patients with grade 3 disease fell into the LR group and 18.5% (N=319) of patients with grade 1-2 disease were in the non-LR group. Rates of RT (71% vs. 36%, OR=3.2, 95% CI: 2.6-3.9, p<0.001) were significantly higher in the non-LR group compared to the LR group. ET did not vary significantly with respect to LR vs. non-LR group (65% vs. 59%, OR=1.2, 95% CI: 1.0-1.5, p=0.1). In the PSM cohort, the rates of RT use were 47% vs. 68% (OR=2.8, 95% CI 2.5-3.2, p<0.001) and rates of ET use were 63% vs. 65% (OR=1.1, 95% CI 1.0-1.3, p=0.1) in patients with DCIS Score vs. without DCIS Score. Patients with a DCIS Score had significantly higher rates of receiving no adjuvant therapy compared to those without a DCIS Score (22.3% vs. 15.0%, OR=1.6, 95% CI 1.4-1.9, p<0.001).
Conclusion: Overall, the adoption of the DCIS Score in patients within the NCDB since 2018 has been low and appears to be decreasing. However, the DCIS Score appears to have clinical utility regarding adjuvant RT in patients that have undergone BCS and DCIS Score receipt was also associated with higher rates of BCS alone. Use of personalized tools such as

the DCIS Score should be encouraged to help patients and physicians optimize adjuvant radiation therapy use for DCIS.

P5-11-04: SHORT-TERM ECOCARDIOGRAPHIC ALTERATIONS AMONG BREAST CANCER PATIENTS WITH HYPOFRACTIONATED RADIATION THERAPY

Ricardo Mendoza Coronado, Christopher Cerda Contreras, Ricardo Mendoza Coronado, Enrique Gonzalez Nava, Rafael Piñeiro Retif, David Hernandez Barajas, Oscar Vidal Gutierrez, Marco Antonio Gamez Ruiz, Melissa Emilia Rodriguez Ruiz

Radiotherapy is one of the mainstays of breast cancer (BC) treatment. In the adjuvant setting, either conventional or hypofractionated radiotherapy (HRT) eradicates subclinical disease (1). Nevertheless, long-term adverse effects such as secondary neoplasms, skin, pulmonary and cardiac toxicities are not infrequent. Radiation-induced cardiotoxicity (RC) involves valvopathies, early atherosclerosis, arrhythmias and heart failure due to acute left ventricle myocardial dysfunction (2). Early cardiac repolarization and mild subclinical myocardial disfunction are found along, 6-week or 9-month after RT by EKG and echocardiography, respectively (3-5).
Objective:
To identify subclinical cardiac changes immediately after hypofractionated RT using global longitudinal strain (GLS) measured by doppler and 2D-echocardiography (2DE).
Methods:
A prospective pilot-cohort study was conducted. Sociodemographic, clinical and paraclinical data of non-metastatic BC patients were collected by the end of last year. Postoperative breast RT was planned for all patients with 40 Gy in 15 fractions to tumor bed and/or chest wall with or without nodal irradiation, followed by sequential boost to tumor bed if required, using sequential helical tomotherapy. Cardiac radiation dose distribution was also registered. A 2DE was performed before starting and the day after completion of RT.
Results:
38 female BC patients were recruited. Median age was 57 years. 60% had hypertension and 39% diabetes. 42% had overweight & 50% were obese. III stage disease accounted for 44,7%. 71% were hormone receptor positive, 15,7% HER2 positive and 26,3% triple negative BC. Mean and maximum heart dose were 3,55 +/- 0,5 mSv and 23,47 +/- 9,2 msV, respectively. Measure of left ventricular ejection fraction with biplane Simpson's method before and after HRT were 59,4% +/- 5,1 and 59,21% +/- 4,9. GLS prior to RT was 19,26 +/- 1,97, and afterwards was 19,11 +/- 2,09. No statistical difference in LVEF (p=0,899) nor GLS (p=0,605) were found previously or following HRT. However, very subtle diastolic changes such as IVSd (interventricular septum thickness), PWd (left ventricular posterior wall) and mitral E wave velocity were statistically significant (p=0,030; p=0,033 and p=0,083). No myocarditis, pericarditis, pericardial effusion or any other significant echocardiographic finding were observed.
Conclusion:

Although no meaningful echocardiographic changes were found after HRT, this pilot study supports the theory that HRT is safe and does not induce relevant hyperacute cardiac anomalies in non-metastatic BC. 2D-echocardiography is a useful tool to diagnose and monitor subclinical disease before long-term radiation-induced cardiotoxicity is established. Middle and long-term cardiovascular changes of this cohort will be analyzed in future publications.

P5-11-05: Phase II Trial of Ultrahypofractionated Image-Guided Partial Breast Irradiation Following Lumpectomy with Optional Oncoplastic Reconstruction for Early-Stage Breast Cancer

Rachel Radigan, Vani Gupta, Andrew T. Wong, Sophia Fu, Austin Barney, Jeffrey Pettit, Shrivedi Singh, Jana Deitch, Johnny Kao

Background & Purpose: Breast conservation surgery followed by adjuvant radiotherapy has shown more positive body image attitudes compared to mastectomy. This study investigates the use of a 5-fraction accelerated partial breast irradiation (APBI) radiation for early breast cancer with or without oncoplastic surgery with the aim to share subjective and objective outcomes, including toxicities and cosmetic results. Methods & Materials: Eligible patients for this single institution phase II trial (IRB 18-002) were aged 50 or older with unifocal stage 0 to 1 breast cancer measuring ≤ 3 cm undergoing breast conserving surgery or oncoplastic reconstruction with negative surgical margins (≥ 2 mm margin width), ER positive, negative nodes and no lymphovascular invasion. Presurgical MRI was routinely performed. Patients were treated to 30 Gy in 5 fractions via intensity-modulated radiation therapy (IMRT) using a QOD schedule on the Varian Edge radiosurgery system. The planning target volume (PTV) was defined as the tumor cavity + 1.5 cm cropped 5 mm off skin with the mean PTV30 of 146 cc (range 43-408). Clinical follow-up included history

and physical, breast imaging, and the validated Breast Cancer Treatment Outcome Scale (BCTOS) at 6 to 12 months intervals. Results: A total of 50 patients with 52 tumors were enrolled with a median age of 76 (range 51 to 89) between November 2018 and July 2022 with 23 patients (46%) undergoing oncoplastic breast surgery. Median follow-up was 37 months (range 9 to 64), the 4-year local control, regional control, distant control, and overall survival were 100%, 96%, 100%, and 94% respectively. There were 2 recurrences (1 regional nodal failure, 1 second primary triple negative breast cancer) and 3 deaths from other causes other than breast cancer occurred in this patient population. Treatment was well tolerated with 22% grade 1 to 2 acute toxicity and 4% late toxicity consisting of grade 1 pain. Physician-rated long-term cosmesis was rated as 83% excellent and 17% good. BCTOS scores at baseline were 58% excellent (91% lumpectomy, 13% oncoplastic), 42% good (9% lumpectomy, 88% oncoplastic), 0% fair to poor, and at ≥2 year follow up were 92% excellent, (100 % lumpectomy, 86% oncoplastic), 8% good (0 % lumpectomy, 14% oncoplastic), and 0% fair to poor. Conclusion: This trial demonstrated the safety and efficacy of a modernized Florence regimen in low-risk stage 0 to 1 breast cancer patients treated at a community hospital. Long-term cosmetic outcomes were excellent and oncoplastic reconstruction does not appear to be a contraindication for APBI.

P5-11-06: Adjuvant radiation therapy following pathologic complete nodal response to neoadjuvant chemotherapy; Real World Data

Fadwa Abdel Rahman, Mohammad Alsmairat, Anoud Al-Nsour, Hikmat Abdel-Razeq, Abdulla Alzibdeh

Background and objectives: After neoadjuvant chemotherapy (NACT), the likelihood of loco-regional recurrence (LRR) within 10 years in locally-advanced breast cancer patients (cT1–3, N0–N1) is substantial, surpassing 10%. Adjuvant nodal irradiation (RNI) has been the standard of care in locally advanced breast cancer patients with affected lymph nodes to lower the chances of loco-regional recurrence of breast cancer despite the response following neoadjuvant chemotherapy for many years. However, it comes with the cost of significant skin, lungs, and heart toxicities. Moreover, post-mastectomy radiotherapy (PMRT) is associated with a high rate of implant-related complications.
Researchers have tried to address if regional nodal irradiation can be safely omitted after achieving lymph nodes pathologic complete response (ypN0) in breast cancer patients with lymph node involvement receiving neoadjuvant chemotherapy. In the recently presented abstract of the NSABP B-51/RTOG 1304 trial, with median follow up of 59.5 months, isolated Loco-regional recurrence was reported in 1.6% of the patients who did not receive RNI and in 0.7% of the patients who did, with invasive breast cancer recurrence reported as 8.2% and 7.3% in both groups, respectively.
This study aims to review treatment outcomes of the same cohort of patients at King Hussein Cancer Center (KHCC) and asses if RNI omission can by safely applied.

Research method: In this study, we will retrospectively analyse treatment outcomes of eligible women who are diagnosed at age of 18 years or older with non-metastatic breast cancer patients with cT1-3 disease, with biopsy proven lymph nodes involvement, received neoadjuvant chemotherapy and completely responded in the nodes as determined by sentinel-lymph-node biopsy or axillary-node dissection. They also should've been treated with regional nodal irradiation after mastectomy or breast-conserving surgery at KHCC. Patients with bilateral, de-novo metastatic disease or residual nodes are excluded. Primary Endpoint is Loco-regional recurrence in the ipsilateral breast or regional nodes. Secondary outcomes include distant Recurrence-free Interval, disease-free and overall Survival.
Result and findings: Of all patients who were retrieved from KHCC cancer registry, treated and followed up at KHCC between Jan, 2013 and Dec 2023, 209 Patients fulfilled the eligibility criteria. Median age was 48 years. Majority had clinical stage cT2. half of the patients had grade 3 and had ductal histology in 92.3%. 86.6% had LVI negative. All patients received radiation with mean dose 47Gy, one third received tumour bed boost. Only 7% were triple negative. 45% achieved complete tumour response while only 7.2% had ypT2-3. The median follow-up period was 55 months. Overall survival (OS) rates were 99.0% at 24 months and 96.6% at 48 months. Progression-free survival (PFS) rates were 97.1% at 24 months and 87.0% at 48 months. Locoregional control rates were 99.0% at 24 months and 93.2% at 48 months. Eleven patients experienced locoregional failure. Histologically, none of them below cT2, 63.6% were grade 2 and 36.4% were grade 3. Lymphovascular invasion was present in 36.4%, and none had perineural invasion. 63.6% received a tumor bed boost, and almost all had negative margins. Regarding receptor status, 36.4% were hormonal receptor-negative and 54.5% were HER2-positive. 18% had ypT2, the rest equally distributed among ypT0, ypTis, and ypT1.

Conclusions: The B-51/RTOG 1304 study indicates that omission of adjuvant radiotherapy in ypN0 isn't negatively impacting outcomes. We would anticipate a locoregional recurrence rate without radiation of 14.46% in our patients compared to 1.375% in the B51 cohort if we applied basic assumptions based on our recurrence rate. Careful selection is warranted.

P5-11-07: A longitudinal analysis of the specific types of anxiety towards radiotherapy in patients with breast cancer before, during, and after radiotherapy

Shi-Jia Wang, Xin Feng, Wei Zhang, Yan Liu, Hong-Xia Gao, Hao Jing, Yi-Rui Zhai, Wen-Wen Zhang, Hui Fang, Yu Tang, Yong-Wen Song, Yue-Ping Liu, Bo Chen, Shu-Nan Qi, Yuan Tang, Ning-Ning Lu, Fu-Kui Huan, Ye-Xiong Li, Shu-Lian Wang

Backgrounds: Most patients have many concerns about radiotherapy (RT) because they know little about it. Radiotherapy Categorical Anxiety Scale (RCAS) was formulated to evaluate the specific types of anxiety among cancer patients receiving RT. This study aims to apply the RCAS to breast cancer patients in China and assess the reliability and validity of the Chinese version; and to investigate its longitudinal changes throughout treatment.

Methods: This prospective, longitudinal study enrolled 504 eligible breast cancer patients receiving RT in China. Patients completed questionnaires assessing the specific types of RCAS, depression (9-item Patient Health Questionnaire [PHQ-9]), and anxiety (7-item Generalized Anxiety Disorder [GAD-7]) before, during, and after RT. Psychometric properties of RCAS including internal consistency, construct validity, convergent validity, and discriminant validity, were assessed. Generalized estimating equations were performed to evaluate dynamic changes in RCAS total and sub-scale scores. Univariate and multivariate regression analyses were conducted to explore factors associated with RCAS score before and after RT.
Results: The Chinese version of RCAS demonstrated its excellent reliability (Chronbach's α 0.89 to 0.92) and construct validity (Bartlett sphericity test $P < 0.001$; Kaiser-Meyer-Olkin index = 0.95). Confirmatory factor analysis further demonstrated its adequate convergent and discriminant validity. RCAS scores decreased significantly during RT over time. RCAS-F3 (treatment effects of RT) remained stable, while RCAS-F1 (adverse effects of RT) and RCAS-F2 (environment of RT) decreased significantly over time. Patients presented higher scores in items about side effects, after-effects, and treatment effects of RT compared with other items in RCAS. Multivariate analysis revealed that only high PHQ-9 and GAD-7 scores were independent factors for high RCAS scores, no matter before or after RT.
Conclusions: The Chinese version of RCAS was eligible for quantitatively evaluating the specific types of anxiety in breast cancer patients receiving RT in China. Clinicians should pay more attention to dispelling patients' concerns of side-effect, after-effects, and treating efficacy of RT, especially for patients with depression and anxiety.

P5-11-08: Primary analysis of radiotherapy data from prospective randomized controlled phase III VENUS trial: sentinel lymph node biopsy Versus No axillary surgery in early breast cancer clinically and UltraSonographically node negative

Danielle Araujo, Giuliano Mendes Duarte, Sergio Carlos Barros Esteves, Rodrigo Menezes Jales, Maria Beatriz Kraft, Amanda Maria Sacilotto Detoni, Julia Yoriko Shinzato, Cassio Cardoso Filho, Renato Zocchio Torresan, Fabrício Palermo Brenelli, Higor Kassouf Mantovani, Grazielle Moraes Tavares, Eduardo Carvalho Pessoa, Idam de Oliveira Júnior, Ruffo de Freitas Júnior, Rosemar Macedo Sousa Rahal, Jorge Villanova Biazus, Andrea Pires Souto Damin, Vinicius Milani Budel, Lucas Roskamp Budel, Roberta Dantas Jales Alves de Andrade, Leonardo Ribeiro Soares, Marcelo Antonini, Francisco Pimentel, Darley de Lima Ferreira Filho, Sabas Carlos Vieira, Kamila Bezerra Fernandes Diocesano, Rafael Henrique Szymanski Machado, Luis Otávio Sarian

Background: Radiotherapy is an important treatment for breast cancer. The axilla possibly receives some dose of radiation from treatment in the breast field and could perhaps treat node-positive disease. Previous trials on de-escalation of axillary surgery, including omitting sentinel lymph node biopsy (SLNB), have not detailed or presented few radiotherapy data. VENUS is an ongoing trial that evaluates omission of SLNB in early breast

cancer clinically and ultrasonographically node negative. This is a partial report on the first interim radiotherapy data collected up to 4.5 years after the VENUS trial has started. The objective is to evaluate radiotherapy dose in axilla and whether radiotherapy is being uniform between VENUS groups.
Methods: prospective, multi-center, non–inferiority, phase III, randomized controlled clinical trial including T1-2 N0 (clinical/ultrasound) M0 breast cancer patients (>18 years old) randomized into: SLNB or no axillary surgery. The sample size is calculated at 800 randomized women, with patients undergoing mastectomy and neoadjuvant chemotherapy being allowed. Randomization (1:1) is being stratified by age and tumor size. Endpoints include disease free survival after 5 years of follow-up (primary endpoint), overall survival, regional recurrence free survival, axillary recurrence rate, axillary morbidity rate, ultrasound accuracy and cost-effectiveness. Adjuvant radiotherapy planning was based on local protocols adopted by each study center. In the no-surgery group, axilla status was considered N0 during planning. Radiotherapy features analyzed were: planning, site, number and location of fields, whole-breast/boost dose, fractioning and estimates of dose volumetry (total and 90%) distribution in axillary levels I-III. VENUS trial is registered at ClinicalTrials.gov (NCT05315154) and ReBEC (RBR-8g6jbf).
Results: Until June 2024, 372 women were randomized. Radiotherapy was performed in 249 (SLNB n=133 and no-surgery n=116). Two-D, 3D-IMRT and 3D-Conformational planning were applied for 7, 26, 200 patients, respectively, with no imbalance across study groups (p=0.34). Mean whole-breast dose was 3558.17cGy in SLNB and 3773.40cGy in no-surgery (p=0.22). Mean percentage of total prescribed breast doses distribution in axillary were: Level I 4.39% SLNB vs 2.34% no-surgery (p=0.21), Level II 0.31% SLNB vs 0.06% no-surgery (p=0.72), Level III 0.72% SLNB vs 0.00% no-surgery (p=0.08). Radiotherapy fields (axilla, supraclavicular fossa, breast and internal mammary) and boost are described and were all evenly balanced across study groups.
Conclusion: Breast radiotherapy has achieved an unintentional low radiation dose in the axilla of some patients, mainly at Level I. However, there was no difference between VENUS trial groups in radiotherapy parameters. So far, with more than 40% of the sample size achieved, there has been no violation of radiotherapy procedure protocol in the VENUS trial. Of the axillary surgery de-escalation trials, up to now VENUS trial presented 42% radiotherapy data.

P5-11-09: Evaluating Setup Accuracy via Daily CBCT of SGRT Based Tattooless vs Tattooed (Non-SGRT) Setup for Tangential Whole Breast Radiation

Mona Karim, Zhanrong Gao, Junsheng Cao

Introduction: Recently Tattooless patient positioning using Surface Imaging Guided Radiotherapy (SGRT) has become popular for the setup of breast cancer radiotherapy. However, the use of permanent skin tattoos in alignment with in-room lasers is still the standard setup approach. In this study, we compared the setup accuracy between

traditional tattoo based and tattooless approaches.

Materials and Methods: This study involved 27 whole breast cancer patients undergoing 3D planned tangent beam radiotherapy via Varian TrueBeam. They were randomly divided into two groups: 13 were positioned using traditional tattoo markers aligned with in-room lasers and without SGRT, and 14 were positioned tattooless using AlignRT surface imaging technology (London, UK). Each patient consented to participate in the study and the study received approval from our institutional IRB. Prior to radiation delivery in each fraction, patient setup for both groups of patients wasverified with onboard daily CBCT. Setup error was defined as position displacement from planning CT to daily CBCT. Wilcoxon rank sum test was used for statistical analysis.

Results and Analysis: A total of 171 daily patient setups were measured from 14 patients with Tattooless setup approach using SGRT while 226 were measured from 13 patients with Traditional Tattoo based setup approach. For tattooless setup, the median absolute shifts were 0.25cm in Anterior-Posterior (AP) direction (range 0~0.88cm), 0.2cm in Superior-Inferior (SI) direction (0~0.94cm) and 0.2cm in Lateral direction (0~0.83cm). For the tattoo based setup approach, the corresponding median shifts were 0.37cm for AP (range 0~2.14cm), 0.25cm for SI (range 0~1.15cm), and 0.2cm for Lateral (0~1.22cm). We found that the setup error was smaller in the AP direction for Tattooless by using the Wilcoxon rank sum test ($p<0.05$) while there was no significant difference in Lateral and SI directions between Tattooless and Tattooed approaches ($P=0.93$ and 0.37 respectively). For Tattooless setup, 10% of absolute shifts exceeded a magnitude of 8mm, while for traditional Tattoo based setup, a corresponding 16.8% exceeded 8mm.

Discussions and Conclusions: Tattooless setup via AlignRT may have a better setup accuracy in the AP direction, and has an equivalent accuracy in SI and LR directions compared to a tattoo-based method. In addition, Tattooless method can reduce the frequency of large shifts from 16.8% to 10% as compared to traditional tattoo based setup approach.

P5-11-10: Analysis of Daily Setup Errors for Patients Undergoing Left Prone Whole Breast Radiotherapy by BMI

Jared Hunt, Lamia Choudhury, Patrick Beagen, Xiao Zhao

Purpose/Objective: For women with early stage left-sided breast cancer who undergo breast conserving surgery, whole breast radiation therapy is often recommended as adjuvant treatment. The most concerning late toxicity in these women is heart toxicity. In recent years, prone treatment techniques have helped reduce heart dose by positioning the breast further from the body. However, this comes with risks as the setup is more unstable and difficult to replicate. Setup uncertainties can lead to higher-than-expected heart doses

or under-dosing of breast tissue. Our objective was to investigate the daily setup errors and potential dosimetric benefit of utilizing a low dose cone beam CT (CBCT) for prone left breast radiation.

Materials/Methods: We performed a retrospective review of consecutive patients treated at our institution with left breast cancer between April 2019 and June 2021 in the prone position. Patients were set up to clinical marks and a custom low dose partial arc CBCT was acquired with each fraction. Daily shifts were recorded for each fraction, with vector displacements calculated for both total magnitude and angular displacement in both the transverse and coronal plane. Using the daily shifts, we calculated the delivered dose if these shifts were not performed. Differences between planned and pre-CBCT shift doses were recorded for the heart and breast tissue clinical target volume (CTV). Patient demographics were also collected. Patient were placed into three groups based on BMI, normal (<25), overweight (25-30), obese (>30). After checking for normality using Shapiro-Wilk tests, statistical comparisons were made using Mann-Whitney, Kruskal-Wallace, Dunn's multiple comparisons and one sample Wilcoxon tests.

Results: 37 patients were included, with 581 daily CBCT shifts and an average of 15.7 CBCTs per patient (13-25). The mean age was 60.8 (39-80), and the mean BMI was 27.6 (19.5 – 45). The median magnitude of daily vector displacement was 8.1 mm (1.0-33.4) and was found to be correlated to BMI ($p = <0.0001$). Obese patients had a significantly higher daily displacement magnitude than normal BMI patients, 10.3 vs. 7.7 mm ($p = <0.0001$). Patients with high BMI showed no consistent pattern in their angular movement in either plane, while normal BMI patients displayed consistent setup errors in both the coronal ($p=<0.0001$) and transverse ($p=<0.0001$) planes.

Obese patients showed significantly larger differences in planned vs received breast CTV coverage compared to normal BMI patients ($p=0.0054$). For heart dose, patients with a normal BMI had significantly higher differences between the planned heart dose and delivered heart dose when compared to overweight patients ($p=0.0020$).

Conclusion: Overall, our study shows significant variation in daily setup for prone breast radiation. All patients demonstrated a degree of error and variability during daily setup. However, the magnitude of error increased with BMI. For patients with lower BMI, the setup error was more consistent and systematic, while higher BMI patients had more randomness to the daily variation. The random error caused some treatments to over-treat the heart where-as other treatments would have under-treated the breast tissue. This highlights a potential danger of not using daily imaging and using previous shifts for future treatments in higher BMI patients. In lower BMI patients, however, we saw that consistent systematic errors could lead to an overdosing of the heart if not corrected properly.

Overall, this data provides more clarity on the importance of imaging for patients undergoing prone left breast radiation. Our data suggests that patients with lower BMI may

not need as frequent imaging due to consistent systematic shifts whereas higher BMI patients would benefit from daily imaging given the daily randomness of shifts.

P5-11-11: Dual–responsive nanoprobe with oxygen economization capacity for potentiating synergistic–checkpoint-blockade–and–radiotherapy-radiodynamic therapy in breast cancer

Yueyang He, Jinyan Lin, Jingwen Bai, Yanbing Cao, Xiao Shen, Fuli Xin, Ming Wu, Zihe Ming, Kangliang Lou, Yuanyuan Zhu, Zishan Qiao, Weiling Chen, Yang Li, Xiaolong Liu, Guojun Zhang

Radio-immunotherapy is a critical therapeutic approach for patients with advanced breast cancer, especially for triple-negative breast cancer (TNBC) patients. However, its efficacy is constrained by inaccurate assessment of the tumor locations, as well as poor sensitization and hypoxia of tumor. To address these clinical dilemmas, we developed a pH/GSH dual-responsive NIR-II fluorescenc nanoprobe, which was designed by co-coordinated indocyanine green (ICG) and Hafnium (Hf, Z = 72) within a glutathione (GSH)-responsive tetra-sulfide-bridged porous organosilica, and afterward enclosed by a pH-responsive catechol-borate crosslinking layer. As the nanoprobe accumulated in tumor regions, the layer dissociated under tumor acidity, which resulted in a charge reversal and facilitated cellular endocytosis. Subsequently, the core of the nanoprobe reacted with the intracellular GSH, decomposing to release ICG-Hf. Upon X-ray irradiation, high Z metal Hf could not only capture X-ray photoelectrons to catalyze the production of hydroxyl radicals (-OH) for enhanced RT, but also transfer X-ray energy to coordinated ICG to initiate the generation of singlet oxygen (1O2) and superoxide anion (-O2-) for RDT. In addition, the generated H2S from tetra-sulfide cleavage by GSH could reprogram oxygen metabolism to intensify RT-RDT efficacy and trigger a robust anti-tumor immune response by induction of immunogenic cell death (ICD). When combined with checkpoint blockade therapy, the nanoprobe mediated a significant inhibition of primary and distant tumors via the stimulation of DCs maturation and T cells infiltration, leading to a robust abscopal effect in vivo. Collectively, this novel nanoprobe exhibited tremendous potential for precise tumor localization and potentiating immunogenic RT-RDT.

P5-11-12: “Less is More”: Multi-institutional Experience with Fast-Forward Dose and Fractionation and the Impact of Dosimetric Parameters on Toxicity in Breast Cancer Patients

Majd Alotaibi, Hanadi Habibullah, Zayd Jastaniah, Hatim Almarzouki, Reem Alahmadi

Background: In 2020, the Fast-Forward trial demonstrated the non-inferiority of a radiotherapy dose of 26 Gy in 5 fractions over 1 week compared to 40 Gy in 15 fractions over 3 weeks for local tumor control and safety for up to 5 years. Additional data is required to assess its side effects and the impact of dosimetric factors on toxicities across diverse

patient populations. Our primary objective is to describe our institutional experience with this dosing schedule in terms of observed breast toxicity and to explore the impact of dosimetric parameters on toxicities as a secondary objective.

Method: This is a multicenter study involving 100 breast cancer patients treated between June 2020 and June 2023 with an adjuvant radiotherapy dose of 26 Gy in 5 fractions at King Faisal Specialist Hospital & Research Center and King Abdulaziz University Hospital in Saudi Arabia. Patients who did not complete their planned radiotherapy treatment course and patients with stage IV breast cancer were excluded.
Data were collected retrospectively from medical records and during follow-up visits, with at least one visit occurring at least 6 months post-treatment. Patients who were lost to follow-up were contacted by phone.
Statistical analysis includes descriptive statistics, bivariate analysis, and regression analyses. Independent variables include breast CTV, boost, plan's Dmax, breast V107%, breast V105%, breast separation, BMI, age, neoadjuvant and adjuvant chemotherapy, and patient comorbidities. Dependent variables include breast pain on a pain scale of 0-10, breast shrinkage, telangiectasia, breast edema, breast discomfort, skin dermatitis graded as per RTOG, breast hardness, hypo/hyperpigmentation, and change in breast shape.

Results: Our study, with a median follow-up of 19 months, revealed that 5% of patients experienced Grade III dermatitis and 15% reported breast pain rated ≥5 out of 10 on the pain scale. Breast pain showed a statistically significant correlation with larger breast CTV in cc and breast V107% (p. 0.013 and p. 0.012, respectively). Furthermore, dosimetric analysis revealed significant correlations between breast dermatitis and breast CTV in cc, BMI, and breast separation (p. 0.0001, p. 0.015, and p. 0.001, respectively).

Conclusions: This radiotherapy dose schedule is tolerable in our patient population. Our dosimetric analysis highlights an association between specific dosimetric parameters and toxicity, suggesting the need to optimize these parameters to minimize treatment-related morbidity and improve the patient toxicity profile.

P5-11-13: A Method for Quickly Estimating Lung V20 for Forward-Planned Breast Patients

Michael Karp, Jonathan Klein, Michael Silver

Purpose/Objective(s): Prolonged dosimetric planning can delay radiotherapy (RT) start time and affect a clinic's efficiency. Planning time may be prolonged when dose constraints are found to be exceeded and repeat planning is required. If a radiation oncologist can reliably predict dose constraints without formal dosimetric planning, then a need for repeat planning may be avoided. The volume of lung receiving ≥20 Gy (V20) is commonly used to

estimate potential lung toxicity and is often exceeded during planning and therefore is a common source of replanning. We developed a novel method to predict V20 for breast cancer (BC) radiotherapy.

Materials/Methods: The method was tested on two groups of BC patients treated at a single center with forward-planned 3D conformal RT: "Group TAN" patients received whole breast RT using tangent fields and "Group RNI" received RT to the breast/chest wall and regional lymph nodes. Using Eclipse planning software, we outlined the boundaries of the RT field. We then created an "Overlap" structure consisting of the portion of the RT field that overlaps the ipsilateral lung. We divided the volume of the Overlap structure (VO) by the total ipsilateral lung volume (TILV) to calculate Percent Overlap Volume (POV). We then subtracted POV from the final plan's calculated V20 (cV20) to determine the difference between the two parameters (V20D). Univariate analysis via SPSS v.29.0 assessed correlation between planning characteristics and V20D.

Results: A total of 92 patients were included, 46 in each group. Within each group, patients were evenly divided between right- vs. left-sided RT and single (6MV) vs. mixed (6/23 MV) energies. For left sided patients in the TAN group, 9 (20%) patients were treated with free breathing and 28 (61%) with deep-inspiration breath holding (DIBH) technique; in the RNI group 15 (33%) were treated using free breathing and 7 (15%) with DIBH.

In Group TAN, mean POV was 10.4% (SD 4.3%) and mean V20D was 0.88% (SD 0.3%). In Group RNI, the mean POV was 28.1% (SD 5.7%) and mean V20D was 4.2% (SD 1.1%). cV20 was larger than POV for all patients, meaning that our method consistently overestimated V20 compared with the actual planned value.

On univariate analysis of Group TAN patients, left-sided RT ($p<0.001$), DIBH ($p=0.026$), cV20 ($p=0.012$), and VO ($p=0.06$) correlated with a lower V20D, while energy group and TILV were not predictive of V20D ($p>0.05$). Within Group RNI, cV20 ($p=0.003$) was correlated with a lower V20D, while no correlation was found between V20D and laterality, DIBH, energy group, TILV, or VO.

Around 95% of the time, the difference between POV and the corresponding cV20 will be equal or less than the mean V20D plus 2SD. For Group TAN, V20D mean+2SD = 1.5% and for Group RNI, V20D mean+2SD = 6.4%. Therefore, to estimate whether a V20 constraint will be met for a tangents-only plan we recommend calculating the estimated V20 as: V20est = POV + 1.5% and for RNI, V20est = POV + 6.4%

Conclusion: Using our method, the POV was consistently larger than the calculated V20 and the differences between these two fell within a predictable range, creating a reliable method to predict ipsilateral lung V20. We found that a radiation oncologist may estimate the

ipsilateral lung V20 by contouring the beam overlap with the lung (POV) and adding 1.5% or 6.4% for tangent-only and RNI plans, respectively, and can safely assume that actual the actual V20 value will be lower than this estimate.
Taking an extra few minutes to estimate the V20 using our method may speed radiation planning and increase clinic efficiency by minimizing the need for replanning. Similar methods may be developed to estimate other dose parameters for both RT planning for breast and other cancers.

P5-11-14: Survival Outcomes of Breast Cancer Patients Underwent Neoadjuvant Radiotherapy vs. Adjuvant Radiotherapy: A Population-based Observational Study

Yue Huang, Xie, Yiqin Xia, Yangyang Cui, Jinhui Peng, Shuhan Zhao, Yuhan Dai, Huilin Chen, Yifan Wu, Yixing Yang, Shui Wang, Mingjie Zheng

Objectives: Neoadjuvant radiotherapy (Neo-Rad) improves locoregional control, down-stages the tumor, and increases the success rate of breast-conserving surgery. However, there remains controversy regarding its effect in long-time survival. The aim of this research was to, combined with various clinicopathologic characteristics, compare the survival outcomes of breast cancer (BC) patients underwent Neo-Rad versus adjuvant radiotherapy (Adj-Rad), and to determine whether the radiation sequence was the independent prognostic factor for BC.
Methods: A total of 128113 BC patients from Surveillance, Epidemiology, and End Results (SEER) database were identified in our study, of whom 127707 patients underwent Adj-Rad and 406 patients underwent Neo-Rad. The Kaplan-Meier function and the COX proportional hazards model were applied to compare overall survival (OS), the Nelson-Aalen cumulative hazard method and competing risk model were applied to compare breast cancer specific survival (BCSS) between two groups.
Results: The OS and BCSS of Neo-Rad group were significantly prolonged than Adj-Rad group ($P<0.001$) in general. The radiation sequence was as an independent prognostic factor for OS (HR 0.61, 95% CI 0.49-0.75, $p<0.001$). Neo-Rad group also showed better survival outcomes than Adj-Rad cohort in stage Ⅰ-Ⅱ patients, LN positive/negative patients, patients with different molecular subtypes, and patients underwent partial/ total Mastectomy ($p<0.05$). By contrast, in stage Ⅲ patients, the OS and BCSS were comparable between two groups ($p>0.05$).
Conclusions: Neo-Rad may be applicable not only for patients with advanced, inoperable, or aggressive subtype of BC, but also in the setting of early-stage, luminal subtype of patients, and it may significantly improve OS and BCSS in most subgroups of patients. These finding warrants more prospective clinical trials to clarify the optimal radiotherapy timing and radiation technologies for corresponding type of patients, and to improve local control and survival outcomes at the same time.

P5-11-15: Application of in vitro 3D models to study the effect of hypofractionated radiation therapy for breast cancer

Hoang Son Pham, Larisa M. Haupt, Akhilandeshwari Ravichandran, Laura J. Bray

Breast cancer (BCa) is a heterogeneous disease and the most common cancer in women. Approximately 50% of BCa treatment is breast-conserving surgery followed by adjuvant radiation therapy (RT). Recently, a study published in The Lancet (Brunt et al, 2021), suggested that a hypo-fractionated RT of 5.2 Gy per fraction (for a total dose of 26 Gy in 1 week) is a safe and effective regime in controlling disease for up to ten years. However, there is a lack of knowledge of cellular responses to hypofractionated RT using relevant preclinical models. Thus, this study utilised a semi-synthetic hydrogel (gelatin methacryloyl; GelMA), which mimics the human tumour microenvironment, to examine cancer cell response when applying hypofractionated RT.
Patient-derived BCa (ER+/PR+/HER2-) cells and Human BCa cell lines MCF-7 (ER+/PR+/HER2-) and MDA-MB-231(ER-/PR-/HER2-) cells were grown in 20 µL GelMA hydrogels for five days and then treated with the hypo-fractionated radiation dose of 26 Gy (5 fractions for 5 days) continuously. Cell viability, metabolic activity, and radiosensitivity gene expression were examined by utilising FDA/PI staining, Prestoblue assay and Q-PCR after RT respectively.
Cell viability decreased on day 7 in MCF-7 cells, and on day 21 post RT in MDA-MB-231 and patient cells when compared to the untreated condition. Cell metabolic activity showed a significant decrease in fractionated RT when compared to control on day 21 in patient and MCF-7 cells, but on day 14 in MDA-MB-231 cells. The fractionated RT reduced the levels of gene expression of the cancer stem cell markers in patient-derived and MCF-7 cells, in contrast to increased expression in MDA-MB-231 cells. The DNA damage repair marker was significantly decreased in both patient-derived and MCF-7 cells but not changed in MDA-MB-231 cells.
This project suggests that patient-derived BCa cells shared similarities with MCF-7 cells in their response to hypofractionated RT for both cell metabolic activity and DNA damage repair, but not in MDA-MB-231 cells. These findings also suggest the GelMA hydrogels can be provided as a tool for pre-clinical models for RT studies. For further investigation, GelMA hydrogels will be utilised to examine the effects of combined radiation-chemotherapy and may provide an opportunity for personalised treatment for patients based on their own BC subtypes.

P5-11-16: Outcomes in Elderly Patients with Triple-Negative Breast Cancer Receiving Neoadjuvant Chemo-immunotherapy and Chemotherapy Alone.

Natalia Polidorio, Lauren M. Perry, Srinivasa Sevilimedu Veeravalli, Giacomo Montagna, Nour Abuhadra, Diana Lake, Mark Robson, Monica Morrow, Stephanie Downs-Canner, Iris Zhi

Introduction: Neoadjuvant chemo-immunotherapy with pembrolizumab (NAC+P) has become the standard care for stage II-III triple-negative breast cancer (TNBC) following the KEYNOTE-522 (KN522) trial, which showed improved pathologic complete response (pCR) rates and event-free survival compared to chemotherapy alone (NAC). We aimed to describe pCR rates by age and treatment in TNBC patients receiving either NAC+P or NAC alone at our institution.

Methods: Women aged ≥65 years with stage I-III TNBC treated with NAC+P from 6/2021 to 9/2023 were compared to patients aged <65 years treated with NAC+P and to patients ≥65 who received NAC alone from 03/2010 to 9/2019. Patients with metaplastic breast cancer and neoadjuvant radiotherapy were excluded. Clinicopathological characteristics and pCR rates (ypT0/is pN0) - were compared between groups using Chi-square tests. Logistic regression for univariate (UVA) and multivariable analysis (MVA) was used to evaluate the association between age, treatment, and pCR.

Results: 481 patients were included: 69 NAC+P ≥65 years (median age 69, IQR: 67-73); 338 NAC+P <65 years (median age 48, IQR: 38-56); and 74 NAC ≥65 years (median age 69, IQR: 66-73).

Compared to younger patients, older patients treated with NAC+P were more likely to have public insurance (87% vs 13%, p<.001), lobular and other non-ductal histologies (6% vs 1.2% and 10% vs 5%, respectively, p= .009), cT1 and cT4 stages (22% vs 11% and 13% vs 3.9%, respectively, p< .001) and cN+ disease at presentation (58% vs 45%, p=.04). In both age groups, 81% received the KN522 backbone regimen with carboplatin, and the remaining mostly received NAC with cyclophosphamide, anthracycline, and taxane. There was no difference in treatment completion rate - defined as the completion of all preplanned neoadjuvant therapy cycles regardless of interruptions, regimen changes, or dose reductions - and in immune-related adverse events (33%) between age groups. However, older patients had a longer time from NAC+P to surgery (38 vs 32 days, p= .002). Breast surgery was similar between age groups, but axillary dissection (ALND) was more common in older patients (32% vs 19%, p= .023). The pCR rates did not differ between older and younger patients (49% vs 58%, p=.2). On MVA, high tumor grade (OR 13.9, 95% CI 4.54-61.7, p< .001) was positively associated with pCR, whereas other histologies (OR 0.13, 95% CI 0.04-0.39, p< .001), cT4 stage (OR 0.10, 95% CI 0.02-0.36, p<.001) and cN+(OR 0.60, 95% CI 0.38-0.95, p= .029) were less likely to facilitate pCR.

In patients ≥65 years, those receiving NAC+P, compared to NAC alone, more frequently had lobular and other histologies (6% vs 0% and 10% vs 4.1%, respectively, p= .028), intermediate tumor grade (15% vs 1.4%, p=0.003), and cT1 and cT2 stages (22% vs 16% and 61% vs 46%, respectively, p= .045).NAC+P patients more frequently received carboplatin (81% vs 6.8%, p<.001). There was no difference in NAC completion and time to treatment start, but the NAC+P group had longer time to surgery (38 vs. 30 days, p = 0.039). More NAC patients underwent ALND (56% vs 32%, p= .005), with no difference in cN+ disease and breast surgery. The pCR rates were significantly higher in the NAC+P group (49%) compared to NAC (23%, p=.001). On UVA, NAC+P significantly improved overall pCR (OR 3.26 p=.001). However, on MVA, after adjusting for tumor histology, grade, stage, neoadjuvant carboplatin, and completion rate, the use of immunotherapy was not

independently associated with pCR.
Conclusions: Within the NAC+P cohort, pCR rates did not differ by age, and no significant increase in irAEs was seen in elderly patients, though we acknowledge a possible selection bias toward healthier elderly patients. Compared to NAC only, NAC+P showed potential for improving pCR in older individuals and could be a viable treatment option for elderly TNBC patients who are likely to tolerate it.

P5-11-17: Clinicopathological characterized by HER2-low-expressing breast cancer in triple-negative breast cancer

Michiko Kato, Hiroko Masuda, Jun Ohara, Miharu Kano, Karen Suyama, Reika Yoshida, Asako Tsuruga, Sayuka Nakayama, Naoki Hayashi, Toshiko Yamochi

Background: Human epidermal growth factor receptor 2 (HER2)-targeting antibody-drug conjugates have been developed and a new treatment option for breast cancer patients, including those with HER2-low-expressing breast cancer. Previous reports have shown that HER2 crosstalk with the estrogen receptor, and that there is a high expression group of genes involved in androgen/estrogen metabolism in the molecular classification of triple negative breast cancer (TNBC). We have been performed to assess basal-like TNBC in clinical practice to immunohistochemical staining of EGFR, CK5/6 and androgen receptor (AR) since 2014. In this study, we evaluated the clinicopathological features of the differences between HER2-negative and HER2-low TNBC and hypothesized that HER2-negative TNBC would have more basal-like features and HER2-low TNBC would have more non-basal-like features.

Methods: From April 2014 to May 2023, 195 patients diagnosed with triple-negative breast cancer (TNBC) through needle biopsy and immunohistochemical staining for EGFR, CK5/6, and AR were investigated. BRCA mutations, which are considered common in basal-like types, were also assessed. BRCA mutations were evaluated in germline-derived samples. PD-L1 and tumor-infiltrating lymphocytes (TILs) were evaluated for immunogenicity assessment. TILs were assessed by averaging the area occupied by lymphocytes and plasma cells (not hotspots) in the interstitial area within the invasive cancer area, as proposed by the International TILs Working Group. They were classified into four levels: 0%, 1-9%, 10-49%, and ≥50%.
PD-L1 was assessed using the SP142 antibody, and positive cells were defined as those with 1% or more positive tumor-infiltrating immune cells. PD-L1 was evaluated at 0%, 1-9%, and ≥10%.

Results: Among the TNBC biopsies, 74 cases (38%) were HER2-low (ITC 1+ or ITC 2+ and FISH negative or not performed), and 121 cases (62%) were HER2-negative. Significant differences were observed between HER2-low and HER2-negative for histological classification (P=0.011), BRCA mutation (P=0.032), and PD-L1 (P=0.008).

Invasive ductal carcinoma (IDC) was found in 65% (48/74) of HER2-low and 79% (95/121) of HER2-negative (P=0.011). Apocrine carcinoma was found in 32% (24/74) of HER2-low and 15% (18/121) of HER2-negative. There was a correlation between apocrine carcinoma and AR expression (P<0.001). AR expression was 50% (37/74) positive and 50% (37/74) negative in HER2-low, while it was 20% (25/121) positive and 80% (96/121) negative in HER2-negative (P<0.001). BRCA mutations were found in 15% (5/34) of HER2-low and 55% (21/58) of HER2-negative. PD-L1 was positive in 43% (43/89) of HER2-low and 63% (54/86) of HER2-negative.
There was a correlation between PD-L1 and TILs (P<0.001).There was no difference in Ki-67 (P=0.100), EGFR (P=0.363), CK5/6 (P=0.452), nuclear grade (P=0.490), neoajuvantchemotherapy treatment response (P=0.468) and TILs (P=0.546) between HER2-low and HER2-negative.

Conclusion: AR is higher in HER2-low-expressing breast cancers and apocrine carcinoma is significantly more frequently classified. BRCA mutation and PD-L1 positivity are higher in HER2-negative TNBC. Our study revealed that HER2-negative breast cancer has more basal-like clinicopathologic features, while HER2 Low TNBC has non-basal features.

P5-11-18: Treatment Strategies and Pathologic Responses in Triple-Negative Breast Cancer: A Retrospective Analysis

Enrique José Zamudio Lozoya, Luisa Fernanda González-González, Victor Baylon-Valdez, Paolo Mendoza-Muraira, Regina Martínez-García-Lascurain, Patricio Ochoa Elizondo, Rafael Martínez-Sanciprián, Beatriz De León-Jiménez, Alma Andrea Elizaldi-San Miguel, Gustavo Gil Reza Bravo, América Susana Mares García, René Lázaro González-Mendoza

Triple-negative breast cancer (TNBC) is a highly aggressive subtype characterized by the absence of estrogen receptors, progesterone receptors, and HER2 amplification. This unique molecular profile limits treatment options, as TNBC does not respond to hormonal or HER2-targeted therapies, making chemotherapy the cornerstone of systemic treatment. Achieving a complete pathologic response (pCR) after neoadjuvant chemotherapy has been associated with improved long-term outcomes and survival rates in TNBC patients. However, pCR rates can vary significantly depending on the chemotherapy regimen used, as well as the inclusion of other modalities such as immunotherapy.
A retrospective, single-center study was conducted at Chihuahua's State Cancer Center, where medical records of patients aged ≥ 18 years diagnosed with TNBC between January 2012 and June 2023 were reviewed to evaluate pCR after neoadjuvant treatment. The study compared the effectiveness of three chemotherapy regimens: anthracyclines and taxanes (AC-T), anthracyclines combined with taxanes and carboplatin (AC-Tcarboplatin), and any chemotherapy regimen paired with immunotherapy (IT). Fisher's exact tests were used to compare pCR rates across these groups, with p-values calculated to determine clinical significance and identify the most effective treatment strategies.
In total, 1279 breast cancer patients were included, with 182 (14.23%) diagnosed with

TNBC. Among these, 92 (50.55%) received neoadjuvant treatment, resulting in 35 (19.23%) achieving pCR. Upon observing the pCR rates among different regimens, we found clinical relevance in the variations. Statistically significant differences were confirmed when comparing neoadjuvant treatments in relation to pCR rates (p=0.029). Sixty patients received the AC-T regimen, achieving a pCR rate of 26.67%. Thirteen patients received AC-Tcarboplatin, with a pCR rate of 46.15%. Thirteen patients received chemotherapy combined with immunotherapy, showing a high pCR rate of 92.31%. Finally, 6 patients received other chemotherapy regimens without immunotherapy or carboplatin, with only 1 (16.67%) achieving pCR.
This analysis highlights significant differences in pCR rates depending on the administered treatment, emphasizing firstly the clear benefits of adding carboplatin to the neoadjuvant regimen. Additionally, although the number of patients treated with immunotherapy was limited, the results unequivocally indicate its benefit in significantly enhancing complete pathological responses compared to other treatment groups. While each therapeutic group demonstrated specific advantages in pCR rates, stressing the critical importance of early access to advanced therapeutic options such as immunotherapy from the time of TNBC diagnosis is crucial. Finally, it is recommended to establish better public policies to improve access to these treatments and explore the potential additional benefits of low-dose immunotherapy in future research to further optimize clinical outcomes.

P5-11-19: Single arm prospective study evaluating the relationship of MRD via ctDNA and pCR in a diverse early TNBC patients receiving neoadjuvant chemotherapy.

Elizabeth John, Simran Sekhon, Terrence Jones, Christine Son, Srishti Sareen, Linnea Cripe, Laila A.Vidal, Sonia Benn, Jeff Harris, Gregory A. Vidal

Background: Chemotherapy plus pembrolizumab in the neoadjuvant (NAC) and adjuvant settings (Keynote 522 (KYN)) is standard of care in early-stage II and above triple negative breast cancer (TNBC), because of improvement in pathologic complete response(pCR), event-free survival, and possibly overall survival. Circulating tumor DNA (ctDNA) has the potential to be used to assess response to chemotherapy, guide de-escalation of chemotherapy and detect early recurrence. Herein, we report the results of a pragmatic, single-center, prospective, observational pilot study to evaluate the ability of tumor-informed, quantitative ctDNA to assess early response in the neoadjuvant setting.
Methods: A total of 31 new breast cancer patients (pts) were enrolled. The inclusion criteria were having early-stage TNBC (ER/PR < 10%, HER2 negative) and meeting criteria for NAC. Serial ctDNA, using a commercial tumor-informed test, was obtained at baseline and prospectively every three weeks (wks) while on NAC and then every 4-12 weeks in the adjuvant setting. Blood was collected immediately before the next dose of chemotherapy. The primary endpoint was the concordance of ctDNA clearance (molecular complete response (mCR)) and pCR. Secondary endpoints include the rate of mCR at 3, 6, and 9 wks, the correlation of imaging CR (iCR) with mCR and pCR, and the rate of pCR in this real-

world diverse population. For the initial treatment, 61% of patients received weekly paclitaxel, carboplatin, pembrolizumab (tcP) prior to doxorubicin, cyclophosphamide, and pembrolizumab (ACP), and 38% received ACP followed by tcP. The change happened to accommodate the carboplatin drug shortage.
Results: Thirty-one female pts signed consent but only 29 had sufficient tissue for tumor informed ctDNA analysis: 20 (64%) African American (AA), 10 (34.4%) Caucasian (CA), and 1 (3.4%) Asian. At baseline 86.2% (25/29) tested positive for ctDNA. The four pts with negative ctDNA at baseline had stage II disease, and one of these had significant residual disease (RCB 2) upon resection. Four pts had not received surgery at time of data cutoff. Two died prior to surgery unrelated to disease progression and 2 experienced surgical delays. Based on ITT, 48% (14/29) of pts experienced pCR. Taking into consideration the 4 censored pts, the pCR rate was 54% (14/26). The mCR at 3 weeks was 38% (11/29), 6 weeks 59% (17/29), and 9 weeks was 65% (19/29). After completion of NAC (24 weeks), 79% (23/29) achieved mCR and 35% (11/31) achieved iCR with all 11 having iCR's having an mCR. Only 6/28 (21%) had mCR, iCR and pCR; all 14/29 who had pCR also had mCR by week six. None of the non-mCR pts at 6 weeks obtained a pCR. In the adjuvant setting, 76% (22/29) continued to have mCR at 4 weeks. Three patients had detectable ctDNA at 4 weeks with 67% (2/3) experiencing progression. Overall, 66%(19/29) pts had RCB 0 or 1 and all of these patients had sustained mCR at 6 weeks. Of the AA patients who received surgery, 75% (12/16) achieved mCR and 43% (7/16) achieved pCR; for CA pts it was 77% (7/9) and 60% (6/10) respectively. The one Asian patient achieved mCR and pCR.
Conclusion: Pre-operative ctDNA measurement was feasible in this pilot study. mCR correlated with but was not predictive of pCR in the diverse population. Lack of mCR at 6 weeks was highly predictive of non- pCR and post-surgery detectable ctDNA resulted in rapid disease progression.

P5-11-20: Impact of Immune-Related Adverse Events on Response to Neoadjuvant Chemoimmunotherapy in Triple Negative Breast Cancer

Michelle Sterpi, Yungtai Lo, Susan Fineberg, Harjot Gill, Della Makower

Background: Addition of the PD-1 inhibitor pembrolizumab to neoadjuvant chemotherapy improves pathologic complete response (pCR) rates and event-free survival in triple-negative breast cancer (TNBC). Immunotherapy may lead to immune-related adverse events (irAE), which can be life-threatening and permanent. Presence of tumor-infiltrating lymphocytes (TILs) in TNBC is also associated with improved prognosis and treatment response. Little data exists regarding associations between irAE and pCR, and between TILs and irAE, in TNBC. This study evaluates associations between irAE, clinicopathologic factors (including TILs), and pCR after neoadjuvant chemoimmunotherapy (NCIT) in a diverse single-institution cohort of TNBC patients (pts).
Methods: Pts who received NCIT at our institution between 2021 and 2023 were identified from pharmacy database. Details of tumor stage, NCIT treatment, response to therapy, and presence or absence of irAE were obtained by chart review. IrAE were graded using

Common Terminology Criteria for adverse events (CTCAE). Stromal TILs were estimated within the borders of the invasive carcinoma as per International TILs Working Group guidelines. Associations of age, race, ethnicity, tumor size (T stage), node involvement (N stage), grade, HER2 IHC status, TILs, and completion of planned NCIT with irAE incidence and pCR were assessed by Wilcoxon rank-sum tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. P-values <0.05 were considered statistically significant.
Results: 46 pts were treated with NCIT [27 (58.7%) Black; 14 (30.4%) Hispanic]. Median age was 60.5 (range 33-88). All NCIT regimens included pembrolizumab and a taxane. 35 pts (76.1%) received doxorubicin, and 25 (54.3%) received carboplatin. 31 (67.4%) pts received 80% or more of their planned NCIT regimen. Reasons for early discontinuation were chemotherapy toxicity (8 pts), irAE (4), progression of disease (POD) (2), unknown (1). 13 pts (28.2%) developed at least 1 irAE, including hypothyroidism (3 pts), rash (3), adrenal insufficiency (2), hepatitis (2), arthritis (2), myositis, pneumonitis, pericarditis, panniculitis, and encephalitis (1 each). irAE was Grade 1-2 in 6 pts, Grade 3 in 5 pts, Grade 4 in 1 pt, and Grade 5 in 1 pt. 41 pts underwent surgery. Reasons for no surgery were POD (2 pts, included in response analysis), fatal irAE (1 pt), pt refusal (1 pt), and unknown (1 pt). Of 43 evaluable pts, 24 (55.8%) achieved pCR. Development of irAE (p=0.039), younger age (p=0.028), and Hispanic ethnicity (p=0.005) were associated with pCR. Black pts were less likely to achieve pCR compared to non-Black pts (p=0.003). T and N stage, tumor grade, HER2 IHC status, and completion of planned NCIT were not associated with pCR. TILs were associated with achievement of pCR (p=0.002), but not with presence of irAE (p=0.341). No associations between irAE and age, race, ethnicity, T or N stage, tumor grade, HER2 IHC status, and completion of planned NCIT were seen.
Conclusion: In this diverse cohort of TNBC pts, TILs and irAE, as well as age, race, and ethnicity, were associated with achievement of pCR to NCIT, while tumor stage and grade, and completion of planned NCIT, were not. No predictive factors for development of irAE were seen.

P5-11-21: Pembrolizumab impact on surgery and radiation therapy in non-metastatic triple negative breast cancer treatment

Alizée Camps Maléa, François Peyre-Pradat, Angelica Conversano, Layal Rached, Julia Dixon Douglas, Chayma Bousrih, Barbara Pistilli, Joana Ribeiro, Sofia Rivera

Background: In recent years, the prognosis for women with non-metastatic triple-negative breast cancer (TNBC) has improved. However, few data are available on the impact of adding immunotherapy to neoadjuvant chemotherapy (NAC) on locoregional treatment toxicity. In this study, we aimed to investigate perioperative and radiotherapy (RT)-related toxicities when incorporating pembrolizumab into standard NAC regimens for non-metastatic TNBC.

Methods: This monocentric retrospective study included patients with non-metastatic

TNBC treated with pembrolizumab and NAC, followed by surgery and adjuvant RT. The safety profiles after surgery and RT were evaluated using CTCAE v4.0. RT items were extracted from the end-of-treatment reports. Patient demographics, clinical and pathological staging, NAC treatment regimen, initiation and completion, as well as date of surgery and postoperative complications were collected via medical reports. Data was analyzed using SAS software version 9.2.

Results: From February 2022 to April 2023, 70 patients with complete treatment data available were selected. The median age of the cohort was 51 years, 98.5% ECOG performance status 0-1, mainly non-smokers, 38.6% premenopausal with a median BMI of 26. Most patients presented T2-T3 invasive breast cancer (91.4%), 47.1% were N0 and 81.2% grade 3, with a median Ki67 of 70% and median TILs of 20%. All received NAC with pembrolizumab. The pathologic complete response rate was 61.4% and 84.1% received adjuvant pembrolizumab.
The median time between the end of neoadjuvant treatment and surgery was 22 days. Surgery consisted of mastectomy in 51.4% of cases and breast conserving surgery in 48.6%. Immediate reconstruction was performed in 24.3% of cases, all using prosthetic implant. Axillary lymph node dissection (ALND) was performed in 52.9% patients and sentinel node biopsy in 47.1%.
Post-operative complications, occurring between 3 days and 2 months after surgery, were reported in 26 patients (37.1%) and identified 29 events, as hematoma (1), necrosis (3), and infections, inflammatory reactions or abscess (4). In 21 patients (80.8%), post-operative complications were lymphatic disorders (lymphangitis/lymphorrhea/lymphoedema/lymphocele/lymphatic cord) and in 18 patients (69.2%) it was not associated with other event.
Five surgical re-interventions were performed with 2 hematoma within 3 days after surgery, 2 necrosis (at 11 and 22 days) and 1 infected periprosthetic seroma (at 15 days) in patients whom were mostly, first operated by mastectomy (80%) with immediate reconstruction (60%).
In 77.1% of patients, RT was concomitant as authorized per Keynote 522 study. RT was performed in 49 patients (70%) with VMAT and 30% with fixed IMRT or conformal 3D. Breath hold was used in 75.7% of RT. A dose of 40.05 Gy in 15 fractions was prescribed in 97.1% of patients and 2.9% patients received 26 Gy in 5 fractions. A tumor bed boost and nodal RT were delivered in 18.6% and 61.4% of cases respectively.
Radiation dermatitis was reported in 51 patients, 98% of which were grade 1. Dysphagia was reported in 14 patients, 92.9% of which were grade 1. No grade >2 RT-related toxicities were reported in our series.

Conclusion: Safety data after surgery and adjuvant RT in women treated with pembrolizumab for non-metastatic TNBC are reassuring regarding the combination of pembrolizumab with locoregional therapy. Despite mostly concomitant pembrolizumab-RT delivery, no grade > 2 RT-related toxicity was reported. Postoperative complications included mostly lymphatic disorders. This is a frequent event after surgery regardless of

concomitant treatment. Despite the limitations of our analysis, the findings suggest that no specific safety concerns were observed regarding the impact of pembrolizumab on locoregional treatment or the concomitant combination of pembrolizumab and RT.

P5-11-22: Neoadjuvant chemotherapy and survival outcomes in triple-negative breast cancer: a population-based study (Queensland, Australia).

Larissa Vaz-Goncalves, Louise Marquart-Wilson, Melinda Protani, Jodi Saunus, Julie Moore, Michelle Morris, Marina Reeves

Background: Assessing the survival benefit of neoadjuvant chemotherapy (NAC) in triple-negative breast cancer (TNBC) patients is typically evaluated through clinical trials. Clinical trials are limited by their highly controlled context, often limiting the generalisability of findings. Globally, there is a lack of population-based evaluations of 'optimal care' for those diagnosed with TNBC, the most aggressive breast cancer type with no targeted treatment. The main advance in clinical practice for TNBC treatment has been the use of NAC, with its use now recommended even for small triple-negative tumours. In this study, we use a Queensland (Australia) population-based study to identify TNBC patients who received NAC and achieved pathological complete response (pCR) to examine associations with overall survival (OS) and breast cancer-specific survival (BCSS).
Methods: All women diagnosed with invasive TNBC between 2017 to 2019 in Queensland, Australia, were identified from the Queensland Oncology Repository (a state-wide database) and followed up to Feb 17, 2024, for OS and up to Dec 31, 2021, for BCSS. Stage IV and patients who had not undergone any treatment were excluded. pCR was defined as no residual invasive breast cancer after NAC regardless of lymph node status. Multivariable logistic regression models were developed using Directed Acyclic Graphs (DAGs) to identify confounding variables to be included in models and were used to assess the likelihood of being treated with NAC and achieving pCR. Survival rates for OS and BCSS were estimated for no NAC versus NAC with pCR and NAC without pCR using Kaplan-Meier, and adjusted hazard ratio (HR) were estimated using flexible parametric survival models to account for time-varying hazards; at one-year, two-year, and four-year survival, adjusting for age, geographic region, prognostic stage, and hospital type (public vs private).
Results: A total of 1,021 TNBC cases were included in the analysis. Overall, 21.5% had received NAC, with NAC more common in 2019 (27.3%) compared to 2017 (16.1%) and more common in those living in major cities (24.4%) and outer regional/rural areas (21.9%) than those in inner regional areas (12.6%). Patients who received NAC (versus those who did not) were younger (mean ± SD 49.0 ± 13.0 vs. 61.4 ± 14.6 years) and were more commonly diagnosed with stage IIIa-IIIc (70.5% vs 53.1%). Among those who had NAC, 42.4% achieved pCR, with higher rates of pCR in 2019 (53.8%) compared to 2017 (31.5%). pCR was more common in those with stage IIa-IIb (62.5%) versus stage IIIa-IIIc (34.9%). The median follow-up was 4.96 years (range, 0.01-7.12) for OS and 3.21 years (range, 0.14-4.99) for BCSS. Compared to those who did not receive NAC, those who did and achieved pCR had better OS (HR 0.27 to 0.41; $p>0.05$) at 1-, 2- and 4-years post-diagnosis,

whereas those who did not achieve pCR had significantly poorer OS (HR 2.22 to 3.57; $p<0.05$) at all follow-up years. Similar trends were observed for BCSS.
Conclusion: The best survival was observed in patients who received NAC and achieved pCR. In this population-based sample, survival differences in those with pCR versus those without were similar to that observed in clinical trials. Receipt of NAC however, differed by age and geographical region, with those living in inner regional areas being less likely to receive NAC. Equitable access to current optimal care is essential for addressing survival disparities, while continued research into tailored treatments for TNBC is vital for improving outcomes for those who do not benefit from current treatments.

P5-11-23: Sociodemographic Factors Associated with Adjuvant Chemotherapy Receipt in Stage I Triple Negative Breast Cancer (TNBC)

Candice Thompson, Fauzia Riaz, Mina Satoyoshi, Kristen Cunanon, Allison Kurian, Melinda L. Telli

Background: Although the National Comprehensive Cancer Network (NCCN) clearly recommends systemic therapy for those with Stage II and Stage III TNBC, guidelines for Stage I disease are less clear, with recommendations such as “consider adjuvant therapy” for many patients. Even without adjuvant therapy, five-year breast cancer-specific survival rates of T1a/1bN0 TNBC exceed 95%. Despite this favorable prognosis, the existing literature reveals that up to 83% of individuals in this group receive chemotherapy. A better understanding of factors associated with receipt of chemotherapy in T1N0 TNBC is helpful for clinical decision making. In this study, we assessed the sociodemographic factors associated with use of adjuvant therapy in the T1N0 TNBC patient population.

Methods: This observational study used the Oncoshare database which integrates electronic medical record and California Cancer Registry data for patients treated in Northern California in the Stanford University Health Care Alliance. We included patients treated for T1N0 TNBC from 2000-2024, obtaining sociodemographic data from our database. Standardized mean differences (SMD) were used to preliminarily analyze imbalances between patients who received adjuvant chemotherapy and those who did not. Descriptive statistics are reported, and a multivariate analysis is anticipated.

Results: The study population included 252 patients with T1aN0/T1bN0 disease and 392 with T1cN0 disease. Approximately 73% of patients with pT1cN0 TNBC and 56% of patients with T1a or T1b disease received adjuvant chemotherapy. We collected extensive data on sociodemographic factors, including age, race and ethnicity, neighborhood socioeconomic status (reported as statewide quintiles), distance traveled for care, rurality, Charlson comorbidity scores, and insurance status.

Initial analysis was completed to determine the SMDs between those who received adjuvant systemic therapy and those who did not. For those with T1aN0/T1bN0 TNBC, there were

small differences between those who received adjuvant therapy and those who did not for SES quintile (0.208), rurality (0.238), and distance to Stanford (SMD 0.254). There were moderate differences between those who received adjuvant therapy and those who did not by race and ethnicity (SMD 0.331) histology (SMD 0.433), BMI (SMD 0.466), and insurance type (SMD 0.545). Of those who received adjuvant chemotherapy, 58% had private insurance, comparatively, of those who did not undergo chemotherapy, 68% had government or other insurance types.

There were large differences between T1aN0/T1bN0 treatment groups for age (SMD 0.658) and grade of the tumor (SMD 0.750). Of those who received adjuvant therapy, 38% were below the age of 50, whereas 14% of those who did not receive adjuvant therapy were below the age of 50.

For T1cN0 TNBC, we found small differences between those who received chemotherapy and those who did not for BMI (SMD 0.307). We observed moderate differences for insurance type (SMD 0.483), age (SMD 0.509), and race and ethnicity (SMD 0.371). Of those who received adjuvant chemotherapy, 49% had private insurance and 74% of those who did not receive chemotherapy had government issued or other types of insurance. We observed larger differences for tumor grade (SMD 0.631); 77% of those who received adjuvant chemotherapy were grade 3 compared to 51% of those who did not receive chemotherapy.

Conclusions: Most patients with T1N0 TNBC still received adjuvant chemotherapy despite studies showing excellent outcomes. Initial data demonstrates that differences exist in clinical and sociodemographic factors between those receiving and not receiving adjuvant systemic therapy, especially regarding age, insurance status, and tumor grade. Multivariate analysis will help us to better understand the association between sociodemographic factors and receipt of adjuvant therapy.

P5-11-24: OUTCOMES IN EARLY-STAGE TRIPLE NEGATIVE BREAST CANCER WITH DOSE-DENSE AC AS PART OF A PEMBROLIZUMAB-BASED REGIMEN

Danielle Roman, Mikaila Eross, Mitchell Mirabile, Rachelle Nadour, Christie Hilton

Background: The KEYNOTE-522 trial established the current standard treatment of high-risk early-stage triple-negative breast cancer (TNBC) with perioperative chemotherapy and immunotherapy. This regimen utilized every-3-week doxorubicin and cyclophosphamide (AC); however, AC given every two weeks (dose-dense) has been historically preferred over every-3-week dosing due to improved disease-free survival (DFS) and overall survival (OS). This study was designed to compare the rate of pathological complete response (pCR) between patients receiving dose-dense AC versus AC administered every 3 weeks within the KEYNOTE-522 regimen for early-stage TNBC and to evaluate the toxicity of dose-dense AC administered with pembrolizumab.

Methods: This single-center, retrospective, cohort study was conducted in patients with newly diagnosed, early-stage TNBC receiving neoadjuvant treatment with the KEYNOTE-522 regimen including AC given dose-dense or every 3-weeks between August 1, 2021 and December 1, 2023. The primary endpoint was pCR defined as ypT0/Tis ypN0 and secondary endpoints included toxicity rates.
Results: A total of 77 patients were included in this analysis (16 in the dose-dense AC group and 61 in the every 3-week AC group). There was no difference between pCR rates in the dose-dense and every 3-week AC groups (62.5% vs 65.6%; p=.82). Safety profiles were similar to previous reported trials, with a higher incidence of dose reductions (62.5 % vs 21.3%) and grade ≥ 3 toxicity (62.5% vs 26.2%) in the dose-dense AC group. Patients receiving dose-dense AC had higher rates of pembrolizumab discontinuation, with a median of 4.5 neoadjuvant cycles compared to a median of 8 neoadjuvant cycles with standard AC.
Conclusion: Use of dose-dense AC within the KEYNOTE-522 regimen did not improve pCR rates for patients with early-stage TNBC compared to every 3-week AC. There was a greater incidence of toxicity in the dose-dense AC group. A more robust comparison with a larger sample size is necessary to confirm a difference in pCR and toxicity between the two groups.

P5-11-25: Impact of Cardiometabolic Comorbidities on Outcomes in Early-Stage Triple Negative Breast Cancer Patients Treated with Neoadjuvant Chemo-immunotherapy (Keynote-522 regimen): A Retrospective Analysis

Asfand Yar Cheema, Jasmin Hundal, Olga Lytvynova, Serhan Unlu, Baidehi Maiti

Background: The presence of cardiometabolic comorbidities, such as hypertension (HTN), obesity, diabetes mellitus (DM), dyslipidemia, and chronic kidney disease (CKD), have been associated with increased mortality and poor prognosis in breast cancer. This study aims to investigate the influence of these comorbidities on overall survival (OS) and pathologic complete remission (PCR) in patients receiving neoadjuvant pembrolizumab plus chemotherapy. Understanding the role of these comorbidities in this context could inform personalized treatment approaches and improve outcomes.
Methods: We conducted a retrospective analysis of 107 early-stage triple negative breast cancer patients treated with neoadjuvant pembrolizumab and chemotherapy, Keynote-522 regimen. Cardiometabolic disease and its components CKD, HTN, obesity (BMI>30), DM, low high-density lipoprotein (HDL) levels (<50 mg/dL), and high triglycerides (TAGs) (>150 mg/dL)) were assessed. PCR and overall survival rates at 1 and 2 years were calculated, and the log-rank test was used to determine the statistical significance of differences in survival between patients with and without cardiometabolic disease. Fisher's exact test and Wilcoxon rank sum test were used to compare factors between cardiometabolic disease status groups as appropriate. Overall survival was estimated by the Kaplan-Meier method and compared using the log-rank test.
Results: Among the 107 patients, 33 (31%) had cardiometabolic comorbidities. The distribution of comorbidities was as follows: CKD (15%), HTN (45%), obesity (48%), DM (31%), low HDL levels (34%), and high TAGs (20%). The median age at diagnosis was 61

years, with a range of 28 to 87 years.
PCR rate was significantly worse in patients with cardiometabolic comorbidities (30% vs 69%, p-value = 0.03) and patients with CKD by subgroup analysis (14% vs. 85%, p-value 0.04). The median follow-up time was 15.0 months (3.4-47.6 months). The median OS was not reached; however, the 1-year and 2-year OS rates were 94% (95% CI: 89-99%) and 92% (95% CI: 87-98%), respectively. Patients with cardiometabolic comorbidities had significantly worse OS compared to those without (1-year OS: 82% vs. 99%, 2-year OS: 77% vs. 99%, p-value=0.0072;). Subgroup analysis revealed that patients with HTN (p-value 0.0099), obesity (p-value 0.03), and DM (p-value 0.03) had significantly poorer survival outcomes. The presence of other factors such as CKD, low HDL levels, and high TAGs did not show statistically significant differences in OS although a trend towards a worse outcome was observed. Additionally, there were no significant differences in survival based on smoking status, ethnicity, ECOG performance status, or cancer stage.
Conclusion: This study shows that the presence of cardiometabolic syndrome is associated with significantly worse OS and PCR rates in triple negative breast cancer patients treated with neoadjuvant chemo-immunotherapy. On subgroup analysis, HTN, obesity, and DM are associated with significantly worse overall survival. These findings underscore the importance of recognizing and managing specific cardiometabolic comorbidities, particularly hypertension, obesity, and diabetes, to potentially improve treatment outcomes and tailor survivorship care plans for this patient population. While other factors such as CKD, low HDL levels, and high TAGs did not show statistically significant differences, their role should not be entirely disregarded. Further research and prospective studies are needed to elucidate this association, underlying mechanisms and explore potential interventions to mitigate the negative impact of these comorbidities on patient outcome.

P5-11-26: Stage-Based Survival Analysis in the TRIple-Negative Breast Cancer PrOspective Registry in MiddLe East AfrIca (TRIPOLI) Study

Loay Kassem, Bernadette Pöllinger, Maja Velkovski-Rouyer, Alaa Kandil, Heba El Zawahry, Hikmat Abdel-Razeq, Hesham Elghazaly, Suad Al Kharusi, Manal Moawad, Salah Fayaz, Ahmed Saadeddin, Huda A. Alabdulkarim, Rasha Aboelhassan, Hassan Errihani, Tahseen Al Rubai, Salha Bujassoum Al Bader, Nashwa Abdelraouf Nashwa Raouf, Nagi El Saghir, Jean-Marc Nabholtz, Mohamed El Leithy, Pari Shahrezaei, Christine König, Nassib Neaimeh, Marwan Ghosn, Hamdy A. Azim

Background: Globally, triple negative breast cancer (TNBC) accounts for ~15% of all breast cancer cases and some retrospective studies have suggested an advanced presentation and poorer outcomes in the Middle East and North African countries. This study aims to address the lack of reliable treatment and efficacy data in this region.
Methods: TRIPOLI is a prospective multinational study from 17 institutions in 9 Arab countries including newly diagnosed patients with early TNBC (eTNBC) followed for a total of 3 years and patients with locally advanced/metastatic TNBC (la/mTNBC) followed for a total of 2 years. Herewith, we report survival analyses by stage in all patients and by

pathological complete response (pCR) in eTNBC patients that received neoadjuvant chemotherapy (NAC) and surgery. Survival analyses include overall survival (OS), real-world progression-free survival (rwPFS) and real-world event-free survival (rwEFS). RwEFS was defined as the time from treatment initiation for eTNBC until the date of recurrence or death by any cause.
Results: We report the data of 702 patients recruited between 2017 to 2019. Breakdown of patients by stage is as follows: 57 (8.1%) with stage I, 349 (49.7%) with stage II, 228 (32.5%) with stage III and 68 (9.7%) with stage IV disease. Of the 573 evaluable patients with eTNBC, the 3-year rwEFS rate was 96.3% in patients with stage I, 81.0% in patients with stage II and 66.5% in patients with stage III (excluding stage IIIc) ($p<0.0001$). Of the 99 evaluable patients with la/mTNBC, rwPFS was reported at 37.4%. The estimated 3-year OS rate for eTNBC patients was 100% for stage I, 94% for stage II and 87% for stage III (excluding stage IIIc). The median OS for patients with stage IIIc/IV was 20 months. As reported in Interim Analysis-2, 205 (39.5%) of 519 patients with eTNBC received NAC and surgery, with a pCR rate of 33.2%. The rwEFS rate was 82.4% in patients that achieved pCR versus 57.6% of patients that did not achieve pCR ($p=0.0004$). Deaths were reported in 9 (13.2%) patients that achieved pCR and in 16 (11.7%) that did not achieve pCR. At 3-year follow-up, OS did not achieve the pre-specified boundary for statistical significance.
Conclusion: Among patients with early and locally advanced/metastatic TNBC, the survival outcomes decrease with higher stages. In patients who received NAC and surgery, achieving a pCR was associated with a higher statistically significant rwEFS compared to those who did not achieve pCR. These findings highlight the importance of early detection and effective treatment strategies for TNBC in the Arab countries, with a particular emphasis on the neoadjuvant approach to improve outcomes.

P5-11-27: Analysis of Nectin-4 and its predictive value of pathological response in early Triple negative (TN) breast cancer

Maria Isabel Gallegos, Pilar Ortega, Aida Molero, Basilisa Gómez, Lourdes García, Ana Gómez, Aldo Fiorini, María Cornide

Background
Early TN breast cancer is a very heterogeneous disease, where neoadjuvant treatment represents the fundamental therapeutic strategy. The complete pathological response allows predicting those patients who will obtain a better chance of cure, and allows redirecting the treatment of those who do not obtain it. However, we do not have tumor biomarkers that allow us to predict this pCR.Nectin 4 is a protein involved in maintaining cell adhesion and stability, a mechanism that is highly altered in tumor processes. There is overexpression in some aggressive tumor subtypes such as TN breast cancer, where some authors point out its unfavorable prognostic role. Our study seeks to describe the expression of Nectin 4 and other variables in a cohort of TN patients, candidates for neoadjuvant therapy in routine clinical practice, evaluating its role as a predictor of response.

Methods: This is a retrospective study of 50 patients with triple negative breast cancer, diagnosed in the General Hospital of Segovia, who received neoadjuvant treatment following standard clinical practice. Patients´ demographics and clinical variables were gathered from medical records. Expression of Nectin-4 in tumor cells was performed by two independent pathologists with immunohistochemistry technique, using a monoclonal antibody against Nectin-4 (Abcam ab 192033), considering Quick score > 100 (high expression) or < or = 100 (low expression). Complete pathological response to treatment (pRC) was evaluated in 45 patients in definitive surgery and its correlation with nectin and tumor Infiltrating Lymphocytes (TILs) expression.

Results: The majority of patients were postmenopausal (70%), with a body mass index greater than 25 (62%), T2 tumors (56%), with lymph node involvement at diagnosis (54%). The 86% received treatment with platinum and 24% also received immunotherapy. The complete pathological response rate was 36%.Patients who receive platinum and tumors with greater infiltration of TILS achieve greater pRC (0,032 y 0,007) respectively.
The 60% of the tumors had a Nectin-4 expression greater than 100, presenting greater infiltration of TILS and CD8 but it is not significant. The 75% of them (High expression Nectin-4) expression had complete pathological response, versus the 48% (0,082).

Conclusions: This study shows a possible prediction of a favorable pathological response in triple negative breast tumors with greater expression of nectin-4. It is necessary to expand this study with a larger number of patients to continue investigating this association.

Scientific Foundation of the College of Physicians of Segovia Table: Nectina-4 Expression and its correlation with pathological response.

P5-11-28: Management of triple-negative breast cancer in renal transplant patients: A case report and multidisciplinary approach

Alexandra Montenegro, Diana Cardoso Simão, Leonor Fernandes, Sónia Duarte Oliveira

Introduction: In renal transplant (ReT) patients, the incidence of breast cancer (BC) is similar to the general population, albeit with a less favorable prognosis. The literature lacks guidelines for the diagnostic and therapeutic approach to BC in ReT patients, thus recommendations are based on those for the general population. It is crucial to manage the oncological disease while preserving the function of the transplanted organ by preventing treatment toxicity and drug interactions between immunosuppressants and oncological treatments.

Case Description: This report describes a 45-year-old woman who detected a painful lump in her left breast (LB), prompting further investigation. The patient underwent ReT in 2017

due to end-stage chronic kidney disease and is on immunosuppressive therapy (tacrolimus 3.5 mg daily and mycophenolate mofetil 250 mg twice daily). Her family history of cancer includes a brother diagnosed with gastric cancer at age 55.
Further investigation of the LB mass revealed a suspicious nodular formation at the transition of the upper quadrants of the LB, measuring 18x14 mm and no suspicious axillary lymphadenopathy (LB BI-RADS 5). Breast MRI revealed a 50mm unilateral atypia. An ultrasound-guided core needle biopsy was performed, which showed a left breast carcinoma of no special type, grade II, estrogen receptor (ER) negative, progesterone receptor (PR) negative (both 0%), HER2 negative (0), and Ki67 60%. Contrast-free CT scan, abdominal ultrasound, and bone scintigraphy showed no suspicious secondary lesions. The patient was referred to Medical Oncology and Genetics consultations, given her young age and diagnosis of triple-negative breast cancer (TNBC) cT2N0M0.
Neoadjuvant chemotherapy (NACT) based on taxanes and anthracyclines was proposed, followed by local therapy. During a nephro-oncology meeting, it was decided to conduct weekly monitoring of renal function (pre-NACT creatinine 1.82 mg/dL). The patient completed the planned NACT without dose reductions, delays or unexpected toxicities. Dose adjustments of immunosuppressants due to subtherapeutic levels were done. Post-NACT, renal function remained stable (post-NACT creatinine 1.72 mg/dL).
The patient underwent a total mastectomy with sentinel lymph node biopsy due to large tumor-to-breast-size ratio. Complete pathological response (pCR) was achieved. At 12 months post-surgery, the patient remains free of disease recurrence.

Discussion and Final Comments: We share a case of a ReT patient presenting a stage IIB TNBC diagnosed five years after the ReT. The patient underwent taxane-anthracycline NACT. There was renal graft function preservation and a pCR was achieved. This was facilitated by regular renal function monitoring and a multidisciplinary approach. However, nowadays, a combination of immunotherapy (IO) and chemotherapy is the standard of care.
Lessons Learned
There is a lack of literature addressing how to manage breast cancer in ReT.
Breast Cancer Treatment in ReT patients can be extrapolated from the general population.
A multidisciplinary approach is crucial and regular renal function monitoring is needed.
Immunotherapy's role in solid organ transplant receipts is being debated.

P5-11-29: Single center experience of the usage of KEYNOTE-522 regimen in patients with high-risk early stage triple negative breast cancer (TNBC)

Graeme Murray, Bryan Chan, Jacob Kattoula, Vivek Pujara, Philomena McAndrew, Yuan Yuan

Introduction: Chemoimmunotherapy, carboplatin/paclitaxel/pembrolizumab followed by adriamycin/cyclophosphamide/pembrolizumab (AC) (KEYNOTE-522 regimen), has shown a remarkable pathological response rate (pCR) of 68% and became the new standard of

care for high risk stage II/III triple negative breast cancer (TNBC). The neoadjuvant use of anthracycline remains an area of debate with added short-term toxicities and well established long-term cardiac toxicity and leukemia risk. Long-term outcomes of the ABC Trial questioned whether anthracyclines are necessary for every patient with TNBC as the inclusion of anthracyclines in older pre-immunotherapy regimens did not show an overall survival (OS) benefit. Additionally, the NeoPACT trial had an encouraging pCR of 58% with 6 cycles of carboplatin/docetaxel/pembrolizumab, providing an alternative regimen for patients with TNBC who are not eligible for anthracycline-based chemoimmunotherapy. A phase 3 SWOG SCARLET trial is ongoing for head-to-head comparison of the efficacy and safety of the NeoPACT and KEYNOTE522 regimen. Therefore, we performed a single center retrospective review on patients with early stage TNBC treated with either the KEYNOTE-522 regimen or a truncated KEYNOTE-522 regimen with weekly carboplatin paclitaxel pembrolizumab without AC. The primary goal is to describe the pCR rate, usage of anthracycline, and tolerance.

Methods: The study was conducted using an IRB approved institutional protocol through Cedars-Sinai Medical Center (CSMC). Inclusion criteria included adults with early stage (I-III) TNBC who were intended to be treated following Keynote 522 with curative intent and were post-surgery by the data cutoff date 06/8/2024 at CSMC or Huntington Health. 70 patients met this criteria. Patients were considered to be treated with AC if they had any exposure neoadjuvantly. We retrospectively recorded baseline patient age, stage, BRCA status disease, and treatment characteristics. “Clinical complete response” (CCR) was defined by the treating physician using imaging and physical exam. We used the D’Agostino & Pearson method for normality testing and the Mann-Whitney test for between-group comparisons. Ninety five percent confidence intervals were calculated with the Wilson-Brown method. Categorical comparisons used Fischer’s exact test. Toxicity was graded according to CTCAEv.5.

Results and Discussion: Most patients (49, 70%) received AC neoadjuvantly. Those who did not receive AC (21, 30%) were further sub-divided by the reason why. The most common reasons were CCR (11, 52%), namely no signs of disease on imaging or physical exam after treatment with carboplatin, paclitaxel, and pembrolizumab or toxicities such as colitis or septic shock due to prior therapy. There were no significant differences between groups in race, initial clinical stage, or BRCA1/2 mutation status. Germline testing data availability (83%-100%) was not significantly different between groups. Those with CCR had an astounding pathological pCR of 91% [62%, 98%] but was not significantly different compared to those treated with Keynote-522 (63% [49%, 75%], p=0.14). These patients with CCR were also significantly younger than those who did not receive AC due to toxicity ($p<0.01$) but not when compared to those who received AC (p=0.09). OS data is not currently mature enough to be significant. Patients who received AC had significantly more grade 3 or 4 cytopenia (34, 72% vs 8, 38% [p=0.01), and more episodes of febrile neutropenia (8, 17% vs 0, 0%, p=0.05). Only two patients who omitted AC initially went on

to receive AC adjuvantly. Based on these initial observations, it appears that AC can be omitted from carefully chosen subpopulation of patients with non-metastatic TNBC to avoid the toxicities of anthracyclines.

P5-11-30: Residual Cancer Burden (RCB) with Dose-Dense versus Every 3-Week AC regimen during Neoadjuvant Chemoimmunotherapy for Early-Stage Triple-Negative Breast Cancer – The Neo-Real Study

Renata Bonadio, Flávia Balint, Isadora Sousa, Ana Carolina Comini, Monique Tavares, Fernanda Madasi, Jose Bines, Rafael Ferreira, Daniela Rosa, Candice Santos, Zenaide Souza, Daniele Assad-Suzuki, Júlio Araújo, Débora Gagliato, Carlos Henrique dos Anjos, Bruna Zucchetti, Anezka Ferrari, Mayana de Brito, Renata Cangussu, Maria Marcela Monteiro, Paulo M. Hoff, Laura Testa, Maria del Pilar Estevez-Diz, Romualdo Barroso-Sousa

Background: Dose-dense chemotherapy regimens have demonstrated survival benefits in early-stage breast cancer treatment. However, it remains unclear whether dose-dense anthracycline and cyclophosphamide (ddAC) offers additional benefits during neoadjuvant pembrolizumab plus chemotherapy (P+CT) for triple-negative breast cancer (TNBC).

Methods: The Neo-Real study is an ongoing multicenter effort evaluating real-world data of patients with TNBC undergoing neoadjuvant P+CT since July 2020. This analysis compares ddAC versus every 3-week (q3w) AC, focusing on updated pathologic complete response (pCR) and residual cancer burden (RCB), with subgroup analyses based on disease stage.

Results: Among the patients included in the Neo-Real study to date, 349 have undergone surgery and had pathology reports available. RCB classification was described for 305 patients. Only 3 patients had a disease progression during the neoadjuvant therapy that precluded surgery; two were in the q3w group and one had the progression during carboplatin and paclitaxel (before AC). The AC regimen was done as ddAC in 56.2% and q3w AC in 42.4% of the cases. Baseline characteristics were similar for the ddAC and q3w AC groups, with the exception of the Ki67 index (Ki67 ≥ 50%: 84.8% in ddAC and 72.5% in q3w AC, P=0.008); 73.2% of the patients had stage II and 26.8% had stage III disease.
In line with our previous report, a pCR was observed in 65.3% with ddAC versus 59.5% with q3w AC (P=0.311), with a numerically higher difference in the stage III disease cohort (pCR 58% with ddAC and 42.1% with q3w AC, P=0.196). In stage II, the pCR rate was 66.9% with ddAC and 65.4% with q3w AC (P=0.455).
Among patients with a RCB description, RCB 0-1 was higher with ddAC (82.8%) than q3w AC (73.3%) in the overall cohort (P=0.049). RCB 0-1 occurred in 71.7% vs 50.0% in the stage III group (P=0.066), and 85.9% vs 82.2% in the stage II group, respectively (0.566). The distribution of patients in each RCB category according to AC regimen was as follows: 65.3% RCB 0 (pCR), 8.7% RCB 1, 13.8% RCB 2, 1.5% RCB 3, and 10.7% residual disease without RCB description with ddAC, and 59.5% RCB 0 (pCR), 5.4% RCB 1, 17.6% RCB 2, 6.1% RCB 3, and 11.5% residual disease without RCB description with q3w AC.

Conclusion: Dose-dense AC was associated with a higher rate of RCB 0-1 compared to q3w AC during neoadjuvant P+CT for TNBC. The absolute difference in RCB 0-1 favoring ddAC was higher in stage III disease. Longer follow-up is warranted to evaluate the impact of AC regimen on long-term outcomes.

P5-12-01: Prognostic implications of tumor size and nodal involvement in invasive lobular carcinoma of breast

Eunhye Kang, Ik Beom Shin, Hyerim Kang, Changhoon Lee, Min Jung Lee, Jinyoung Byeon, Ji-Jung Jung, Hong-Kyu Kim, Han-Byoel Lee, Wonshik Han, Hyeong-Gon Moon

Background: Invasive lobular carcinoma (ILC) represents the second most prevalent histological subtype of breast cancer, comprising 3-15% of all diagnosed cases. Despite its unique clinical and pathological profile when compared to invasive ductal carcinoma (IDC), there remains significant debate regarding the prognosis and optimal management strategies for ILC. This study aimed to investigate the differences in clinical and pathological features, survival between ILC and IDC and their impact on prognosis.

Methods: We reviewed the data of the 15,489 IDC patients and 966 ILC patients who were treated between January 2005 and December 2022 at Seoul National University Hospital. The clinical and pathological characteristics of ILC and IDC were compared, and survival outcomes were analyzed using cox proportional hazard models. We conducted a parallel analysis using the Surveillance, Epidemiology, and End Results (SEER) database. We extracted data from 247,290 breast cancer patients diagnosed between 2010 and 2015, comprising 219,404 cases of IDC and 27,886 cases of ILC.

Result: ILC had a larger tumor size, higher proportion of HR+/HER2- subtype, lower tumor grade, and lower Ki-67 index compared to IDC. Kaplan-Meier survival analysis with log-rank tests showed no statistically significant differences in breast cancer-specific survival (BCSS) or overall survival (OS) between patients with ILC and IDC ($p = 0.52$, 0.27, respectively). After adjusting for histologic grade and subtype, we found distinct patterns in survival determinants between ILC and IDC. In IDC, both tumor size (T stage) and nodal status (N stage) showed consistent prognostic significance. Compared to T1, T2 and T3 stages had 2.5-fold (95% CI: 2.00-3.00) and 4.4-fold (95% CI: 3.40-5.72) higher breast cancer-specific death risks, respectively. N1, N2, and N3 stages showed 2.5-fold (95% CI: 2.08-3.06), 3.8-fold (95% CI: 3.06-4.74), and 6.0-fold (95% CI: 4.66-7.67) increased risks compared to N0. Interestingly, in ILC, tumor size did not significantly impact survival ($p=0.38$ for T2, $p=0.12$ for T3 vs T1). However, advanced nodal involvement in ILC showed markedly higher risk, with N2 and N3 stages having 5.2-fold (95% CI: 1.66-16.57) and 26.1-fold (95% CI: 10.54-64.69) increased risks, respectively.
SEER data analysis corroborated these findings. For IDC, T2 and T3 stages showed 2.2-fold

(95% CI: 2.14-2.29) and 3.4-fold (95% CI: 3.20-3.51) increased risks, while N1, N2, and N3 stages had 1.7-fold, 2.8-fold, and 4.2-fold higher risks, respectively. In ILC, the impact of tumor size was less pronounced, with T2 and T3 stages showing 1.9-fold (95% CI: 1.69-2.04) and 2.43-fold (95% CI: 2.17-2.71) increased risks. However, nodal involvement in ILC again showed higher risk, with N2 and N3 stages having 3.5-fold (95% CI: 1.66-16.57) and 6.18-fold (95% CI: 5.53-6.90) increased risks, compared to 2.83-fold and 4.17-fold in IDC for N2 and N3, respectively.

Conclusion: In conclusion, our study highlights that ILC exhibits distinct characteristics and prognostic patterns compared to IDC. Although ILC is often detected at a larger size, the impact of tumor size on survival differs from that of IDC. In ILC, tumor size alone may not be as strong a predictor of survival as it is in IDC. Conversely, nodal involvement in ILC, especially at advanced stages, carries a particularly high risk for breast cancer-specific mortality. These findings underscore the need for tailored prognostic assessments and potentially different treatment strategies for ILC and IDC.

P5-12-02: Is BRCA2 a marker for worse prognosis in Breast Cancer?

Fatima Vaz, Rita Calisto, Sofia Fragoso, Luzia Garrido, Pedro Meireles, Rosário Couto, Suzy Costa, Gabriela Sousa, Rita Sousa, Olga Caramelo, Joana Ribeiro, Cristiana Marques, José Miguel Fernandes, Catarina Pulido, Ana Martins, Mafalda Casanova, Rui Dinis, Manuel Teixeira, José Luis Passos Coelho, Maria José Bento, Steven Narod, Joana Paredes

Background: Data regarding survival outcomes in BRCA1/2 Breast Cancer (BC) patients (pts) is controversial. Better chemosensitivity and survival was associated with triple negative BRCA1/2 BC, while positivity for the estrogen receptor (ER) was associated with worse prognosis. In BRCA2-BC, chemotherapy and exposure to ovarian hormones were described as modifiers of this ER effect. The objective of this national study is to analyze prognosis (overall, (OS) and breast cancer specific survival, (BCSS) of BC associated with the germline BRCA2 Founder variant c.156_157insAlu (BRCA2-P)
Methods: National retrospective case control study. From 224 BC pts from 16 Portuguese Hospitals 198 (F-184; M-14) pts diagnosed between 09/1982-12/2021 with a BRCA2-P, were included in this study. Survival cutoff date: 31/12/2022. Controls: 3 BC pts per case, matched by gender, stage, year of birth and cancer diagnosis, from the national oncological registry. Kaplan-Meier method was used to estimate OS and BCSS. Cox proportional hazards regression analyses to compute hazard ratios for all-cause and breast cancer mortality with the corresponding 95% CIs. Statistical analysis was performed using the software R (v4.3.3).
Results: Cases had a median age of 44 yrs (26 – 78) at BC diagnosis and 50 yrs at genetic testing. Eleven of the 198 pts had bilateral BC and 29 developed contralateral BC. Staging: I+II (145; 73%), III (48; 24%) and IV (5; 3%). Most (178) were invasive carcinomas NST. Subtype: 19 (9.6%) triple negative, 15 HER2+ (7,6%) and 168 (84.8%) were Luminal. Treatments: Surgery: 193 pts (137 primary); chemotherapy: 166 (83.8%);

hormone therapy: 167 (84.3%); radiotherapy: 141 (71.2%); anti-HER2 16 (8.1%). Uptake of Risk Reduction (RR) surgeries: mastectomy (RRM): 87 females (35 simultaneous and 52 after a previous therapeutic surgery); Bilateral salpingo-oophorectomy (BSO): 121 (117 after and 4 before BC diagnosis). Second cancers: BC: 29/198 pts (15%); Ovarian Cancer: 10/184 (5.4%); prostate cancer: 4/14 (28.6%); pancreatic cancer: 3/198 pts (1.5%); GIST, thyroid, melanoma, lung cancer, MDS: 2 cases each (1%). At the cutoff date for survival analysis, 62 pts died: 50 (80.6%) from cancer, 5 (8.1%) from other causes, 7 (11.3%) unknown. BC was the leading cause of cancer-related death (39; 78%) followed by ovarian (4; 8.7%) and pancreatic (3; 6%) cancer.
OS and BCSS: Median survival was 20.85 and 34.3 yrs for the BRCA2-P and Control group (p=0.12), respectively. To minimize immortality bias, OS and BCSS were analyzed separately for diagnoses after 2006: 88.7% of cases were alive at 5 yrs (vs 88.4% of controls) while at 10 and 15 yrs this difference was 72% vs 78.4% and 68% vs 73.8%, respectively (p=0.44).
Multivariate analysis: variables associated with lower risk of death (OS and BCSS) were adjuvant chemotherapy (HR 0.24 CI: 0.08-0.69, p=0.01 and HR 0.21 CI: 0.06-0.82, p=0.03) and RR mastectomy* (HR 0.37 CI: 0.16-0.88, p=0.02 and HR 0.34 CI: 0.12-0.94, p=0.04), respectively. BSO* was associated with a better BCSS (HR 0.36 CI:0.13-0.93, p=0.35), but not with OS (HR 0,45 CI: 0.19-1.05, p=0.06). Staging III and higher were associated with worse OS and BCSS (HR 6.27 CI: 1.37-28.58, p=0.02 and HR 24.16 CI: 2.39-244.32, p=0.01, respectively).The association of ER/PR with OS and BCSS was not significant: (HR 0,52 CI 0.15-1.73, p=0.3 and HR 0,27 CI 0.07-1.06, p=0,06).
Conclusions: No significant differences in OS and BCSS were observed for BRCA2-P BC when compared to sporadic BC controls. Variables with a positive impact on OS for BRCA2-P pts were stages under III, adjuvant chemotherapy and RR mastectomy. BSO was associated with better BCSS. In this study, where virtually all Luminal BRCA2-P BC pts were treated with hormonotherapy and 65% underwent RRBSO, we did not observe a negative association of ER and survival.

*Cox proportional hazards regression model with time co-variates

P5-12-03: Influence of antibiotic use on the efficacy of neoadjuvant chemotherapy in breast cancer

Manuel Zalabardo Aguilar, Inés Fernández Sánchez, Alberto Girona Torres, Álvaro González Ortiz, José Manuel Jerez Aragonés, Alfonso Sánchez Muñoz, Javier Pascual López, María José Bermejo Pérez, Antonia Márquez Aragonés, Bella Pajares Hachero, Francisco Carabantes Ocón, Begoña Jiménez Rodríguez, María Emilia Domínguez Recio, Ana Godoy Ortiz, Tamara Díaz Redondo, Ester Villar Chamorro, Marcos Iglesias Campos, Irene Zarcos Pedrinaci, Nuria Ribelles Entrena, Emilio Alba Conejo

Introduction: The rediscovery of the microbiota has revealed its influence on carcinogenesis and response to treatment. Antibiotic use is common in cancer patients, potentially causing

intestinal dysbiosis, disturbing the tumor microenvironment, intratumoral microbiota and affecting pharmacokinetic interactions with chemotherapy. These factors seem to influence cancer treatment benefits, but this is not well understood. Small studies suggest antibiotic use may reduce neoadjuvant treatment benefits in breast cancer.

Objectives: This real-life, retrospective study includes a broad series of women diagnosed with breast cancer between 2009 and 2023, candidates for neoadjuvant chemotherapy based on anthracyclines, cyclophosphamide, taxanes +/- antiHER2. We analyze the influence of antibiotic use during neoadjuvant treatment or within 30 days prior to its initiation on pathological complete response (pCR/RCB-0) and achieving a good response defined as RCB-0 and RCB-1, according to residual cancer burden (RCB) index.

Methods: The analysis included 1314 patients, divided into two groups: those who did not receive antibiotics during neoadjuvant treatment (60.6%) and those who did while or within 30 days prior to it (39.4%). Clinical and pathological variables were compared using the chi-square test, with a significance level set at <0.05. The average relative dose intensity (RDI) was calculated using the Hryniuk method for each type of chemotherapy administered. To identify the most significant predictors for our logistic regression model, we employed a stepwise selection procedure. Variables were selected based on the Akaike Information Criterion (AIC), which balances model fit and complexity by penalizing less significant predictors.

Results: The clinico-pathological characteristics were balanced between groups, with no significant differences. 66% were in stage II and 29% in stage III (p 0.92), 54% and 56% were premenopausal (p 0.66), and 54% and 57% were grade 3 tumors (p 0.22) in both groups respectively. Regarding phenotypic subtypes, there were no differences between the two groups (p 0.85). Among patients without antibiotics, 35% were luminal tumors, 39% HER2+, and 26% triple-negative. Among those with antibiotics, 34% were luminal, 39% HER2+, and 27% triple-negative.
Significant differences were observed in achieving an optimal RDI >85%. 95% of patients without antibiotics had an RDI >85% compared to 89% with antibiotics. However, the frequency of patients with an average RDI ≤85% was low in both groups: 5% without antibiotics and 11% with antibiotics (p 0.00026).
The effect of antibiotics on neoadjuvant therapy efficacy was explored based on the pathological evaluation of residual disease using the RCB index. Significant associations were observed, indicating patients who received antibiotics were less likely to achieve optimal pathological responses. Complete pathological responses (RCB-0) were higher without antibiotics: 33% vs 28% (p 0.04). For RCB 0/I vs RCB II/III, 49% of patients without antibiotics achieved RCB 0/I vs 37% of those with antibiotics (p <0.0001). This trend was significant too in luminal tumors: 21% without antibiotics achieved RCB 0/I vs 13% with antibiotics (p 0.03) and in HER2+ and triple-negative tumors (63% vs 50%,

p<0.0001).
The multivariate analysis revealed antibiotic use had a negative effect on achieving pCR (p 0.03) and RCB 0/1 (p<0.0001), along with other predictive variables. Our model demonstrated the RDI did not influence the pathological response.

Conclusion: This study suggests that antibiotic use during neoadjuvant treatment may negatively impact the pathological response in breast cancer. These results highlight the need to consider antibiotic use during chemotherapy to optimize outcomes and the need for prospective studies to explain the mechanism of this influence.

P5-12-04: BRCA genetic testing and treatment patterns for patients with early-stage HER2-negative breast cancer in the United States (U.S.) community setting, 2016–2022

Kathryn Mishkin, Yezhou Sun, Ke Meng, Xiaoqing Xu, Qixin Li, Yu-Han Kao, Kim M. Hirshfield, Jaime Mejia

Background: The presence of a germline pathogenic variant in BRCA1/2 (gBRCAm) markedly increases the risk of breast cancer and its recurrence after standard therapy. Adjuvant olaparib received regulatory approval in the U.S. in March 2022 for treating adult patients with gBRCAm early-stage, high-risk HER2-negative breast cancer who had received neoadjuvant or adjuvant chemotherapy and who were selected for therapy based on an approved companion diagnostic test. This retrospective cohort study aimed to describe BRCA testing and subsequent treatment patterns with olaparib.
Methods: We studied adults (≥18 years) with initial diagnosis (1-Jan-2016 to 30-Dec-2022) of HER2-negative and clinical stage I, II, or III breast cancer who were included in a longitudinal, real-world dataset from the Syapse Learning Health Network, drawn from large community US health systems. Patients with unknown hormone receptor (HR) status and those enrolled in a clinical trial or with lobular carcinoma in situ, lymphoma, or other primary cancer were excluded. Testing for BRCA status was summarized by year. Patient characteristics were described by BRCAm status.
Results: Of the 15,784 eligible patients, 5,821 (37%) had a BRCA test (>99% for gBRCA, <1% somatic) before a diagnosis of metastatic disease, including 4,762 (35%) of 13,748 with HR-positive tumors and 1,059 (52%) of 2,036 with triple-negative breast cancer (TNBC). The timing of BRCA testing, when recorded, was on/before surgery for 74% of patients and after surgery and before recurrence/metastasis for 26%. Testing rates rose by year from 28% in 2016 to 46% in 2022. The percentages of patients tested across all years ranged from 36% to 39% by known race: namely, 37% of White patients (n=12,588), 36% of Black/African American patients (n=2,323), 39% of Asian patients (n=591), and 39% of American Indian/Alaska Native patients (n=49) had a BRCA test. Sampling for BRCA was primarily derived by blood (86%) followed by saliva (12%). Overall, among the 5,821 patients tested, BRCAm were identified in 205 cases (3.5%), including in 117 (2.5%)

patients with HR-positive tumors and 88 (8.3%) patients with TNBC, respectively. Of the tested patients, surgery at the primary site was conducted for 97% with BRCAm vs. 96% non-BRCAm, including mastectomy (84% vs. 51%), and lumpectomy only (12% vs. 44%), respectively. Radiation to the primary site was administered to 44% with BRCAm vs. 60% non-BRCAm. Among patients tested for BRCAm, seven were treated with olaparib and 6 of 7 patients had TNBC.
Conclusions: The results of this study indicate that BRCA genetic testing rates have increased from 2016 to 2022 in the US, but fewer than half of eligible patients received a BRCA test. We observed that, for patients with early-stage, HER2-negative breast cancer, BRCA testing rates are greater among patients with TNBC than among those with HR-positive tumors (52% vs. 35%), indicating an opportunity for HR-positive tumors. Further, roughly 26% received a BRCA test after surgery, which suggests an opportunity to improve timing of testing to before surgery. The percentages of patients tested were similar across racial groups. A more contemporary cohort may extend our understanding of olaparib use in this patient population. Future work will investigate use of olaparib for early-stage HER2-negative breast cancer in the U.S. in subsequent years.

P5-12-05: Current delivery and challenges in breast cancer care in the UK in 2023

Richard Simcock, Helen Flint, Julie Douglas, Philipp A. Dietrich, Victoria Bush, Jas Singh Cooner, Stuart A McIntosh

The National Health Service (NHS) in the UK is committed to providing consistent quality of care and to achieving equality objectives, however variation in care remains a significant issue. The treatment of Early Breast Cancer (EBC) has seen an influx of additional therapeutic agents that intend to improve patient outcomes. We hypothesized that the rapidly changing and increasing demands in the EBC landscape may have resulted in significantly heterogenous development of services. Understanding and highlighting these differences may encourage proactive service evaluation and improvement. Additionally, this may provide rationale for standardised approaches to reduce variation in both care and patient outcomes.
This study aimed to identify the current state of the nation and the challenges facing UK oncology teams. Healthcare Professionals (HCPs) from across the UK involved in EBC patient management (n=70, Oncologists, Surgeons, Pharmacists, and Nurses) were surveyed from August to December 2023.
Most (90%) MultiDisciplinary Team meetings (MDTs) were weekly, utilised local guidelines (81%) with Clinical Oncologists, Medical Oncologists, Surgeons, Radiographers and Breast Care Nurses present (>60%). Of note, other roles such as Pathologists (53%) and Pharmacists (13%) were less consistently reported in attendance. Only 34% had separate MDTs for Early and Advanced Breast Cancer (ABC) despite the different workforce involved in each pathway. Each MDT discussed up to 110 cases (average 53) for 1-15 minutes each with some (39%) using a triage system to streamline the MDT process.

The majority (77%) reported conducting joint (ABC and EBC) clinics with 40% indicating they have a separate EBC clinic, which may be in addition to a joint clinic. A variety of HCPs were involved in the follow up care of EBC patients, such as Pharmacists, Nurses, Surgeons, Radiographers and Physician Associates. Patients were prioritised to be seen in clinic in 57% of responses, largely based on risk factors such as nodal status, time from surgery, inflammatory Breast Cancer and suitability for Neoadjuvant Chemotherapy. Comparatively 43% of responders did not prioritise patients when scheduling for clinics.
Key challenges described in systemic adjuvant therapy provision were staff shortages (71%), clinic capacity for increased patient numbers (68%) and the increased time required to discuss new therapies (41%). The introduction of CDK4/6 inhibitor therapy to the adjuvant setting was noted to have had various impacts with patients requiring more intensive Medical Oncologist involvement than those on endocrine therapy alone.
In conclusion, changes in the treatment landscape have resulted in high levels of inconsistency between services delivered across the UK. These differences include varieties of MDT composition and process streamlining, HCP deployment and patient follow-up models. Despite these innovations in approach patient volume, clinic and staff availability are still significant issues in meeting the delivery demands of new therapies. Together these findings emphasize that proactive service evaluation and adaptation may be urgently required to accommodate increased demand and to reduce variation in care quality.

P5-12-06: Elucidating the role of NEAT1_2 in DCIS malignancy

Aditi Rastogi, Yan Hong, Andrew K. Godwin, Shane R. Stecklein, Devin C. Koestler, Linheng Li, Hua Li, Jerome Lin, Nicholas Navin, Alastair Thompson, Fariba Behbod

Background: Ductal carcinoma in situ (DCIS) is the most common form of non-invasive breast cancer where the epithelial cells are cancerous but have not spread beyond the breast milk tubes or ducts. A large fraction of human DCIS (>50%) may not need the multimodality treatment currently offered to most patients. More importantly, while we may be overtreating many, challenges remain in the identification of those most at risk for invasion/metastasis. Revealing the cellular and molecular mechanisms by which some DCIS remain indolent while others advance to invasive and metastatic breast cancers is currently an unmet need. To address this gap and to study molecular and cellular mechanisms associated with DCIS invasive and metastatic progression, we developed the Mouse-INtraDuctal (MIND) model, in which patient-derived (PDX) DCIS epithelial cells are injected into mouse mammary glands by the intraductal method and allowed to progress naturally, forming in situ lesions that, in some cases, progress to invasive ductal carcinoma. Methods: Single cell RNAseq was performed on 17 DCIS samples, including nine progressors and eight non-progressors. Progressors are patient-derived DCIS cells that show invasive progression, while non-progressors are patient-derived DCIS cells that remain non-invasive in our MIND model. Single cell RNAseq analysis identified differentially expressed genes that were upregulated in progressors compared to non-progressors in stroma and epithelial cells. CellPhoneDB was utilized to identify receptor-ligand interaction pairs in progressors vs. non-progressor DCIS MIND models. Results: We observed a significant upregulation of

NEAT1_2 expression in our progressed patient samples as well as our progressed xenografts compared to non-progressors. NEAT1_2 is a long non-coding RNA that is a major rate-limiting factor in paraspeckle formation. Paraspeckles are believed to promote tumor progression by retaining double-stranded RNA (dsRNA) and microRNA. Retention of dsRNA by paraspeckles may prevent the expression of interferon alpha (IFNa) and suppress anti-tumor immune responses. Indeed, analysis of the breast cancer TCGA dataset revealed that NEAT1_2 expression showed a significant upregulation with MYC targets and downregulation of IFNa signaling. The MYC pathway is associated with high expression of dsRNA. Upregulated MYC expression and downregulated IFNα in NEAT1_2 high samples suggest a link between MYC, increased expression of dsRNA, dsRNA retention by the paraspeckles, and a subsequent decrease in anti-tumor immune responses. To study the role of NEAT1_2 in DCIS invasive and metastatic progression, a NEAT1_2 antisense oligo (ASO) was used. We showed that NEAT1_2 ASO was an effective strategy for NEAT1_2 knockdown (KD) in DCIS cell lines. Based on preliminary data, we hypothesize that NEAT1_2 may play a role in DCIS invasive progression through the retention of dsRNA by paraspeckles to restrain an anti-tumor immune response. NEAT1_2 KD may provide an effective strategy for the induction of anti-tumor immunity and prevention of DCIS invasive and metastatic progression. Future Directions: Immunocompetent mouse mammary precancerous progression models will be used to test the efficacy of NEAT1_2 ASO in preventing DCIS invasive and metastatic progression. We will also study the mechanism by which NEAT1_2 remodels the tumor immune microenvironment to drive DCIS malignancy.

P5-12-07: Increase of repeated biopsies in metastatic breast cancer over time: Results from the Austrian AGMT_MBC-Registry

Simon Gampenrieder, Gabriel Rinnerthaler, Angelika Pichler, Walter Herz, Renate Pusch, Clemens Dormann, Christoph Suppan, Sonja Heibl, Lukas Scagnetti, Margit Sandholzer, Thomas Winder, August Felix Zabernigg, Clemens Schmitt, Daniel Egle, Christopher Hager, Petra Pichler, Florian Roitner, Johannes Andel, Kathrin Strasser-Weippl, Rupert Bartsch, Vanessa Castagnaviz, Michael Hubalek, Michael Knauer, Christian Fridolin Singer, Richard Greil

Background: Predictive biomarkers have become increasingly important to guide treatment decisions for metastatic breast cancer (MBC). Some of these biomarkers, especially estrogen receptor (ER), HER2, and ESR1 mutations, are known to change over time due to therapeutic pressure and tumor evolution. Consequently, an increase in biopsies of metastatic sites at diagnosis of metastatic disease and during the course of the disease is expected. To test this hypothesis, we analyzed data from the Austrian Study Group of Medical Tumor Therapy (AGMT) MBC-Registry.
Patients and methods: The AGMT_MBC-Registry is a multicenter nationwide ongoing retrospective and prospective registry for MBC patients in Austria. For this analysis, only patients with sufficient data quality were included. All biopsies, fine needle aspirations or surgical procedures of metastatic sites were evaluated. The relative frequency of

biopsies/surgeries per patients on antitumoral treatment per year and per year category were calculated (2010-2012, 2013-2015, 2016-2018, 2019-2021, 2022-2024) and categorized according to the line of treatment (before first-line, before second-line etc.). In cases with reported ER and HER2 status, differences between the most recent primary tumor and samples from metastatic sites were investigated.
Results: As of 26-June-2024, 2,850 patients were included in the registry. Out of 2,630 evaluable patients, 1,437 (54.6%) had at least one histologic confirmation of a metastasis during the course of disease: 1,124 (42.7%) via core needle biopsy, 116 (4.4%) via fine needle aspiration, and 352 (13.4%) via surgery. The ratio of biopsies/surgeries per patients per year significantly increased over time with 0.32, 0.30, 0.40, 0.54, and 0.56 in the years 2010-2012, 2013-2015, 2016-2018, 2019-2021, and 2022-2024, respectively (Pearson's Chi-squared test P <0.001). Most of the biopsies (66.9%) and surgeries (63.3%) were performed before first-line (65.7% in total), with decreasing numbers from line to line (14.2% before second-line, 5.4% before third-line, 2.5% before forth-line and 2.6% before fifth-line). Only 20.7% of patients had more than one biopsy of a metastatic site with an increasing ratio over time (0.049, 0.067, 0.077, 0.128, and 0.165 in the years 2010-2012, 2013-2015, 2016-2018, 2019-2021, and 2022-2024, respectively Pearson's Chi-squared test P <0.001). The discrepancies between ER (ER- vs ER+) and HER2 status (HER2 0 vs. HER2-low vs. HER2+) between the primary breast cancer and at least one metastatic lesion were 6.4% and 14.4%, respectively.
Conclusion: The rising number of biopsies, before first- and second-line treatments reflects the increasingly stratified treatment strategies in MBC. It can be assumed that less invasive measures, such as liquid biopsies, will further increase the number of repeated biomarker assessments to guide treatment decisions.

P5-12-08: Single-center experience in antibody drug conjugate sequencing in HER2-low metastatic breast cancer

Utsav Joshi, Junmin Whiting, Mo Qianxiang, Melissa Armitage, Jorge Avila, Kimberley T. Lee, Avan Armaghani, Tracey O'Conner, Ricardo Costa, Aixa Soyano Muller, Loretta Loftus, Hatem Soliman, Hyo S. Han

Introduction: Two antibody-drug conjugates (ADCs), trastuzumab deruxtecan (T-Dxd) and sacituzumab govitecan (SG), were approved by the FDA for HER2 low and HER2 negative metastatic breast cancer (MBC) respectively and the current data of the optimal sequencing of ADCs is limited. This study evaluated the efficacy of the second ADC (ADC2) following the first ADC (ADC1) in HER2-low MBC patients (pts) who have received both ADCs of T-Dxd and SG.

Methods: This study represents an IRB approved retrospective cohort study of adult pts (age ≥ 18 years) at Moffitt Cancer Center between December 1, 2019, to January 31, 2024 with HER2-low MBC treated with both ADCs. Data was obtained via abstraction of the electronic medical record. The primary objective was to evaluate progression free survival

(PFS) after ADC 1 (PFS1) and after ADC2 (PFS2). PFS is defined as the time from first dose of ADC to time of imaging showing progression or death. The Kruskal-Wallis test was applied to assess the association between continuous and categorical variables, while the Chi-square test or Fisher's exact test was used to evaluate the association between two categorical variables. All statistical tests were two-sided, with a significance level set at $p < 0.05$.

Results: Overall, 34 pts met inclusion criteria. Seventeen pts received T-Dxd as ADC1 and 17 patients received SG as ADC1. The cohort included one male patient, 41.2% (14/34) were hormone receptor (HR) positive, and 58.8% (20/34) were triple negative breast cancer (TNBC) from metastatic biopsy. Two of the patients with TNBC MBC had ER or PR positive ≤ 10%. Two of the 34 patients were still receiving ongoing therapy with ADC2 at the time of the data cutoff. All of the HR positive subgroup received T-Dxd first followed by SG, and most TNBC patients (85%) received SG first followed by T-Dxd. Overall median PFS1 (mPFS1) with ADC1 in all comers was 5.8mo, and median PFS2 (mPFS2) with ADC2 was 2.4mo. PFS1 and PFS2 by drug sequence can be seen in table 1. Eight patients had significantly longer PFS2, defined as having received at least 8 cycles of therapy, and six of these patients received T-Dxd as ADC2. Five of the eight pts with this longer PFS2 were TNBC at the initial diagnosis and remained TNBC at time of ADC treatment. The other three pts were TNBC at initial diagnosis and changed to HR positive disease at time of ADC treatment.
67.6% (n=23) of pts received ADC therapies back-to-back with no lines of therapy in between, while 20.6% (n=35) of pts received one line of therapy in between ADCs. mPFS1 for those who received back-to-back therapy was 5.8mo while those with one line of therapy in between had a mPFS1 of 4.3mo.
Of the 7 pts with brain metastases at start of ADC1, mPFS1 was 8.5mo. Of the 10 pts with brain metastases at the start of ADC2, mPFS2 was 2.9mo. Ten (29.4%) pts experienced any grade 2 or above adverse events (AEs) with ADC1, while 12 (35.3%) pts experienced any grade 2 AEs with ADC2. Further description of AEs will be discussed at the presentation.

Conclusion: Our data demonstrates that mPFS is shorter following ADC2 which is consistent with limited available data to date. Interestingly, there were 8 pts with prolonged PFS2 of over 6 months, having received 8 or more cycles of therapy prior to progression. Overall, our study is limited by its retrospective nature and small sample size.

P5-12-09: Pathologic complete response (pCR) rate in patients with a germline pathogenic variant in ATM and early breast cancer

Haven Garber, Amanda Lanier, Angelica Gutierrez, Hyunsoo Hwang, Constance Albarracin, Isabelle Bedrosian, Banu Arun

Background: The incidence of ATM (ataxia telangiectasia mutated gene) pathogenic variants in breast cancer patients is estimated at ~ 1%. ATM is a serine/threonine protein kinase that is activated by double strand DNA breaks and, upon activation, ATM phosphorylates several downstream proteins integral to double strand DNA repair. Hereditary loss of function mutations in ATM (gATM) moderately increase the risk of female breast cancer by ~2-4x that of the general population. Higher rates of pathologic complete response (pCR) after pre-operative chemotherapy have been reported in patients with breast cancer and germline pathogenic variants in other DNA damage repair associated genes such as BRCA1, BRCA2, and PALB2. We sought to determine the rate of pathologic complete response in patients with early-stage breast cancer and gATM.

Methods: Patients with invasive breast cancer and gATM who were treated at our institution between 1994 and 2022 were identified from prospectively maintained research databases. Data analyzed included breast cancer subtype and stage at diagnosis, treatment, and residual cancer burden status. pCR was defined as the absence of residual invasive cancer on hematoxylin and eosin evaluation of the complete resected breast specimen and all sampled regional lymph nodes.

Results: We identified 86 patients with invasive breast cancer and gATM. Pre-operative chemotherapy (anthracycline and/or taxane-based with or without anti-HER2 therapy) was utilized in 31 of the 86 (36%) patients. The pCR rate was 5/31 (16.1%). Of the 5 patients with pCR, 2 had triple positive subtype and 1 patient each had ER-/HER2+, ER+/HER2 neg, and triple negative breast cancer subtype.

Conclusion: The pCR rate was modest (16.1%) in our cohort of patients with invasive breast cancer and gATM. This suggests that altered ATM may not augment chemosensitivity in breast cancer, however larger studies are needed. Additional pre-operative agents including immunotherapy, platinums, new anti-HER2 therapies, and ATM inhibitors may improve the pCR rate.

P5-12-10: Overall survival in patients with recurrent breast cancer in stage II-III using surveillance imaging detection vs symptomatic disease at a reference hospital in Mexico

Rocio Crystal Grajales Alvarez

Background: Breast cancer is the most common cancer worldwide, the annual risk of locoregional recurrence is 1-1.5% for at least 15-20 years. The relationship between an early recurrence detection and the impact on quality of life and overall survival (OS) has been analyzed for decades and yet according to international guidelines, the only approved image study for follow-up is the annual mammography because there hasn't been enough

evidence for additional imaging surveillance that impact in OS nor disease free survival (DFS). Most of this evidence comes from studies prior the implementation of the intrinsic subtypes which are the main prognostic factor and current therapeutic guide. There is a recent retrospective protocol which demonstrated a benefit in OS of asymptomatic detection of distant recurrences in patients with HER2+ and triple negative breast cancer (TNBC) compared with symptomatic detection.
Methods: The aim of this study is to determine the OS in patients with stage II-III breast cancer whose recurrence is documented by symptomatic disease vs asymptomatic detection by surveillance imaging. A retrospective observational cohort study was performed. Patients diagnosed with stage II-III breast cancer, treated at the UMAE Hospital de Oncología of the CMN Siglo XXI from January 2018 – December 2022 were included. OS and DFS were calculated with Kaplan- Meier method with Log Rank, Breslow and Mantel tests. The prognosis analysis of the complete models was performed using Cox proportional hazards model. The analysis was stratified according to intrinsic subtype and site of recurrence (local and distant).
Results: A total of 618 patients were included. Local recurrence (31.1%) was less common than distant recurrence (68.9%). Most of the patients were luminal (75.2%), 22.4% HER2-positive, and 15.3% TNBC. The median OS was 83 months. A total of 434 patients (70.2%) were symptomatic detections while 184 patients (29.8%) were detected by surveillance imaging. The median OS (mOS) in the asymptomatic group and the symptomatic group were 92 months and 80 months, respectively (p= 0.895). In those with distant recurrence, the subgroup analysis by breast cancer subtype showed no difference between the luminal and TNBC groups, according to symptomatic vs asymptomatic detection (mOS 111 months vs 95 months, p= 0.37 in luminal; and 45 months vs 36 months, p= 0.73 in TNBC) but there was a statistically significant association in the HER2-positive group by the Breslow test with improved survival in those with imaging detection (53 months vs 95 months, p=0.034) which means the survival benefit is seen during the first follow-up months. There was no difference in OS in patients with locoregional recurrences by intrinsic subtype.
Conclusions: In patients with breast cancer stage II-III there is no benefit in OS with an asymptomatic surveillance imaging recurrence detection vs a symptomatic disease. Those with HER2-positive breast cancer showed a significant benefit in survival of an asymptomatic detection during the first months of follow-up, probably related to antiHER2 therapy available for the first-line treatment for this population.

P5-12-11: Differences in overall survival between patients with fungating and non-fungating breast cancer with distant metastases at the time of diagnosis

Tamaki Tamanuki, Maki Namura, Tomoyoshi Aoyagi, Haruhito Sakata, Mika Iwai, Shinichirou Shimizu, Hiroshi Matsuzaki

Background: Giant fungating breast cancers (FBCs), characterized by exudative discharge, foul odor, massive tumor formation, and extensive ulceration, often require palliative

treatment, even without distant metastasis. However, our results presented at SABCS2023 indicated that multimodal therapy, including surgery, results in equivalent overall survival (OS) in patients with FBC and stage III non-fungating breast cancers (non-FBCs). Notably, reports on the treatment and outcomes of patients with stage IV FBC with distant metastases are limited. Therefore, we tested the hypothesis that the OS of patients with stage IV FBC at diagnosis is equivalent to that of patients with stage IV non-FBC.

Methods: We identified 112 patients diagnosed with stage IV breast cancer at initial presentation between June 2012 and March 2020, of whom 24 had FBC and 88 had non-FBC. We analyzed the clinicopathological characteristics, metastatic sites, and treatment modalities of both groups. We further subcategorized the patients into two groups based on the presence of single or multiple visceral metastases and compared their survival rates. We used Kaplan-Meier curves and log-rank tests d for statistical analyses, while a Cox proportional hazards model was used to determine predictors of OS.

Results: The mean ages of the FBC cohort and non-FBC cohort were 61.5 years (range: 41–92) and 65.0 years (range: 31–89), respectively. There were no statistically significant differences in subtype distribution or nuclear grades between the two cohorts. The number of patients receiving initial chemotherapy was similar in both groups (58.3% vs. 61.4%, p=0.817). In the non-FBC cohort, isolated bone metastases were observed in 19 cases (21.6%), whereas in the FBC cohort, they were observed in only one case (4.2%). However, there was no difference in the proportion of cases with visceral metastases between the FBC and non-FBC cohorts, both for single (50.0% vs 56.8%, p=0.350) and multiple visceral metastases (28.6% vs. 21.6%, p=0.484). The 2-year survival rate tended to be lower in patients with FBC than in patients without FBC (75.0% vs. 85.0%, p=0.235). At 3 years, the survival rate for the FBC cohort was significantly lower (52.5% vs. 80.0%, p=0.015), and this difference became more pronounced at 5 years (29.5% vs. 73.9%, p<0.001). The median OS time was also significantly shorter in patients with FBC than in those without FBC (3.1 years vs. 7.0 years, p=0.003). Among cases with visceral metastases excluding those with isolated bone metastases, the FBC cohort exhibited markedly lower 3-year survival rates in both the single (63.5% vs. 81.3%, p=0.061) and multiple organ metastases subgroups (33.3% vs. 73.7%, p=0.012). In a multivariate Cox model involving 112 patients, the diagnosis of FBC was a significant independent predictor of a poorer OS (hazard ratio=2.264, p=0.011).

Conclusion: While the OS of patients with stage III FBC was comparable to that of non-FBC, survival rates were significantly lower for patients with stage IV FBC than those with non-FBC. These findings provide an important reference to help clinicians determine treatment strategies for patients with stage IV breast cancer.

P5-12-12: Refining Sentinel Lymph Node Biopsy Decisions for Clinically Node Negative Microinvasive DCIS

Priyanka Parmar, Cein Huang, Noor Habboosh, Fardeen Bhimani, Yu Chen, David Entenberg, Maja Oktay, Anjuli Gupta, Maureen McEvoy, Sheldon Feldman, Jessica Pastoriza

Background: With improved screening and detection of breast cancer, we are diagnosing breast cancer at early stages. Consequently, there is a need to better understand how to manage early diseases such as Ductal Carcinoma In Situ with Microinvasion (DCISM). DCISM is defined as an invasion ≤ 1 mm in size and is typically found in 5-10% of ductal carcinoma in situ (DCIS) cases. The appropriate management of DCISM remains debated, as it is unclear whether these lesions should be treated similarly to DCIS or as a small invasive disease. As we advance towards precision medicine and emphasize enhancing patients' quality of life, there has been a concerted effort to further stratify patients to identify those at low risk, allowing for the de-escalation of morbid treatments such as axillary surgery during initial surgical intervention. However, optimal axillary management of DCISM remains elusive due to limited literature on this topic. This study aimed to identify pre-operative predictive variables that increase the risk of upstaging to invasive cancer on final pathology, enabling stratification of patients into low- and high-risk groups and guiding the de-escalation of sentinel lymph node biopsy (SLNB).
Methods: A retrospective chart review was conducted of women over the age of 18 who had DCIS with confirmed or suspected microinvasion on initial breast biopsy and were clinically node-negative at Montefiore/Einstein Comprehensive Cancer Center from 2013 to 2023. A chi-squared analysis of pre-operative factors associated with the histopathologic upgrade to invasive carcinoma on final pathology was conducted, including hormone negativity, mass size on mammogram and MRI, palpable mass, high grade, comedonecrosis on pathology, guidance method, biopsy device, biopsy needle gauge size, and number of cores obtained.
Results: A total of 68 women were identified with DCISM on initial biopsy. Among them, 40% (n=27/68) were upstaged to invasive carcinoma on final pathology, and 66% (n=45/68) underwent SLNB at the time of surgical resection. For those who underwent SLNB and were upstaged on final pathology, 19% (n=4/21) had positive lymph node metastasis, whereas those who underwent SLNB and did not upstage had 0% (n=0/24) lymph node metastasis. The time from the initial biopsy to the final surgery did not differ significantly between those who upstaged and those who did not (p = 0.2446). Pre-operative variables that predicted higher odds of upstaging included a palpable mass (OR 7.62, 95% CI 2.06-28.18; p=0.002) and a size on mammogram ≥ 3.5 cm (OR 4.12, 95% CI 1.22-13.95; p=0.020). During the initial biopsy, using a 9-gauge needle and obtaining ≥ 4 cores resulted in a sensitivity of 80% for the final diagnosis of DCISM, compared to a sensitivity of only 18% when using a smaller 14-gauge needle and obtaining < 4 cores.
Conclusion: Patients with a diagnosis of DCIS with microinvasion who are clinically node-negative, and have pre-operative characteristics including size on mammogram < 3.5 cm and lack of a palpable mass, may benefit from the de-escalation of SLNB, as these patients have low odds of upstaging to invasive carcinoma and potentially, low rate of lymph node metastasis. These findings underscore the importance of thorough pre-operative

assessment in patients with DCISM to guide surgical management. Identifying predictive factors for upstaging can help stratify patients into low- and high-risk groups, potentially guiding the de-escalation of SLNB and reducing the morbidity associated with more invasive procedures. As we move towards improved early detection and diagnosis of early-stage disease, there is a need for guidelines addressing these early lesions and larger prospective studies.

P5-12-13: Does Ductal Carcinoma in Situ have metastatic potential? A nationwide cancer registry-based study of Ductal Carcinoma in Situ with sentinel lymph node positivity

Merle van Leeuwen, Sandra van den Belt-Dusebout, Petra Kristel, Lennart Mulder, Joyce Sanders, Carmen Vlahu, Esther Lips, Jelle Wesseling

Background: The current clinical paradigm around Ductal Carcinoma in Situ (DCIS) is that it consists of malignant cells confined to the breast ducts, and therefore cannot metastasize. Nonetheless, several studies have reported DCIS with metastasis in the sentinel lymph node. For accurate risk communication and management, we aimed to assess to what extent registered “metastatic spread” in DCIS could be explained by limitations in registration or missed invasive breast cancer at time of diagnosis.

Methods: Nationwide data on women diagnosed with DCIS and a positive sentinel node (DCIS SN+) between 2005 and 2021 were obtained from the Netherlands Cancer Registry (NCR) and the Dutch Nationwide Pathology Databank (Palga). The incidence of registered DCIS SN+ and the size of the metastasis was determined with data from NCR. Pathology data of the primary DCIS diagnosis was thoroughly reviewed, with all known corresponding history pathology reports of in-situ or invasive breast cancer or unknown primary. Cases were excluded from further analysis if PALGA data indicated registration errors, DCIS mixed with other types of lesions, or diagnostic uncertainties such as suspicion of microinvasion, uncertain sentinel node status, poor tissue quality or positive surgical margins.
Next, hematoxylin and eosin stained tissue slides of eligible DCIS SN+ cases were independently reviewed by two expert breast pathologists to assess the presence of (micro)invasion and sentinel node status. Presence of invasion and sentinel node positivity was scored as yes, uncertain, no or not applicable. For cases scored as uncertain, additional immunohistochemical (IHC) stainings with cytokeratin 5/6 or 8/18 were used. Agreement between the two pathologists was assessed using the linearly weighted Kappa statistic.

Results: A total of 30,863 patients were identified with a DCIS diagnosis between 2005 and 2020, of which 16,070 (52.1%) underwent sentinel lymph node biopsy according to NCR data. SN+ was identified in 454 (2.8 %) patients: 47 (10 %) had macrometastases (>2 mm), 78 (17%) had micrometastases (>0.2 - <= 2 mm), and 329 (73%) were positive for isolated tumor cells (ITCs) (<= 0.2 mm). Out of the 454 registered DCIS SN+ cases, 273 (60%) were

excluded from further investigation based on pathology data from Palga, based on registration errors (n=44), due to the presence of other lesions (n=147), or diagnostic uncertainties (n=82). There was no significant difference in reasons for exclusion between micrometastases, macrometastases or ITCs (p = 0.36). Tissue material of 47 out of 181 DCIS cases with macro- and micrometastases were reviewed by the pathologists. Initial agreement on sentinel node status was weak with a kappa statistic of 0.33 (95% CI 0.15 – 0.52; p = 0.003. Agreement on the presence of an invasive component was minimal with a kappa statistic of 0.14 (95% CI 0.08 – 0.34 ; p = 0.12). The most frequent discrepancies were between 'uncertain' and 'no' scorings. After reaching consensus, three cases were scored as having an invasive component, and additional IHC staining was requested for 40 cases due to suspicion of the presence of (micro)invasion. Review results of these 40 cases will be presented at the conference.

Conclusions: Our study offers a nuanced understanding of DCIS SN+ cases, suggesting that while these cases pose diagnostic challenges, the metastatic potential of pure DCIS remains low.

P5-12-14: IMPACT OF HER2-LOW STATUS ON SURVIVORSHIP IN HER2-NEGATIVE EARLY BREAST CANCER PATIENTS UNDERGOING NEOADJUVANT TREATMENT WITHOUT PATHOLOGICAL COMPLETE RESPONSE

Matilde Corianò, Chiara Tommasi, Anh Thi Lan Dinh, Jazmine Needham, Hala Aziz, Nalinie Joharatnam-Hogan, Niamh Cunningham, Jasmin Waterhouse, Mingze Sun, Fiona Turkes, Benedetta Pellegrino, Sophie McGrath, Alicia Okines, Marina Parton, Nicholas Turner, Stephen Johnston, Antonino Musolino, Alistair Ring, Nicolò Matteo Luca Battisti

Purpose: Despite recent improvements in the preoperative management of early breast cancer (eBC), many patients still do not achieve pathological complete response (pCR) and have inadequate treatment outcomes. Our analysis aims to investigate the role of human epidermal growth factor receptor 2 (HER2)-low status in predicting survival outcomes in patients not achieving a pCR.

Methods: We retrospectively identified patients with stage I-III HER2-negative breast cancer receiving neoadjuvant treatment and who did not achieve pCR at The Royal Marsden NHS Foundation Trust, London, between 2013 and 2023. Disease characteristics including HER2-low status, defined as HER2 1+ on immunohistochemistry (IHC) or 2+ on IHC without in situ hybridization (ISH) gene amplification, were collected. We analysed relapse-free survival (RFS) and overall survival (OS) based on HER2 status in the overall population and in patients with oestrogen receptor (ER)-positive (ER+) and ER-negative (ER-) cancers.

Results: Overall, 565 patients were included in the analysis. The mean age of the study

population was 50.0 ± 11.1 years. Median follow-up time was 44.9 months (interquartile range 13.8-69.8).
370 patients (65.5%) had stage II disease, 390 (69.0%) had grade 3 disease, and 502 (88.8%) had ductal histopathology. 321 patients (56.8%) had ER+ BC, while 244 patients (43.2%) had ER- BC. Overall, 254 patients (45.0%) had HER2-low disease, while 174 (54.2%) ER+ BC patients and 80 (32.8%) ER- BC patients had HER2-low BC.
HER2-low BC patients had significantly improved OS [HR 0.65 (95% CI, 0.45-0.95, p=0.026)] and a trend towards improved RFS compared to HER2-zero BC patients. Multivariable analysis did not confirm any impact of HER2, whereas ER status and BC stage impacted survival outcomes.
In the ER- population, HER2-low status did not have any impact on RFS nor on OS.
In the ER+ population, HER2-low BC patients had significantly improved RFS [HR 0.65 (95% CI, 0.43-1.00, p=0.047)] and OS [HR 0.50 (95% CI, 0.29-0.85, p=0.009)] compared with HER2-zero disease. In the same cohort, multivariable Cox-regression model confirmed the positive impact of HER2-low status on OS independently from stage, age, grade and ER-low/high positivity [HR 0.51 (95% CI, 0.30-0.88, p=0.015)].

Conclusions: The study highlights the potential relevance of HER2-low status as a predictive factor for survival outcomes in HER2-negative early BC patients, particularly in the context of ER+ disease. These findings underscore the importance of considering HER2 status (including HER2-low status) alongside traditional prognostic factors when assessing the prognosis and treatment strategies for this patient population.

P5-12-15: Survival Nomogram Including Lymph Node Ratio for Patients with Invasive Micropapillary Breast Cancer

Yi-Zi Zheng, Yan Liu, Ai-Na Zheng, Yan-Ling Xiao, Er-Jie Xia, Ou-Chen Wang

Objectives: Invasive micropapillary carcinoma (IMPC) stands out as a distinct and notably aggressive variant of breast cancer, and is known for its propensity for spreading to regional lymph nodes. The variability in the number of lymph nodes removed during surgery complicates assessment of the metastatic risk, an issue that is even more pronounced in IMPC due to its tendency for lymphatic spread. In this study, we evaluated the role of the lymph node ratio (LNR) in forecasting the outcomes of IMPC and developed a predictive nomogram for breast cancer-specific survival (BCSS) in patients with IMPC.
Methods: We analyzed data from 1,697 female patients diagnosed with IMPC, gathered from the Surveillance, Epidemiology, and End Results (SEER) database spanning 2010 to 2020. Participants were randomly assigned to either a training set or an internal validation set in a 7:3 ratio. An additional group of 176 patients from our institution was an external validation cohort (SZSPH cohort). Key prognostic indicators were identified by univariate analyses and the least absolute shrinkage and selection operator (LASSO) regression technique. Then we crafted a novel nomogram that integrates all independent prognostic indicators and a thorough validation of the nomogram's predictive capability was

conducted.
Results: A significant observation was the prevalence of high-grade (II-III) and undifferentiated tumors across both datasets, accounting for 93.5% in the SEER cohort and 95% in the SZSPH cohort, highlighting the aggressive nature of IMPC. Lymph node metastasis was notably prevalent among the patients, with 54.4% in the SEER dataset and an even higher rate of 71% in the SZSPH group, underscoring the propensity for IMPC to spread to lymphatic structures. From the LASSO regression analysis, six factors emerged with nonzero coefficients, signifying their statistical significance in relation to BCSS. Of note, LNR emerged as the most influential prognostic factor, followed by T-stage, radiotherapy, surgery, ER status, and chemotherapy, respectively. By incorporating these six significant variables, we developed a nomogram aimed at predicting 3- and 5-year BCSS for IMPC patients, which underwent the calibration and validation phases successfully. Its concordance indexes (C-indexes) for the training, internal validation, and external validation sets were 0.838, 0.871, and 0.758, respectively. The time-dependent receiver operating characteristic (ROC) curves also affirmed its clinical utility. The DCA curves illustrated that our nomogram provided greater net clinical benefits for predicting 3- and 5-year BCSS across all three cohorts. In the training set, the nutritional risk indexes (NRIs) for 3- and 5-year BCSS were 0.37 (95% CI 0.286–0.545) and 0.295 (95% CI 0.226–0.418), respectively, while the integrated discrimination improvement (IDI) values for the same time intervals were 0.043 (95% CI 0.035–0.235, $P < 0.001$) and 0.163 (95% CI 0.025–0.197, $P < 0.001$). These findings were corroborated in both the internal and external validation sets. In the final step, we computed risk scores for each patient utilizing the developed nomogram and proceeded with risk stratification: low risk (points <90.4) and high risk (points ≥90.4). Kaplan–Meier survival curves exhibited pronounced discrimination between the low-risk and high-risk subgroups, underscoring the nomogram's ability to effectively stratify patients based on their prognosis.
Conclusions: In the context of treating patients with IMPC, the LNR has emerged as a robust prognostic indicator. Utilizing LNR as a key parameter, we developed a nomogram designed to offer a practical and dependable method for predicting BCSS in patients with IMPC. This innovative tool serves to facilitate the identification of patients at high risk of adverse outcomes, providing clinicians with valuable insights to guide decision-making in patient care.

P5-12-16: Impact of Metastatic Sites Including Brain and Liver in Overall Survival Among Patients With Breast Cancer

Ajay Dhakal, Yusheng Jia, Sujan Niraula, Chelsea Marin, Huina Zhang, David Hicks, Allison Magnuson, Carey Anders, Nimish Mohile, Ruth O'Regan, Yue Li, Anna Weiss

Background: The development of Brain Metastasis (BM) among patients (pts) with Metastatic Breast Cancer (MBC) is generally considered to have a worse prognosis than metastasis at other sites. However, BM often develops later than metastasis at other sites. Hence, the perceived poor prognosis with BM may be confounded by prior treatments,

more advanced tumors and frailer pts. Here we compare median overall survival (mOS) of de novo MBC pts stratified by metastatic sites (brain, liver, both, neither) at the time of diagnosis.

Methods: The National Cancer Database (NCDB) was screened to identify pts with de novo MBC, aged 18 or older, with available brain and liver metastasis (LM) information. Pts were divided into 4 groups (grp) based on metastatic sites at diagnosis: 1. With BM without known LM 2. With LM without known BM 3. With BM and LM 4. Without known BM or LM. mOS among grp were assessed with Kaplan Meier method, compared with Log Rank test. Multivariate analyses were done using Cox proportional hazard model. In secondary analyses, mOS among these 4 grp were individually analyzed in 3 subsets: ER or PR (ER/PR) +, HER2- BC, HER2+ BC and triple negative BC (TNBC).

Results: 98503 pts from 2010 to 2019 were included in the analyses. Among grp 1 through 4 respectively: number of pts (%) included were 5227 (5.3), 21661 (22.0), 2420 (2.5), and 69195 (70.2); mean age (standard deviation) were 61.55 (12.60), 60.18 (14.39), 58.58 (12.76), 63.60 (14.01) years; % female >98% in each group; % of white pts were 76.7, 75.4, 74.9, 77.9; % of non-Hispanic pts were 89.6, 91.5, 90.9, 91.2; % of total Charlson Deyo score (for comorbidity) 0 were 80.2, 81.1, 81.0, 79.6; % of lung metastasis at diagnosis were 38.3, 32.9, 59.2, 27.2; % of ER+ tumors were 58.0, 60.6, 54.0, 75.0; % of HER2 + tumors were 21.7, 33.3, 34.2, 16.9. mOS in years (95% CI) for grp 1 through 4 were 1.05 (0.98-1.10), 1.68 (1.64-1.73), 0.61 (0.54-0.69), 3.14 (3.10-3.18); $p<0.001$. In multivariate analysis, grp 1, 2, 3 were associated with increased risk of death vs grp 4 [Hazard ratio (HR), 95% CI: 1.84 (1.78-1.90), 1.64 (1.61-1.67), 2.51 (2.39-2.62) respectively; $p<0.001$]. Secondary Analyses: 1. ER/PR+ HER2- BC: 54271 pts included, 2335 (4.3%), 8908 (16.4%), 884 (1.6%), 42143 (77.6%) in grp 1 through 4. mOS in years (95% CI) in grp 1 through 4: 1.51 (1.36-1.66), 1.91 (1.84-1.97), 0.87 (0.71-1.02), 3.58 (3.54-3.63). In multivariate analysis, grp 1, 2, 3 were associated with increased risk of death vs grp 4 [HR, 95% CI: 1.86 (1.77-1.95); 1.81 (1.76-1.86); 2.68 (2.49-2.89)]; $p<0.001$. 2. HER2+ BC: 20863 pts included, 1133 (5.4%), 7219 (34.6%), 828 (3.9%) and 11683 (55.9%) in grp 1 through 4. mOS in years (95% CI) in grp 1 through 4: 1.77 (1.49-1.94), 3.13 (3.0-3.3), 1.17 (0.96-1.37), 4.49 (4.32-4.64). In multivariate analysis, grp 1, 2, 3 were associated with increased risk of death vs grp 4 (HR, 95% CI: 2.0 (1.86-2.16); 1.46 (1.40-1.52); 2.47 (2.27-2.68)), $p<0.001$. 3. TNBC: 12221 pts included, 1034 (8.4%), 3035 (24.8%), 433 (3.5%), 7719 (63.1%) in grp 1 through 4. mOS in years (95% CI) in grp 1 through 4: 0.54 (0.49-0.59), 0.81 (0.76-0.86), 0.29 (0.24-0.35) and 1.21 (1.18-1.26). In multivariate analysis, grp 1, 2, 3 were associated with increased risk of death vs grp 4 (HR, 95% CI: 1.76 (1.64-1.89), 1.41 (1.34-1.48), 2.42 (2.18-2.69)), $p<0.001$.

Conclusion: Among de novo MBC pts in NCDB, those with BM and LV, or with BM without LM or with LM without BM, all had significantly worse OS compared to pts with neither BM or LM. The risk of death was highest for those with BM and LM, followed by those with BM without LM, then those with LM without BM. Similar results were seen in TNBC and HER2+ subsets. In ER/PR+ HER2- MBC also, having both LM and BM and having neither were

associated with the worst and best survival, however, the risk of death between pts with BM without LM vs LM without BM were not statistically different.

P5-12-17: Breast MRI and FDG-PET/CT for Evaluation of Pathologic Response to Neoadjuvant Chemotherapy in Patients With Breast Cancer

Emel Sezer, Halil Çelik, Kadir Eser, Pınar Pelin Özcan, Yüksel Balcı, Ferah Tuncel, Fatma Esra Erdem Palaz, Elif Ertaş

Introduction: This study compared the diagnostic test accuracy of magnetic resonance imaging (MRI) with that of 18F-fluoro-2-glucose-positron emission tomography/ computed tomography (FDG-PET/CT) imaging in assessment of response to neoadjuvant chemotherapy (NAC) in breast cancer.

Methods: A total of 202 eligible patients diagnosed with stage II and stage III breast cancer were given neoadjuvant chemotherapy at Mersin University Faculty of Medicine Hospital from 2019 to 2023. When performing data statistics in a continuous structure, mean and standard deviation, median minimum and maximum values of the features; Frequency and percentage values were used when defining categorical variables. Breast MRI and FDG-PET/CT were evaluated to evaluate response to treatment. After surgery, pathological complete response (pCR) was determined based on the final pathology reports. Tumors were divided according to hormone receptor (HR) and human epidermal growth factor receptor (HER2). As the gold standard treatment response method, evaluation was made according to pathological response status. Diagnostic test statistics, sensitivity, specificity, positive predictive value, negative predictive value and accuracy statistics, 95% confidance interval values are given. The statistical significance level of the data was taken as $p < 0.05$. IBM SPSS 21 version was used to evaluate the data.

Results: The total age was minimum 30, maximum 75, mean age was 50.4±11.2 and median age was 50. At the time of diagnosis, the disease stage was stage 2 in 24.8% of the patients and stage 3 in 75.2%. Histology was Invasive ductal carcinoma in 65.3%, invasive lobular carcinoma in 13.5%, other in 21.2%. Minimum Ki-67 was 3, maximum was 95, average was 31.9±18.8, and median Ki-67 was 30. Hormon receptor status (estrogen or progesteron positivity) was evaluated. While ER (estrogen reseptor) was positive in 59.4% of the patients, PR (progesteron receptor) was positive in 52.5%. Human epidermal growth factor receptor 2 (HER2) positive was 38.1%. HR+HER2- was in 42.7%, HR+,HER2- in 21.1%, HR+,HER2+ was in 17.6%, and triple negative in 18.6%. Grade 1 was in 11.9% of the patients, grade 2 in 43.6%, and grade 3 in 44.6%.
When postoperative pathology reports was evaluated, pathological complete response was achieved in 69 of 202 patients(%34.1). When FDG-PET/CT was evaluated determining complete response; Sensitivity 90% (95% CI: 0.83-0.97, $p<0.05$), Specificity 51% (95% CI: 0.42-0.59, $p<0.05$), PPV value 48% (95% CI: 0.40-0.57 , $p>0.05$), and NPV was 91% (95% CI:

0.84-0.97, p<0.05), and the accuracy rate was low and significantly 64% (95% CI: 0.57-0.71, p<0, 05). As a result of these meaningful statistical calculations; FDG-PET/CT diagnostic method was not reliable in terms of specificity and positive predictive value.
When magnetic resonance was evaluated, in determining complete response; Sensitivity 72% (95% CI: 0.63-0.82, p<0.05), Specificity 90% (95% CI: 0.85-0.95, p<0.05), PPV(positive predictive value) 78% (95% CI: 0.68-0.88 , p<0.05), and NPV(negative predictive value was 86% (95% CI: 0.80-0.92, p<0.05), and the accuracy rate was high and significantly 85% (95% CI: 0.78-0.89, p<0, 05). As a result of these meaningful statistical calculations; Response to treatment status (complete response/non-response) MRI diagnostic method was reliable and can be used instead of the currently used Gold Standard pathology diagnostic method.

Conclusion: Our study showed that breast MRI is superior to PET CT in predicting pathological complete response. This study showed that MRI is very important in evaluating treatment response in patients diagnosed with breast cancer receiving neoadjuvant chemotherapy.
Keywords
Breast cancer, magnetic resonance imaging, positron emission tomography/ computed tomography, neoadjuvant chemotherapy, pathologic complete response

P5-12-18: Characteristics, treatments and outcomes of localized synchronous bilateral breast cancers in the CANTO French prospective cohort study

Augusta d'Huy, Julie Blanc, Anne-Laure Martin, Dominique Delmas, Jean Zeghondy, Laurence Vanlemmens, Courèche Kaderbhai, Anne Kieffer, Baptiste Sauterey, Olivier Tredan, Christelle Levy, Inès Vas-Luis, Aurélie Bertaut, Paul Cottu

Background: Synchronous bilateral breast cancer (sBBC) is a rare occurrence. There is currently no consensus on the optimal management strategy for this condition, particularly when there is discordance between the clinical or biological presentations. Some studies have reported that sBBC is associated with poorer outcomes compared to unilateral breast cancer. The objective of this study was to describe the incidence, clinical, pathological and biological presentations, treatments and outcomes of sBBC in the prospective CANTO cohort.

Methods: We reviewed and included patients (pts) diagnosed with sBBC in CANTO, a French prospective cohort study which enrolled 12012 women with localized invasive breast cancer. Data on clinical and pathological patterns, locoregional and systemic treatments were collected. Pts characteristics were compared with those of patients with unilateral cancers. Survival endpoints were event free survival (EFS) and overall survival (OS).

Results: Of the 11341 analyzable pts of the cohort, 259 had sBBC (2.3%). Median age was 60.4y, vs 56.4y in pts with unilateral BC (p<.0001). Of those, 30.9% (79 pts) had a first-degree family history of breast cancer, vs 22.2% in pts with unilateral BC (p=.001). However, the proportion of BRCA mutations was similar in both groups (7.8% out of 90 tested pts vs 10% out of 2592 tested pts, p=.48). Median body mass index was slightly higher in the sBBC pts (25.7 vs 24.8, p=.003).
Concordant bilateral stage I and stage II disease was observed in 32% and 13.7% of sBBC pts, respectively. Discordant stage I/II, II/III and I/III disease was observed in 36.3%, 7.8% and 5.5% of pts, respectively. Conversely, pathological subtypes were predominantly concordant: 75.6% of pts had bilateral carcinoma of non-specific type (NST) while 10.5% had bilateral invasive lobular carcinoma. Bilateral ER+ RP+/HER2-, HER2 overexpressed/amplified and triple negative subtypes were identified in 77.4%, 2.8% and 1.6% of pts, respectively. Molecular subtype was discordant in 18.2% of cases. Tumor grade was concordant in 66.9% of pts (grade 2 or 3: 58.4%), while Ki67 was ≤30% in 80.5% of pts.
Locoregional and systemic treatments were tailored to stage and pathological subtype of each side. Overall, 22.2% of pts underwent a bilateral mastectomy, 73.6% had bilateral radiotherapy and 64.7% received neoadjuvant and/or adjuvant chemotherapy.
After a median follow-up of 60 months, median EFS and OS were not reached: OS and EFS at 5y were approximately 90% and 80%, respectively, regardless of discordance in stage, molecular subtype, or grade. Furthermore, EFS and OS were identical whether patients had bilateral or unilateral BC.

Conclusions: Women with sBBC were more likely to be overweight and older, and to have a family history of breast cancer than pts with unilateral BC. However, there was no evidence of a higher frequency of genetic predisposition. Approximately half of sBBC pts had discordant stages at diagnosis, in contrast to the majority of cases, which exhibited similar pathological and biological presentations. It can be observed that the locoregional and systemic treatments were adapted to the stage and presentation of the disease. It is of note that the prognosis was not influenced by stage or pathological discordance, or bilaterality.

P5-12-19: Patient-reported outcomes from CIPHER study evaluating patient attitude about ctDNA testing in early-stage breast cancer

Mridula A. George, Coral Omene, Ekaterina Kalashnikova, Janie Fielder, Trishala Meghal, Charuta C. Palsuledesai, Deborah Toppmeyer, Shridar Ganesan, Angel A. Rodriguez, Minetta C. Liu

Background; CIPHER study (NCT05333874), a pilot, single-institution study, previously reported that ctDNA dynamics during neoadjuvant therapy (NAT) can serve as an early indicator of treatment response and inform disease management in the adjuvant setting among patients with early-stage breast cancer (eBC). However, the perceived utility of ctDNA testing and the impact of ctDNA results on pts' anxiety about cancer recurrence are

not well known.

Methods: This study included 30 patients with stage II-III triple-negative (TN) and HER2+ eBC receiving neoadjuvant therapy, who underwent longitudinal ctDNA testing (SignateraTM, Natera, Inc.) during standard of care treatment. The primary aim of the study was to evaluate the role of ctDNA in treatment decisions in the adjuvant setting. Two optional patient surveys were administered by paper at 6 (n=24) and 12 (n=17) months (mos) post-surgery: (1) Fear of Cancer Recurrence (FCR-4), and (2) ctDNA utility questionnaire (perceived utility and impact of ctDNA test results on pts' anxiety about recurrence). The score ranges were: FCR-4: 0 (minimal) to 20 (maximum) fear of cancer recurrence; ctDNA utility: 5=all the time, 4=a lot, 3=sometimes, 2=a little, 1=not at all.

Results: A total of 168 responses for the FCR-4 questionnaire and 118 responses for the ctDNA utility questionnaire were received from 24 patients. The survey revealed a marginal numerical difference in the mean FCR-4 score at 6 mos vs 12 mos (12 vs 11.4). Regardless of the ctDNA result, 88% (21/24) of responders at 6 mos and 100% (17/17) at 12 mos said they valued the additional information received from ctDNA results, 91% (20/22) at 6 mos and 94% (15/16) at 12 mos said they would continue using the ctDNA test to monitor cancer, and 82% (18/22) at 6 mos and 88% (15/17) of pts at 12 mos reported feeling they were receiving the right treatment after receiving their ctDNA results. ctDNA results reduced anxiety about cancer recurrence in 32% (7/22) at 6 mos and 29% (5/17) of pts at 12 mos. Notably, a patient whose ctDNA+ result after surgery triggered a change in therapy reported (1) an anxiety score decrease from 20 to 14 while maintaining a high degree of reassurance in receiving correct treatment, and (2) the intention to use ctDNA testing in future.

Conclusions: In this study, most pts with eBC valued the information they received through the personalized, tumor-informed ctDNA test and would continue ctDNA testing. Monitoring ctDNA led to minimal to no change in average anxiety scores even after a positive result.

P5-12-20: Clinicopathological Correlates of Immunohistochemistry Subtypes in Ductal Carcinoma In Situ: A Retrospective Analysis

Je Hyun Chin, Doo Reh Kim, Young Joo Lee, Chang Ik Yoon, Woo Chan Park, Soo Youn Bae

Introduction: Ductal carcinoma in situ (DCIS), an early neoplastic lesion confined within the mammary ductal system, exhibits considerable molecular heterogeneity, reflected in distinct immunohistochemistry (IHC) subtypes such as hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) status. It's well-established that while DCIS represents a non-obligate precursor to invasive breast cancer (BC), a subset of cases

harbors the potential for progression to invasive disease. Understanding the intricate molecular landscape of DCIS, particularly the interplay between IHC subtypes and the propensity for invasive progression, holds paramount importance in clinical decision-making. This study aims to investigate how IHC subtypes such as ER, PR, and HER2 in DCIS correlate with the tumor's clinicopathological characteristics.
Methods: We analyzed data from the Korean Breast Cancer Society registration database, focusing on patients aged 20 and older who underwent surgery for DCIS between 2000 and 2019. Patients with confirmed lymph node metastasis or distant metastasis were excluded from the analysis.
Results: A total of 11,812 patients were analyzed. Among them, 7,427 (62.9%) had HR+/HER2- breast cancer (BC), 611 (5.2%) had triple-negative breast cancer (TNBC), 1,904 (16.1%) had HR-/HER2+ BC, and 1,870 (15.8%) had HR+/HER2+ BC. At the time of diagnosis, the median age was higher in HR-BC compared to HR+ BC (HR+/HER2-: 48years, HR+/HER2+: 49years, TNBC: 53years, HR-/HER2+: 53 years). Family history was more prevalent in HR+ BC (10.5%) compared to HR-BC (8%). The proportion of asymptomatic cases was higher in HR+ BC (HR+/HER2-: 39.9%, HR+/HER2+: 45.1%) compared to HR-BC (TNBC: 34.2%, HR-/HER2+: 35.5%). Among HR-BC, the percentage of cases with a palpable lump was higher (TNBC: 30.3%, HR-/HER2+: 26.3%). Bilateral BC was more common in HR+ BC (0.5%). Tumor size (median) was larger in HER2+ BC (HR+/HER2-: 1.1 cm, TNBC: 1.2 cm, HR+/HER2+: 1.5 cm, HR-/HER2+: 1.9 cm). Mastectomy was more frequent in HER2+ BC (HR+HER2+ 40.4%, HR-/HER2+: 51.6%). Regarding nuclear grade, HR+/HER2- BC had the lowest proportion of high-grade tumors (12.5%), while HR-/HER2+ BC had the highest (73.6%).
Conclusion: This study reveals the diverse clinicopathological features of DCIS based on IHC subtypes, emphasizing the importance of molecular characterization in guiding clinical management decisions. Understanding these distinct profiles can enhance prognostication and facilitate tailored treatment approaches for patients with DCIS.

P5-12-21: The utility of antiestrogen therapy in early-stage, pure mucinous carcinomas of the breast

Lyndsay Cooper, Dipika Misra, Kristina Shaffer, Austin Gratton, Saheli Parekh

Background: Pure mucinous breast tumors are rare and characterized by cluster-like hyperplasia of tumor cells floating in extracellular mucous fluid, comprising 90% of the tumor mass. Despite their generally favorable prognosis, optimal management, particularly regarding antiestrogen therapy, in small (less than or equal to 3 cm), node-negative breast cancers, remains uncertain.
Methods: We conducted a retrospective review of 77 women treated between 2010 to 2018 and diagnosed with node-negative, pure mucinous breast tumors less than or equal to 3 cm, with a follow-up period of at least 5 years. Factors including age, type of surgery, margin status, adjuvant therapies, and treatment outcomes were analyzed. Patients with non-pure mucinous histology were excluded.

Results: Of the 163 patients identified, 86 were excluded due to non-pure mucinous histology, nodal involvement, tumors >3 cm, or less than 5 years of follow-up. The median age at diagnosis was 70 years (range 40-88), with a median follow-up of 93 months (range 60-158). Average tumor size was 1.42 cm (range 0.10-3.0 cm). Surgical management included lumpectomy alone in 4 patients (5.2%), lumpectomy with lymph node evaluation in 53 patients (68.8%), and mastectomy with or without lymph node evaluation in 20 patients (26.0%). Adjuvant treatments included radiation in 38 patients (49.4%) and endocrine therapy with aromatase inhibitor or tamoxifen in 45 patients (58.5%). Of these, 2 patients received chemotherapy followed by endocrine therapy (2.6%). 36 patients (46.8%) completed at least 5 years of endocrine therapy. Only 3 (3.9%) local recurrences were seen and no distance recurrences. Of the patients with a local recurrence, none of them completed 5 years of antiestrogen therapy following breast conservation and 2 received radiation. The average time to recurrence was 69 months (range 30-120). Overall survival was 88.3%, and breast cancer-specific survival was 100%.
Conclusions: Our findings call attention to reconsidering the necessity of antiestrogen therapy for pure mucinous breast tumors less than or equal to 3 cm with node-negative status, given the very low local recurrence rate observed overall. Despite fewer than half of patients completing a 5-year course of antiestrogen therapy, no distant recurrences or breast cancer related deaths were observed with a median follow-up exceeding 7 years, suggesting a limited benefit with antiestrogen therapy. These results underscore the favorable prognosis of mucinous carcinomas, supporting a more personalized approach for adjuvant endocrine therapy recommendations, such as considering patient comorbidities and life expectancy. Further research with larger cohorts and extended follow-up would be beneficial to further refine treatment guidelines for early stage mucinous breast carcinomas.
Keywords: Mucinous breast cancer, antiestrogen therapy, node-negative breast cancer, adjuvant treatment, early-stage breast cancer

P5-12-22: Semi-Quantitative Stratification of Breast Cancer Biomarkers using the APIS Breast Cancer Subtyping Kit

Anna Gasior, Joanna Gorniak, Anne-Sophie Wegscheider, Andreas Voss, Kimberly Howard, Mathew Harrison, Leanne Gough, Sara Rollinson, Zoe Pounce, Axel Niendorf

Background: Precise evaluation of breast cancer biomarkers is crucial for determining appropriate patient management strategies. Histopathologists typically use semi-quantitative scoring systems to translate subjective immunohistochemistry (IHC) observations into objective quantitative data, enhancing the categorization of marker status. The APIS Breast Cancer Subtyping Kit, an RT-qPCR based diagnostic tool, measures the relative expression of mRNA target genes (ESR1, PGR, ERBB2, and MKI67) from invasive breast cancer tissue, providing both positive/negative results for each biomarker and a molecular classification. This study introduces additional RNA expression cut-off values to demonstrate that a semi-quantitative approach can further stratify target expression using

the APIS kit.

Methods: Formalin-fixed paraffin-embedded (FFPE) breast cancer samples (N=368), obtained via core needle biopsy or resection, were analyzed. IHC scores were correlated with copy numbers, determined by a validated digital PCR (dPCR) assay, to establish cut-off values corresponding to IHC classifications. The dynamic ranges of the normalized RNA copy numbers for each target were also evaluated. These copy number cut-offs were then used to assess the corresponding ΔCt values (RNA expression results) from the APIS kit. This allowed for the expression of each target to be classified into 3-4 semi-quantitative ranges.

Results: The semi-quantitative approach successfully classified the expression levels of all targets. A broad dynamic range of normalized RNA copy numbers was observed for ESR1, PGR, and ERBB2 (0-767, 0-307, 0-422 RNA copies, respectively), whereas MKI67 showed a narrower range (0-1.8 RNA copies). Central IHC categories exhibited overlapping ΔCt values for all targets, likely due to tumor heterogeneity and the different measurement techniques of IHC and RT-qPCR. Despite these variances, the established cut-off values defined a semi-quantitative scale for each target, facilitating refined classification of biomarker expression into high positive, moderate, low positive, and negative categories. For HER2/ERBB2 expression, the categories were high positive, low positive (HER2-low) and negative.

Conclusions: This study established a ΔCt semi-quantitative scale for evaluating targets with the APIS Breast Cancer Subtyping Kit, by leveraging the dynamic range of RNA expression. This is particularly significant for classifying HER-low, which has emerged as crucial for identifying patients who may benefit from novel anti-HER2 therapies.

P5-12-23: Effectiveness of Online Education in Improving Clinicians' Knowledge and Confidence in Managing Adverse Events Associated with Novel Antibody-Drug Conjugate Therapy for Breast Cancer

Zhizhi Fiske, Stephen Dunn, Eloise Ballard, Jamie Habib, Rebecca Dent, Giuseppe Curigliano

Background: Antibody-drug conjugates (ADCs) have significantly improved treatment outcomes for breast cancer, and optimal adverse event management is key to maintaining a good quality of life for patients. The objective of this study was to assess the effect of an online continuing medical education (CME) activity on clinicians' knowledge in the different safety profiles of ADCs used for the treatment of breast cancer and their confidence in implement appropriate strategies in clinical practice to monitor and manage adverse events associated with novel ADCs.
Methods: This CME activity consisted of a 15-minute video discussion between 2 expert faculty with synchronised slides. Educational effect was assessed using a repeated-pair

design with pre-/post-assessment. 3 multiple choice questions assessed knowledge, and 1 question rated on a Likert-type scale assessed confidence, with each individual serving as their own control. A McNemar's test assessed significance of improvement in the percentage of correct responses to knowledge questions from pre- to post-assessment. P values < .05 are statistically significant. The activity launched on 27th of June, 2023, with data collected through 5th September, 2023 being reported in the current study.
Results: 64 oncologists and 33 obstetricians/gynaecologists who answered all the assessment questions were included in this analysis. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge of both physician learner groups, with 56% more oncologists answering all questions correctly after education (64% post- vs 41% pre-CME) and 100% more obstetricians/gynaecologists answering all questions correctly after education (36% post- vs 18% pre-CME). Specifically, the knowledge regarding the different safety profiles of ADCs used for the treatment of breast cancer increased from 76% pre- to 85% post-CME for oncologists (P<.001) and from 55% pre- to 69% post-CME (P<.01) for obstetricians/gynaecologists, respectively. Additionally, 27% of oncologists and 27% of obstetricians/gynaecologists reported increased confidence in effectively managing adverse events associated with novel ADC therapy for breast cancer, and that increase was, on average, 57% and 100% among the two physician groups, respectively.

Conclusions: This analysis demonstrates the positive educational impact of an online CME activity on the essential aspects of adverse event management of novel ADC therapy for breast cancer among key physician learner groups, including in areas where clinicians' baseline knowledge levels are already relatively high. As ADCs become more widely used in clinical practice, it will be important to educate clinicians on appropriate approaches to monitoring and managing treatment-related adverse events for individual patients and provide guidance to help facilitate best practices of interdisciplinary working.

P5-12-24: Outcomes of Metastatic Breast Cancer Patients Initiated on Inpatient Chemotherapy Due to Visceral Crisis

Ernestine Muanya, Amber Potter, Kelly Waldvogel, Akshara Singareeka Raghavendra, Sarah Pasyar, Roland L. Bassett, Vicente Valero, Debu Tripathy, Carlos H. Barcenas, Jason A. Mouabbi

Background: Historically, oncological patients received chemotherapy while hospitalized to closely monitor treatment-related adverse events. Currently, outpatient administration is standard for metastatic breast cancer (mBC) patients, with hospitalization typically reserved for acute complications. While inpatient chemotherapy/biotherapy (IC) remains a selectively used treatment option for admitted patient with visceral crisis, guidelines for selecting appropriate patients for this therapy are lacking. This study aims to analyze the characteristics and outcomes of mBC patients who were admitted with visceral crisis and received IC. The results will be used to inform early guideline development.

Methods: In an observational, single-institution, retrospective descriptive study using data from the prospectively collected MD Anderson Breast Cancer Management database, we identified patients with mBC who received Cycle 1 Day 1 (C1D1) of a systemic therapy regimen while inpatient between 2016-2023. The primary objective was to assess the relationship between variables including breast cancer subtypes, age, systemic therapy regimen, and overall survival (OS) defined as the time to death or to hospice enrollment. Tumor characteristics included histology type and receptor status (estrogen receptor (ER), progesterone receptor (PR), and HER2). The median overall survival was calculated by checking the median time between the initiation of C1D1 to death or to enrollment into hospice care. For the secondary objective, the Cox regression models were utilized to examine the association between these variables and OS.
Results: We identified 76 female mBC patients, with a median age of 52 years, and a relatively equal distribution among the three subtypes. The median OS was 3.28 months for all patients. Patients with HER2+ subtypes had a lower risk of death or hospice enrollment compared to other subtypes. HER2+ mBC patients had better outcomes and longer median OS (18.99 months) compared to TNBC (2.52 months) and HR+ (2.73 months). Multivariate analysis showed that a higher baseline INR was independently associated with worse OS, while age at the time of IC administration, breast cancer subtype, systemic therapy regimen, and number of prior lines of systemic therapy did not influence OS.
Conclusion: Our study highlighted the overall poor outcomes of mBC patients who receive IC. However, the data suggest that IC might be most appropriate for selected patients with HER2+ mBC. These results should be validated in prospective and/or large multi-center retrospective data analyses.

P5-12-25: Single-center retrospective cohort study evaluating neutropenia and growth factor use with sacituzumab govitecan in patients with HR+/HER2- and triple negative metastatic breast cancer

Samantha Fisch, Joshua Chin, Laura Quintal, Melanie Majure, Michelle Melisko, Jo Chien, Hope S. Rugo, Laura A. Huppert

Introduction: Sacituzumab govitecan (SG) is FDA-approved for the treatment of both metastatic triple negative breast cancer (mTNBC) and hormone receptor positive (HR+)/HER2- metastatic breast cancer (MBC). In phase III clinical trials, SG caused grade 3 neutropenia in ~50% of patients. However, the real-world incidence of SG-induced neutropenia and the practice patterns regarding the use of adjuvant growth factor use are not well characterized.

Methods: In this single retrospective cohort study, we identified patients with HR+/HER2- or TNBC MBC who received SG between 2020-2024 per standard of care. We used manual review of electronic health records to identify key clinical characteristics, treatment history, safety parameters, and documented use of growth factor support via granulocyte colony stimulating factor (GCSF, either filgrastim or pegfilgrastim) while on treatment with SG.

Results: We identified 74 patients with MBC who were treated with SG, including 45 patients with mTNBC (60.8%), 27 patients with HR+/HER2- MBC (36.5%), and 2 patients with heterogenous expression who were categorized as HR+/HER2+ MBC (2.7%). Median age was 56.5 years (range 28.4 - 81.1 years). Patients with mTNBC received a median of 2 prior lines of chemotherapy (range 0-5) and patients with HR+/HER2- disease received a median of 8 lines of prior therapy including 4 prior lines of chemotherapy (range 2-14 total lines, 0-8 lines of chemotherapy). Median time on SG was 4.4 months (range 0.26-39.8 months) for patients with mTNBC and 1.9 months (range 0.26-15.6 months) for patients with HR+/HER2- MBC. Most patients experienced any grade neutropenia while on SG (n=60, 81.1%), including most patients with mTNBC (n=37, 82.2%) and HR+/HER2- MBC (n=21, 77.8%). Grade 3 neutropenia was common during SG (n=39, 52.7%), with similar rates among patients with mTNBC (n=25, 55.6%) and HR+/HER2- MBC (n=12, 44.4%). Rates of neutropenic fever were low: in total 5/74 (6.8%), of whom 4/45 (8.9%) were mTNBC. A total of 8/74 (10.8%) patients were hospitalized for SG-related neutropenia with median length of stay 3.5 (range 1-10) days. Dose delays for any reason occurred in patients with mTNBC (n=18, 40.0%) and HR+/HER2- MBC (n=8, 29.6%), about half of which were due to neutropenia (for mTNBC n=7, 15.6%, HR+/HER2- MBC n=4, 14.8%). Dose reductions for any reason were also common among patients with mTNBC (n=21, 46.7%) and HR+/HER2- MBC (n=18, 66.7%), including some due to neutropenia (for mTNBC n=7, 15.6%, for HR+/HER2- n=4, 14.8%). Most patients discontinued SG due to disease progression for both mTNBC (n=43, 95.6%) and HR+/HER2- MBC (n=24, 88.9%). Two patients with HR+/HER2- MBC (7.4%) discontinued therapy due to toxicity. The remaining patients are still on therapy or discontinued for unrelated reasons. Most patients received GCSF during treatment with SG (n=64, 86.5%), most of whom received filgrastim (n=62, 83.8%) and a minority of whom received peg-filgrastim (n=7, 9.5%). In total 34/74 (45.9%) patients received primary GCSF prophylaxis and 24/74 (32.4%) patients received secondary GCSF prophylaxis. Rates of primary and secondary prophylaxis varied by subtype for mTNBC and HR+/HER2- respectively (primary: 37.8% and 55.6%; secondary: 40.0% and 22.2% respectively).

Conclusion: In this single center retrospective study, >80% patients with mTNBC and HR+/HER2- MBC on SG experienced any grade neutropenia. Similar to published trials, nearly half of patients in both subgroups experienced grade 3 neutropenia but rates of hospitalizations and neutropenic fever were <10% in this heavily pre-treated, real-world cohort. Rates of SG dose reduction occurred in ~50% of patients, but rates of discontinuation due to toxicity were low. GCSF prophylaxis, either primary or secondary, was used in ~80% of patients. Additional studies are needed to clarify which patients may be at highest risk for SG-induced neutropenia and the optimal growth factor regimens to improve outcomes.\

P5-12-26: The Reuse of Cyproheptadine, a First-Generation Antihistamine, as an N-WASP Inhibitor in Breast Cancer Metastasis

Rhiannon Yannan Yu, Q Ping Dou, Elyas Khan, Wen G. Jiang, Tracey A. Martin

Background: Cyproheptadine is a first-generation antihistamine primarily used to alleviate allergy symptoms, with a long clinical use history and a well-established safety profile. Recently, the concept of drug repurposing has gained traction, and Cyproheptadine has shown potential applications in cancer treatment. Breast cancer metastasis continues to be a major clinical hurdle, making the exploration of new therapeutic strategies imperative for enhancing the survival rates of breast cancer patients. N-WASP is a protein crucial for cytoskeletal reorganization, facilitating cell motility and invasion, both of which are essential processes in cancer metastasis. We hypothesis that it may be possible to improve patient outcomes by blocking the pathways through which cancer cells metastasise by inhibiting N-WASP.
Methods: To investigate the effect of Cyproheptadine on cell proliferation, adhesion, motility, and its specific impact on N-WASP protein expression at both mRNA and protein levels as well as downstream events, two breast cancer cell lines, MDA-MB-231 and MCF-7, and HECV, an endothelial cell line, were subjected to comprehensive in vitro biological assays (including cytotoxicity tests, cell growth assay, Electric Cell-substrate Impedance Sensing (ECIS), wound scratch assay, immunofluorescence, qPCR and western blotting). Molecular docking was carried out by computer-assisted modelling to model the interaction between N-WASP and Cyproheptadine at the atomic level.
Results: Cyproheptadine demonstrated a significant inhibitory effect on cell proliferation in all three cell lines tested. In MDA-MB-231 cells treated with the drug, proliferation decreased by 15.72% ($P=0.0007$), while in MCF-7 cells, it decreased by 43.18% ($P<0.0001$), and in HECV cells, it reduced by 33.51% ($P<0.0001$). Furthermore, Cyproheptadine markedly impaired cell adhesion and migration in the ECIS assay. Wound healing assay revealed a 16.68% reduction in migration rate in MDA-MB-231 cells ($P=0.0002$), 35.89% reduction in MCF-7 cells ($P <0.0001$) and 27.32% reduction in HECV cell lines ($P= 0.0070$) indicating diminished motility.
Cyproheptadine treatment led to a significant downregulation of N-WASP protein expression confirmed using immunofluorescence assays and Western blot analysis. Additionally, qPCR results demonstrated that Cyproheptadine was not able to regulate N-WASP mRNA expression, suggesting that the mechanism of action likely occurs at the post-transcriptional, translational or posttranslational level. Molecular docking revealed that Cyproheptadine had a binding profile with multiple amino acids of key domains of N-WASP protein. These results indicate that Cyproheptadine effectively impairs key cellular functions associated with cancer metastasis, including proliferation, adhesion, and migration, through the downregulation of N-WASP protein expression, but not at the transcription level.
Conclusion: These results propose a new therapeutic application for Cyproheptadine, beyond its conventional use as an antihistamine. Cyproheptadine shows significant promise in inhibiting N-WASP protein expression, thereby disrupting critical processes necessary for

breast cancer metastasis. This could potentially offer a dual-purpose treatment strategy for managing metastatic breast cancer.

P5-12-27: HER2 Status and Clinical Outcomes in Breast Cancer: A Retrospective Analysis

Brooke Fishman, Elizabeth Crenshaw, Megan Finch, Neeharika Srivastava Makani

Background: HER2 status is a prognostic marker in breast cancer (BC). Studies have demonstrated that patients with high HER2 expression have poor prognosis compared to HER2 negative (HER2-neg) disease.(1,2) Currently, BC is classified into categories based on HER2 expression and hormone receptor status (estrogen receptor (ER) and progesterone receptor (PR)). Previously, HER2 status was defined as HER2-neg or HER2- high; however, in 2022, the FDA approved fam-trastuzumab deruxtecan-nxki in the management of metastatic HER2-low BC.3 Though publications from large international academic institutions have studied HER2-low BC, there is a need to understand the biology and characteristics of HER2-low BC patients in the United States in a community cancer setting.(4,5,6) 85% of cancer patients in the US receive oncologic care at a community cancer center.7

Methods: In this retrospective study of metastatic BC patients, the prevalence, histology, and clinical outcomes were analyzed based on HER2 status in a community cancer center in the United States. 2,637 patients were diagnosed with BC between 2010-2020, and 2,470 were excluded due to their early stage diagnoses, male sex, or indeterminate HER2 status. Patients with stage IV BC as defined by the American Joint Committee on Cancer criteria were included. Patients were classified as HER2-high, low, or negative based on IHC scores and FISH. HER2-high is defined as IHC Of 3+ or 2+ with FISH amplification, HER2-low is IHC 1+ or 2+ and FISH negative whereas HER2-neg is IHC 0. Demographic, histologic, and outcome data was abstracted. Z-test of proportions were performed to compare the groups.

Results: 167 patients were studied, 21.6% being HER2-high, 40.7% HER2-low, and 37.7% HER2-neg. The median age at diagnosis of stage IV BC for HER2-high was 65, HER-low was 66.5, and HER2-neg was 70. No statistically significant difference was observed between ductal or lobular histology. Hormone receptor positive (HR+) disease was more prevalent among all HER2 groups than hormone receptor negative (HR-). 86% of the HER2-neg patients were HR+ compared to 58% HER2-high ($P<0.01$). Additionally, 84% of HER2-low patients were HR+ compared to 58% HER2-high ($P<0.01$). HR- disease was more prevalent in HER2-high patients at 41.6% compared to 16.1% in HER2-low and 14.2% in HER2-neg patients ($P<0.01$). 89.4% of HER2-high patients had a high Ki-67 proliferation rate (above 20%) compared to 64.1% of HER2-low ($P<0.05$) and 67.6% of HER2-neg ($P=0.08$). Brain metastatic disease was more common in HER2-high (11.1%) compared to HER2-low (8.8%) and HER2-neg (6.3%). Bone metastatic disease was more commonly seen in HER2-low

(57.4%) and HER2-neg (57.1%) compared to HER2 high disease (47.2%). The median time from initial BC diagnosis to development of stage IV was 5.9 months in HER2-neg, 14 months in HER2-low, and 13.3 months in HER2-high patients. Of the HER2-neg patients, those with triple negative BC defined as HR- and HER2-neg had a median time of 2.1 months from diagnosis to developing stage IV disease. Majority of patients were treated with chemotherapy, and HER2 targeted treatment was only given to HER2-high patients. 68 patients were lost to long term follow-up; however, of the patients evaluable, the median overall survival (mOS) in HER2-high patients was 24 months, HER2-low was 36.4 months, HER2-neg was 33 months, and the triple negative subgroup was 20.2 months.

Conclusion: Stage IV BC accounts for 5% of all BC. HER2-high patients presented with high Ki-67 rates and had the lowest mOS. HER2-low patients had the highest mOS and the longest median time between initial BC diagnosis and development of stage IV disease. Future studies with larger cohorts of ethnically diverse, metastatic BC patients treated in community cancer centers should be pursued evaluating the clinical and cost-effectiveness of HER2 targeted therapy in HER2-low BC patients.

P5-12-28: Single Institutional Experience with Metaplastic Breast Cancer Comparing Outcomes based on Timing of Chemotherapy, Chemotherapy Regime and Subtypes of Metaplastic Breast Cancer.

Courtney Pisano, Yilun Sun, Reine Abou Zeidane, Samuel Lichtman-Mikol, Janice Lyons, Alberto Montero, Amanda Amin, Corey Speers

Background: Metaplastic breast cancer (BC) is a rare, aggressive form of breast cancer that generally does not respond well to standard chemotherapy. Optimal treatment for patients presenting with metaplastic breast cancer is yet to be defined. Here we review our institutional experience and compare outcomes based on timing of chemotherapy, chemotherapy regimen used and subtypes of metaplastic BC.
Methods: We conducted a retrospective analysis of patients diagnosed with metaplastic BC at our institution between 2002 and 2023. Patients were analyzed based on receipt of chemotherapy and timing of chemotherapy administration. For patients receiving neoadjuvant chemotherapy (NAC), pathologic complete response rates (pCR) based on chemotherapy regimen were determined. Additionally, we compared outcomes based on subtype of metaplastic BC. 3-year overall survival (OS) and 3-year progression free survival (PFS) were estimated using Kaplan Meier method.
Results: Of the 31,292 patients treated with breast cancer at our institution, there were 60 patients with metaplastic BC. Patients were excluded if they presented with metastatic disease or if they did not undergo active treatment, which left 52 patients for this analysis. The median age at diagnosis was 64.9 (range=32-93.1). All patients were female. 63.5% self-identified as White, 32.7% as Black, and 3.8% as other. Poorly differentiated tumors comprised 84.6% of the total. TNBC phenotype made up 80.7%, while 7.7% of patients had HER2+ disease and 11.5% were ER+. One patient had both ER+ and HER2+ disease. The median pathologic tumor size was 2.8 cm (range=0-15.5) and 11.5% were clinically node positive at presentation. Metaplastic subtypes included 19 squamous (37%), 15 matrix-producing (29%), 9 spindle cell (17%), 6 mixed (12%) and 3 were not further classified (6%). Chemotherapy choice was at the providers discretion.
Overall, 45 patients (86.5%) received chemotherapy, with 21 (40.3%) receiving adjuvant chemotherapy and 24 (46.1%) receiving NAC. Of those receiving NAC, 3 (12.5%) achieved a pCR. 6 (25%) patients received a neoadjuvant regimen containing pembrolizumab, one of which achieved pCR. There was no difference in pCR rates among patients receiving a pembrolizumab containing regimen vs those who did not, 16.7% vs 11.1% (p=1), though the numbers were small. NAC receipt was associated with higher clinical stage; 41.6% of patients receiving NAC had clinically Stage IIA and 20.8% were clinically Stage IIB. For those

receiving NAC the 3-year OS was 66% and the 3-year PFS was 51%. This was significantly worse than those that received adjuvant chemotherapy (3-year OS was 84%, 3-year PFS was 77%) or no chemotherapy at all (3-yr OS 83%, 3 year-PFS 67%), though these patients had earlier stage disease (the majority were clinical stage IA in both groups). 93% of matrix producing tumors were TNBC. 83% of spindle cell subtype were TNBC and had the best 3-year OS (86%) and PFS (88%). Squamous histology tumors were the most diverse with 63% TNBC, 26% ER+, and 11% HER2+. The 3-year PFS for mixed histology (33%) was significantly worse than for spindle cell subtype (88%) (p=0.02).
Conclusions: This study provides valuable insights into the treatment outcomes and subtype-specific characteristics of metaplastic BC. Despite the small sample size, notable correlations between intrinsic breast cancer phenotypes and metaplastic subtypes emerged, with the spindle cell subtype exhibiting the highest 3-year OS and PFS while the mixed phenotype had the lowest PFS and OS. This stands in contrast to other similar series previously published, with many reporting spindle cell as having worse overall outcomes. Although neoadjuvant chemotherapy, including regimens with pembrolizumab, showed limited pCR rates, these findings underscore the need for more extensive research to define optimal therapeutic strategies for metaplastic BC.

P5-12-29: Treatment outcomes of patients with de novo oligometastatic breast cancer treated with “curative intent” at a single institution

Emily L. Chen, Hillary Heiling, Tianyu Li, Jennifer Bellon, Faina Nakhlis, Heather Parsons, Alyssa R. Martin, Harold Burstein, Sara M. Tolaney, Melissa Hughes, Nabihah Tayob, Nancy U. Lin, Sarah Sammons

Background: De novo oligometastatic breast cancer (OMBC) is often defined as limited disease with up to five distant lesions in two or fewer organs at initial presentation. Studies have suggested overall favorable outcomes for OMBC patients, making curative intent treatment appealing. Trials have attempted to address primary surgery in all de novo MBC (not OMBC) and, separately, ablative metastasis-directed therapy in OMBC (not all de novo) without survival benefits. However, no trial has addressed the cumulative benefits of removing the primary tumor, ablating all detectable distant metastatic lesions, and optimal systemic therapy with molecular subtype-specific multidrug systemic therapy in de novo OMBC. Management of de novo OMBC remains controversial. We analyzed outcomes of patients with de novo OMBC treated with curative intent.
Methods: We analyzed data for patients with de novo OMBC who were treated with physician-expressed curative intent at a single institution between 1/2000 – 12/2020. We identified patients by performing a simple keyword search within institutional electronic medical records that included physician-entered terms “oligometastases” AND “breast cancer” AND “curative intent” or “curative hope” and had at least one visit in clinic. Term variants such as “oligometastatic” for “oligometastases” were also included. All resulting charts were then manually reviewed for inclusion criteria. We more strictly defined OMBC as one organ (including bone) involved with metastatic lesions and 4 or fewer lesions per

metastasized organ. All patients were required to have had definitive breast surgery for inclusion into the analytic cohort. Recurrence-free survival (RFS) and overall survival (OS), beginning at time of surgery, were evaluated using Kaplan-Meier methods.
Results: A total of 39 patients were identified: 12 hormone-receptor (HR) positive (+)/HER2+, 2 HR negative (-)/HER2-, 21 HR+/HER2-, 4 HR-/HER2+. Most patients (33, 84.6%) had 1 oligometastatic lesion at diagnosis, 3 (7.7%) had 2 lesions, 2 (5.1%) had 3 lesions, and 1 (2.6%) had 4 lesions. 100% of patients underwent breast surgery; 15 (38.5%) underwent lumpectomy and 24 (61.5%) underwent mastectomy. Median age at time of surgery was 47 (range 28-69). Most patients (29, 74.4%) also underwent radiation therapy (RT) to the breast. Two-thirds of patients (26, 66.7%) underwent metastasis-directed therapy (MDT). The most common MDT type was RT (22/29, 75.9%). With median follow-up of 5.8 years (y), 27/39 (69%) patients had not recurred. Of 12 recurrences, 100% were new distant metastases. Median RFS was 7.1y (95% CI 4.87-not reached). Five-year RFS was 62% (95% CI 46-84%). Median RFS was 7.1y (95% CI 2.01-not reached) among HER2+ patients and 6.98y (95% CI 4.62-not reached) among HR+/HER2- patients. Landmark RFS was not impacted by whether a patient received MDT. Median OS was not reached (95% CI 7.42-not reached) and five-year OS was 77% (95% CI 61-95%).
Conclusions: The use of curative intent treatment in OMBC at a single institution was most common in patients with a single metastasis in one organ. Survival outcomes were favorable among this highly select cohort of patients, with nearly two-thirds of patients free of relapse at 5y and similar RFS among the HER2+ and HR+/HER2- cohorts. Validation of these findings in prospective series and further studies evaluating optimal treatment strategies in this setting are needed. The benefits of primary surgery and MDT in this population remain unknown.

P5-12-30: Characterizing Metastatic Breast Cancer (MBC) Exceptional Responders

Ahmed Mohamed, Hadil Zureigat, Beatriz Sorato, Jame Abraham, Shimoli Barot

Background: While the 5-year survival for MBC remains dismal at 29%, certain patients with a significant and/or long-lasting treatment response are known as exceptional responders. They are characterized by either having a partial or complete response (PR/CR) to treatment that is otherwise effective in <10% of similar-stage patients orexhibiting an unusually sustained response, at least 3x the median response.

Aim: We identified clinical, pathological, genetic, and genomic characteristics of MBC exceptional responders.

Methods: We included individuals ≥18 years old diagnosed with MBC by pathology and treated at Cleveland Clinic Taussig Cancer Institute from 2000-2023. The 3-year mark was used to define an exceptional treatment response. We obtained demographics, medical history, and details of BC diagnosis and treatment using electronic medical records. Genetic

results were obtained using the common hereditary cancer gene panel while comprehensive genomic profiling provided the genomic data.

Results: 27 exceptional responders were identified, all female with a median age at diagnosis of 53 years (range 46-61). 23/27 (85.2%) were White, 3 were Black, and 1 was Hispanic. 20/27 (74.1%) had never smoked, while the remainder were former smokers. 40.7% (11/27) of the exceptional responders had a previous history of early-stage BC. Most exceptional responders (18/27, 66.7%) had ER-positive/HER2-negative disease while 6/27 (22.2%) had HER2-positive and 3/27 (11.1%) had triple-negative MBC. Metastatic sites included bone (16/27, 59.3%), distant lymph nodes (16/27, 59.3%), lung (13/27, 48.1%), liver (10/27, 37%), pleura (5/27, 18.5%), and brain (3/27, 11.1%). Throughout their treatment course, 32 instances of exceptional response to various treatments were observed, including: aromatase inhibitors (AI, 11/32, 34.3%), CDK4/6 inhibitor+AI (5/32, 15%), capecitabine (3/32, 9%), T-DM1 (2/32, 6%), CDK4/6 inhibitor+fulvestrant (2/32, 6%), fulvestrant (2/32, 6%), trastuzumab+AI (2/32, 6%), trastuzumab (2/32, 6%), trastuzumab+pertuzumab (1/32, 3%), capecitabine+tucatinib (1/32, 3%), and capecitabine+neratinib (1/32, 3%). The best response to treatment among exceptional response instances was CR in 3/32 cases (9.3%), and PR in 29/32 cases (90.6%). The average duration of exceptional response was 4 years (range 3-6). 2/27 patients (7.4%) had a germline pathogenic BRCA2 mutation, and 1 had a BRCA1 mutation. Additionally, 11/27 (40.7%) had other germline genetic mutations, including CDKN2A p.16INK4a, MSH3 c.2254-19T>G, MSH6 c.3740C>G p.Thr1247Ser, and MSH2 c.874A>T. Genomic abnormalities were identified in 9/27 (33.3%) patients, including MAGI2 N477fs* 1+, MAP2K4 loss exons1-7, ESR1 Y537S, ERBB2 p.L755_E757delinsS, GATA3 P409fs, MSH6 c.3740C>G p. Thr1247Ser, MTOR C1483Y, ROS1 amplification, NF1 S1470N, FGFR1 14981, GNAS R201C, MYC amplification, PIK3CA E545K, PTCH1 c.3025G>A p.G1009R, BRCA2 D2084Y, PARK2 duplication exon 2-4, PTEN Y27N, FBXW7 S203L, RICTOR amplification, TP53 L111M0, NTRK1 V588V, MTOR D371H, DDR2 L623F, FBXW7 S203L, ATM G558A, PRDM1, WISP3, TP53 E51*, TP53 loss S367fs* 1+, MTOR L943V, ATM L3026H, and NTRK1 A457S.

Conclusions: MBC exceptional responders were mostly White females with a median age of 53 years, never smokers and had a history of early-stage disease prior to metastases. Endocrine therapy, CDK4/6 inhibitors, HER2 targeted treatments and capecitabine combinations predominantly led to exceptional responses. A significant portion of patients had germline mutations and genomic abnormalities. Our findings can provide insight on potential shared factors influencing exceptional responses in MBC, guiding future research and personalized treatments.

PS4-09: Investigating the Impact of a Culturally Tailored Education Intervention Cancer Clinical Trial Participation

Jesutomisola Onafowokan, Nikita Nikita, Iqra Siddiqui, Ana María López

Background: Cancer clinical trials (CCT) advance knowledge in cancer care. Access to CCT may be facilitated by patient knowledge. We evaluated the impact of a culturally tailored CCT educational video intervention via a pre- and post-test survey on CCT interest and knowledge dissemination.

Methods: A CCT education intervention was developed with community engagement from persons who identified as Black, Hispanic, or Chinese, the predominant background of persons in our immediate catchment area. The video educational intervention was available in Spanish and Chinese. Community input was to make the survey available prior to the diagnosis of cancer; therefore, participants included a general population (GP), persons who did not have a cancer diagnosis. Pre and post knowledge assessments were utilized to evaluate knowledge (11 questions) and intention-to-share information/participate in a CCT (6 questions) using a Fisher-exact test. Data were analyzed after stratifying by race.

Results: The sample size included: 148 (70%) men, 58 (28%) women, 2 (1%) transgender, 2 (1%) non-binary; white, non-Latinx 125 (60%), Black 60 (29%), Asian 2 (1%), Latinx 52 (25%). Significant findings included, for Black participants, the score for the question "Once I sign a consent form, I must stay in the clinical trial until my doctor tells me I'm done" improved significantly between pre- and post-intervention ($p=0.0104$). For white, non-Latinx participants, CCT knowledge improved for the following questions "Once I sign a consent form, I must stay in the clinical trial until my doctor tells me I'm done." ($p = 0.0181$), "Clinical trials of new medicines or treatments are carefully reviewed for safety by a group of research experts and community members." ($p = 0.0314$) and "You can only join a clinical trial after you have tried all other options." ($p = 0.0316$). The intention to gain more information about CT from their physicians and discussing CT with family ($p<0.05$) improved significantly in all groups.

Conclusion: A tailored educational intervention significantly knowledge based questions and impacted the intention to learn more about CCT and to share the CCT information learned.

PS10-01: Racial differences in the prevalence of biomarker alterations, treatment patterns, and clinical outcomes in hormone receptor–positive, human epidermal growth factor receptor 2–negative metastatic breast cancer: A national cohort study

Pegah Farrokhi

Background: Despite advancements in targeted therapies for hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2−) metastatic breast cancer (mBC), data assessing racial differences in biomarker prevalence and outcomes are lacking. This study assessed the prevalence of biomarker alterations, treatment patterns, and clinical outcomes in Black and White patients with HR+, HER2− mBC in the United

States (US) who received next-generation sequencing (NGS)-based testing.
Methods: This observational cohort study utilized the nationwide, electronic health record–derived, de-identified Flatiron Health–Foundation Medicine Clinico-Genomic Database. Adult patients with mBC diagnosed from January 2017 to March 2022 were included and followed until September 2022. Patients who lacked race data, participated in a clinical trial, or had <6 mo of follow-up were excluded. This subgroup analysis included only patients with HR+, HER2− mBC, and assessed PIK3CA, AKT1, PTEN, ESR1, and BRCA1/2 alterations. All patients had NGS-based tumor tissue testing and/or liquid biopsy. Pathogenic variants, or those likely to be pathogenic, were used to identify alteration status. BRCA1/2 results were available with no distinction between somatic or germline mutations. A logistic regression analysis was used to assess the likelihood of receiving treatment. The Kaplan–Meier method and a Cox regression analysis were used to assess overall survival (OS) from diagnosis of mBC.
Results: Of 2,384 patients with HR+, HER2− mBC, 303 (13%) were Black and 2,081 (87%) were White. Median time from mBC diagnosis to first NGS testing was similar in both groups (4.6 vs 4.8 mo; p=0.12). Compared with White patients, Black patients had a lower prevalence of PIK3CA mutations (34% vs 42%; p=0.03), but there was no significant difference in the prevalence of PTEN (13% vs 12%; p=0.70), ESR1 (16% vs 17%; p=0.60), AKT1 (4% vs 7%; p=0.06), or BRCA1/2 (12% vs 10%; p=0.20) alterations. A total of 2,191 patients received first-line (1L) treatment: 90% of Black patients and 92% of White patients. In the 1L, CDK4/6 inhibitors (CDK4/6i) were used less frequently in Black vs White patients (53% vs 66%; p<0.01), whereas chemotherapy (CT) was used more frequently (27% vs 18%; p<0.01). After adjusting for baseline characteristics, the odds of receiving 1L CDK4/6i was 38% lower in Black vs White patients (OR 0.62; 95% CI: 0.48–0.81; p<0.001). In the second line (2L; n=1,527), where standard of care varies depending on clinical characteristics and biomarkers, CDK4/6i (37% vs 38%; p=0.88) or CT (32% vs 30%; p=0.49) use was similar between Black and White patients. In patients receiving 2L therapy having PIK3CA mutations, there was no significant difference in 2L PI3Kα-specific inhibitor use between Black and White patients (34% [14/41] vs 26% [74/285]; p=0.40). Median OS was significantly shorter in Black vs White patients (34.1 vs 42.1 mo; p=0.004). After adjusting for baseline characteristics, biomarkers, and treatments, Black patients had a shorter OS (HR 1.23; 95% CI: 1.01–1.50; p=0.04). There was a nonsignificant trend toward a shorter OS in Black vs White patients treated with 1L CDK4/6i after adjusting for baseline characteristics and biomarkers (HR 1.24; 95% CI: 0.94–1.64; p=0.13).
Conclusions: In this US study, Black patients with HR+, HER2− mBC who received NGS testing were less likely to have PIK3CA mutations, more likely to receive 1L CT, and less likely to receive 1L CDK4/6i vs White patients, with worse outcomes. This survival difference highlights unmet medical needs in Black patients. Further research is warranted to identify and mitigate racial disparities with HR+, HER2− mBC.

PS10-02: Pre-diagnosis Physical Activity and Racial Disparities in Breast Cancer Survival Outcomes: a Multiethnic Cohort Study

Yijia Sun

Background and objectives: Physical activity (PA) is widely recognized for its health benefits, but its association with breast cancer (BC) survival remains inconclusive. Racial differences in this context have not been well-studied. In this study, we aimed to assess whether racial disparities exist in pre-diagnosis (3 years before diagnosis) PA, adolescent PA, and lifetime PA among BC patients. We also examined the association between PA and BC survival outcomes and whether PA could explain racial differences in these survival outcomes.
Methods: We included BC patients from the Chicago Multiethnic Epidemiologic Breast Cancer Cohort who completed a baseline questionnaire on demographic and risk factors. PA was measured using the metabolic equivalent of task (METs) - hours/week based on patients' self-reported PA duration and intensity. A neighborhood disadvantage index was calculated after geocoding of patients' residential addresses. Ordered logistic regression models were used to assess adjusted odds ratios (aOR) comparing African American (AA) to European American (EA) patients across different PA categories and levels. Cox proportional hazards models were fit to estimate adjusted hazard ratios (aHR) for 3 survival outcomes: overall survival, BC-specific survival, and recurrence-free survival (RFS). Further, we conducted mediation analysis to examine whether racial differences in PA and neighborhood disadvantage influenced BC patients' survival outcomes.
Results: A total of 2,020 patients were incuded in the study, with a median follow-up of 5.4 years. The mean age was 54.7 years, and the mean pre-diagnosis PA was 20.3 METs hours/week. Compared to EA patients (n=1,361 [67%]), AA patients (n=659 [33%]) were significantly less likely to participate in higher levels of total (aOR=0.62, 95% CI: 0.49-0.77), vigorous (aOR=0.61, 95% CI: 0.49-0.76), and moderate (aOR=0.65, 95% CI: 0.52-0.81) pre-diagnosis PA. Similar disparities were observed in lifetime PA, but no substantial differences were found in adolescent PA between AA and EA patients. AA patients had a significantly higher risk of all-cause mortality (aHR=1.53, 95% CI: 1.15-2.04) and a greater risk of recurrence or death (aHR=1.56, 95% CI: 1.18-2.04) than EA patients; the higher risk was for BC-specific mortality, though was not statistically significant (aHR=1.39, 95% CI: 0.84-2.29). We observed a "J-shaped" relationship between survival outcomes and pre-diagnosis total PA. Compared to physically inactive participants (<4 METs hours/week) before diagnosis, those with total PA level of 14-30 METs hours/week had a 43% lower all-cause mortality risk (aHR=0.57, 95% CI: 0.36-0.89) and a 36% reduced risk of recurrence or death (aHR=0.64, 95% CI: 0.42-0.98). However, excessive pre-diagnosis total PA (>30 METs hours/week) was not found to be beneficial for survival outcomes. Mediation analysis revealed there was not a mediation effect of PA on racial differences in survival outcomes. Interestingly, we observed that neighborhood disadvantage could explain 53% of the overall survival difference and 50% of RFS difference between AA and EA patients with stage I-III BC.
Conclusion: Moderate-to-vigorous PA before diagnosis significantly reduced mortality and

recurrence risk in this multiethnic BC patient cohort. AA patients showed lower engagement in pre-diagnosis and lifetime PA compared with EA patients, potentially contributing to racial disparities in BC survival outcomes. While PA did not mediate the racial disparities in survival, promoting moderate levels of PA could improve health outcomes among breast cancer patients, particularly among those living in disadvantaged neighborhoods.

PS10-03: Socioeconomic disparities in long-term heart failure risk of trastuzumab with or without anthracyclines in early-stage breast cancer: A SEER-Medicare Database Analysis

Karissa Britten

Background: Our group recently presented data from the SEER-Medicare database describing long-term cardiotoxicity associated with trastuzumab (T) and/or anthracyclines (A) in early-stage breast cancer (EBC) patients (SABCS 2022, P3-03-13). Here, we present the disparities analysis stratified by available socioeconomic variables (SEVs) from individual zip code and census data.
Methods: We performed an analysis of the SEER-Medicare database from 2005 to 2016, including patients with stage I-III EBC at diagnosis with no prior history of congestive heart failure (CHF). The primary outcome was development of CHF based on ICD coding. Patients were connected to most recently available census data via state and zip codes. SEVs included race/ethnicity, per capita income (PCI), level of education, percent (%) living in poverty, and % not speaking English at home. Descriptive statistics compared SEVs to clinicopathologic characteristics. Multivariate cox proportional hazards models were built stepwise down with an alpha of 0.05, first accounting for all planned SEVs, then including cardiac comorbidities, and finally the primary exposure variables (T and/or A).
Results: Of the initial 214,014 patients with EBC identified in the primary analysis, census data was available for 206,605 patients, with 8,302 receiving T without A, 1,977 receiving T and A, and 13,176 receiving A without T (the remainder received neither T nor A). Patients of Black, Hispanic, and American Indian/Alaskan Native (AIAN) race/ethnicity had increased incidence of large, high-grade tumors and nodal involvement as compared to White and Asian American/Pacific Islander (AAPI) patients. Lower PCI, higher % living in poverty, and lower level of education were also linearly associated with increased tumor size, grade, and N stage. Only the highest quartile of patients not speaking English at home was associated with these higher risk clinical features. Univariate cox proportional hazards model showed that all SEVs were associated with significant differences in the risk of developing CHF; however, multivariate analysis revealed % not speaking English at home and % living in poverty were no longer significant so were removed from subsequent models. Adjusting for significant cardiac covariates and the exposure variables, the multivariate socioeconomic model revealed that Black patients had a 23% higher risk of CHF (Hazard Ratio [HR] 1.23, 95% CI 1.19-1.27, $p<0.001$) and AAPI patients had a 22% lower risk of CHF (HR 0.88, 95% CI 0.83-0.93, $p<0.001$) compared to White patients.

Hispanic and AIAN patients did not have a significantly different risk of CHF than White patients (HR 1.00, 95% CI 0.92-1.08, p=0.99 and HR 1.13, 95% CI 0.96-1.35, p=0.149; respectively). Adjusting for race/ethnicity and cardiac comorbidities, patients living in a zip code in the lowest quartile of PCI had an 18% higher risk of CHF (HR 1.18, 95% CI 1.15-1.22, p<0.001) as compared to those in the highest quartile. Risk of CHF associated with the exposure variables showed similar trends as those reported in the primary analysis: patients receiving both T and A remained at highest risk of developing CHF (HR 1.23, 95% CI 1.13-1.34, p<0.001) compared to the baseline population (who had received neither T nor A), followed by A without T (HR 1.20, 95% CI 1.16-1.24, p<0.001) and T without A (HR 1.15, 95% CI 1.09-1.21, p<0.001).
Conclusions: Among patients with EBC, after adjusting for cardiac comorbidities, Black patients and those living in an area with low PCI had higher risk of developing CHF. The addition of socioeconomic variables to a multivariate model did not impact the primary analysis trend showing increased risk of CHF with T and A, followed by T without A, as compared to the baseline population. These findings illustrate the importance of developing strategies that address both risk factor modification and social determinants of health to mitigate disparities in cardiac outcomes in oncology.

PS10-04: Identifying Risk Factors for High Allostatic Load in a Racially/Ethnically Diverse Cohort of Breast Cancer Patients

Anna Vaynrub

Introduction: Allostatic load (AL), an indicator of cumulative physiological stress and neuroendocrine dysregulation in response to chronic environmental challenge, has been associated with breast cancer (BC) incidence and mortality. Prior studies have found a 1.5-1.8-fold relative increase in all-cause mortality among BC patients with higher AL. Our objective was to determine whether demographic, clinical, and lifestyle factors are associated with AL in a diverse cohort of BC patients.

Methods: Patients diagnosed with stage 0-IV breast cancer between 2007-2023 at Columbia University Irving Medical Center (CUIMC) in New York, NY were consented to complete a survey on demographic, clinical and lifestyle factors and allow access to their electronic health record (EHR) for research purposes. To calculate AL score, we extracted EHR data on systolic/diastolic blood pressure, heart rate, and laboratory results (albumin, alkaline phosphatase, BUN, creatinine, glucose, white blood cells). AL was calculated by assigning one point for each of 9 diagnostic biometrics exceeding the reference range. Patients were dichotomized into “high” and “low” AL groups based on the median score. Descriptive statistics, univariate and multivariate logistic regression analyses were conducted to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between demographic, clinical and lifestyle factors with the main outcome of high AL.

Results: Among 1730 evaluable patients, median age at diagnosis was 57 years (IQR: 47, 67) and 37.8% self-identified as non-Hispanic White (NHW), 12.8% non-Hispanic Black (NHB), 35.8% Hispanic, and 8.1% Asian/Pacific Islander/Other. Based upon survey responses, 29.1% had a high school education or less, 42.8% were married, 44.2% were employed, and 29.9% reported an annual household income <$15,000. Median body mass index (BMI) was 26.63 kg/m2 (IQR: 23.02, 30.90). In terms of lifestyle factors, 32.8% of patients were ever smokers, 56.8% self-reported regular alcohol use, 60% followed a restricted diet of some variety (e.g., low fat, low carbohydrate, vegetarian, vegan), 46.7% did not exercise regularly, 65.4% endorsed taking vitamins regularly, and 31.8% reported taking herbal supplements. The median AL score was 3.0 (IQR: 2.0, 4.0) (approximating the mean score and binarized score distribution of a BC cohort based in the U.K. Biobank). Pulse, systolic blood pressure, and blood glucose were the most common biomarkers to contribute to high AL (elevated in 74.3%, 67.1%, and 65.3% of high AL patients, respectively). BC patients with high vs. low AL were older, more likely to self-identify as NHB or Hispanic, have lower education and income, report other chronic illnesses, have a higher BMI, report less regular alcohol use, have lower physical activity levels, and lower vitamin/supplement use. In multivariable analysis, factors associated with high AL included older age (OR=1.01, 95% CI=1.00-1.01), NHB vs. NHW race (OR=1.14, 95% CI=1.04-1.24), and being unemployed vs. employed (OR=1.12, 95% CI=1.02-1.22). Diagnosis of stage III or IV BC compared to stage I disease was also significantly associated with high AL (OR=1.23, 95% CI=1.02-1.50 and OR=1.20, 95% CI=1.02-1.41, respectively).

Discussion: In our diverse study population of BC patients, we found a significant correlation between sociodemographic and clinical factors and a biomarker of physiological stress, which has been associated with BC mortality. AL may be a useful biomarker to assess the effects of modifiable lifestyle factors and social determinants of health to improve BC clinical outcomes and reduce health disparities.

PS10-05: Door-to-door Breast Cancer Screening in 22,278 populaces from Feb. 2020-April 2024: Breast Cancer Hub's Trendsetting Grassroots Sustainable Solutions, overcoming the Disparity, & Challenges in the Rural Remote Villages in Poverty, of Assam, India

Lopamudra Das Roy

Background: There is a huge gap in Breast Cancer survival globally with the death rate being significantly higher in developing countries due to taboo, ignorance, lack of awareness, sociocultural, economic, and environmental barriers, leading to inaccessibility to healthcare facilities, proper guidance, and treatment management. Healthcare providers in rural India regularly see women coming in an advanced stage and in Assam, Northeast (NE) India, the situation is grimmer.
This study is based on an analysis of the database of door-to-door Breast cancer screening

of the rural villages in Assam from February 2020 to April 2024, reporting the Breast Cancer Screening status, disparities leading to late detection and death, and the success of Breast Cancer Hub's Grassroots approach, providing sustainable solutions.
Methods: In this study, we report the data from February 2020 to April 2024 (N=22,278), of in-person Door-to-Door Breast Cancer Screening by Breast Cancer Hub (BCH), a nonprofit organization in the remote 18 villages in Assam, India. BCH-generated questionnaire on health and lifestyle, family history, demography, socio-economic condition and other determining conditions. The data was incorporated from notebook used by BCH teams in the field, into Excel sheets. A complete descriptive statistics is used for understanding the data. For goodness of fit test, chi square is used. All the analysis have been compiled with the help of SPSS version 21.
Results: This is the pioneering study, as BCH is the first group to conduct door-to-door Breast Cancer Screening in N=22,278 villagers (8085 families), in the underprivileged rural Seventeen villages and One Tea Garden Estate in Assam.
From our evaluation, we confirm that the awareness of Breast Cancer Symptoms was <1% among the villagers. The Breast Self-Exam was performed by 0% of the populace. No participant (0%) underwent Clinical Breast Exam. Women 40 years and above, never performed screening mammograms (0%) or ultrasounds (0%) but only visited the hospital when the symptoms were extremely severe eventually getting diagnosed at a late stage leading to death. We investigated the socio-economic condition and huge barrier to care due to financial constraints, villagers living on a daily wage and health always took the last priority as they fall below the poverty line. In addition, the lifestyle is influenced by the tremendous intake of tobacco in all forms, especially adding tobacco, betel nut, slaked lime, and other ingredients to the betel leaves and chewing in the form of Paan. We encountered 76 suspicious cases, that needed further evaluation and screening. But, during screening, the team faced challenges, as the villagers could not financially afford to travel to cancer diagnosis-equipped hospitals which are extremely far away, leading them to succumb to faith healers and eventually death. The family members avoided taking patients to hospitals as it would be a full-day affair and they couldn't miss their daily wage, as food is their priority. Also, they were not aware of government healthcare cards for the Below Poverty Line population. Therefore, BCH created a sustainable framework, by teaching every member Breast Self-Examination (BSE), providing BSE card in local language, accompanying suspicious cases to hospitals, providing transport, generating villagers' income certificates and health cards, helping with hospital registration, patient communication with healthcare professionals, providing Aid for diagnosis and treatment not covered under the government schemes, dropping patients home with follow-ups, counseling, support, taking the same patients back to the hospital on the next appointments, assisting with the comprehensive treatment process, case by case.
Discussion: BCH is the trendsetter to execute this framework in the untapped villages in India, revolutionizing the Breast cancer scenario, and driving impactful changes in Breast Cancer survival.

PS10-06: Access to Innovative Medicines for Advanced Breast Cancer as a Catalyst for Health Systems Strengthening in Low- and Middle-Income Countries

Fatima Cardoso

Background: Breast cancer (BC) is the leading cause of cancer-related deaths among women worldwide, with a disproportionate number of these deaths occurring in low- and middle-income countries (LMICs) due to limited access to effective therapies. In response, The Max Foundation (Max) and its Humanitarian PACT for Advanced Breast Cancer (ABC) partners, including the ABC Global Alliance, the American Society for Clinical Pathology, Cepheid, Novartis, and Lilly, launched a multi-stakeholder program to provide treatment access and address broader healthcare barriers in select LMICs. A country's ability to achieve its health goals largely depends on the capacity of its healthcare workforce. The introduction of innovative medicines for ABC has created the catalyst for the Humanitarian PACT to support both individual patients and broader health systems strengthening in LMICs through healthcare professional (HCP) training.
Methods: The Humanitarian PACT for ABC provides access to CDK4/6 inhibitors and aromatase inhibitors for women living with HR+/HER2- ABC in select LMICs free-of-charge, while also supporting the strengthening of healthcare infrastructure and knowledge through clinical and diagnostics training for HCPs in the country. Training sessions, both on-site and virtual, were led by Experts Consultants covering diagnosis, pathology, clinical decision-making, medication management, and disease monitoring as part of the program's implementation. Medical oncology training sessions focused on situational analysis, patient selection, side effects management, and patients monitoring. Pathology training sessions focused on diagnosis and biomarker assessment.
Results: From October 2023 to June 2024, 96 post-menopausal HR+/HER2- ABC patients from 8 countries; the Bahamas, Benin, Cambodia, Jamaica, Mozambique, Nepal, Saint Lucia, and Seychelles were enrolled in the program and received access to treatment. On-site and virtual training was provided to 29 HCPs, including oncologists, pathologists, and pharmacists from these countries. Patient retention, adherence, and side effects management will be analyzed in each country with main challenges and barriers to be further identified.
Conclusions: We believe that by providing access to high-impact oncology medicines in LMICs, we are equipping HCPs with the most important tools they need to treat patients effectively. Access to medicines serves as the most critical catalyst for strengthening health systems, ensuring that other investments in infrastructure and clinical care improvement occurs and have lasting impact for patients. HCP training plays a crucial role in supporting health systems strengthening by building the capacity of HCPs to deliver quality care, improve patient outcomes, and address health system challenges. This program underscores the transformative impact of leveraging novel medicines as a pathway to strengthening health systems in LMICs, paving the way for sustainable advancements in global oncology, and most importantly providing patients with access to care and medicines resulting in improved outcomes.

PS10-07: The Molecular Subtypes of Breast Cancer: A Single Institution Experience after a Decade of the Syrian War

Maher Saifo

Background: Breast cancer is the most commonly diagnosed type of cancer and the leading cause of cancer-related death among women. Breast cancer mortality rates in Syria rank among the highest in the world. There are few studies about breast cancer epidemiology or patient characteristics in Syria. This study aimed to evaluate estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) expression in Syrian patients with breast cancer.
Methods: This retrospective study included all new patients with a confirmed diagnosis of breast cancer via biopsy in 2023. The data were retrieved from the Albairouni University Hospital (ABUH) cancer registry.
Results: 1460 patients were included in the study. BC is the most commonly diagnosed cancer in ABUH (21.6%). The patients were distributed among the majority of hormonal receptors (HR)+/HER2- (711, 48.7%), followed by HR+/HER2+ (327, 22.4%), followed by HR-/HER2+ (271, 18.6%) and HR-/HER2- (151, 10.3%).
Conclusion: More than 50% of breast cancer cases in Syria are HER2+ and triple-negative, which may indicate a poor prognosis. Syrian healthcare practices, including cancer registry practices, were negatively impacted by a decade-long war. Data collection regarding other pathological findings, patients' characteristics, and clinical outcomes is still in progress.

PS10-08: Appalachian Mobile Mammogram Program Achieves Unprecedented Outcomes by Repeatedly Reaching Underserved Women

John L. Bell

Introduction: Breast cancer remains the number one incident female cancer in the United States (US). In 2024, it is estimated that 310,720 new breast cancers will be diagnosed in US women and approximately 42,250 women will die of the disease.1 Despite ongoing controversies and conflicting data, screening mammography remains the gold standard examination for early detection and improved survival related to breast cancer. Mobile mammography units (MMU) are especially crucial for patient populations that lack access to recommended routine screening. Detecting breast cancer at earlier stages leads to a reduction in disease progression and mortality.2,3,4Through multiple return visits by the MMU to the same sites and outreach efforts in underserved areas, The University of Tennessee Medical Center's (UTMC) MMU now presents one of the largest series ever published or reported in the US. This series includes 48,385 mammograms conducted between 2008 and 2023, serving 20,254 unique women. The underserved population in this area faces barriers such as receiving fewer healthcare services, socioeconomic disparities, and lack of transportation to fixedmammography sites. Many of these women are without permanent mammography equipment in their home counties so the MMU allows accessible mammographyscreening. Disadvantaged women are more heavily impacted by breast

cancer compared to less vulnerable populations.4 UTMC's MMU service area covers 23 counties (five of which have no "fixed/permanent" mammogram services) in East Tennessee consisting of both urban and primarily rural Appalachian populations.METHODS: A retrospective data analysis was performed on a prospectively maintained database for our MMU Breast Health Outreach Program (BHOP). Data points included demographic information, date of mammogram, sequence of imaging (first, second, third, etc. study), BIRADS assignment (initial and final), biopsy results (if obtained), and status (alive/dead with/without disease). Frequency and percentage statistics were performed.RESULTS: Of the 20,254 women screened on the MMU, 11,037 (54.5%) women were screened once. However, 9,217 (45.5%) women had two or more screeningsperformed on the MMU (range - 2 to 16 mammograms). Due to this high follow-up rate supported by the MMU program administrative infrastructure and our stated intention to return annually to identical locations, 238 cancers were identified in women for an incidence proportion of 0.5% (238/48,385). Of the cancers, 190 were either Stage 0 (n=54) or Stage I (n=136) representing 80% of the diagnosed cancers. In addition, only two (0.8%) patients have expired due to breast cancer and only one patient has experienced a distant failure (bone only) for a distant failure proportion of 0.4%.DISCUSSION: This is one of the largest analyses ever undertaken regarding mobile screening mammography in the US. The results reveal the expected incidence proportion of 0.5% in this asymptomatic, primarily rural population. More importantly, of the cancers identified, 80% were early stage which led to a disease-specific mortality of 0.8%. Focused follow-up of this vulnerable population leads to early-stage diagnosis and improved outcomes, not otherwise seen in underserved, rural screening populations.

PS10-09: Occupational Pesticide Exposure and Poor Prognosis Breast Cancer in Brazilian Women: Epidemiological Insights and Molecular Mechanisms.

Carolina Panis

The participation of women in the agricultural sector and its associated health consequences are inadequately addressed. In countries such as Brazil, where agriculture is a primary economic driver, female rural workers are at an increased risk of developing chronic diseases, including cancer, due to frequent exposure to harmful substances such as pesticides. This study aimed to characterize pesticide contamination among women during occupational activities, assess its impact on breast cancer (BC) aggressiveness, and explore the underlying molecular mechanisms. Conducted in the Southwest region of Paraná state in Brazil, an area characterized by extensive pesticide use and family-based farming, the study found that this region has higher rates of BC diagnoses and mortality compared to the national average, with pesticide usage reaching six times the national average. This case-control study prospectively included 758 individuals. We identified that the primary routes of contamination for these women are during equipment decontamination and clothes washing. Urine tests from most BC-affected women revealed the presence of glyphosate, atrazine, or 2,4-D. Epidemiological analysis demonstrated that this population has a 41% higher diagnosis rate and a 14% higher mortality rate than unexposed women. The crude association indicated a significantly higher risk of BC among women exposed to pesticides (OR: 1.58, 95% CI 1.18-2.13). Adjusted analyses showed a lower, non-statistically significant association (OR: 1.30, 95% CI 0.87-1.95). Stratification based on disease profile revealed a significantly higher risk of lymph node metastasis (adjusted OR: 2.19, 95% CI 1.31-3.72) in women exposed to pesticides. Analysis of non-tumoral mammary tissue from women without BC but exposed to pesticides showed elevated levels of oncogenic mediators such as PPAR-γ and TNF-α compared to unexposed women. Additionally, in a subset of BC patients with a poor prognosis, pesticide exposure was linked to impaired systemic immune responses (with reduced levels of interleukins 1ß, 12, and 17A), oxidative stress imbalance, and increased expression of tumor-promoting molecules (TGF-β1 and CTLA-4). These findings indicate that occupational pesticide exposure significantly increases the risk of developing aggressive BC, which is associated with a poor prognosis signature due to immune response impairment. In response to the severity of these findings, we have initiated an educational program to raise awareness among rural women about the risks related to pesticide exposure. Over 1500 women have participated in this project, receiving training on safe pesticide handling and the use of protective equipment during clothes washing. Additionally, free personal protective equipment and periodic medical screenings are being provided.

PS1-01: Tumor Infiltrating Lymphocytes (TILs) as a Predictive Marker of Pathological Complete Response (pCR) in a Diverse Patient Population with Early Triple Negative Breast Cancer (TNBC) Treated with the Neoadjuvant KEYNOTE-522 Regimen.

Riya Albert, Joshua Thomas, Navid Sadeghi, Sangeetha Reddy, Glenda Delgado, Heather McArthur, Samira Syed, Deborah Farr, Nisha Unni

Background: Triple negative breast cancer (TNBC) is a highly heterogeneous and aggressive subtype of breast cancer that accounts for approximately 15% of all breast cancer diagnoses and is associated with a poor prognosis. Based on the KEYNOTE-522 (K522) trial, the FDA approved the use of neoadjuvant immunotherapy, Pembrolizumab along with chemotherapy for high-risk early stage TNBC in July 2021. Specifically, the K522 study demonstrated an increased pathological complete response (pCR) rate of 64.8% vs 51.2% and 36-month event-free survival (EFS) of 84.5% vs 76.8% for Pembrolizumab with chemotherapy vs. chemotherapy alone, respectively. The presence of tumor infiltrating lymphocytes (TILs) is a predictive biomarker of pCR and improved survival in patients with TNBC. In this retrospective cohort study, we examine a clinically diverse patient population who received the K522 regimen to determine whether TILs confer a predictive value in response to neoadjuvant pembrolizumab treatment compared to other tumor and clinical factors.

Methods: We reviewed electronic medical records of 271 patients with early TNBC who received neoadjuvant chemo immunotherapy with the K522 regimen at a tertiary care university hospital, UT Southwestern (UTSW), and affiliated safety-net hospital, Parkland Memorial (PM) between August 2021 and May 2024. 184 patients completed the neoadjuvant portion of treatment followed by surgery and fit the criteria for our analysis (UTSW: 120, PM: 64). Baseline patient and tumor characteristics were described. Two proportion Z-tests and Chi-squared tests for independence were used to compare pCR rate between patient ethnicities and univariate logistic regression was used to evaluate the association between binary presence of TILs, grade, and residual cancer burden.

Results In total, 57% achieved a pCR; TILs were reported in 52.8% of pathology reports. The presence of TILs was associated with a significantly improved pCR rate of 70% compared to 48% in individuals without TILs (p=0.0027). The median age of our patient population was 51 years. Of which, 34.8% self-identified as Caucasian, 31.0% Hispanic, 25.5% Black, and 8.7% other. There was no statistically significant difference in pCR rate or presence of reported TILs across different ethnicities. Of note, Hispanic patients with TILs had an increased rate of pCR (80.0%) than Hispanic patients without TILs (54.3%) (p=0.0323). No other ethnic group with TILs showed any statistical association with pCR when compared to their non-TIL presenting counterparts. Controlling for tumor grade, patients with TILs were 2.442 times more likely to have a pCR (CI: 1.310—4.553; p=0.0050). Patients with grade 3 TNBC were 2.89 times more likely to have a pCR (CI: 1.275—11.822; p=0.0170). Node positivity in conjunction with TILs also showed statistically significant pCR rates versus all other subgroups (p=0.0051).

Conclusions The K522 trial did not collect racial data as a baseline demographic characteristic, while our study had a significant percentage of Hispanic and Black populations treated with this regimen. This may account for our pCR rate of 57%, which is lower than what was reported on the K522 trial as studies have shown a lower pCR rate in Black population compared to other ethnicities. Our data suggests that TILs can be considered a predictive marker of pCR rate and treatment response in patients with early-stage TNBC. This is particularly relevant in Hispanic patients with TILs achieving a higher rate of pCR than the rest of our population. This may indicate that TILs have potential to guide treatment decisions for certain subgroups. Current College of American Pathologists guidelines do not mandate standardized or uniform reporting of TILs in pathology reports. While TILs could be considered a potential predictive marker in early stage TNBC, more emphasis needs to be placed in standardized reporting of TILs and larger studies are needed for further validation.

PS1-02: Impact of racial differences in circulating blood components and stromal tumor-infiltrating lymphocytes (sTILs) on outcomes in triple negative breast cancer (TNBC)

Priyanka Sharma, Rachel Yoder, Joshua M. Staley, India Fernandez, Adam Heinrich, Spencer Thompson, AnneMarie Ball, Trinity Kemp, Andrew K. Godwin, Rashna Madan, Qamar J. Khan, Robert Salgado, Shane R. Stecklein

Introduction: TNBC is overrepresented in Black women, and Black patients (pts) with TNBC have worse clinical outcomes compared to non-Black pts. Neoadjuvant chemotherapy (NACT) +/- immunotherapy is current standard of care for early-stage TNBC. Immune response parameters including sTILs are important predictors of response to NACT and long-term outcomes in TNBC. Circulating blood cell counts may be indicators of the systemic immune environment and thus play a role in response to NACT. Racial differences in sTILs and peripheral white blood cell components and their combined impact on outcomes are not well studied in TNBC.
Methods: 469 pts with stage I-III TNBC enrolled in a prospective registry between 2011-2023 who received NACT (n=321) or NACT + pembrolizumab (P) (n=148) were included in analysis. Absolute neutrophil count (ANC), absolute lymphocyte count (ALC), and absolute monocyte count (AMC) were extracted from complete blood count (CBC) obtained prior to starting NACT. sTILs were centrally quantified as previously described. Impact of sTILs and CBC components (ANC, ALC, AMC, NLR (neutrophil to lymphocyte ratio), LMR (lymphocyte to monocyte ratio), and platelet to lymphocyte ratio (PLR)) on pathologic complete response (pCR) and recurrence free survival (RFS) was evaluated.
Results: Among 469 pts, 33% had node positive disease; 81% were White, 14% Black, and 2% Asian. Pts who received NACT+P were more likely to have higher T stage (p=0.005) and TNM stage (p=0.004) and shorter follow up compared to those who received NACT alone. Black pts had lower ANC (median 3.6 vs 4.6 k/uL, p<0.001) and NLR (median 1.6 vs 2.5, p<0.001), and higher ALC (median 2.2 vs 1.8 k/uL, p=0.003) and LMR (median 4.4 vs 3.8,

p<0.001) compared to non-Black pts. AMC was numerically lower in Black pts, and PLR was similar between Black and non-Black pts. sTILs were available for 55% (n=257) of pts; Black pts had higher sTILs compared to non-Black pts (median 40% vs 10%, p=0.019). There was no association of sTILs with ANC, ALC, NLR, LMR, or PLR. There was a weak inverse association of sTILs with AMC (p=0.013). pCR rate was similar in Black and non-Black pts (52% vs 55%). sTILs were associated with pCR both as a continuous variable (odds ratio, OR 1.12 for every 10% increase, p=0.009) and at 30% cut point. None of the CBC components were associated with pCR. Increasing AMC and LMR were associated with lower RFS (AMC: hazard ratio, HR 1.11 for every 0.4 k/uL increase, p=0.019, LMR: HR 1.28 for every 1.0 increase, p=0.002). None of the other CBC components, sTILs, nor race were associated with RFS. On multivariable analysis that included T stage and nodal status, AMC and LMR were each independently associated with RFS (AMC: HR 1.10, p=0.054; LMR: HR 1.07, p=0.016).
Conclusion: Among all circulating blood cell components, only the ones that included monocytes (AMC and LMR) independently impacted RFS, with higher monocytes being associated with worse outcomes in TNBC. Positive correlation between circulating monocytes and tumor-associated macrophages (TAMs) has been previously reported. It is also possible that the chemokine axis may recruit inflammatory monocytes into tumor sites, which may in turn differentiate into TAMs. We noted weak inverse association of AMC with sTILs, which also suggests some relationship between monocytes and the tumor immune microenvironment (TIM). Compared to non-Black pts, Black pts were more likely to have immune-enriched tumors (higher sTILs) but had more unfavorable peripheral white blood cell immune environment (higher LMR). These findings may partly explain why high sTILs do not translate into improved pCR rate and RFS in Black pts. Further investigation is warranted into the interaction between TIM, circulating monocytes, and race and how these interactions impact response to therapy.

PS1-03: Prediction of Prognosis and Efficacy of Neoadjuvant Therapy in HER2-Positive Breast Cancer Patients Based on Tertiary Lymphoid Structures

Kejing Zhang, Mengxi Li, Jianmin Wu, Jing Cao, Ziru Zhao, Shouman Wang

Background: Tertiary lymphoid structures (TLS) are lymphoid tissues that form in pathological conditions such as chronic inflammation, infection, or tumors. TLS play a crucial role in antigen-specific immune responses, participating in anti-tumor immune reactions and other immune-related processes. Studies have shown that TLS expression is associated with the efficacy of immunotherapy in triple-negative breast cancer (TNBC). However, the significance of TLS in HER2-positive breast cancer remains unclear. Trastuzumab plays a vital role in blocking the HER2 signaling pathway and, through antibody-dependent cellular cytotoxicity (ADCC), enhances the killing effect of immune cells on tumors. The relationship between TLS expression and the efficacy of targeted therapy is not well-defined. This study utilizes public databases (METABRIC) to confirm the significant

association between TLS and patient prognosis. Moreover, the correlation between TLS expression and the efficacy of neoadjuvant therapy in HER2-positive breast cancer is validated using the I-SPY2 data. Additionally, pre-treatment biopsy samples from HER2-positive breast cancer patients were collected, and multiplex immunofluorescence staining was employed to verify the close relationship between TLS expression and therapeutic efficacy.

Methods: We first explored the prognostic value of TLS expression levels in HER2-positive breast cancer patients from the METABRIC database. A total of 224 HER2-positive breast cancer patients were selected from the METABRIC dataset. Using the R software's survminer package res.cut function, we determined the optimal cutoff value for TLS expression at 0.32, categorizing patients into high TLS group (n=53) and low TLS group (n=171). Furthermore, the CIBERSORT algorithm was used to illustrate the differences in the immune microenvironment between the high and low TLS expression groups in HER2-positive breast cancer patients. Signal pathway enrichment analysis was performed on HER2-positive breast cancer sequencing data from the I-SPY2 publicly available dataset (n=245), and samples were grouped based on TLS expression (high TLS group n=68, low TLS group n=177). By analyzing the I-SPY2 data, we evaluated the role of TLS expression in predicting the pathological complete response rate (pCR) in HER2-positive breast cancer patients receiving dual-targeted therapy, as well as the impact of adding pertuzumab. Additionally, pre-treatment biopsy samples from HER2-positive patients undergoing neoadjuvant therapy were collected, and multiplex immunofluorescence staining was employed to verify the close relationship between TLS expression and therapeutic efficacy.Results: In HER2-positive breast cancer patients from the METABRIC database, Kaplan-Meier survival curves showed that the survival probability of the high TLS group was significantly higher than that of the low TLS group. At a median follow-up of approximately 60 months, the survival probability of the high TLS group was about 75%, compared to less than 60% in the low TLS group. The survival difference between the two groups was statistically significant (HR 1.644, 95% CI 1.082 to 2.500, p=0.041). CIBERSORT algorithm analysis revealed that in HER2-positive breast cancer tumors, those with high TLS expression had significantly increased infiltration of CD8+ T cells, activated memory CD4+ T cells, follicular helper T cells, and M1 macrophages. In contrast, tumors with low TLS expression had higher levels of M0 macrophages and resting dendritic cells. Subsequently, GSEA analysis was conducted on two cohorts, using NES > 1, p-value < 0.05, and p.adjust < 0.25 as criteria for significant enrichment pathways. Significant differences were found in tumor signaling pathway activation between patients with different TLS expression levels in HER2-positive breast cancer samples. High TLS expression patients showed upregulation of immune and inflammation-related pathways, indicating a stronger immune response. In contrast, low TLS expression patients showed upregulation of cell proliferation and signaling pathways, indicating increased tumor cell proliferation activity. In I-SPY2 trial, the high TLS group showed enrichment in immune-related pathways such as B cells, dendritic cells, and mast cells, with more active inflammatory features (e.g., STAT1 signaling and chemokine 12). Conversely, the low TLS group was more enriched in proliferation-related pathways (e.g., Module11_Prolif) and Basal index, suggesting

significant biological differences in immune and proliferative activities between high and low TLS tumors. Data from the publicly available I-SPY2 dataset suggested that in the control group (paclitaxel + trastuzumab), the pCR rate for "TLS high" patients was 45%, whereas the pCR rate for "TLS low" patients was 17%. In the pertuzumab group (control group plus pertuzumab), the pCR rate for "TLS high" patients was 63%, compared to 58% for "TLS low" patients. The addition of pertuzumab significantly improved the pCR rate in the TLS low expression group. Univariate interaction analysis of TLS expression with the addition of pertuzumab showed significance (P = 0.019). In "TLS low" group, the addition of pertuzumab significantly increased the pCR rate, more than tripling it (58% vs. 17%, P = 0.0027), while there was no statistically significant difference in "TLS high" group (63% vs. 45%, P = 0.6372). Biopsies from the primary tumors of 20 newly diagnosed HER2-positive patients who received neoadjuvant therapy were collected, and multiplex immunofluorescence staining was performed using markers DAPI, CD20, CD4, and CD8. Preliminary results indicated that patients with a Miller-Payne (MP) score of G5 had tumors with abundant TLS structures, whereas patients with MP scores of G1-G2 had significantly fewer TLS in their tumor sections.
Conclusion: Our study demonstrates that TLS expression is a significant prognostic marker in HER2-positive breast cancer. High TLS expression is associated with improved survival and a more active immune microenvironment, as evidenced by increased infiltration of immune cells such as CD8+ T cells and activated memory CD4+ T cells. Conversely, low TLS expression correlates with increased tumor cell proliferation and poorer prognosis. Furthermore, our analysis of the I-SPY2 dataset reveals that TLS expression can predict the efficacy of neoadjuvant therapy, with the addition of pertuzumab notably enhancing the pathological complete response rates in TLS low-expressing tumors. Multiplex immunofluorescence staining of pre-treatment biopsies corroborates these findings, showing a close relationship between TLS abundance and therapeutic efficacy. These results suggest that TLS could serve as a valuable biomarker for stratifying patients and tailoring treatment strategies in HER2-positive breast cancer, potentially leading to improved clinical outcomes.

PS1-04: Tumor-infiltrating lymphocytes (TILs) and response to neoadjuvant chemotherapy in young patients with breast cancer

Megan Tesch, Yaileen D. Guzmán-Arocho, Laura C. Collins, Yujing J. Heng, Shoshana M. Rosenberg, Kathryn J. Ruddy, Rulla Tamimi, Lidia Schapira, Jeffrey Peppercorn, Virginia Borges, Steven E. Come, Craig Snow, Eric P. Winer, Elizabeth A. Mittendorf, Ann H. Partridge

Background: Increased TILs are associated with higher pathologic complete response (pCR) rates after NACT for breast cancer, but scant data exist in patients ≤ 40 years old, in whom age-related differences in host and tumor immune microenvironment may exist. We assessed the extent and composition of immune infiltration in breast tumors of young women undergoing NACT and correlated with clinicopathologic features and treatment response.

Methods: Patients with stage I-III breast cancer who had NACT and available pre-treatment tumor tissue were identified from a prospective cohort study of women with breast cancer diagnosed at age ≤ 40 years. Multiplexed immunofluorescence was used to quantify cytotoxic T (CD8+), T helper (CD3+CD8-), T regulatory (Treg, FOXP3+CD3+), exhausted T (PD1+CD8+), and PDL1+ cells in stroma and tumor as a percentage value of positive cells. Univariate analyses tested associations of TIL levels (high vs. low, divided based on median) with clinicopathologic variables and compared TIL levels (continuous) between pCR and non-pCR cases. Logistic regression tested associations between TIL subtypes (continuous, per 10% increase) and pCR.
Results: Among 194 patients, median age was 36 years (range 22-40 years), 14% were positive for BRCA1/2 mutations, and most had grade 3 (71%), > 2 cm (87%), node-positive (79%) tumors. Forty-one percent of tumors were hormone receptor (HR)-positive/HER2-negative, 33% HER2-positive/HR-positive or -negative, and 27% triple-negative. Sixty-one patients (31%) experienced pCR after NACT. Patients with recent pregnancies (≤ 5 years prior, n=80) had higher stromal infiltration of T helper (P=.020) and cytotoxic T (P=.002) cells as well as higher intratumoral infiltration of cytotoxic T (P=.001), Treg (P=.018) and exhausted T (P=.049) cells compared to those who were nulliparous (n=52), pregnant at diagnosis (n=7) or pregnant > 5 years prior (n=24). BRCA1 mutations (n=19) were associated with high levels of exhausted T cells in stroma (P=.021) and tumor (P=.048). Grade 3 tumors (n=137) had higher levels of T helper cells in stroma (P=.030) and tumor (P=.010). Triple-negative (n=52) and HER2-positive (n=63) tumors had higher stromal Treg infiltration (P=.046). Triple-negative and stage III tumors (n=66) were associated with high levels of PDL1+ cells in stroma (P=.033) and tumor (P=.005), respectively. No differences in TILs were seen according to age, race, ethnicity or histological subtype. Patients with pCR had greater stromal Treg (P=.0189), intratumoral T helper (P=.0043) and intratumoral PDL1+ cell infiltration (P=.0372). Increased stromal Tregs was predictive of pCR, controlling for breast cancer stage, grade and subtype (OR 1.63, 95% CI 1.12-2.28, P=.011). Increased levels of all intratumoral TIL subtypes was predictive of pCR, with odds ratios ranging from 1.14 (95% CI 1.02-1.29, P=.026) for PDL1+ cells to 2.02 (95% CI 1.31-3.12, P=.002) for Tregs for each 10% increment, controlling for breast cancer stage, grade and subtype.
Conclusions: The distribution of TIL subtypes in young patients' breast tumors pre-treatment varied according to recency of pregnancy, BRCA1/2 mutation status and tumor characteristics. High levels of most TIL subtypes was associated with improved response to NACT, independent of breast cancer subtype. The relationship between TILs and pCR in young women appears similar to that in older women, suggesting that tumors of younger and older patients may not be fundamentally different when analyzed according to clinically relevant biologic features. Characterization of immune subpopulations could help refine the predictive value of TILs in young patients with breast cancer, who may benefit from individualized escalated and de-escalated treatment strategies.

PS1-05: Genomic characteristics related to histology-based immune features in breast cancer

Yoon Jin, Constandina E. O'Connell, Benjamin C. Calhoun, Christian Brueffer, Christer Larsson, Åke Borg, Lao H. Saal, and Charles M. Perou

Background: The immune cell component of the tumor microenvironment is an important modulator of tumor progression and suppression. In patients with breast cancer, tumor-infiltrating lymphocytes (TILs) represent a large part of antitumor immunity along with tertiary lymphoid structure (TLS), as they predict favorable prognosis and good treatment response. In this study, we scored for immune-related histology features using whole slide H&E images of the TCGA-BRCA dataset and analyzed these distinct features relative to gene expression patterns and molecular intrinsic subtypes.
Method: A total of 1035 cases from TCGA-BRCA dataset were evaluated for TILs, plasma cells, high-endothelial venule associated lymphoid aggregate (HALA) and TLS. For HALA and TLS, location relative to tumor (non-tumor, peritumor, and intratumoral area) and number was determined. For each pathologically defined immune feature (i.e., no TLS vs TLS+), we then searched for associated gene expression features and used the top 100 significantly upregulated genes to make signatures for tumor group-based analyses. Upregulated immune modules in high-TIL tumors using a 10% TIL level cutoff were compared based on PAM50 molecular subtype (luminal A/B, HER2-enriched, basal-like). The clinical significance of histology-based gene signatures and high-TIL related immune modules was validated using bulk RNAseq and survival data from the SCAN-B cohort (N=6329).
Results: HER2-enriched (HER2E) and basal-like breast tumors exhibited the highest mean TILs, with plasma cells more frequently observed in these subtypes. HALAs were present in 36.4% of cases and TLS were found in 6.5% of cases, also predominantly in HER2E and basal-like tumors. Gene signatures related to intratumoral HALA and intratumoral TLS correlated with better survival outcomes, while peritumoral HALA correlated with worse outcomes on the overall TCGA data set. In addition to TILs- and plasma cell-associated gene signatures, intratumoral HALA and intratumoral TLS correlated with HER2E and basal like tumors. High-TIL tumors revealed 164 enriched immune modules, with unique upregulated modules in each molecular subtype. For example, in luminal tumors, immune modules had little relation to favorable prognosis. High-TIL HER2E and basal-like tumors had distinct immune gene signatures linked to improved survival, with HER2E being more associated with B-cell prognostic features and basal-like subtype more associated with T-cell prognostic features.
Conclusion: Different subtypes of breast cancer exhibit distinct tumor immune microenvironments, both histologically and molecularly. These differences in immune properties and biological characteristics should be considered when developing precise treatment strategies to achieve the best therapeutic efficacy for patients.

PS1-06: Intratumor tumor-infiltrating lymphocytes (iTILs) and spatial distribution pattern of stromal TILs (sTILs) evaluated by HALO AI are prognostic indicators of triple-negative breast cancer

Makiko Fukumura-Koga, Takanori Watanabe, Keita Kouzu, Kimi Kato, Kosuke Miyai, Tamio Yamasaki, Takahiro Einama, Hideki Ueno, Yoji Kishi, Kimiya Sato, and Hitoshi Tsuda

Introduction: A high density of tumor-infiltrating lymphocytes (TILs) has been recognized as an indicator of favorable prognosis of triple-negative breast cancers (TNBCs), and measurement of TILs infiltrating in the stroma of peripheral zone of cancer tissue are considered to be of the optimal clinical significance. However, some studies on other cancer types have indicated that TIL densities in both stromata of peripheral and central zones and in tumor cell nests were associated with prognosis. In this study, we evaluated the density and spatial distribution pattern of TILs manually and with an artificial intelligence (AI) modality and investigated their prognostic implication.
Materials and methods: We evaluated 70 surgically resected TNBC specimens from patients who did not receive neoadjuvant chemotherapy. CD3+ TILs and CD8+ TILs were detected by immunohistochemistry. The manual evaluation was performed by counting the total number of CD3+- and CD8+- TILs in peripheral stroma (psTILs), in central stroma (csTILs), and in tumor cell nests (iTILs) in five high-power fields (HPFs) on photomicrographic images. The evaluation with AI was performed by calculating densities of these TILs in 10 tiles (one tile: 500 x 500 μm square) after deep-learning of annotated areas of tumor cell nests, stroma, and other regions on digital slide glasses with HALO AI (Indica Labs, NM, U.S.A.). With AI, the peripheral zone was defined as the region centered on the boundary separating the host tissue from the cancer tissue with a width of 1 mm, and the central zone as the tissue inside the peripheral zone. psTILs, csTILs, and both peripheral and central iTILs (piTILs and ciTILs) were measured. With reference to receiver operating characteristic curves, the optimal cut-off values between high and low TILs were determined to discriminate clinical outcome of the patients. Spatial distribution patterns of TILs were also defined: infiltrated (high psTILs/high csTILs) and non-infiltrated patterns. Recurrence-free survival and overall survival analyses were performed with Cox proportional hazards model analyses.
Results: Median follow-up duration was 9.4 years, and 14 patients suffered recurrences and 13 patients died. In manual measurements, cut-off values in totally five HPFs were 1000, 300, 700, 300, 10, and 5 in CD3+ psTILs, CD8+ psTILs, CD3+ csTILs, CD8+ csTILs, CD3+ iTILs, and CD8+ iTILs, respectively. In AI measurements, cut-off values in totally 10 tiles were 1,500, 1,000, 500, 250, 30, and 15 in CD3+ psTILs, CD8+ psTILs, CD3+ csTILs, CD8+ csTILs, CD3+ ciTILs, and CD8+ ciTILs, respectively. By Cox univariate analyses, low CD3+ iTILs and low CD8+ iTILs with AI measurements showed higher risks [recurrence: hazard ratio(HR) 3.11, 95% CI 1.01-9.59, P = 0.047 for CD3+ ciTILs; HR 4.30, 95% CI 1.18-15.7, P = 0.027 for CD8+ ciTILs; HR 5.88, 95% CI 1.30-26.6, P = 0.021 for CD3+ csTILs; death: HR 3.57, 95% CI 1.16-11.0, P = 0.026 for CD3+ ciTILs; HR 4.30, 95% CI 1.18-15.7, P = 0.027; HR 2.23, 95% CI 0.99-10.5, P = 0.052; HR 3.98, 95% CI 1.09-14.5, P = 0.036 for CD3+ csTILs], but other psTILs and csTILs did not show prognostic significance. With regard to spatial

distribution of CD3+ TILs, non-infiltrated patterns showed significantly worse prognoses than infiltrated pattern (recurrence: HR 8.52, 95% CI 1.11-65.7, P = 0.039; death: HR 8.98, 95% CI 1.16-69.3, P = 0.035). Similar results were shown by manual evaluations. The CD3+ ciTILs, CD8+ ciTILs, CD3+ csTILs, and spatial distribution pattern with AI measurements were significantly or nearly significant prognostic values independently of patient age, pT, pN, stage, and adjuvant chemotherapy.
Conclusions: Evaluation of TILs not only in peripheral stroma but also in central stroma and tumor cell nests appeared important in TNBCs. iTILs and spatial distribution pattern of TILs might be applicable to discern patients who are eligible for dose de-escalation from those who require standard perioperative systemic therapy to TNBC.

PS1-07: AI-Derived Tumor-Infiltrating Lymphocytes Enhance the Model with Baseline Stromal Tumor-Infiltrating Lymphocytes and Ki-67 in Predicting Pathologic Complete Response in an Early-Stage Triple-Negative Breast Cancer Prospective Trial

Xiaoxi Pan, Caner Ercan, Zhongya Wang, Roland Bassett Jr., Karina B Pinao Gonzales, Clinton Yam, Lei Huo, Yinyin Yuan

Background: The tumor immune microenvironment is crucial in shaping the response to neoadjuvant chemotherapy in triple-negative breast cancer (TNBC). Stromal tumor-infiltrating lymphocytes (sTILs) and Ki-67 are important biomarkers to predict treatment response in TNBC (Abuhadra et al., 2023). However, manual assessment of sTILs faces challenges due to variability in interpretation across different observers (Van Bockstal et al. 2021). To obtain a consistent predictive model for treatment response with chemotherapy in TNBC, we utilized artificial intelligence (AI) methods for enhancement.

Material & methods: We collected 408 hematoxylin and eosin (H&E)-stained images from ARTEMIS (NCT02276443) arm 1 pretreatment core biopsies, divided into discovery and validation cohorts as per a previous work (Abuhadra et al., 2023). We also used the same criteria to evaluate pathologic complete response (pCR), Ki-67, and sTILs. H&E images exhibiting metaplasia and giant cells were excluded, resulting in 201 slides for the discovery cohort and 193 slides for the validation cohort, with one slide per case.
To calculate the TILs score, we applied AI pipelines on H&E images to identify epithelial, lymphoid, stromal, and other cells (AbdulJabbar et al., 2020), and to segment tissue into tumor, stroma, parenchyma, necrosis/hemorrhage, and adipose tissue (unpublished). To ensure the accuracy of cell classification, we combined the two pipelines to refine cell recognition. Specifically, cell types identified outside the tumor area but misclassified as epithelial cells underwent a secondary prediction. AI-derived TILs (AI-TILs) was calculated as the proportion of identified lymphoid cells within the tumor and stromal tissues, excluding other cell types.

Results: To evaluate the AI pipelines, 20 images from discovery cohort were manually

annotated by three pathologists, resulting in 8010 cells. We achieved an average balanced accuracy of 91.2% across the identified cell types. In the discovery cohort (n=201; pCR rate 42%, 85/201), AI-TILs was notably associated with manual sTILs (Spearman's rho=0.49, P<0.001). In a multivariable model consisting of AI-TILs and Ki-67 to predict pCR, with AI-TILs cutoff (0.173, range: 0.03-0.73) established through recursive partitioning analysis, we found that higher AI-TILs levels were significantly associated with pCR (Odds ratio, 4.57, 95% CI=1.63-12.80, P=0.004). Manual sTILs showed a similar pattern (Odds ratio, 3.71, 95% CI=1.97-6.99, P<0.001) in a multivariable model with Ki-67. When combining Ki-67, sTILs and AI-TILs, the significant association between AI-TILs and pCR was retained (Odds ratio: 3.01, 95% CI=1.04-8.72, P=0.042). Using the same model, we achieved an AUC of 0.74 and a precision of 0.68, marginally improving the model consisting of Ki-67 and sTILs (AUC 0.71, precision 0.68). In the validation cohort (n=193; pCR rate 42%, 82/193), the AI-TILs score performed consistently, maintaining correlation with sTILs (rho=0.39, P<0.001). By employing the model constructed in the discovery dataset with Ki-67, sTILs, and AI-TILs to predict pCR, we achieved an AUC of 0.69 and a precision of 0.67, comparable to the model with Ki-67 and sTILs alone (AUC 0.68, precision 0.66). Calibration plots and Hosmer-Lemeshow test indicated that the model including AI-TILs aligned better with the actual data compared to the model without AI-TILs.

Conclusion: This study demonstrates that AI-TILs from baseline biopsies can be a promising biomarker to enhance the prediction for neoadjuvant chemotherapy response in TNBC, alongside existing predictors such as manual sTILs, underscoring the potential clinical value of AI-TILs due to its reproducibility and objectivity.

PS1-08: Deciphering the Tumor-Immune Landscape and Mechanisms of Response and Resistance to Neoadjuvant Therapy in Early-Stage Breast Cancer Using Single-Cell RNA Sequencing

Marcela Carausu, David Gacquer, Xiaoxiao Wang, Samira Majjaj, Delphine Vincent, Laurence Buisseret, Michail Ignatiadis, Jérémy Blanc, Daphne T'Kint de Roodenbeke, Isabelle Veys, Filip De Neubourg, Denis Larsimont, Françoise Rothé, and Christos Sotiriou

Background: For most early-stage aggressive breast cancers (BC), neoadjuvant therapy (NAT) with chemotherapy (CT), with/without HER2 blockade or immune checkpoint blockade (ICB), is the current standard of care. However, around half of them will not respond to NAT and have a higher risk of recurrence. This study aims to provide insights into the cellular and molecular heterogeneity, potential resistance mechanisms, and predictive biomarkers for NAT response by analyzing the tumor and immune landscape using single-cell RNA sequencing (scRNA-seq).

Methods: Tissue samples were prospectively collected from pre-treatment biopsies, post-treatment tumor beds, and normal adjacent tissue of patients treated with NAT for luminal B-like (LumB), HER2-positive (HER2+), and triple-negative breast cancer (TNBC). Cells

were processed using the 10x Genomics Chromium Next GEM Single Cell 5' platform and analyzed for gene expression and T-cell and B-cell repertoire profiling. Following data pre-processing, cell clusters were annotated using unsupervised clustering and canonical marker genes. Comprehensive analyses involving copy number variation (CNV), pathway analysis, pseudotime trajectory, and ligand-receptor (LR) interactions were conducted. Differences in gene expression and cell proportions were assessed using t-tests and Wilcoxon rank-sum tests.

Results: We obtained high-quality scRNA-seq data from 30 patients across various time points, totaling 286,346 cells. NAT responders were 1/4 in LumB, 5/5 in HER2+, 7/14 in TNBC with CT alone, and 5/7 in TNBC treated with CT-ICB. After annotation, tumor tissue was enriched in immune cells and specific cancer-associated fibroblasts (CAFs) compared to normal adjacent tissue. Across BC subtypes, we observed differences in tumor cell origins, tumor microenvironment (TME) composition, and its dynamics under NAT. TNBC tumor cells indicated a basal/luminal progenitor origin, while LumB and HER2+ tumor cells displayed a luminal hormone-responsive origin. Also, LumB had lower levels of immune cells compared to TNBC and HER2+, especially tumor-reactive CXCL13+ and effector T cells. NAT influenced cell subtype dynamics, decreasing T and B cells and increasing CAFs in all BC subtypes. Post-NAT, there was a reduction in naïve CD4 and CD8 T cells and Tregs, but an increase in resident memory and T helper cells. Of interest, responders showed a significant increase in the CD8 effector/Treg ratio post-NAT compared to non-responders ($p<0.001$), likely due to the higher cytotoxic effect of CT on Tregs, which contributes to its antitumor efficacy. Response to NAT also correlated with higher proportions of proliferating T cells in the G2/M cell cycle phase ($p<0.01$), while higher levels of T cells in the G1 phase were associated with non-responders.
Of interest, a granular analysis of the T cell compartment revealed clonotypic variations and CXCL13+ CD8+ T cell expansion in pre-treatment samples linked to NAT response. Cell-cell interaction analyses further highlighted LR interactions specific to responders between tumor cells and CXCL13+ CD4+/CD8+ T cells, NK cells, proliferative T cells, and B cells. On the other hand, LR interactions specific to response to CT-ICB versus CT alone in TNBC were primarily observed among immune cell subsets, particularly between CXCL13+ CD4/CD8+ T cells and T regs and B cells (via CXCL13/CXCR5, TNFSF4/TNFRSF4, CCL5/CR5, CCL3/CCR5 or TNF/ICOS LR pairs), suggesting the necessity of immune cell communication in lymphoid aggregates for an effective immune response.
Finally, tumor cell sub-clonal analysis by inferred CNV revealed distinct patterns of genomic and transcriptomic heterogeneity among epithelial cells and TMEs.

Conclusions: Our findings underscore tumor-immune landscape complexity and offer insights into cellular dynamics, potentially unveiling predictive biomarkers of response to NAT in BC.

PS11-01: [18F]Fluoroestradiol (FES)-PET as a predictive measure for endocrine therapy in patients with newly diagnosed metastatic breast cancer: Results from EAI142

Hannah Linden, Fenghai Duan, Farrokh Dehdashti, Amy M Fowler, Amy S Clark, Jennifer M Specht, Jian Q Yu, Hsiaoj Lee, Lanell M Peterson, Mark Muzi, Jennifer S Winn, Hayley Knollman, Mark E Burkard, Foluso O Ademuyiwa, Rathan M Subramaniam, Lucy Hanna, Angela M DeMichele, Jonathan E McConathy, Antonio C Wolff, David A Mankoff

Background: Multiple single institution studies have shown that FES-PET predicts clinical benefit of endocrine based therapy for patients with metastatic breast cancer (MBC). ECOG-ACRIN trial EAI142 is a multicenter imaging biomarker study of FES-PET to assess baseline FES uptake qualitatively and quantitatively prior to initiation of first-line endocrine therapy with or without CDK4/6 inhibitors in MBC. The primary objective is to determine the negative-predictive value (NPV) of FES uptake for predicting clinical benefit in patients with estrogen-receptor positive (ER+) MBC at 6 months after treatment with endocrine based therapy. In this analysis, we present the primary analysis: the imaging results and 6-month follow-up data in the fully enrolled cohort.

Methods: From 2016-2022, 14 centers enrolled 105 female patients; 98 completed study procedures and were treated with endocrine based therapy. [18F]Fluorodeoxyglucose (FDG)-PET at baseline was encouraged, but not required, and was obtained in 66 patients. SUVmax of up to 5 of the most prominent lesions were recorded and qualitatively assessed for FES uptake in all patients. A sub-set analysis was done using FDG to guide lesion selection in the 66 patients who had both FES and FDG scans with the goal to better identify FES-negative lesions and heterogeneity in FES uptake. Patients were followed for progression-free survival (PFS) at 6 months (primary endpoint) and at 2 years (secondary endpoint). To determine the reproducibility of quantitative assessment of tumor FES uptake, 10 patients underwent a second FES-PET scan within 12 days of the first scan and prior to initiation of treatment in a test-retest sub-study.

Results: Of the 450 lesions identified at baseline, the majority were in bone or soft tissue (262 bone, 124 lymph node, 40 visceral). Most patients had 5 or more evaluable lesions (83/98, 85%). The majority of patients were postmenopausal (80/98, 82%) and treated with an aromatase inhibitor (69/98, 70%) and CDK4/6 inhibitor (73/98, 74%). We identified a wide range in uptake (SUVmax of 1.2-44.7), but only 19/98 (19%) patients had any lesions with qualitatively mild, minimal or absent FES uptake. No patient had an average SUVmax for the most prominent lesions less than the pre-specified cut-off of 1.5, therefore an NPV was unattainable. A total of 16/98 (16%) patients progressed at 6 months. Of 4 patients with heterogenous uptake, 1 (25%) progressed at 6 months. In the sub-set analysis, FDG -guided lesion location did not identify any additional FES-negative lesions. We observed excellent reproducibility in 79 test-retest lesions (SUVmax 1.5-20.2)

with a lesion level intra-class correlation coefficient of 0.94. Two-year PFS will be updated at the time of presentation.

Conclusions: In patients undergoing first-line therapy for ER+ MBC, we evaluated ER expression by both qualitative and quantitative FES-PET. NPV could not be assessed due to a lower than expected proportion of FES-negative scans and rate of progressive disease at 6 months needed to meet the assumptions used for power calculations. Test-retest studies confirmed quantitative overall and lesional reproducibility of FES-PET.

PS11-02: [18F]fluoroestradiol (FES) PET/CT to guide 2nd line treatment decision in patients with ER-positive HER2-negative advanced breast cancer (ABC) progressing on 1st line aromatase inhibitor and CDK4/6 inhibitor: early results of the ESTROTIMP trial.

Francois-Clement Bidard, Bidard, Romain-David Seban, Stephanie van de Ven, Sylvain Ladoire, Audrey Bellesoeur, Sandrine Parisse-Di Martino, Olivier Humbert, Thibaut Cassou-Mounat, Emmanuel Deshayes, Loic Djaileb, Khaldoun Kerrou, Eve Piekarski, Elise Deluche, Alexandre Cochet

Introduction: Post CDK4/6i second line endocrine therapy-based treatment options have recently expanded for patients with ER-positive/HER2-negative ABC, with new endocrine therapies (ngSERDs) and combination therapies (PI3KCA/AKTi, CDKi) being available or under investigation. Additionally, antibody-drug conjugates such as T-DXd (Destiny-Breast 06, ASCO 2024) have also demonstrated prolonged efficacy in the post-CDK4/6i setting and could become an attractive treatment option. Interestingly, while ER loss/downregulation is a universal mechanism of resistance to endocrine therapy, [18F]fluoroestradiol (FES) PET/CT enables non-invasive assessment of ER expression and heterogeneity in ABC lesions. This information may guide therapy selection in the post-CDK4/6i setting, potentially reducing the use of ineffective endocrine therapies in these patients.

Methods: ESTROTIMP is an ongoing multicenter trial in France, prospectively enrolling 152 patients with progression of ER-positive/HER2-negative ABC on first-line endocrine therapy in combination with a CDK4/6 inhibitor. After standard of care [18F]fluorodeoxyglucose (FDG) PET/CT, all patients undergo an FES PET/CT scan. Treating physicians complete therapeutic management questionnaires before and after the FES PET/CT to evaluate the impact on therapeutic management. Nuclear medicine physicians complete reading forms for both FDG and FES PET/CT scans. Patients score pain and apprehension for both FES PET/CT and biopsy on a Visual Analogue Scale (VAS). Quality of life and second-line progression free survival (compared to a matched retrospective cohort) will be assessed after 12 months. An interim analysis of the first 30 assessable prospective

patients has been conducted.

Results: FES uptake in ABC lesions was classified as all lesions ER-positive (when compared with FDG PET/CT) in 19 of 30 patients (63.3%), mixed ER-positive/negative lesions in 7 (23.3%), and all lesions ER-negative in 4 patients (13.3%). A therapeutic management change based on incorporation of FES PET/CT results was implemented in 11 of 30 patients (36.7%; 99% confidence interval 16.0 - 61.6). Therapy selection was changed in 9 patients and diagnostic testing in 5, including 3 patients with changes in both. FES PET/CT helped confirm the initial management plan in 17 of 19 patients without changes in the management decision. Patients reported significantly lower pain and apprehension VAS scores for FES PET/CT compared to biopsy (Pain: Mean [SD], 1.00 [2.304] vs. 2.95 [3.197]; p=0.0051. Apprehension: Mean [SD], 2.47 [3.126] vs. 4.81 [3.636]; p=0.0111).

Conclusions: FES PET/CT is a helpful tool to inform therapeutic management decisions in patients with progression of ER-positive/HER2-negative ABC on first-line therapy and procedurally showed lower pain and apprehension scores compared to biopsy.

PS11-03: Comparative analysis of [18F]FES- and [18F]FDG-PET in patients with metastatic ER+ lobular breast cancer

Jasmine Moustaquim, Gabriëlle E. van Wonderen, Jasper J. L. van Geel, Michel van Kruchten, Erik F.J. de Vries, Agnes Jager, Evelien Kuip, Marcel P. M. Stokkel, Andor W.J.M. Glaudemans, Geke A. P. Hospers, C. Willemien Menke van der Houven van Oordt, Bert van der Vegt, Elisabeth G.E. de Vries, Carolina P. Schröder

BACKGROUND: Detection of invasive lobular carcinoma (ILC) with standard imaging modalities can be challenging. [18F]fluorodeoxyglucose (FDG) PET is commonly used in the work up of first presentation of metastatic breast cancer (MBC), but may be suboptimal for ILC due to lower metabolic activity compared to invasive ductal cancer. Imaging with [18F]fluoro-17b-estradiol (FES) PET measures whole-body estrogen receptor (ER) expression, which is generally high in ILC. Whether FES-PET outperforms FDG-PET in detecting metastatic ILC (mILC) lesions -and should therefore be the first-step imaging modality for mILC work up- remains unclear. Therefore, we compared the sensitivity of FDG- and FES-PET to detect ILC metastases, in patients who were enrolled in the prospective IMPACT-MBC study.
METHODS: In IMPACT-MBC (NCT01957332), 200 patients with newly diagnosed MBC underwent baseline FDG-PET, FES-PET, computed tomography (CT) scan and bone scintigraphy in addition to a metastasis biopsy. In this subanalysis, patients with ER+ mILC were included. Metastases were visually identified on FDG- and FES-PET and expressed as the total number and percentage of all metastases detected on all imaging modalities together. Results were analyzed on patient and lesion level.
RESULTS: Twenty-six patients with ER+ ILC were included, with a median age of 57 years.

Mean number of detected metastases per patient was 34 (range 2-77) with FDG-PET and 33 (range 0-88) with FES-PET. In 12 patients (46%), FES-PET detected more metastases than FDG-PET, whereas FDG-PET detected more metastases than FES-PET in another 12 patients (46%), and in two patients (8%) the same number of metastases was detected with both scans. In total, 1101 metastases were detected with all imaging modalities. A total of 853 metastases were detected with FDG-PET and 859 metastases were detected with FES-PET. This results in a sensitivity of 77.5% (95% CI 75 – 80) for FDG-PET and 78% (95% CI 76 – 80) for FES-PET.
CONCLUSIONS: This is the largest prospective cohort comparing FDG-PET with FES-PET for baseline work up in mILC. FES-PET does not outperform FDG-PET in detecting ILC metastases, and the two techniques have similar sensitivity on a group level. For clinical practice, in light of wider availability of FDG-PET and detection of equal or more ILC metastases in the majority of patients, FDG-PET remains the first-step imaging modality for mILC. However, in a considerable part of patients with mILC, FES-PET detects more ILC metastases than FDG-PET. Therefore, in case of persistent clinical dilemmas or doubts, an additional FES-PET should certainly be considered in mILC.

PS11-05: Novel 4D radiomics applied to dynamic FES PET images to improve prediction of ER-positive breast cancer outcomes for ER-targeted therapy

Carla Zeballos Torrez, Andrew Chen, Lanell M. Peterson, Mark Muzi, Jennifer M. Specht, Eric A. Cohen, Hannah M. Linden, Despina Kontos, David A. Mankoff

Introduction: Identification of noninvasive biomarkers to predict tumor biology and provide prognostic indicators in ER positive breast cancer are of essence. [18F]fluoroestradiol (FES) is an FDA-approved tracer that measures functional ER expression and predicts response to ER-targeted therapy. The goal of this study was to test novel 4D analysis of dynamic volumetric FES PET patient imaging data to predict outcomes in patients with metastatic ER positive breast cancer undergoing endocrine therapy.
Methods: We utilized the Rad-Fit method, previously tested in 4D analysis of dynamic [18F]fluorodexosyglucose (FDG) breast cancer patient data sets, to identify and characterize intratumor subregions through unsupervised clustering of tumor voxels according to each voxel's time-activity information, summarized by functional principal components (Chitalia, PMID: 3367764). The analysis was performed on a set of dynamic FES PET data taken over a single body section with one or more tumor sites from a previously studied cohort of 38 patients with locally advanced or metastatic breast cancer taken prior to endocrine therapy (Linden, PMID: 1668272). The FES imaging data were analyzed using the Rad-fit method and radiomics measures were compared to patient outcome data (PFS and OS) collected in the original study. Tumors were clustered from two up to twelve clusters and the optimal clustering of each tumor was chosen by utilizing a scaled silhouette score. The mean, standard deviation, minimum, and maximum values of the 4D features of subregion sum of squared error (SSE), distance between sub regions, and

the total number of intratumor subregions were used to build prognostic models of overall survival (OS) and progression free survival (PSF). We employed Kaplan-Meyer plots to determine if our prognostic models could significantly separate our population into high and low risk groups.
Results: 4D features significantly separated this cohort into a high or low risk group for OS in a single tumor per subject (C=0.73, p=0.0018) or averaging all features per subject (C=0.65, p<0.00025) model. Mean and maximum distance are the most significant radiomic features in the Cox-PH model with all features. Combining the significant radiomic predictors of maximum and mean distance with tumor site SUV Max resulted in improved separation of high and low risk groups for the single tumor (C=0.71, p=0.0014) and average tumor (C=0.61, p=0.00018) models.
Conclusions: In this exploratory study, we show that 4D radiomic features extracted from dynamic FES PET images using the established Rad-Fit method can add significantly to prediction of OS in advanced ER positive breast cancer. Metrics of tumor subregion distance, reflective of the overall tumor heterogeneity in FES PET images, appear to perform as the best radiomic predictors for risk stratification of OS.
Supported in part by Komen Grant SAC232145 and NIH/NCI Funding R50 CA-211270

PS11-06: Leveraging AI to Predict Recurrence-Free Survival in Breast Cancer Patients through Image-Based assessment of Tumor Characteristics

Poornima Saha, Frederick M. Howard, Erica M. Stringer-Reasor, Yara Abdou, Jennifer McMahon, Yuhan Zhang, Joseph R. Peterson, Bradley Feiger, Michelle Weitz, Judy C Boughey, Matthew P Goetz

Background: Early-stage hormone receptor positive (HR+) human epidermal growth factor receptor 2 negative (HER2-) breast cancer is typically treated with endocrine therapy with or without chemotherapy. While several commercially available genomic assays exist to assess risk of recurrence and guide adjuvant systemic therapy selection, these platforms are time consuming, costly, and may not fully capture disease heterogeneity when performed on a single tissue block. Radiographic imaging allows for a global assessment of tumor heterogeneity, but new approaches are needed to develop effective prognostic imaging tools. Therefore, we developed and validated an AI-based model incorporating pre-treatment DCE-MRI features with clinicopathologic features to predict recurrence risk in HR+/HER2- breast cancer.

Methods: The model was trained on 522 women (29.5% neoadjuvant chemotherapy), pooled from a multi-institutional clinical trial and one independent institution, and validated on 496 women (31.2% neoadjuvant chemotherapy), pooled from three independent health systems. All patients had HR+/HER2- breast cancer and pre-treatment DCE-MRI. The model inputs included clinicopathological data (age, race/ethnicity, T stage, N stage, grade) and DCE-MRI features that capture the spatial characteristics of the tumor and

surrounding tissues. These image-based features are computed using a validated AI-based segmentation model developed for early-stage breast cancer. Model outputs are thresholded to optimize patient stratification in the training set, resulting in categorical outputs of high or low risk. Finally, we assessed the added prognostic value of our model trained with both clinicopathologic and imaging features against the model trained with clinicopathologic features alone.

Results: In the validation cohort, patients had a median follow-up time of 4.6 years, median age of 53 years, and 16% were African American. The majority (90.3%) of women had T1-T2 disease, and 34.9% had 1-3 involved lymph nodes. The 5-year recurrence free survival (RFS) for women predicted as low risk by the model was 93.1% (95% CI: 89.0, 95.6%) compared to 78.0% (95% CI: 67.3, 85.6%) for women predicted as high risk. The unadjusted hazard ratio (HR) for the predicted high vs low recurrence risk groups was 3.8 (95% CI: 2.0, 7.2) at 5 years. After adding age, race/ethnicity, T stage, N stage, and grade into a Cox model, the adjusted HR for high vs low risk groups was 3.2 (95% CI: 1.6, 6.6). The prognostic signature was added to the clinical-only risk score both as a continuous variable and as risk groups, with significant improvement in RFS prediction ($p<0.01$) over the clinical-only model, as assessed using a likelihood ratio test.
Subgroup analyses indicated the model was prognostic regardless of age or nodal status. In women less than 50 years, the 5-year RFS for the low risk group was 89.1% versus 75.9% in the high risk group (HR: 2.8, 95% CI: 1.1, 7.1). In women greater than 50 years, the 5-year RFS was 94.6% in the low risk group vs 80.3% in the high risk group (HR: 4.4, 95% CI: 1.8, 10.6). Effective risk stratification into low risk and high risk was accomplished in both the lymph node negative (HR: 3.8, 95% CI: 1.6, 9.1) and lymph node positive patients (HR: 4.0, 95% CI: 1.5, 11.1).

Conclusions: Our AI-based prognostic tool incorporating pre-treatment DCE-MRI allows personalized treatment planning in real time in women with early-stage HR+/HER2- breast cancer. The prognostic benefit exceeded that of clinical features alone and was observed regardless of age and lymph node involvement. Further studies are ongoing to assess the ability of the model to identify patients most suitable for therapy escalation (e.g., chemotherapy, CDK 4/6 inhibitors) or de-escalation (endocrine monotherapy).

PS11-07: Predicting the response of locally advanced breast cancer to neoadjuvant therapy using MRI-based mathematical modeling of the I-SPY 2 dataset

Reshmi Patel, Chengyue Wu, Casey E. Stowers, Rania M. M. Mohammed, Jingfei Ma, Gaiane M. Rauch, Thomas E. Yankeelov

Introduction: Neoadjuvant therapy (NAT) is the standard of care for patients with locally advanced breast cancer; unfortunately, 30-65% of patients have residual disease after completion of NAT.1-2 Accurate and early prediction of individual patient response to NAT

is essential for clinicians to make changes to improve patient outcomes. Unlike current population-based methods, mechanism-based mathematical models make patient-specific predictions that capture tumor heterogeneity and longitudinal changes.3
We previously developed a model3 that achieved a concordance correlation coefficient (CCC) of 0.95 for total tumor cellularity (TTC) and a CCC of 0.94 for tumor volume (TV) between the observed and predicted changes in a dataset of 56 triple negative (TN) breast cancer patients.4 Here, we aim to show the generalizability of this approach by applying it to the multi-site, multi-subtype I-SPY 2 trial dataset of patients imaged with standard-of-care magnetic resonance imaging (MRI).5

Methods: I-SPY 2 is a clinical trial for locally advanced breast cancer that acquired dynamic contrast-enhanced (DCE) and diffusion-weighted (DW) MRI scans before (V1), three weeks into (V2), and after completion of (V3) the first course of NAT.5 Our subset of 93 patients includes 42 hormone (estrogen and/or progesterone) receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-), 22 HER2+, and 29 TN breast cancer patients.
Our mathematical model is a partial differential equation characterizing the rate of change in voxel-wise tumor cellularity, NTC($\bar{x}$,t), as a function of cell movement constrained by tissue mechanical properties, logistic proliferation, and death due to NAT.3-4 We calculated NTC($\bar{x}$,t) at each visit from the apparent diffusion coefficient maps obtained from DW-MRI scans.3 The breast and tumor tissue was segmented by clustering and defined the modeling geometry. Drug concentration was initialized as proportional to contrast agent accumulation obtained from DCE-MRI. We calibrated global drug efficacy and spatially-resolved proliferation rates to the V1 and V2 NTC($\bar{x}$,t) data and ran the calibrated model forward to make patient-specific predictions of tumor status at V3.3

Results: At the time of submission, we have completed our analysis on 77 patients, achieving CCC values of 0.94 and 0.91 between the observed and predicted TTC and TV (from V1 to V3), respectively. Fisher's z-tests between these CCC values and those achieved in the previous single site study4 indicated our model's predictive accuracy was statistically equivalent in the two data sets. In general, model predictions for TTC at V3 were highly accurate, but the predictions for TV and local cellularity at V3 were less accurate. The model was limited in capturing tumor tissue compression, which often led to overestimated TV and underestimated local cellularity at V3. However, our model was successful in predicting which voxels will have no observable tumor cells at V3. As a result, the median absolute percent difference across all voxels between the observed and predicted change in NTC($\bar{x}$,t) had a cohort mean of 11.3%.

Discussion: Our results indicate our mechanism-based mathematical model informed by early changes to NAT can accurately predict tumor status after a course of NAT, supporting the feasibility of personalized treatment using only clinically-available MRI data. For

instance, after a patient receives three NAT cycles and imaging, we can calibrate a model and make predictions for different available treatment schedules, and a clinician can use the optimal predicted schedule(s) to guide treatment.

PS11-08: MRI improves multi-modal AI system for breast cancer diagnosis and prognosis

Yanqi Xu, Jungkyu Park, Yiqiu Shen, Frank Yeung, Joe Cappadona, Jan Witowski, Linda Pak, Freya Schnabel, Krzysztof J. Geras

Background: MRI is the most sensitive imaging modality for breast cancer detection and is not affected by breast density. Screening MRI has higher specificity than mammography in high-risk populations, including women with a family history of breast cancer, BRCA1/2 mutations, and a personal history of breast cancer. The ACS screening guidelines recommend MRI supplemented with mammography for women at high risk (≥ 20%-25% lifetime risk). MRI is also used for diagnosing breast cancer when mammography and ultrasound are inconclusive. We investigate how MRI can improve cancer detection and risk prediction with a multi-modal AI system. Current standard-of-care risk models, such as the TC model, rely solely on clinical variables and do not account for the rich information in imaging data. Other existing AI systems typically analyze single imaging modality, usually mammography. Our multi-modal transformer (MMT) learns from longitudinal imaging data of multiple modalities, FFDM, DBT, US and MRI.

Methods: We utilized the NYU Multimodal Breast Cancer Dataset, comprising 1,372,455 exams from 298,670 patients (age 30-108, mean 56.55 years, SD 12.00 years) between 2010 and 2022, for MMT training and evaluation. Our objective is to predict whether a patient currently has cancer and, if not, assess the risk of developing cancer in the future, incorporating data from all available, present and prior, breast imaging. Our method involves three steps: (1) training modality-specific feature extractors separately to generate image-level and patch-level feature embeddings; (2) combining image embeddings with additional variables including age, modality, study date and view; (3) feeding the combined embeddings into a transformer for cancer prediction. The model outputs two predictions, the patient's probability of having cancer and the patient’s risk of getting cancer within 5 years.

Results We evaluated our model on a subgroup of patients who had at least one MRI in their records. The MMT model achieved an AUROC of 0.943 (95% CI: 0.935, 0.950) for cancer detection and 0.796 (95% CI: 0.765, 0.826) for 5-year risk prediction across all modalities. We separately compared our model’s AUROC on non-MRI exams and MRI exams with the corresponding baselines. For non-MRI exams, the MMT model with MRI data, achieved an AUROC of 0.939 (95% CI: 0.929, 0.948) for cancer detection and 0.778 (95% CI: 0.742,

0.810) for 5-year risk prediction, which improved the baseline MMT model without MRI by 0.024 and 0.044 (two-sided DeLong's test, P < 0.01 for both) respectively. These results demonstrate that incorporating MRI improves both cancer detection and risk prediction for non-MRI exams. For MRI exams, the MMT model achieved an AUROC of 0.947 (95% CI: 0.934, 0.958) for cancer detection, improving by 0.029 (two-sided Delong's test, P < 0.01) compared to an MRI-only baseline. This indicates that including prior imaging enhances the effectiveness of MRI in detecting cancer. However, for risk prediction on MRI exams, there was no significant improvement (ΔAUROC 0.004: two-sided DeLong's test, P = 0.94). Additionally, MMT's risk prediction AUROC on MRI exams was lower than other modalities (0.719, 95% CI: 0.615, 0.813), suggesting that MRI alone has less predictive power for future risk.

PS11-09: Improving risk estimation for women with dense breasts

Shu (Joy) Jiang, Debbie Bennett, Graham Colditz

Purpose: Women with dense breasts on screening mammography present a clinical challenge as the USPSTF guidance is lacking on recommendations for supplemental screening. Therefore, we aimed to apply a dynamic risk prediction model that incorporates current and prior screening mammogram images to better refine risk among women with dense breasts.
Methods We analyzed a prospective WashU clinic-based cohort of 10,099 cancer-free women at cohort entry (recruited from women attending routine screening between Nov 3, 2008 and February 2012). Follow-up through October 31, 2020 identified 478 pathology-confirmed breast cancer cases. The cohort included 27% non-Hispanic Black women. An external validation cohort included 18,360 women screened at Emory from January 1, 2013 and followed through December 31, 2020. This included 42% non-Hispanic Black women and 332 pathology-confirmed breast cancer cases.
We trained a dynamic model using repeated screening mammograms at WashU to predict 5-year risk. We then applied the model to the external validation data to evaluate discrimination performance measured by AUC and calibrated to US incidence from SEER.
Results In the overall external Emory validation data set, 48.6% of women who remained free from breast cancer were classified as dense (BI-RADS C or D) and 49.1% of women who developed breast cancer (cases) were classified as dense. Time to diagnosis of breast cancer was evenly distributed from first available mammogram to 8 years of repeated screening. Using 3 years of prior mammogram images available at the current screening visit, we obtained a 5-year AUC of 0.80 (95% CI, 0.78, 0.83) for prediction of subsequent breast cancer risk when controlling for age and BI-RADS density. This represents a significant improvement over only using the current visit mammogram AUC 0.74 (95% CI, 0.71, 0.77) for risk estimation (p<0.01). We repeated analysis in women with dense breasts (n cases = 163) and the 5 year AUC was 0.79 (95%CI 0.75 to 0.84) for risk prediction. When calibrated to SEER incidence rates, a risk ratio of 15.7 was observed comparing high (>0.04%) to very low (<0.003%) 5-year risk. The dynamic model classified 14.8% of the women with dense breasts as high risk among whom 53% of all cases were diagnosed within 5 years. The

dynamic model effectively identifies a subgroup of women with dense breasts who are at high risk and exceeding lifetime risk thresholds in current guidelines for risk reduction. This subgroup of women with dense breasts would be the most likely to benefit from additional imaging. Identification of very low-risk groups of women with dense breasts would also allow for appropriate reassurance and standard mammography screening protocols without need for supplemental screening recommendations.
Conclusion Among women with dense breasts, incorporating information from previous screening mammogram images improves 5-year breast cancer risk prediction beyond static models used in clinics today. This model can identify those women with dense breasts who are at high risk of developing breast cancer, who might most clearly benefit from supplemental screening or risk reduction strategies.

PS12-01: Olaparib-induced early dynamics of tumor immune microenvironment in triple-negative or ER-low breast cancer: insights from a window of opportunity MEDIOLA trial of olaparib and durvalumab with serial biopsies

Jiwon Koh, Kyung-Hun Lee, Ahrum Min, Han Suk Ryu, Dae-Won Lee, Jinyong Kim, Yoon-Jung Shin, Yu-Jin Kim, Changhee Park, Hyeong-Gon Moon, Wonshik Han, Han-Byoel Lee, Tae Yong Kim, Nariya Cho, Gi-Jeong Cheon, Seock-Ah Im

Background: Increasing evidence indicates that PARP inhibitors can modulate the tumor microenvironment (TME), making them promising candidates for combination therapy with immune checkpoint inhibitors (ICIs). To demonstrate the clinical efficacy and biological impact of PARP inhibitor treatment followed by ICIs, we conducted a window of opportunity MEDIOLA trial with olaparib and durvalumab before standard neoadjuvant chemotherapy (NAC) in stage II/III triple negative breast cancer (TNBC) or ER-low breast cancer (NCT03594396).

Methods: Olaparib (300mg bid) was given continuously for 4 weeks, with a single 1500 mg dose of durvalumab on day 15, followed by standard NAC (4 cycles of doxorubicin /cyclophosphamide, then 4 cycles of docetaxel). FDG-PET/MRI scans were performed at baseline, 2 weeks, and 4 weeks; CT scans at baseline and 4 weeks. Serial tumor biopsies were collected at baseline, after 2 weeks of olaparib (before durvalumab) (on treatment 1; OT1), and 2 weeks post-durvalumab after 4 weeks of olaparib (OT2). Whole exome sequencing (WES) and functional RAD51 foci assays were conducted on fresh frozen baseline biopsies. Immune cell dynamics were analyzed using multiplex IHC (mIHC) on baseline, OT1, and OT2 samples.

Results: Fifty-four female patients (median age 40, range 24-68) were enrolled. Pathologic complete response (pCR) was achieved in 38 patients (70.4%) (Im SA et al. SABCS 2021). Pathogenic germline BRCA1/2 (gBRCA1/2) mutations were present in 17/54 (31.5%), and functional RAD51 foci assays showed homologous recombination deficiency (fHRD) in

27/54 (50.0%). fHRD was significantly associated with early metabolic response to olaparib by FDG-PET at 2 weeks (63.0% vs 25.9%; p = 0.006), and borderline association after 4 weeks of olaparib and durvalumab (85.2% vs 63.0%; p = 0.062). fHRD was linked to RECIST response by CT at 4 weeks (63.0% vs 33.3%; p = 0.029), and pCR rate was significantly associated with metabolic and RECIST responses at 4 weeks (p < 0.001 and 0.027, respectively). WES revealed mutations including TP53 (79.6%), PIK3CA (11.1%), PTEN (7.4%), RB1 (5.6%), and PALB2 (1.9%). There was significantly more infiltration of CD3+, CD4+, and CD8+ T-cells at OT1 and OT2 compared to baseline (all adjusted p < 0.05). Surprisingly, patients with metabolic response at either 2 or 4 weeks and those who achieved pCR showed unique temporal changes in the TME. The boosted infiltration of exhausted CD8+PD-1+ and CD8+TIM3+ T-cells, along with activated CD8+CD25+ T-cells, was prominent at OT1 timepoint in metabolic and pathologic responders (all adjusted p < 0.001). This finding suggests that olaparib can induce significant immune modulation in CD8+ T-cell subsets as early as 2 weeks after treatment initiation. Moreover, both CD8+ and CD4+CXCL13+ T-cells expanded in responsive tumors at OT1 (all adjusted p < 0.01), underscoring the crucial role of CD4+ helper T-cells during olaparib-mediated immune modulation. Most of these changes observed at OT1 persisted through OT2 biopsies. However, immune cell densities at baseline by themselves showed no correlation with pCR or metabolic/radiological responses. From a tumor biology perspective, baseline CD4+CXCL13+ and CD20+CXCR5+ cells were higher in fHRD tumors (all adjusted p < 0.05). Temporal expansions of CD8+PD1+ and CD8+TIM3+ T-cells at OT1 were more pronounced in those with fHRD or gBRCA1/2 mutations, suggesting a significant influence of fHRD at baseline on the TME.

Conclusions: The unprecedentedly high rate of pCR in this study highlights the enhanced anti-tumor effects mediated by olaparib-induced immune modulation followed by ICI. Through mIHC, we demonstrated that temporal changes in the TME were reflective of early response and pCR and in part dependent on HRD status. More in-depth analyses of TME dynamics linked with genomic and transcriptomic information are underway, which may provide further insights into tumor cell characteristics and their temporal interactions with TME.

PS12-02: CXCL11 in the tumor immune microenvironment modulates resistance to endocrine therapy in hormone receptor-positive breast cancer

Fabiana Napolitano, Yunguan Wang, Dhivya R. Sudhan, Paula I. González-Ericsson, Luigi Formisano, Lei Guo, María Rosario Chica-Parrado, Chang-Ching Lin, Kyung-Min Lee, Hongli Ma, Nathaniel Evans, Alberto Servetto, Saurabh Mendiratta, Spencer Barnes, Yisheng V. Fang, Lin Xu, Gordon B. Mills, Marilyne Labrie, Ariella B. Hanker, Carlos L. Arteaga

Despite advances in the treatment of hormone receptor-positive (HR+) breast cancer (BC), this disease subtype continues to be a major cause of mortality. The tumor immune microenvironment (TIME) plays a crucial yet not fully understood role in the natural history of HR+ BC. This study aims to clarify the impact of the TIME on HR+/HER2-negative BC response to antiestrogen treatment.

We collected samples from postmenopausal patients with stage I-III HR+ BC, treated for 2-3 weeks with estrogen deprivation (ED) induced by letrozole. Treatment response was categorized based on the Ki67 scores at the time of the surgery (on treatment tumors, onTx): ED-sensitive (ED-S) if natural log (ln) of the Ki67 score ≤1.0 (i.e. ≤2.7% Ki67+ cells) vs. ED-resistant (ED-R) if ln ≥2.0 (i.e. ≥7.4% Ki67+ cells).

Analysis of H&E tumor sections revealed that stromal tumor-infiltrating lymphocytes (sTILs) were significantly higher in ED-R compared to ED-S tumors ($p=0.0001$). Next, using both cyclic immunofluorescence (cycIF) and spatial transcriptomics, we found that the TIME of ED-R breast tumors was primarily infiltrated by CD8+ T cells, with their abundance being significantly higher in ED-R vs. ED-S tumors both prior to and after letrozole treatment ($p<0.001$ in preTx and $p<0.001$ in onTx tumors). In ED-R tumors specifically, CD8+ T cells were further enriched upon estrogen suppression ($p<0.001$), while Tregs decreased upon treatment ($p<0.01$).

We next utilized a co-culture system to determine whether CD8+T cells can stimulate the proliferation of HR+BC cells. MCF7 and T47D cells were seeded in estrogen-free medium (EFM) in multi-well plates, with transwell inserts containing CD8+ T cells separated by a membrane with 3.0-μm pores. In this system, the cancer and T cells share the conditioned medium, thus allowing for paracrine cell-cell communication without direct contact between T cells and cancer cells. MCF7 and T47D exhibited 1.5- to 2.0-fold higher estrogen-independent proliferation when co-cultured with CD8+T cells ($p=0.0115$ and $p=0.0003$, respectively).

Immune cell recruitment to cancer sites occurs through chemotactic cytokines. Thus, we investigated chemokine expression in RNA-seq data of ED-R vs. ED-S tumors. CXCL9, CXCL10, and CXCL11 chemokines were significantly enriched in ED-R compared to ED-S tumors ($p<0.0001$ for all genes; both preTx and onTx). Likewise, their receptor CXCR3 was similarly enriched in ED-R vs. ED-S tumors (preTx $p=0.0106$, onTx $p<0.001$). Publicly available datasets of patients with HR+BC treated with antiestrogen therapy showed that higher expression of CXCL9 (HR 1.36; $p=0.016$), CXCL10 (HR 1.71; $p<0.0001$), and CXCL11 (HR 1.5; $p=0.0016$) is associated with shorter relapse-free survival.

We next investigated whether these chemokines play a causal role in resistance to ED using hormone-dependent MCF7 and T47D cells. Treatment with recombinant CXCL11 markedly upregulated phospho-AKT and phospho-ERK1/2 and stimulated estrogen-independent proliferation of both cell lines ($p<0.0001$). In addition, CXCL11 levels measured by ELISA increased 1.5- to 2.0-fold in media conditioned by breast cancer cells for 6 days when co-cultured with CD8+T cells compared to breast cancer cells alone.

CXCR3 and CXCR7 are key receptors that interact with CXCL11. To assess their role in CXCL11-induced signaling, MCF7 and T47D cells were treated with a CXCR3 inhibitor (AMG487) and a CXCR7 antagonist, alone or in combination, in EFM with CXCL11. In

particular, AMG487 strongly inhibited CXCL11-induced p-AKT/p-ERK activation in MCF7, while the effect was only partial in T47D cells.
Taken together, our results suggest that CXCL11, a CD8+T cell-associated chemokine expressed in the breast TIME, promotes resistance to estrogen deprivation in early HR+BC, possibly through CXCR3. Further studies will investigate the use of inhibitors of CXCL11 receptors as a therapeutic strategy to reverse the TIME-mediated antiestrogen resistance.

PS12-03: Molecular characterization of the NeoPalAna Endocrine Resistant (ET-R) Cohort: implications for CDK4/6 inhibitor (CDK4/6i) and ET resistance mechanisms in primary estrogen receptor positive (ER+) and HER2 negative (HER2-) breast cancer (BC)

Tim Kong, Alex Mabry, Jingqin Luo, Anthony Z. Wang, Jeremy Hoog, Zhanfang Guo, Shana Thomas, Yingduo Song, Feng Gao, Mateusz Opyrchal, Lindsay Peterson, Foluso Ademuyiwa, Julie Margenthaler, Rebecca Aft, Katherine Glover-Collins, Leslie Nehring, Yu Tao, Souzan Sanati, Ian Hagemann, Fouad Boulos, Matthew Holt, Li Ding, Wenge Zhu, Jason Weber, Matthew Goetz, Donald Northfelt, Cynthia X. Ma

Background: Resistance to ET is a major contributor to BC mortality. CDK4/6i overcomes ET-R. However, some ER+/HER2- BC are intrinsically resistant to ET/CDK4/6i. Here we report the primary endpoint of complete cell cycle arrest (CCCA) and correlative studies of the NeoPalAna (NCT01723774) ET-R Cohort to examine resistance biomarkers for palbociclib (PAL) + anastrozole (ANA).

Methods: NeoPalAna is a multi-cohort single arm phase 2 neoadjuvant endocrine (NET) trial of PAL/ANA in clinical stage II/III ER+/HER2- BC. The ET-R Cohort enrolled patients (pts) with tumor Ki67 >10% after at least 4 weeks of standard (SOC) NET to receive PAL/ANA for 4 28-day cycles before surgery if Ki67 was ≤10% on C1D15 biopsy (Ki67C1D15). Pts switched to chemotherapy or underwent surgery if Ki67C1D15 >10%. The primary endpoint was C1D15 CCCA (Ki67C1D15 ≤2.7%). Simon's optimal 2-stage design (stage 1 n=12, stage 2 n=25) was used to detect a CCCA rate ≥20% vs ≤5% (power 0.9, alpha 0.1).
Correlative endpoints included genomic and proteomic analyses of tumor tissues in relation to response by Ki67C1D15 ≤10% (PAL-Sensitive or PAL-S) or >10% (PAL-Resistant or Pal-R). Tumor biopsies prior to SOC ET (Baseline or BL), before PAL/ANA (C1D1), and at C1D15 were analyzed for whole exome sequencing (WES) for 27 pts at the earliest timepoint (13 BL, 5 at C1D1, and 9 at C1D15), RNAseq for 33 pts at all possible timepoints (BL n=20, C1D1 n=15, C1D15 n=28) and global proteomic analysis on 16 C1D15 frozen cores (11 PAL-S and 5 PAL-R). Differentially expressed genes (DEGs) and Hallmark gene set enrichment analyses (GSEA) were performed controlling false discovery rate (FDR).

Results: Between Aug 2016 and Mar 2021, 34 pts were enrolled, with a median age 53 (30.4~77.6) years and a median 6 weeks of prior NET. This ET-R cohort was enriched for high grade tumors (3% G1, 47% G2, 47% G3) and mutations implicated in ET resistance. The top 6 mutated genes included TP53 (41%), PIK3CA (33%), NCOR1 (22%), NF1 (22%), RUNX1 (19%) and CDH1 (19%), similar between PAL-S vs -R BCs. CCCA rate was 57.6% (19/33; 95% CI: 39.2-74.5%). The trial met its primary endpoint (exact binomial test $p<0.0001$ against null CCCA of 5%).
At BL, PAM50 subtype was determined for 20 pts with RNAseq performed, which revealed 8 LumA (all PAL-S), 8 LumB (5 PAL-S, 3 PAL-R) and 4 non-Lum BCs (3 Basal and 1 HER2 E, all PAL-R). Principal component analysis (PCA) of 630 DEGs (FDR adj. $p\leq0.5$) at BL demonstrated tight clustering of PAL-S BCs, with PAL-R BCs appeared to scatter away in a gradient. Top positively enriched DEGs in PAL-R BCs included CCNE1, IDO1, IRF4, BRCA2, EZH2, and several immune cell markers. Top upregulated signaling pathways in PAL-R BCs included interferon (IFN) γ signaling, E2F targets, allograft rejection, MYC targets, G2M checkpoint, mTORC1 and TNF signaling, inflammatory response, IL6-JAK-STAT, and IFN α signaling. Estrogen response pathways were significantly downregulated in PAL-R BCs. Comparing C1 and BL, ET upregulated multiple pathways including allograft rejection, EMT, IFN γ response, etc. Adding PAL led to significant reductions in G2M checkpoints, E2F and MYC targets, IFN, mTOR pathways by both RNA and proteomic analyses. However, these pathways remain highly upregulated in PAL-R vs PAL-S at C1D15. CIBERSORT analysis which deconvoluted bulk RNAseq to estimate and compare cell type fractions at C1D15 and BL indicated a significant increase in several immune cell types including CD8 T cells, Plasma cells, M1 and M2 macrophages, and monocytes in PAL-S but not PAL-R BCs.

Conclusion: Neoadjuvant PAL/ANA led to 58% CCCA at C1D15 in ET-R BC. Specific oncogenic pathways and immune tolerance markers, such as IDO1, were enriched in PAL-R. Our data also suggest immune modulatory effects of CDK4/6i/ET in association with ET/PAL response.

PS12-04: HDACi combined with anthracycline elicits interactions between MHC-II+ triple-negative breast cancer and CD69+CD4+Trm orchestrating synergistic immunotherapy

Zehao Wang, Xue Jingyan, Xiu Bingqiu, Wu Jiong

Background: Early TNBC (eTNBC) lacks biomarkers for predicting the benefits of immune checkpoint blockade (ICB). Therefore, identifying indicators for the high-benefit patients and finding synergistic target for low-benefit populations are crucial. Tumor-associated MHC-II (tsMHC-II) are linked with the benefits of ICB in eTNBC, though the mechanisms remain to be explored. This study aimed to research the interaction mechanisms and translational targets between tsMHC-II and CD4+ T cell subgroups by NeoTennis clinical trial cohorts.

Method: RNA-seq, mIHC, and spatial analysis were used to quantify MHC expression in the tumor and spatial relations within the TME. In vivo murine cohorts combined with CyTOF were utilized to elucidate the mechanisms of tsMHC-II and CD4+ Trm cells in chemo-ICB. Co-culture of cell line, organoid, and T cell were used to investigate the regulatory factors of tsMHC-II. TMA and sc-RNA seq were used to explore the clinical significance, molecular characteristics of MHC-II+ tumor.
Results: The NeoTennis trial included eTNBC patients in a two-phase clinical trial involving anthracycline induction followed by sequential nab-paclitaxel and PD-1 inhibitor (Toripalimab). Analysis of baseline and anthracycline-induced biopsy samples using mIHC (Pan-CK, HLA-A, HLA-DR, CD4, CD8, CD69, Foxp3, T-bet) allowed for the clustering of patients based on MHC-I and MHC-II expression in the tumor epithelium, resulting in four subtypes. The ROC predictive model based on the outcomes and MHC subtypes was constructed to find that the MHC-I+ MHC-II+ subtype and tsMHC-II had the highest AUC scores (0.811 and 0.848, respectively), whereas the CPS was only 0.419. Meanwhile, tsMHC-II expression in the pCR group was significantly higher than in the Non-pCR group at baseline while MHC-I showed no difference. Spatial analysis revealed that CD69+CD4+ resident-memory T cells (Trm) had the strongest spatial association with MHC-II+ tumors, with this relationship being most prevalent in the pCR group. Dynamic analysis of changes before and after anthracycline showed that the proportion of MHC-II+ tumors and CD4+ Trm cells increased in the pCR group after treatment. In vivo models combined with CyTOF revealed that there was a significant increase in CD4+ Trm cells, Th1 cells, and iNOS+ macrophages in the tumor after anthracycline. After knocking out the MHC-II molecules in tumor cells, the anthracycline-induced increase in CD4+ Trm cells and Th1 cells was reduced, and the tumors grew faster than the control group. Conversely, when CD4+ T cells were depleted following doxorubicin-treated, the efficacy of sequential anti-PD1 was diminished. The above findings showed that anthracyclines could upregulate tsMHC-II, leading to the production of CD4+ Trm. Analysis of TMA from 300 cases in FDSCC and sc-RNA seq of TNBC confirmed that MHC-II+ TNBC was associated with an extremely good prognosis (HR=0.28, 95%CI=0.12-0.64; p=0.003), while 22.4% of TNBC patients had high tsMHC-II. Moreover, the tsMHC-II+ tumor cells exhibited upregulated IFN-gamma response. RNA-seq showed that patients resistant to anthracycline-induced MHC-II upregulation had highly active HDAC. In vitro, HDAC inhibitors (Entinostat) could upregulate MHC-II in TNBC cell line and PDOs, thereby promoting increased contact with CD4+ T cells. In vivo, combining anthracyclines with Entinostat increased the infiltration of CD4+ Trm cells, Th1 cells, and CD8+ T cells, and inhibited tumor proliferation, after which, sequential anti-PD1 therapy further inhibited tumor growth for a longer time.
Conclusion eTNBC patients with high tsMHC-II expression benefited from neoadjuvant anthracycline with sequential anti-PD1 ICB. Anthracyclines could promote the upregulation of tsMHC-II in tumor cells and induce the production of CD4+ Trm. For anthracyclines-resistant patients, combining neoadjuvant anthracycline with HDACi could significantly enhance the effectiveness of ICB.

PS12-05: PARP7 inhibition combined with radiotherapy overcomes ICI resistance in breast cancer

Lynn Lerner, Anna M. Goddard, Qinhong Wang, Kevin R. Mott, Charles M. Perou, Gaorav P. Gupta

Background: Radiotherapy (RT) has shown promise in overcoming immune checkpoint inhibitor (ICI) resistance in breast cancer preclinical models and early-stage clinical trials. However, RT/ICI synergy is not observed in all tumors and the induction of systemic anti-tumor (i.e., "abscopal") responses is relatively infrequent. The goal of this study was to identify targetable pathways that may guide patient selection and augment RT/ICI synergy by screening a panel of clinically representative breast cancer immune-competent mouse models. Our studies identify the mono-ADP-ribosyltransferase PARP7 as a biomarker of RT/ICI responsiveness that, when inhibited, results in significantly greater induction of interferon-stimulated genes (ISGs) and systemic anti-tumor immune responses.
Methods: We profiled four Trp53-/- breast cancer syngeneic allograft tumor models (2250L, 2208L, 2336R, 2225L) in vivo for RT/ICI abscopal effects. Female BALB/c mice were bilaterally injected in the fourth mammary fat pad with tumor cells. Treatment began once the tumor reached 6mm, with mice being randomly divided into 4 groups: non-treated (NT), RT (3 x 8Gy), ICI (anti-PD-1, anti-CTLA4, both at 10mg/kg, 2x/week), and RT+ICI. RT was administered only to the left tumor and abscopal effects were based on measurement of the contralateral tumor relative to NT animals on day 10 after treatment initiation. Additional treatment arms were added for 2250L tumor: PARP7i (RBN-2397, 30mg/kg, daily for 10 days), RT+PARP7i, ICI+PARP7i, and RT+ICI+PARP7i. mRNA-sequencing was performed on the four syngeneic NT tumor models or 48h after treatment with RT (8Gy) +/- PARP1/2i (Olaparib, 1uM), using Illumina TruSeq stranded mRNA library prep on a NextSeq2000. DESeq2 was used for differential gene expression analysis of normalized read counts. A panel of three human (MDA-MB-231, MDA-MB-436, and MCF7) and six murine breast cancer models (2250L, 2336R, 2208L, 2225L, EO771, and mWnt) were profiled in vitro for ISG expression 48hr following treatment with RT (8Gy) +/- PARP7i (RBN-2397, 50nM) using RT-qPCR. Cells were transfected with synthetic nucleic acids using lipofectamine 3000 and RNA was isolated 6h post treatment for RT-qPCR. Statistical comparisons used two-tailed t-tests with a $p<0.05$ significance threshold.
Results: All four syngeneic breast cancer models were ICI resistant, and only two demonstrated abscopal response when treated with RT/ICI (2250L, 2208L). RNA-sequencing of NT and RT samples identified genes in the PARP family as being significantly upregulated between abscopal responding models (2250L, 2208L) and non-abscopal models (2336R, 2225L), with PARP7 being uniformly higher expressed among the abscopal competent lines ($p <0.000001$). RT+PARP7i induced significantly greater IFNB1 levels compared to RT+PARP1/2i in 2250L cells (85-fold vs 6-fold, $p<0.0001$). Synergistic induction of ISGs by RT+PARP7i was observed across the panel of human and murine models (response additivity scores of 1.38-12.94). PARP7i enhanced IFNB1 induction in response to both ISD90 and poly(I:C) suggesting that PARP7 suppresses both RNA- and DNA- sensing pathways. In vivo, RT+ICI+PARP7i can overcome ICI resistance and induce a

systemic immune response in the 2250L model, resulting in significantly smaller contralateral tumors compared to RT+ICI alone (p=.0483).
Conclusion: Breast cancers that express PARP7 may be targetable with PARP7i in combination with RT/ICI to enhance ISG expression in the tumor microenvironment and overcome ICI resistance. Future studies will characterize the mechanism of this effect and its potential clinical translation.

PS12-06: An In Situ Tumor Vaccine Against Triple Negative Breast Cancer

Nicole McCuen, Chantal Vidal, SM Nashir Udden, Prasanna Alluri

Objective: Immunotherapies offer limited clinical benefit as a monotherapy in triple negative breast cancer (TNBC) and require the addition of cytotoxic chemotherapy to improve responses in patients. Resulting from the Keynote-522 clinical trial, the current standard-of-care chemo-immunotherapy regimen for localized TNBC patients causes Grade 3 or higher toxicity in 76% of patients with chemotherapy contributing to over 90% of the observed toxicity. Therefore, there is an urgent need to develop novel chemotherapy-free immunotherapy regimens with superior tumor control and minimal toxicity. Although radiation therapy (RT) has traditionally been used as an adjuvant local treatment, in rare cases it can serve as an in situ tumor vaccine by eliciting a systemic anti-tumor immune response through the “abscopal” effect. The goal of this study is to identify novel RT and targeted therapy combinations that serve as a potent anti-tumor vaccine in TNBC patients with minimal toxicity. Methods: A 4T1 syngeneic, orthotopic mouse model of TNBC was used to screen a library of 19 epigenetic drugs in combination with tumor-directed RT in vivo. The efficacy of OTX015, the top hit from the screen, in combination with RT was validated and compared to each treatment component alone and a chemo-immunotherapy regimen of doxorubicin + paclitaxel + PD1 inhibition. Tumor-free mice following treatment were administered a tumor re-challenge in the contralateral mammary fat pad to assess the development of tumor-specific immune memory. Cytotoxic T cell depletion studies were performed to establish the role of CD8+ T cells in mediating the effects of the RT + OTX015. Results: We identified OTX015, a bromodomain and extraterminal domain (BET) inhibitor, as the top hit in our in vivo drug screen. RT (8 Gy x 2 on days 2 and 4) + OTX015 (100 mg/kg by oral gavage on days 1-4) promoted significant tumor control relative to vehicle ($p < 0.0001$), OTX015 alone ($p < 0.0001$), RT alone ($p = 0.0015$) and the chemo-immunotherapy regimen ($p = 0.0129$). 2/8 mice treated with RT + OTX015 not only showed complete tumor regression but also resisted tumor re-challenge. Mice treated with RT + OTX015 also exhibited significant reduction in metastatic burden. CD8+ T cell depletion abrogated both the local and systemic tumor control afforded by RT + OTX015. Conclusions: Using an in vivo drug screen, we identified that a short course of tumor-directed RT in combination with pharmacological BET inhibition serves as an in situ tumor vaccine. Our results support that RT + OTX015 offers superior tumor control relative to the current standard-of-care chemo-immunotherapy regimen and elicits immunological memory in a cytotoxic T cell dependent fashion in a pre-clinical model of TNBC.

PS12-07: DNA methyltransferase 3A (DNMT3A) protein expression in triple-negative breast cancer (TNBC): Impact on clinical outcomes, gene expression, and tumor microenvironment

Roberto Leon-Ferre, David M Zahrieh, Sarah K Reed, Jodi M Carter, Saba Yasir, David Hillman, Judy C Boughey, Krishna Kalari, Peter C Lucas, Saranya Chumsri, Jennifer M Kachergus, Yi Liu, E. Aubrey Thompson, Harry D Bear, Fergus J Couch, James N Ingle, Liewei Wang, Matthew P Goetz

Background: Given the heterogeneity of TNBC, identification of biologically and clinically distinct TNBC subtypes with unique therapeutic vulnerabilities is critically needed. Preclinically, DNMT3A protein expression is predictive of sensitivity to DNMT inhibitors (DNMTi). Additionally, treatment with DNMTi enhances antitumor immune responses. Ongoing (NCT05673200) and completed (NCT02957968) trials are evaluating the addition of DNMTi to chemoimmunotherapy for TNBC. However, it is unknown whether DNMT3A expression is associated with distinct TNBC biology or clinical outcomes.
Methods: We measured DNMT3A protein using immunohistochemistry in early-stage TNBC tumors and evaluated its association with clinicopathologic characteristics, gene expression (RNASeq), spatial tumor immune microenvironment features (52 proteins using Nanostring GeoMx® Digital Spatial Profiler [DSP]), and recurrence-free survival (RFS). DNMT3A expression was categorized as negative (no staining) or positive (high: moderate/strong staining in >25% of nuclei; low/intermediate: weak staining in any % nuclei or moderate/strong staining in ≤25% of nuclei).
Results: Among 345 patients, the median age was 54 years; most tumors were > 2 cm (53%) and N0 (62%). 281 (81%) were DNMT3A+ (high: 127 [37%], low/intermediate: 154 [45%]). DNMT3A+ TNBC were more often grade 3 (94% vs 86%, p = 0.037), with Ki-67 >15% (85% vs 67%, p = 0.002), and N+ (40% vs 26%, p= 0.043). There were no differences in age, menopausal status, tumor size, PD-L1 or stromal tumor-infiltrating lymphocytes (sTILs) between DNMT3A+ or DNMT3A- TNBC. To assess the impact of DNMT3A on the natural history of early TNBC, we focused our survival analyses on a subset of 103 (30%) patients who did not receive systemic therapy. DNMT3A expression was associated with worse RFS on a multivariable model adjusting for tumor size, nodal status, and sTILs (aHR 4.6, 95% CI 1.05-19.96, p=0.043; univariable results: HR 3.3; 95% CI: 0.79, 13.99; p = 0.102). The 5-year RFS (95% CI) of DNMT3A+ TNBC without chemotherapy was 66% (53-76), compared with 93% (59-99) for DNMT3A- TNBC. While TNBC with sTILs ≥ 30% had favorable 5-year RFS regardless of DNMT3A expression (86% DNMT3A+ vs 100% DNMT3A-), TNBC with sTILs <30% had particularly poor outcomes when also expressing DNMT3A (5y RFS 54% [38-67] for sTIL low and DNMT3A+ TNBC vs 90% [47-99] for sTIL low and DNMT3A- TNBC). RNA-Seq data (available for 154 [63%] of 345 tumors, regardless of receipt of chemotherapy) revealed differential expression of 234 genes between DNMT3A+ (n=126) and DNMT3A- (n=28) TNBC (e.g. MUC19, CEACAM5, and ZNF606, among others). GeoMx® DSP data (available for 289 [84%] tumors) showed that DNMT3A+ TNBC exhibited lower expression of CD3, CD4, CD8 (T cells) and granzyme B in the tumor compartment; lower expression of HLA-DR (antigen presentation), CD56 (NK cell), FAP

alpha, SMA (fibroblasts) and CTLA4 (immune checkpoint) in the stromal compartment; and lower expression of CD127 (memory T cell), CD11c, CD14, CD68 (myeloid/macrophages), CD34 (stem cell), EpCAM and PanCK (epithelium), fibronectin (extracellular matrix) and TIM3 (immune checkpoint) in both the tumor and stromal compartments. Expression of Ki-67 was higher in both the tumor and stromal compartments of DNMT3A+ TNBC.
Conclusions: DNMT3A expression was associated with worse clinical outcomes in TNBC (particularly in sTIL-low tumors), higher tumor proliferation, and diverging gene expression and tumor immune microenvironment profiles. While no differences in sTILs were noted by H&E quantification according to DNMT3A status, GeoMX DSP analyses revealed an immunosuppressed tumor and stromal microenvironment in DNMT3A+ tumors, characterized by decreased T, NK, myeloid, and antigen presentation markers. These data support targeting DNMT along with immunotherapy in DNMT3A+ TNBC as is currently being evaluated in NCT05673200.

PS12-08: Biological sex-linked immune modulation but not cross-sex estrogen therapy reduces the efficacy of PARP inhibition in the treatment of Brca1 breast tumors.

Jan Heng, Lin Wang, Abhishek Thavamani, Erica S. Massicott, Brian R. Sardella, Vanessa C. Bret-Mounet, Zhaoji Liu, Steven R. Vandal, Emily K. Aronson, Gabrielle M. Baker, John G. Clohessy, Gerburg M. Wulf

Background: Breast cancer (BC) treatment for trans feminine individuals is complicated by their use of gender-affirming estrogen therapy (ET). There is no clinical guideline to manage ET during BC treatment in these medically underserved patients. It is unknown whether continuing ET during BC treatment affects a successful outcome. We used a preclinical model to study the response of Brca1mut breast tumor to a PARP-inhibitor, in the presence of ET.
Method: Tumor survival study using immune competent FVB/NJ mice was conducted by implanting fragments of K14-Cre Brca1f/fp53f/f tumors into female (n=45), male (n=28), and male mice receiving 60 µg of weekly subcutaneous ET (n=44). When the tumor reached 5 mm, male mice receiving ET were first randomized to stop or continue ET, then mice in each arm were randomized to be treated with a PARP inhibitor (olaparib) or were left untreated until study endpoint where the tumor reached 20 mm. A 10-day study in FVB/NJ mice was set up with the same eight arms as above (n=5/arm) whereby tumors were harvested after 10 days of olaparib treatment for RNASeq. Finally, to test the hypothesis that the male immune system modulated PARP inhibition, we conducted a six-arm tumor survival study in immune deficient NSG mice (n=15/arm): female+olaparib, female, male+olaparib, male, male+continued ET+olaparib, male+ continued ET. Log-rank test was used to compare tumor-specific survival. Differential gene expression was analyzed using limma. Gene set enrichment was conducted using mouse Hallmark gene sets and Camera.
Results: Only arms treated with olaparib were reported here. In the tumor survival study using FVB/NJ mice, females had the longest median survival time of 103 days. Males had

significantly a shorter survival than females (75 days, p=0.02). Males that stopped ET had significantly shorter survival (38.5 days) than females (p=0.003) and males (p=0.004). Males that continued ET also had shorter survival (50 days) than females (p=0.001) and males (p=0.16). There was no difference between males that stopped and continued ET (p=0.56). There was no survival difference between untreated study arms (median 14 to 19 days; p>0.05).
No gene was differentially expressed between FVB/NJ male and female mice at FDR<0.05. Interferon alpha and gamma response gene sets were significantly upregulated in males compared to females while six gene sets (xenobiotic metabolism, bile acid metabolism, heme metabolism, reactive oxygen species, peroxisomes, and adipogenesis) were significantly downregulated (FDR<0.05). Tumors from males that continued ET were significantly upregulated for proliferative gene sets—G2M checkpoint, E2F targets, MYC targets, and mitotic spindle—compared to males, males that stopped ET, and females (FDR<0.05). Tumors from males that stopped ET showed decreased proliferation and increased inflammatory responses when compared to males, males that continued ET, and females (19 to 23 significantly enriched gene sets; FDR<0.05).
The differences in tumor-specific survival previously observed in FVB/NJ mice were ablated in NSG mice. There was no difference between NSG females, males, and males that continued ET (median 69 days, all p>0.05).
Conclusion: Male mice have poorer outcomes with PARP-inhibition than females, irrespective of cross-sex hormone treatment. Our survival study and transcriptomic data in immune competent mice suggested that although ET had profound molecular effects in the tumors, ET-modulated effects were not as strong as the effect of biological sex on olaparib efficacy. Our study in immune deficient mice confirmed that the male innate immune system played a major role in conferring poorer response to PARP-inhibition in males.

PS12-09: Neoadjuvant pembrolizumab or placebo plus chemotherapy followed by adjuvant pembrolizumab or placebo for high-risk, early-stage triple-negative breast cancer: Overall survival and subgroup results from the phase 3 KEYNOTE-522 study

Rebecca Dent, P. Schmid, J. Cortés, H. McArthur, L. Pusztai, S. Kuemmel, C. Denkert, Y.H. Park, R. Hui, N. Harbeck, M. Takahashi, S.-A. Im, M. Untch, P.A. Fasching, M.-A. Mouret-Reynier, T. Foukakis, M. Ferreira, F. Cardoso, Y. Ding, C. Pinheiro, J. Mejia, J. O'Shaughnessy

Background: In the phase 3 KEYNOTE-522 study (NCT03036488), neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab showed statistically significant and clinically meaningful improvements in the dual primary endpoints of pathological complete response and event-free survival versus neoadjuvant placebo + chemotherapy followed by adjuvant placebo in patients with high-risk, early-stage triple-negative breast cancer (TNBC). At the prespecified analysis of the key secondary endpoint of overall survival (OS) (data cutoff, 22 Mar 2024), the hazard ratio (HR) for OS favored pembrolizumab (0.66 [95% CI], 0.50-0.87; P=0.0015). KEYNOTE-522 met the success

criterion for OS, with a P value that crossed the prespecified significance boundary of 0.00503. Here, we present OS results in key prespecified subgroups, including patients by residual cancer burden (RCB) categories. Post-hoc analyses of OS in patients with T2N0 disease at baseline are also provided.
Methods: Eligible patients with previously untreated, nonmetastatic, centrally confirmed TNBC (stage T1c N1-2 or T2-4 N0-2 per American Joint Committee on Cancer) were randomized 2:1 to neoadjuvant pembrolizumab 200 mg Q3W or placebo, both given with 4 cycles of paclitaxel + carboplatin, followed by 4 cycles of doxorubicin or epirubicin + cyclophosphamide. After definitive surgery, patients received adjuvant pembrolizumab or placebo for 9 cycles or until recurrence or unacceptable toxicity. The Kaplan-Meier method was used to estimate the subgroups for OS. HRs (95% CIs) for OS subgroups were based on the Cox regression model with Efron's method of tie handling with treatment as a covariate. RCB was assessed by the local pathologist at the time of definitive surgery.
Results: 1174 patients were randomized to pembrolizumab (n=784) or placebo (n=390). At the prespecified data cutoff for OS (22 Mar 2024), median follow-up (range) was 75.1 (65.9-84.0) months. In patients with baseline T2N0 disease (pembrolizumab, n=315; placebo, n=159), deaths occurred in 24 (7.6%) patients in the pembrolizumab group and 23 (14.5%) patients in the placebo group (HR, 0.51 [95% CI, 0.29-0.90]). OS rates (95% CIs) at 5 years were 93.3% (89.9%-95.6%) vs 89.2% (83.2%-93.1%), respectively. RCB rates were 63.5% in the pembrolizumab group vs 56.2% in the placebo group for RCB-0, 8.8% vs 11.5% for RCB-1, 18.4% vs 20.3% for RCB-2, and 5.1% vs 6.7% for RCB-3. Deaths occurred in 26/498 (5.2%) patients in the pembrolizumab group vs 17/219 (7.8%) patients in the placebo group in the RCB-0 subgroup (HR, 0.66 [95% CI, 0.36-1.23]), 10/69 (14.5%) vs 5/45 (11.1%) patients in the RCB-1 subgroup (HR, 1.35 [95% CI, 0.46-3.96]), 35/144 (24.3%) vs 35/79 (44.3%) patients in the RCB-2 subgroup (HR, 0.50 [95% CI, 0.31-0.80]), and 27/40 (67.5%) vs 16/26 (61.5%) patients in the RCB-3 subgroup (HR, 1.26 [95% CI, 0.68-2.34]). OS in subgroups based on PD-L1 combined positive score will be included in the presentation.
Conclusions: In patients with high-risk early-stage TNBC, neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab showed clinically meaningful improvements in OS compared with neoadjuvant chemotherapy alone, with the highest survival benefit observed in patients with the least RCB.

PS13-01: Evaluation of breast cancer stem cell gene expression signatures in single-cell RNA sequencing (scRNAseq) data from the OPPORTUNE and FELINE trials, and the association with treatment resistance

Peter Hall,Alejandro Chibly, Peter Schmid, Sarah E Pinder, Arnie Purushotham, Alastair Thompson, Steven Gendreau

Background: Cancer stem cells (CSCs) play a key role in tumor initiation, progression, and resistance to conventional therapies. These cells possess the ability to self-renew and differentiate, contributing to tumor heterogeneity and recurrence. Preclinical data indicate

that targeting cancer stem cell-specific pathways could lead to more effective treatments and prevent relapse, thereby improving outcomes. However, there is limited clinical data to support this, in part due to the challenges of measuring CSCs in the clinical setting. Single-cell RNA sequencing (scRNAseq) data in combination with stemness gene expression signatures were investigated as a novel approach to detect and assess changes in CSC numbers in response to treatment.
Methods: Single-cell RNAseq datasets from two clinical trials were interrogated – OPPORTUNE, a window-of-opportunity trial evaluating anastrozole vs anastrozole plus pictilisib (PI3K inhibitor) in 75 patients with ER+ HER2- early breast cancer, and FELINE, a neoadjuvant trial which compared letrozole plus placebo with letrozole plus ribociclib (CDK4/6 inhibitor) in 120 patients with ER+ HER2- early breast cancer. The primary endpoint for OPPORTUNE was the inhibition of tumor cell proliferation as measured by Ki67. The primary endpoint for FELINE was the rate of preoperative endocrine prognostic index (PEPI) score 0 after neoadjuvant endocrine therapy. Thirty-four patients from the FELINE study had available scRNAseq data for analysis; this number was 62 patients for the OPPORTUNE study. Stemness gene expression signatures with published evidence of selectivity for breast CSCs were identified from the literature and their utility in detecting CSCs compared in the datasets. Subsequently, changes in CSC fraction with treatment was assessed.
Results: Eight different stemness gene signatures were identified from the published literature. Among these, four (Kim_myc, benporath_es2, Bhattacharya_hESC, and Shats_consensus) exhibited selective expression in a minority of tumor cells, with the Shats consensus signature demonstrating the highest specificity to tumor cells over non-malignant cells. Utilizing a Gaussian mixture model, we estimated that approximately 4.5% of cells within a tumor are likely stem cells. In the OPPORTUNE study, higher stemness scores were observed in luminal B compared to luminal A tumors, but there was no association with PIK3CA mutation status. Changes to Ki67 were inversely associated with the CSC fraction – tumors with higher stemness scores were less likely to achieve a complete cell cycle arrest versus endocrine-sensitive tumors. Similarly, in the FELINE trial, non-responders in the letrozole arm showed a trend towards elevated stemness scores.
Conclusion: The use of stemness gene expression signatures in scRNAseq data is a feasible method to assess changes in putative CSC fraction with treatment in breast cancer. Increased stemness scores were associated with more aggressive subtypes and resistance to treatment.

PS13-03: Decoupling of oestrogen response and proliferation in post-menopausal ER+ HER2- primary breast cancer after 2-week aromatase inhibitor treatment in the POETIC trial

Istvan T. Kleijn, Eugene F. Schuster, Anastasia Alataki, Holly Tovey, Elena López-Knowles, Lucy Kilburn, John Robertson, Ian Smith, Maggie Chon U Cheang, Judith M. Bliss, Mitch Dowsett, Nicholas C. Turner, and Stephen Johnston

Background: Aromatase inhibitor (AI) treatment is well established and highly effective in early ER+ HER2- breast cancer (BC), but recurrence eventually develops in ~20% of patients. The PeriOperative Endocrine Therapy for Individualizing Care (POETIC) trial demonstrated that high levels of the proliferation marker Ki67 maintained after a 2-week neoadjuvant AI treatment were associated with increased risk of recurrence. We conducted bulk and spatial transcriptomics analyses to identify the tumour features that associated with poor response to AI treatment.

Methods: We analysed ER+ HER2- tumours from the POETIC trial. Included were 177 poor responders (PRs) to AI treatment corresponding to the bottom 15% Ki67 change, 190 good responders (GRs) taken from the top 50% Ki67 changes and matched to PRs for baseline Ki67 scores, and 20 untreated controls. PRs were split into 119 ESR1-high and 58 ESR1-low patients based on baseline ESR1 expression.
Bulk RNA-seq was used to determine PAM50 intrinsic subtypes. Differential expression (DE) and gene set enrichment analysis (GSEA) was performed between paired baseline and surgery samples in the three responder groups, separately for core and excision samples at surgery. DE significance was tested against a 0.1 fold change (FC) threshold and defined as padj < 0.05. The effect size of oestrogen (PGR, TFF1, GREB1 and PDZK1) and proliferation (18 genes from PAM50) responses was quantified by their mean log2 FC.
Spatial transcriptomics analysis was performed on a subset of 12 paired samples that passed quality control. Robust cell type deconvolution with the single cell BC atlas was used to define regions of stromal and tumour-rich content. Spots were clustered using a spatially aware algorithm and copy number alteration (CNA) was inferred in tumour-rich regions against a stromal reference.

Results: Broad DE was seen in response to 2-week AI treatment in GRs (4105 genes in tumours with surgical core-cuts) and PRs, ESR1-high (534 genes), but not in PRs, ESR1-low (5 genes). E2F targets and oestrogen response early hallmark genes were significantly repressed in both GRs (padj < 2.2e-16 for both) and PRs, ESR1-high (padj < 2.2e-16 and padj = 4.3e-14) relative to PRs, ESR1-low according to GSEA. However, the effect size in GRs was similar for both oestrogen response (-2.56 mean log2 FC) and proliferation genes (-2.44), but discordant in PRs ESR1-high (oestrogen response -1.93; proliferation -0.47).
As previously shown, baseline distributions of PAM50 subtypes were similar between GRs and PRs, ESR1-high. However, the number of non-LumAs switching to LumA was significantly different between the two (p < 2.2e-16; Fisher exact). In GRs 98% (118/121) of non-LumAs switched to LumA after treatment whereas only 33% (27/82) did so in PRs ESR1-high. The majority of PRs ESR1-low exhibited Basal subtype both before (~62%, 36/58) and after (~60%, 35) treatment; only 4% (2/54) of non-LumAs switched to LumA.
Spatial gene expression analysis showed substantial evidence of heterogeneity. CNA differences were found between surgery and baseline samples in 8/12 tumours. In 2 of the 8, there were >5 spatially distinct subclones across both cores. Differences in expression of oestrogen signalling and proliferation between two tumour regions in a single core were

observed in multiple tumours both with and without corresponding CNA differences.

Discussion: In PR ESR1-high tumours, AI therapy is associated with suppressed oestrogen signalling without a corresponding antiproliferative response, suggesting a decoupling of oestrogen response and proliferation in these tumours. Spatial analysis reveals frequent gene expression and copy number heterogeneity in ER+ HER2- BC. Work aiming to quantify gene expression differences between subclones is ongoing.

PS13-04: DREAM complex assembly and stable cell cycle control underlies long-term clinical response to CDK4/6 inhibition

Rei Kudo, Anton Safonov, Enrico Moiso, Catherine Jones, Hong Shao, Sharanya Nag, Selma Yeni Yildirim, Edaise M. da Silva, Qing Li, Marie Will, Atsushi Fushimi, Harikrishna Nakshatri, Andrew Koff, Britta Weigelt, Qamar J. Khan, Pedram Razavi, Sarat Chandarlapaty

Background: Combinations of endocrine therapy and CDK4/6 inhibitors (CDK4/6i) used in metastatic breast cancer (MBC) result in heterogenous clinical benefit with subsets of patients having disease control ranging anywhere from a few months to more than 5 years. Understanding the mechanisms that account for these differences can enable new pharmacologic approaches to convert more of these cancers into the long-term control subset.
Methods: To elucidate the causal factors that underlie the observed clinical variability, we have utilized multi-omic analyses of patient samples as well as experimental modeling using a diverse cohort of ER+ breast cancers. For clinicogenomic analyses, we analyzed 467 patients with ER+/ HER2- MBC treated with first-line CDK4/6i at our institution (MSK) with detailed clinical follow annotation and follow up. For genomic/transcriptomic studies, we analyzed single cell RNA sequencing data, whole genome sequencing data, and Ki67 score from the neoadjuvant CDK4/6i containing arms in the FELINE trial (NCT02712723). Patient derived xenografts, patient derived organoids, isogenic cell lines were used to define the underlying mechanisms. Live cell imaging assays were performed by FUCCI cell cycle sensor to assess cell cycle transitions.
Results: Of 467 patients from MSK cohort, 129 (27.6%) had pre-CDK4/6i loss-of-function variants in TP53, corresponding to short PFS (median PFS= 8.7 months, 95% CI: 6.6–10.3; HR = 2.12, 95% CI: 1.68 to 2.68; p = 2.64e-10). This finding was validated in two large independent clinical cohorts outside MSK. In patient derived and isogenic cell lines, p53 loss had no impact on initial drug response but promoted long-term cell outgrowth and prevented emergence of senescence phenotypes. Following cells in detailed time courses revealed the propensity of p53 mutant but not wild type cells to reenter the cell cycle after initial arrest by CDK4/6 inhibition. Gene expression analysis of RNA seq data revealed a significant positive association between TP53 mutation status and DREAM complex genes, assessed by GSEA (NES= 1.51, p = 1e-4)
In models, deletion of DREAM complex component, p130-Rbl2 was found to fully recapitulate the effects of p53 loss: promoting long-term outgrowth from CDK4/6i, blocking

therapy induced senescence, and promoting cell cycle re-entry. To validate these results, we analyzed the multi-omic and histologic characteristics of serial samples from the FELINE trial. Compared with WT cases, baseline TP53 LOF had a higher amount of proliferating cells at the end of treatment, measured by Ki67 > 10% (4.5% of WT cases vs. 60% of mutant cases, respectively, OR = 26.8, p = 0.014), the per cell proliferation score, measured by ssGSEA (log2FC: 0.2 vs. 2.8, respectively) as well as a higher pseudobulk expression of DREAM complex related genes (GSEA: NES = 2.0, q = 3.7e-4).
Finally, to identify strategies that might facilitate stable cell cycle control of p53KO tumors, we investigated which targets of p53 regulate DREAM and identified p21. Given role of p21 in regulating both CDK4/6 and CDK2 we investigated whether CDK2 inhibitors would provide additional benefit to CDK4/6i. Addition of CDK2i was able to fully restore efficacy in p53KO lines as well as a patient derived model with TP53 mutation enabling irreversible cell cycle arrest and long-term growth suppression.
Conclusion: Wild type p53 facilitates DREAM complex assembly in response to CDK4/6i in ER+ breast cancer, underlying long-term disease control. p53 loss enables cells to reenter the cell cycle and facilitates the development of CDK4/6i resistance. Combined inhibition of CDK2 with CDK4/6 represents a promising therapeutic strategy for overcoming loss of p53 and enabling long-term antitumor efficacy.

PS13-05: The UNDERSTAND trial: a multi-omic platform for investigating CDK4/6 inhibitors resistance mechanisms in HR+ advanced breast cancer

Andrea Vingiani, A. Belfiore, T. Torelli, D. Stetco, F. Ligorio, E. Minna, A. Bertolotti, S. Brich, A. Piccolo, E. Conca, E. Tamborini, F. Perrone, A. Busico, I. Capone, C. Sposetti, G. Scaperrotta, C. Depretto, R. Lanocita, D. Lorenzini L. Provenzano, G. Mazzoli, G. Fotia, I. Maugeri, C. Ferraris, S. Folli, G. Bianchi, F. Ravera, M. Dameri, L. Agnelli, L. Ferrando, G. Zoppoli, L. Magnani, C. Vernieri, G. Pruneri

Introduction: Hormone receptor-positive, HER2-negative metastatic breast cancer (HR+/HER2- mBC) is an almost invariably incurable disease. Endocrine therapy plus CDK4/6 inhibitors (ET+CDK4/6i) represents the standard-of-care for 1st line treatment. However, primary or acquired resistance leads to tumor progression in most patients, and there is therefore an unmet need to unravel mechanisms of resistance and actionable targets in patients progressing upon CDK4/6i. To date, genomic studies pinpointed several putative resistance biomarkers. including alterations in ESR1, PIK3CA, FGFR1, TP53, RB1, KRAS, HRAS, NRAS, AURKA, AKT1, FGFR2, and CCNE2 genes. However, genomics can only partially explain resistance to CDK4/6i in HR+/HER2- mBC patients, while a combined analysis of genomic, transcriptomic and epigenetic profiles could potentially provide a more accurate characterization of primary and acquired resistance mechanisms. In this scenario, in June 2022 we launched the UNDERSTAND trial, an observational, open-label study aimed at identifying markers of resistance and tracing cancer cell evolution by sequential multi-omic analysis, in prospectively collected tissue and plasma samples from 100 HR+/HER2-

mBC patients undergoing 1st line ET+CDK4/6i.

Methods: The trial plans to collect tumor tissue at baseline (T0, prior to ET+CDK4/6i) and at disease progression (T1) in patients with accessible metastatic sites (cohort A) to longitudinally obtain genomic (FFPE), methylomic (fresh/frozen), bulk transcriptomic (fresh/frozen), single cell RNAseq (fresh tissue) and spatial transcriptomic (FFPE) data. If tumor biopsy would not feasible (bone-only disease, refusal of the biopsy procedure, lack of accessible tumor sites), blood samples will be prospectively collected at baseline, after 15 days of treatment, 3-months, 1-year or at tumor progression, for circulating methylome and ctDNA analysis (cohort B). Blood samples will be collected in cohort A patients as well. A dedicated electronic clinical record was set up with REDCap to collect demographic, clinical and sample information.

Results: Between January 2022 and July 2024, we enrolled 56 patients with HR+/HER2- advanced breast cancer. Multiple plasma samples were longitudinally collected (cohort A + B). We were able to collect baseline tumor tissue in 20 patients, including 3 relapses (cohort A). T0 samples were genomically characterized with the Illumina TSO500 NGS panel. scRNAseq data were obtained from 14 samples (ChromiumX platform, 10X Genomics), including 7 nodal, 4 liver and 3 local relapses. After stringent quality controls, we identified and annotated 90.000 high quality (mean: 6400 cells per sample), including 43000 neoplastic cells, as well as T cells, B cells, plasma cells, mast cells, myeloid cells, endothelial cells, perycites, fibroblasts and liver cells. Intra- and inter-tumor heterogeneity was investigated, and the PAM50 classifier was used, highlighting a site-specific variability of molecular subtype proportion. Exploratory case-control analysis on patients with early (<6 months) and late (>12 months) relapses confirmed the role of PIK3CA and MAPK pathway activation in therapy resistance, identifying neoplastic cells as the primary contributors. Additionally, other pathways, such as WNT, NF-κB, and JAK/STAT, were implicated in resistance, suggesting areas for further investigation. For the upcoming SABCS, we plan to analyze and present the complete results of translational analyses on matched T0/T1 tissue samples from 30 patients, including genomic profiling, bulk and scRNA sequencing data.

Conclusions: Our highly integrated infrastructure allows us to collect and integrate unprecedented longitudinal multiomic molecular data from HR+/HER2- mBC patients. A combination of genomic, transcriptomic, and epigenetic analyses will provide a more accurate characterization of primary and acquired resistance mechanisms to CDK4/6i.

PS13-07: Enhancing T-DXd Efficacy in HER2-positive Breast Cancer Resistant to HER2 ADC by Non-biased Kinase-related Target Screening

Jangsoon Lee, Kumiko Kida, JiwonKoh, Huey Liu, GanirajuC. Manyam, Young JinGi, Dileep Reddy, Asha S. Multani, Jing Wang, Gitanjali Jayachandran, Dae-Won Lee, James M. Reuben, AysegulSahin, Lei Huo, DebuTripathy, Seock-Ah Im, and Naoto T. Ueno

Background: Anti-HER2 antibody-drug conjugate (HER2-ADC) therapies, such as trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd), significantly prolong survival in patients with HER2-positive metastatic breast cancer (BC) compared to physician's choice of chemotherapy with trastuzumab (The EMILIA, TH3RESA, and DESTINY-Breast clinical trials). Intrinsic or acquired resistance to HER2-ADC therapies remains a substantial clinical challenge since there is no established standard of care following progression on T-DXd. This study aimed to elucidate novel therapeutic targets that can overcome resistance to HER2-ADC therapies using unbiased approaches with synthetic lethal kinome RNA interference screening.
Methods: We conducted targeted DNA sequencing (n=15) and whole transcriptome sequencing (n=11) to investigate genetic aberrations following anti-HER2 and/or HER2-ADC therapy (T-DM1 or T-DXd) in BC patient tissue samples. We generated HER2-positive human BC cell lines resistant to T-DM1 or T-DXd. To determine the effect of the T-DM1 and T-DXd on the ERBB2 gene and HER2 protein expression, we used fluorescence in situ hybridization, droplet digital PCR, and Western blotting assay. To discern resistance mechanisms of T-DXd and identify kinase targets whose inhibition might synergistically enhance the efficacy of T-DXd, we conducted whole-genome sequencing, cDNA microarray analysis, and synthetic lethal kinome RNA interference screening using T-DXd resistant HER2-positive BC cell lines. To determine the synergistic antitumor effect of T-DXd combined with targeted therapy, we conducted Bliss synergy analysis, colony formation, and xenograft assays by mammary fat pad injection of T-DM1- or T-DXd-resistant BC cells in nude mice.
Results: Increased amplification of DNA repair-related genes (TOP2A, RAD21, RAD52, and CDK12) was found in patient tissue samples after progression to HER2 antibodies, T-DM1, or T-DXd. Significant enrichment of DNA damage repair-related gene sets was observed in the transcriptome of post-treatment human samples. Further, ERBB2 gene or HER2 protein expression was reduced compared to levels before such treatment. In HER2-ADC-resistant HER2-positive BC cell lines, we had similar upregulation of DNA repair-related genes (PCNA, ATM, RAD52) and reduction of ERBB2 gene and HER2 protein expression. By synthetic lethal kinome RNA interference screening, this non-bias screening identified the PI3 kinase, cell cycle, and DNA repair canonical pathways as potential targets to enhance the efficacy of T-DXd therapy in HER2-ADC–resistant HER2-positive BC. We confirmed that ectopic HER2 expression does not improve the efficacy of HER2 ADC in HER2-ADC–resistant HER2-positive BC. After further screening all potential targets, we found that the drugs targeting the DNA damage repair pathway were the most effective in enhancing the efficacy of T-DXd. Indeed, ATR inhibitor elimusertib led to significant HER2-ADC–resistant BC cell death in vitro (Bliss synergy score >5.0, $P<0.01$) and in four xenografts in vivo ($P<0.01$) compared to cell death with T-DXd alone. Importantly, we further observed the synergy of elimusertib and T-DXd in parental HER2-positive BC cell lines, ensuring the observed effects are not limited to resistant cell lines only.
Conclusions: Our findings indicate that resistance to HER2-ADC therapies is associated with increased DNA repair-related genes. By non-biased screening, this study provides robust evidence that targeting DNA repair pathways can significantly enhance the efficacy of T-DXd

in HER2-ADC-resistant HER2-positive BC. The potential of combining ATR inhibitors with T-DXd to overcome resistance and improve patient outcomes is a promising avenue that warrants further exploration in a clinical trial for patients with HER2-ADC-resistant- HER2-positive BC.

PS13-08: ARID1A as a Novel Regulator of Trop2-ADC Efficacy in Trop2-Low Hormone Receptor–Positive Breast Cancer

Nanae Ogata, Nakyung Oh, Dileep R. Reddy, Lan Vo, Naoto T. Ueno, Jangsoon Lee

Background: The Phase 3 TROPiCS-02 study found that the efficacy of sacituzumab govitecan (SG), an antibody-drug conjugate (ADC) directed to tumor-associated calcium signal transducer 2 (Trop2), in breast cancer (BC) does not depend on Trop2 expression levels. SG is the only FDA-approved ADC for advanced HR+/HER2− BC and triple-negative BC; it targets Trop2 by delivering SN-38, a topoisomerase I inhibitor. AT-rich interactive domain–containing protein 1A (ARID1A) is the most prevalent mutation in the SWItch/Sucrose Non-Fermentable (SWI/SNF) complexes in metastatic BC. ARID1A interacts with transcription factors involved in gene transcription and DNA repair, acting as a tumor suppressor. It is essential for maintaining luminal characteristics and influences treatment response. Patients with tumors harboring ARID1A alterations experience significantly shorter progression-free survival on selective estrogen receptor degraders than those with tumors with wild-type ARID1A. We hypothesize that loss or suppression of ARID1A expression results in a high level of Trop2 expression in HR+/HER2− BC. Identifying the mechanism linking ARID1A and Trop2, as well as determining the presence or absence of ARID1A mutations, could help identify patient groups that may benefit from combination therapy with SG and other inhibitors, enhancing treatment efficacy even in those with ARID1A mutations.
Methods: We used transposase-accessible chromatin sequencing (ATAC-seq) and an RNA-seq database (GSE124228) from ARID1A-knockout MCF7 cells to determine whether ARID1A regulates Trop2 gene transcription. To elucidate how SG regulates the ARID1A-Trop2 axis in HR+/HER2− BC, we used specific small-molecule inhibitors, siRNA, and an expression plasmid targeting ARID1A. Target proteins in the ARID1A-Trop2 axis were detected with immunofluorescence staining, immunohistochemistry, flow cytometry, Western blotting, quantitative real-time PCR, and the TCGA database.
Results: ARID1A protein expression negatively correlated with Trop2 expression in HR+/HER2− BC cell lines. Through Ataxia-Telangiectasia Mutated (ATM), the protein kinase critical for the cellular response to DNA damage activation, SG or SN-38 reduces ARID1A protein expression in HR+/HER2− BC cells. Further, ARID1A expression is diminished in tissue samples from SG-treated MCF7 xenografts resistant to both tamoxifen and abemaciclib. Mechanistic studies showed that overexpression of ARID1A reduces Trop2 mRNA and protein expression, whereas ARID1A knockdown elevates Trop2 levels in HR+/HER2− BC cells. Immunofluorescence staining data indicated an inverse correlation between ARID1A expression and Trop2 expression. ATAC-seq data revealed increased

chromatin accessibility at the Trop2 promoter in ARID1A-knockout MCF7 cells. T47D cells, which exemplify low ARID1A and high Trop2 expression, are approximately ten times more sensitive to SG than MCF7 and HCC1428 cells, which have high ARID1A and low Trop2 expression. Thus, low ARID1A expression leads to elevated Trop2 levels, resulting in increased therapeutic activity of SG.
Conclusion: We discovered that SG induces Trop2 expression through SN-38–mediated reduction of ARID1A protein expression in HR+/HER2− BC cell lines. Moreover, lower ARID1A in HR+/HER2− BC cells was associated with increased sensitivity to SG. These results suggest a novel mechanism for Trop2 ADC efficacy in HR+/HER2− BC with low Trop2 expression. Our findings highlight the importance of knowing a patient's ARID1A status to predict the efficacy of Trop2-ADCs. Further mechanistic studies will be presented at SABCS.

PS13-09: Mechanisms of Resistance to Trastuzumab Deruxtecan in Breast Cancer Elucidated by Multi-omic Molecular Profiling

George Sledge, Joanne Xiu, Reshma L. Mahtani, Ana C. Sandoval Leon, Matthew J. Oberley, Milan Radovich, David Spetzler

Trastuzumab deruxtecan is widely used as a treatment for metastatic HER-2 low and HER2-positive breast cancer, and preclinical studies have suggested multiple potential mechanisms of resistance. There have, however, been few large population-based studies of resistance. Following the course of trastuzumab deruxtecan (T-DXd) through the cancer cell, we combined Next Generation Sequencing (NGS), immunohistochemistry (IHC) and claims data to evaluate clinically relevant mechanisms of resistance to this agent.
A total of 1220 T-DXd-treated breast cancer samples tested at Caris Life Sciences (Phoenix, AZ) underwent whole transcriptome sequencing (Illumina, NovaSeq). HER2 IHC was performed (4B5) and scored following ASCO/CAP guidelines. Real-world clinical data were obtained from insurance claims. Time-on-treatment (TOT) and post-treatment overall survival (OS) were determined as the interval from the T-DXd initiation to the end of treatment and the last recorded clinical activity, respectively. RNA expression of 86 genes linked to numerous reported ADC resistance mechanisms were investigated for association with clinical outcome, including antigen/dimerization partners (N=5), ABC transporters (N=38), lysosomal genes (N=16), genes involved in ADCC pathway (N=9), endocytosis, intracellular trafficking and cytoskeleton organization pathways (N=6), topoisomerase isoforms (N=4), tubulin isoforms (N=5) and well-established prognostic markers in breast cancer (N=3). Multivariate analysis was conducted using RNA transcript per million (TPM) inputs as continuous variables in a Cox-Proportional Hazard model, with significance determined at $p<0.05$.
In the multivariate analyses performed in 1144 tumors collected prior to T-DXd start, associating expression levels of the 86 genes with TOT and OS revealed ERBB2 as the strongest positive predictor of TOT ($p<0.0001$; FDR adjusted $p =0.0011$) and OS ($p<0.0001$; FDR $p =0.011$); conversely, ABCC1 expression (MRP1, multidrug-resistance associated

protein 1) emerged as the strongest negative predictor of TOT (p=0.0009, FDR p=0.030) and OS (p=0.0004, FDR p =0.011). Notably, MKI67 (p=0.0099), TUBB3 (p=0.005) were negatively associated with OS, not with TOT.
Using the top quartile of ABCC1 expression (35 TPM) as cutoff, T-DXd outcome was better in ABCC1-low vs. ABCC1-high tumors (TOT: 6.0m vs. 5.2m p=0.09; OS: 24 vs. 15m, p=0.0005).
When combined with ERBB2 RNA expression (using median of 63 TPM as a cutoff), ABCC1-high tumors showed significantly shorter TOT compared to ABCC1-low in both the ERBB2-high (TOT: 4.7m, 95% CI [3.9-5.1] vs. 9.1m, 95% CI [7.3-10.7m]) and ERBB-low group (TOT: 3m [2.3-4.3] vs. 6.3 [5.1-7], p<0.0001); similar differences were observed for OS.
When ABCC1 RNA expression was combined with ERBB2 IHC, amongst all subgroups, tumors with HER2 IHC 0+ and ABCC1-high showed the shortest TOT (2.3m, [1.6-3.5m]) and OS (10.7m, [6-30.1m]) while tumors with HER2 IHC 3+ and ABCC1-low showed the longest TOT (10.7m [7.7-13.4m]) and OS (30.8 [24.1-not reached]). Patient age was not significantly associated with TOT or OS in our analyses. As expected, ERBB2 RNA expression was strongly associated with HER2 IHC results: median ERBB2 = 31 TPM in IHC intensity of 0+, 48 TPM in IHC of 1+; 84 TPM in IHC of 2+, and 445 TPM of IHC of 3+ (p<0.0001).
Using a multi-omic approach, we thoroughly surveyed gene expressions on pathways associated with antibody-drug conjugate resistance mechanisms. By examining clinical outcome data from 1144 breast cancer patients treated with T-DXd, our data suggest that at an intracellular level TDXd outcome is a function of drug concentration influx and time to efflux.

PS14-01: Rhenium (186Re) obisbemeda (rhenium nanoliposome,186RNL) for the treatment of leptomeningeal metastases (LM): Update on Phase 1 dose escalation study

Andrew Brenner, Michael Youssef , Priya Kumthekar, Ande Bao, Joel Michalek, William Phillips, Toral Patel, John Floyd, Marc Hedrick, Melissa Moore, Leonardo Juverdianu, Barbara Blouw

Background: Leptomeningeal metastases (LM) is a devastating systemic cancer complication most often seen with breast, lung, and melanoma, with limited treatment options and poor survival. Rhenium (186Re) Obisbemeda (186RNL) provides the combination of effective therapeutic beta radiation, simultaneous gamma decay for imaging, and ~90-hour physical half-life for optimal radiation delivery. A summary of the Phase 1 dose escalation study, expected to be completed, will be presented.
Methods: ReSPECT-LM is a Phase 1 dose escalation study for patients with LM from any primary cancer. Adult patients are given a single dose of 186RNL via intraventricular catheter (Ommaya reservoir) in an outpatient setting to determine the maximum tolerated/feasible dose (MTD/MFD), safety, tolerability, and response. Seven administered dose cohorts in a 3+3 design, from 6.6 mCi to 109.96 mCi, were anticipated.
Results: For the first 5 cohorts (n=25), doses were well-tolerated; most AEs were Grade 1

and 2 with 1 DLT in Cohort 5 (at time of abstract submission). 12 patients (48%) had breast cancer as their primary cancer. Of those evaluable at the time of abstract submission, 4 were triple negative (ER negative/PR negative/HER2 negative); 2 were ER positive/HER2 negative; and 2 were HER2 positive. Median overall survival for all patients at time of reporting was 12 months. CSF tumor cell enumeration assays were performed with a maximum reduction over baseline seen at Day 28. Radiation absorbed doses were calculated for the ventricles, cranial subarachnoid space, and spinal fluid and showed a linear increase with administered dose, with liver and spleen remaining low. Neurological symptoms were reported to improve. We expect the Phase 1 conclusion and the RP2D to be determined for conference reporting, with an additional subset analysis of the breast cancer patients.
Conclusion: A single dose of 186RNL for patients with LM has been well-tolerated, with high absorbed doses to the treatment area, acceptable organ doses, and promising clinical improvement and reductions in tumor cell count. Phase 2 is expected to begin enrollment by Q4 2024. Additionally, based on these data, a Phase 1 multidose study is planned to be initiated this year.

PS14-02: A Prospective Phase II Trial of Hypofractionated Stereotactic Radiotherapy (FSRT) for Patients with 1-10 Brain Metastases from Breast Cancer

Jin Meng, Zhaozhi Yang, Li Zhang, Wei Shi, Jingyao Chen, Xiaofang Wang, Xingxing Chen, Xin Mei, Jinli Ma, Zhen Zhang, Zhimin Shao, Xiaomao Guo, Xiaoli Yu, Zhaozhi Yang

Purpose: Single-fraction stereotactic radiotherapy (SRT) is widely recommended in modern breast cancer brain metastasis treatment for 1-4 lesions, while hypofractionated SRT (FSRT) is rarely reported. This study aims to evaluate the efficacy and safety of FSRT in patients with 1-10 brain metastases from breast cancer.
Methods and Materials: From March 2019 to August 2023, we conducted a prospective, single-arm, phase II trial of FSRT in BM patients from breast cancer. Patients received FSRT delivered at 8 Gy per fraction in 3-5 fractions. The main inclusion criteria were breast cancer patients with 1-10 brain metastases. The primary endpoint was the local control (LC) rate, and the secondary endpoints included intracranial distant control, intracranial progression-free survival (iPFS), overall survival (OS), treatment-related toxicities, and assessments of neurocognitive function. The study is registered at clinicaltrials.gov with the identifier NCT04061408.
Results: A total of 173 patients with 436 brain lesions underwent treatment with FSRT. The median age of patients was 51 years (IQR 43-59), of which 16.1% (28/173) had 5-10 lesions, and 30.0% (52/173) had the largest lesion over 2 cm. As of February 2024, at a median follow-up time of 15 months (IQR: 8-29 months), the local control rate at 1 year and 2 years was 88.6% (95% CI: 83.6-93.9%) and 77.1% (95% CI: 69.4-85.6%), respectively. The intracranial distant control at 1 year and 2 years was 51.8% (95% CI: 44.5-60.5%) and 26.7% (95% CI: 19.5-36.6%), respectively. The median OS for these patients was 29 months

(95% CI: 21-36 months); the estimate of OS at 1 year and 2 years was 73.8% (95% CI: 67.2-80.9%) and 55.3% (95% CI: 46.4-65.8%), respectively. We included age, KPS score, presence of neurological symptoms, presence of extracranial metastases, molecular subtypes, number of lesions, maximum tumor diameter and total volume of lesions into multivariate regression analysis, and found that KPS was the only prognostic factor associated with local control rate. Among the 137 patients with evaluable lesions, the optimal treatment response was assessed by RANO-BM criteria. Except for 10 patients who did not have efficacy evaluation data, 33 patients (24.1%) achieved CR, 72 patients (52.6%) achieved PR, 18 patients (13.1%) achieved SD, and 4 patients (3.1%) were evaluated as PD. The median iPFS time for these patients with evaluable lesions was 11 months (95% CI: 9-15 months). Among the treated lesions, 27 cases out of 436 lesions (6.2%) experienced radiation necrosis. No grade 3 or 4 adverse events related to FSRT occurred in this study. Conclusions: This study demonstrated that FSRT treatment for breast cancer brain metastasis with 1-10 lesions is safe and effective option with excellent local control and a lower risk of radation necrosis.

PS14-03: Updated analyses from a Phase I study of the brain-penetrant oral SERD- SIM0270 in patients with ER-positive,HER2-negative advanced breast cancer

Qingyuan Zhang,Huiping Li, Yongmei Yin, Jiong Wu, Jian Zhang, Min Yan, Wenfeng Li, Sanyuan Sun, Yehui Shi, Hongtao Li, Hong Wang, Xiyuan Wang, Lili Zhu, Ya Li, Chunyan He, Chen Yang

Background: This is a phase I, multi-cohort, open label study of SIM0270 in patients with ER+/HER2- advanced breast cancer and the dose escalation part of phase Ia examined SIM0270 as monotherapy has been presented previously1. Here we present data from patients in the dose expansion part (Cohort S1)of SIM0270 monotherapy at the recommended dose (60mg PO QD) of phase Ia.
Methods: In Cohort S1, SIM0270 was administered orally once daily in patients with ER+/HER2- locally advanced/metastatic breast cancer who had received ≥1 prior endocrine therapy(secondary endocrine resistant) and there was no upper limit on the number of lines of prior endocrine treatment in the advanced setting; ≤2 chemotherapy regimens; prior treatment with fulvestrant or CDK4/6 inhibitors were permitted. Pre-/peri-menopausal women received ovarian suppression treatment. The key endpoints included safety, tolerability and efficacy.
Results: As of June 17, 2024, 51 patients received SIM0270 (60mg PO QD) in Cohort S1. Of all treated patients, median age was 60y and 90.2% were post-menopausal. ESR1 mutation was detected in 23.5% patients at baseline, and 74.5% patients had visceral metastases at baseline (liver 35.3%, lung 54.9%). Patients had received a median of 1 prior chemotherapy and 1 prior endocrine therapy in the advanced setting; 45.1% had prior fulvestrant, and 39.2% had prior CDK4/6 inhibitors treatment. The median duration of treatment was 114 days with a median 6.4 months follow up. The overall safety profile was consistent with that

of the dose escalation part, the incidence of TEAE was 100% and most of them were CTCAE grade 1 or 2; the most common TEAEs (incidence ≥20%) were sinus bradycardia 45% (most were grade 1 asymptomatic), ALT increased 31%, ALT increased 27%, hypertriglyceridemia 24% and urinary tract infection 24%; the incidence of ≥G3 TEAE was 24% and ≥G3 TRAE was 12% (hypertriglyceridemia 4%, electrocardiogram QT prolonged 2%, neutrophil count decreased 2%, sinus bradycardia 2%, anemia 2%). In total, 3 patients had dose interruptions and dose reductions due to TRAEs (1 hypertriglyceridemia, 1 electrocardiogram QT prolonged and 1 sinus bradycardia) and all resolved with dose modification. No patient discontinued SIM0270 due to TRAEs and no treatment related SAEs were observed. The confirmed ORR was 8.3% in 48 response evaluable patients, and CBR was 40% in 45 CBR evaluable patients. Seventeen patients remained on treatment, and the most common reason for treatment discontinuation was disease progression. Conclusions: In the expansion cohort of patients with ER+/HER2- locally advanced or metastatic breast cancer, SIM0270 monotherapy demonstrated promising evidence of clinical activity based on ORR and CBR that compared favorable to historical controls despite extensive pre-treatment including chemotherapies, CDK4/6 inhibitors and fulvestrant, which were enhanced in the subgroup patients refractory to the last treatment of patients with ESR1 mutations. SIM0270 monotherapy was well tolerated with manageable AE profile and low number of treatment discontinuation due to related AEs observed in the dose escalation part was maintained during cohort expansion part at dose of 60mg QD. Additional analyses are ongoing. (NCT05293964)

Reference ：
1. 2023 SABCS PS 15-01, A first-in-human phase 1 study of SIM0270, a brain-penetrant oral selective estrogen receptor degrader (SERD),in patients with ER+/ HER2- locally advanced or metastatic breast cancer.

PS14-04: SIM0270, a brain-penetrant oral SERD, in combination with everolimus in patients with ER+/HER2- advanced breast cancer: the phase Ib study

Jian Zhang, Jiong Wu, Xinhong Wu, Huiping Li, Wenfeng Li, Yongmei Yin, Sanyuan Sun,Yuping Sun, Ying Wang, Hong Wang, Weimin Xie, Xiyuan Wang, Lili Zhu,Ya Li, Qi Fu, Chunyan He, Chen Yang

Background: SIM0270 is a novel, brain-penetrant orally biologically active SERD with pure antagonistic properties that result in sustained inhibition of ER-dependent gene transcription and cell growth. Preclinically, SIM0270 has favorable efficacy and PK properties, including antitumor activity in ESR1-mutant models and brain-metastatic models, along with enhanced efficacy when combined with everolimus which was a mTOR inhibitor. In phase Ia, SIM0270 monotherapy was well tolerated with favorable safety, PK and encouraging antitumor activity and recommended dose of SIM0270 monotherapy was determined as 60mg QD. Here, we present the results from phase Ib of SIM0270 combined

with everolimus in patients with ER+/HER2- advanced breast cancer (NCT05293964).
Methods: Patients with ER+/HER2- aBC shown secondary resistance to prior endocrine therapy were enrolled to Cohort B(the dose escalation part) and Cohort B1 (the dose expansion part). Key inclusion criterias of cohorts B and B1 were same as follows: ≤2 prior chemotherapies and allowed to have received prior fulvestrant or/and CDK4/6 inhibitors in the advanced setting. Serial plasma samples were obtained for PK and ctDNA analysis. Key endpoint of cohort B was DLT, and key endpoints of Cohort B1 included safety and tolerability, PK and preliminary efficacy.
Results: As of June 17,2024, 8 patients were enrolled to Cohort B at SIM0270 60mg PO, QD combined with everolimus 10mg PO, QD, and DLT events were observed in 2 patients (grade 3 blood creatinine increased in 1 patient, grade 3 hypertriglyceridemia and grade 2 interstitial lung disease in 1 patient), no further dose escalation was recommended by the SRC guided by BOIN. Additional 32 patients were enrolled at the same dose in Cohort B1. In total of cohorts B+B1,75.6% patients had visceral disease and 22.0% patients had ctDNA ESR1 mutations detected at baseline. Patients were predominantly ET pre-treated in the advanced setting, 68.3% with AI, 58.5% with fulvestrant, and 68.3% with prior CDK4/6 inhibitors. 43.9% of patients had been treated with chemotherapy in the advanced setting, while 17.1% of patients had received 2 lines of chemotherapy. The incidence of TEAEs was 97.6%. The most common TEAEs (incidence ≥30%) were hypercholesterolemia 65%, hypertriglyceridemia 65%, anemia 55%, AST increased 50%， ALT increased 47.5%, hyperglycemia 45%, decreased appetite 42.5%, WBC count decreased 37.5%, hypokalemia 35%, Sinus bradycardia 35%, proteinuria 32.5%, asthenia/hypoalbuminemia/neutrophil count decreased/stomatitis 30% each. Grade ≥3 TEAEs and grade ≥3TRAEs occurred in 68.3 and 58.5% of patients, respectively. In B+B1, 65.9% patients had dose interruptions and 34.2% had dose reductions due to TEAEs, 4 patients (1 hypertriglyceridemia, 1 arrhythmia, 1 rash, 1 ILD) discontinued study treatment (SIM0270 or everolimus or both) due to TEAEs. The confirmed ORR was 19.4% in 36 response evaluable patients, and CBR was 65.5% in 29 CBR evaluable patients (per RECIST v1.1). Four patients with stable brain metastases were enrolled to cohorts B and B1: 2 confirmed CR and 2 SD (per RANO-BM), and 3 of these 4 patients were still under treatment. After the first dose and daily dosing for 15 consecutive days, the exposure of SIM0270 was not significantly different from that of SIM0270 alone, the exposure of everolimus was consistent with reported data of everolimus monotherapy.
Conclusions: SIM0270 in combination with everolimus showed acceptable safety and tolerability, comparable to BOLERO-2 trial of exemestane +everolimus, along with promising evidence of clinical activity in patients with ER+/HER2- aBC. Further data will be presented at the meeting.

PS14-05: Clinically actionable genomic alterations in breast cancer brain metastases

Gaia Griguolo, Antonio Collesei, Elisabetta Lazzarini, Maria Vittoria Dieci, Susan Fineberg, Michele Bottosso, Luc Bauchet, Federica Miglietta, Jack Jacob, Valerie Rigau, Valerio

Pellegrini, Francesca Zanghi, Maria Cristina Guarascio, Matteo Fassan, William Jacot, Stefano Indraccolo, Amelie Darlix, Valentina Guarneri

Background: Breast cancer brain metastases (BCBM) represent a critical unmet clinical need in metastatic BC, as they are associated with significant morbidity and poor prognosis. The identification of novel therapeutic targets is therefore urgently needed in this context. In this study, we aimed to describe clinically actionable targets in breast cancer brain metastases (BMs) using comprehensive genomic profiling.

Patients and methods: Genomic DNA was extracted from formalin-fixed paraffin-embedded archival BCBM samples from three institutions (all selected for tumor cellularity>30%). DNA samples with adequate quality were then analyzed using the commercially available Agilent SureSelect V6 whole exome sequencing (WES) kit and an Illumina NovaSeq 6000 platform.
Pathogenic alterations were classified as actionable alterations (AA) if they met the updated metastatic BC or tumor-agnostic ESCAT I or II criteria of the ESMO Scale for Clinical Actionability of Molecular Targets (ESCAT) (Mosele et al, Ann Oncol 2024). Due to technical limitations, gene fusions and MSI-H status were not assessed.
Hormone receptor (HR) and HER2 status were evaluated on the BCBM by ASCO-CAP criteria. Overall survival (OS) was defined as interval from first BM diagnosis to death or last follow-up, whichever occured first.

Results: Tumor WES data from 56 BCBM samples was available.
Thirty-three BCBMs (59%) were classified as HER2-. Among these, 8 (24%) presented AA of BRCA1 (N=2, 6%), BRCA2 (N=5, 15%), and PALB2 genes (N=1, 3%). These alterations were observed in 26% of HR-/HER2- BCBMs (5/19; N=2 BRCA1 and N=3 BRCA2, respectively) and in 21% of HR+/HER2- BCBMs (3/14; N=2 BRCA2, N=1 PALB2).
ESCAT I/II PIK3CA/AKT1/PTEN-pathway alterations were also present in 50% (7/14) of HR+/HER2- BCBMs: 6 PTEN (2 mutations, 4 deletions) and 1 hotspot PIK3CA mutation. A rare non-hotspot PIK3CA mutation was also detected in an additional HR+/HER2- BCBM sample. Interestingly, we did not detect ESR1 mutations in HR+/HER2- BCBMs.
Twenty-three BCBMs (41%) were classified as HER2+; among these, 3 (13%) presented a hotspot PIK3CA mutation and 7 (30%) presented a PTEN deletion. Among patients with HER2+ BCBMs, the identification of a hotspot PIK3CA mutation was significantly associated with worse prognosis (median OS from BM diagnosis 22.2 versus 53.0 months, log-rank p=0.034).
Overall, an ESCAT I/II AA was detected in 66% (N=37) of all BCBMs, and in particular in 64% of HR+/HER2- BCBMs. Tumor mutational burden (TMB) data will be presented at the meeting.

Conclusions: ESCAT I/II actionable genomic alterations are frequent in BCBMs, with a particularly high rate of tumor BRCA1/BRCA2/PALB2 alterations in the HER2- subgroup. These data highlight the potential for genomically targeted treatments in this setting. Furthermore, the negative prognostic impact of PIK3CA mutations in HER2+ BCBMs

provides the rationale for the potential combination of PIK3CA inhibitors and HER2-targeted agents in this setting.

PS14-06: Gene expression profiling of brain metastases and matched primary breast tumours with focus on the immune system and tumour microenvironment

Anna Thulin, Anika Kovacs, Anne-Vibeke Laenkholm, Henrik Fagma

Background: Despite advances in the treatment of breast cancer, brain metastases (BM) remain a significant clinical problem. Detailed biological information is increasing on extracranial metastases through for example the AURORA program, however the biology of BM is less studied. Immune checkpoint inhibitors (ICI) are efficient in treatment of early and disseminated TNBC but the effect on BM seems to be modest.
Aims: To compare gene expression (GE) signatures between BM and the primary breast tumours (PT) by use of NanoString nCounter 360™ Panel with a focus on signatures involved in the immune system and microenvironment (ME), as well as levels of CD4+, CD8+, CD68+ and Treg cells by immunohistochemistry. We also wanted to compared GE signatures between BM according to mutational status i.e. wildtype (wt) or somatic mutations in TP53 and PIK3CA respectively.
Methods: Patients with surgery of BM between 1994-2014 were identified. Clinical data and presence of TP53 and PIK3CA mutations have been published previously. The Breast Cancer 360TM panel version 2 (nCounter® platform) was used according to the manufacturer's specifications (NanoString Technologies, Inc., Seattle, WA, USA). IHC was performed according to the manufacturer's specifications with the following antibodies: CD4(1:100; IR649), CD8 (1:100; M7103), CD68 (1:200; IR613) (DAKO, Glostrup, Denmark) and FOXP3 (1:200; AB20034) (Abcam, Cambridge, United Kingdom). Stained slides were scanned on Hamamatsu Photonics NanoZoomer s210. Differences between GE signatures in BM and PT were calculated with Anova and Bonferroni post hoc analysis and for IHC with Wilcoxon paired test. Significance was set at 0.05 unless otherwise specified.
Results: Analyses were performed on 60 BM out of which 23 cases had the matched PT and five single PT. The following GE signatures were statistically significantly lower in BM than in PT: PD-L1, PD-1, PD-L2, CD8+ T-Cells, Treg, B7-H3 or CD276 (type I membrane protein with a sequence similar to the extracellular domain of PD-L1), IFN Gamma, MHC2, apM (antigen processing machinery), TGF-Beta, TIS (tumour inflammation signature), TIGIT (T cell immunoreceptor with Ig and ITIM domains), Stroma, IDO1, Mast Cells, Endothelial Cells (all p< 0,001) and Inflammatory Chemokines (p=0,02). The following GE signatures were upregulated in BM compared with PT; SOX2 (p < 0,001), Genomic Risk (p <0,001), BRCA-ness (p < 0,001), Differentiation (p= 0,004), Hypoxia (p <0,001), BC Proliferation (p=0,002) and HRD (p=0,047). The IHC staining showed statistically significant lower expression of CD4+ T helper cells (p=0.007), cytotoxic CD8+ T cells (p=0.04), TILs (p=0.004) and a trend not reaching statistical significance of Treg (p=0.07). No difference was found on the levels of CD68+ (p=0.35). BM with TP53 mutations had higher expression of BC proliferation

(p=0.001), HRD (p=0.007) and mast cells (p=0.001) compared with BM with wt TP53. BM with PIK3CA mutations had higher expression of MHC class 2 (p = 0.027) and BC proliferation (p = 0.033) compared with BM with wt PIK3CA.
Conclusions: We found a downregulation of GE signatures related to the immune system and tumour ME in BM compared with PT. This was validated by the lower levels of TILs, CD4+ and CD8+ T cells in BM. The lower immunogenicity of BM may partly explain the reduced effect by immunotherapy intracranially. New treatment combinations that enhance the immunogenicity of BM deserve further investigations.

PS14-07: Spatial transcriptomics of matched breast cancer brain metastases and primary tumors identifies a brain-specific immune-suppressive transcriptional program

Patrick Kurnia, Sheheryar Kabraji, Busem B. Kurt, Maria-Anna Chrysovergi, Melissa E. Hughes, Nancy U. Lin, Rinath Jeselsohn

Background: Breast cancer brain metastases (BCBM) affect up to 50% of patients (pts) with metastatic breast cancer (MBC). However, therapies to specifically activate the intracranial anti-tumor immune response against BCBM are lacking due to incomplete understanding of brain-specific immune alterations. Here we use GeoMX Digital Spatial profiling of samples from 33 pts with BCBM and matching breast primary (n=5) over 62 immune-rich and 124 tumor-rich areas of interest (AOI) to reveal brain-specific transcriptional programs that may drive immune-suppression.
Methods: We previously collated a cohort of pts with matched BCBM and primary tissue at a single institution under an IRB-approved biobanking protocol (DFCI 93-085). A tissue microarray of 1.5 mm cores was generated with each sample duplicated. Nanostring GeoMX Digital Spatial analysis was used for AOI spatial transcriptomics using GeoMX Cancer Transcriptome Atlas gene panel(v1.0). The GeoMx Solid Tumor TME Morphology Kit was used to identify tumor-rich areas (cytokeratin positive) and immune rich areas (CD45+) for AOI identification. Eluted RNAs underwent next-generation sequencing and analyzed using the R packages NanoStringNCTools and GeomxTools. DE comparisons used linear mixed-effects models to account for patient as a random effect and the package clusterProfiler was used for GSEA on the resulting lists ranked by fold change.
Results: After filtering samples for quality, we identified 33 BCBM [HR+ HER2- (n=10), HER2+ (n=10) and TNBC (n=7)], 5 primary breast [HR+ HER2- (n=1), HER2+ (n=1) and TNBC (n=3) and 1 lung metastasis [HR+ HER2-], tissues suitable for immune analysis. 6 additional BCBM patient samples [HR+ HER2- (n=2), HER2+ (n=4)] were available for tumor analysis only. We analyzed 124 tumor-rich and 62 immune-rich AOIs. Principal component analysis (PCA) of the top 1000 variable genes separated immune-rich and tumor-rich AOIs, with greatest separation of tumor AOIs by patient compared to immune AOIs. To identify alterations in BCBM TME we focused on immune-rich AOIs [n=62, 47 brain, 12 breast, 3 lung, 5405 genes]. PCA showed clustering of immune AOI by tissue site. We next focused on immune AOIs in TNBC, given its poor prognosis and potential

sensitivity to immunotherapy. Gene set enrichment analysis (GSEA) found significant enrichment of Estrogen Response Early, Estrogen Response Late, G2M Checkpoint and E2F Targets Hallmark Gene Sets (ES < -0.3, FDR < 0.001) in TNBC brain immune AOIs compared to primary TNBC immune AOIs where Interferon Gamma Response, Allograft Rejection, Complement and Interferon Alpha Response (ES > 0.3, FDR < 0.001) were enriched. S100A1, CD24, ELF5, IGFBP2 were the top 5 differentially expressed genes (DEGs) in immune AOIs from TNBC brain tissue compared to primary tumors where B2M, HLA-B, IGKC, POSTN, HLA-DRA were enriched. Comparing TNBC immune AOIs to HR+ or HER2+ immune AOIs in the brain did not identify significant DEGs. We also compared tumor AOIs between TNBC brain and breast samples. GSEA found significant enrichment of Estrogen Response Early, Estrogen Response Late and KRAS Signaling Down (ES < -0.3, FDR < 0.001) in TNBC brain tumor AOIs compared to primary TNBC tumor AOIs where Interferon Gamma Response, Interferon Alpha Response, MTORC1 Signaling and Epithelial Mesenchymal Signaling were enriched (ES > 0.3, FDR < 0.001). S100A1, HOXC10, CLPSL1, ITGA6, ZG16B were the top 5 DEGs in tumor AOIs from TNBC brain tissue compared to primary tumors where BST2, LGALS3BP, EIF2AK2, TAP1, IFI27 were enriched.
Conclusion: We performed region-of-interest spatial transcriptomics to identify gene expression differences between primary breast tumors and matching BCBM. We identified estrogen receptor signaling as a key immune and tumor signaling pathway that was differentially expressed in BCBM compared to primary tumors in TNBC. These results have potential therapeutic implications and warrant validation in additional cohorts. Further analyses of HR+ and HER2+ tumor and immune AOIs and spatial proteomic analysis will be presented at the conference.

PS14-08: Targeting CXCL1-CXCR2 axis blocks brain metastasis in inflammatory breast cancer

Xiaoding Hu, Yun Xiong, Emilly S Villodre, Juhee Song, Maria Stenkamp, Natalie Fowlkes, Elizabeth Leigh, Jeffery, Savitri Krishnamurthy, Junjie Chen, Wendy A Woodward, Debu Tripathy, Bisrat G Debeb

Background: Brain metastasis is a frequent site of relapse in patients with inflammatory breast cancer (IBC) - a rare, highly aggressive and metastatic variant of breast cancer. We have discovered that soluble E-cadherin (sEcad), an 80-kDa proteolytic fragment of full-length E-cadherin, correlated with increased risk of brain metastasis and death in patients with metastatic IBC. Additionally, we demonstrated that sEcad promotes brain metastasis growth and progression in HER2+ and triple-negative IBC brain metastasis models. However, how sEcad promotes brain metastatic progression is unknown. We hypothesize that sEcad promotes the production of specific cytokines, which, upon extracellular release, promote the activation of astrocytes, priming the brain microenvironment for metastatic growth.
Methods: Stable overexpression of sEcad in IBC cell lines (MDA-IBC3 (ER–/HER2+) and SUM149 (ER–/HER2–) was achieved using lentiviral vectors. We injected MDA-IBC3-sEcad

and control cells (tail-vein) and SUM149-sEcad and control cells (intracardiac) into SCID/Beige mice to assess brain metastasis burden and survival in mice. Human cytokine array was used to examine conditioned medium from sEcad high and control cells. Clinical datasets were used to compare expression and percent risk of brain relapse. Mice were treated with brain-permeable CXCR2 inhibitor in both IBC brain metastasis models. Multiplex quantitative imaging was used to visualize cells of the brain metastatic microenvironment.
Results: Higher serum sEcad levels were significantly associated with reduced OS, earlier metastasis onset, and increased brain metastasis incidence. sEcad is an independent predictor of OS on multivariate analysis (hazard ratio [HR]=2.07 [95% CI 1.19-3.60], p=0.01). Treatment of astrocytes with recombinant sEcad increased reactive astrocytosis, in vitro and in vivo. Cytokine array analysis showed increased levels of pro-inflammatory cytokine CXCL1, DKK1 and CXCL8 in conditioned medium from sEcad-overexpressing IBC cells compared with control cells, which was validated by ELISA. In patient samples, CXCL1, CXCL8 and CXCR2, the receptor for CXCL1 and CXCL8, were expressed higher in brain metastasis compared to other metastases. Additionally, patients with high CXCL1/CXCL8 or CXCR2 expression had reduced brain metastasis relapse. Inhibition of CXCR2 decreased sEcad-mediated induction of reactive astrocytes. Treatment of mice bearing MDA-IBC3-sEcad and SUM149-sEcad brain metastases with the brain permeable CXCR2 inhibitor reduced number of brain metastasis, metastasis burden and prolonged survival of mice. Multiplexed immunofluorescence staining showed a significant reduction of reactive astrocytes in brain metastasis lesions treated with the CXCR2 inhibitor.
Conclusion: Our findings underscore that sEcad drives brain metastasis by promoting an inflammatory brain microenvironment via a targetable CXCL1/CXCL8-CXCR2 axis. Targeting this axis presents a promising therapeutic strategy to effectively block brain metastasis in aggressive breast cancers.

PS14-09: Central Nervous System as the Primary Site of First Relapse in Patients with Triple-Negative Breast Cancer Achieving Pathological Complete Response After Neoadjuvant Treatment

Davide Massa, Esther Lips, Sylvie Giacchetti, Claudio Vernieri, Federico Piacentini, Luisa Carbognin, Moira Ragazzi, Carmen Criscitiello, Andrea Botticelli, Giorgio Bonomi, Federica Miglietta, Gaia Griguolo, Francesca Zanghì, Davide Napetti, Marina La Commare, Giuseppe Fotia, Giacomo Mazzoli, Clementine Bouchez, Laetitia Someil, Giulio Martinelli, Elisa Gasparini, Emilio Bria, Marleen Kok, Valentina Guarneri, Maria Vittoria Dieci

Introduction: In patients with triple negative breast cancer (TNBC), achieving a pathological complete response (pCR) after neoadjuvant treatment (NAT) is associated with better survival. However, up to 10% of these patients relapse after surgery. Understanding the pattern and determinants of this failure is essential. This study aims to describe the pattern of relapse in patients with pCR after NAT and to compare it with the non-pCR counterpart.
Methods: This retrospective, multicenter study included 898 patients with TNBC (estrogen-

receptor <10%, HER2-negative) treated with NAT between 2001 and 2023 at nine European Institutions. We collected the type of first relapse-free survival (RFS) event (locoregional relapse, distant relapse, death without other event) and the site of metastasis for patients with distant relapse as the first event. The cumulative incidence of specific events was evaluated using competing risk analysis and compared between pCR (ypT0/is ypN0) and non-pCR cohorts.

Results: The study population included 443 (49.3%) patients with pCR and 455 (50.7%) with non-pCR. Patients with pCR had less frequently stage III disease (22.1% vs 33.3%, p<0.001). Median TILs were higher in the pCR vs non-pCR group (median 15% [IQR 7-40] vs 10% [IQR 5-30], p<0.001). As part of NAT, most patients received anthracyclines (95.8%) and taxanes (89.2%), more patients in the pCR group received carboplatin (45.8% vs 38.0%, p=0.017) and immunotherapy (8.6% vs 5.1%, p=0.038). Adjuvant chemotherapy was more common in the non-pCR cohort (46.5% vs 6.3%, p<0.001).

With a median follow up of 4.6 years (95%CI 4.3-4.9),171 events occurred: 30 in the pCR cohort and 141 in the non-pCR cohort. RFS was significantly longer for pCR vs non pCR (5-yr RFS 92.7% vs 67.2%, p<0.001). The cumulative incidence of distant metastasis in the overall population was 15.4% at 5 years, significantly lower in pCR vs non-pCR cohort: 4.1% vs 25.8%, p<0.001. The same was observed for distant metastasis involving visceral site as first event: 5-yr cumulative incidence was 10.6% in the overall population, 3.6% in pCR vs 17.1% in non-pCR cohorts, p<0.001. No difference in the cumulative incidence of CNS relapse without extracranial disease (CNS-only) as first event was observed between the two groups: 5-yr cumulative incidence was 2.6% in pCR vs 2.3% in non-pCR cohorts, p=0.693.

Next, we analyzed the frequency of site-specific first metastasis among patients who experienced a distant metastasis as first event. Over the total of distant relapse events, visceral involvement was more frequent in pCR vs non-pCR cohorts (15/17 88.2% vs 74/110 67.3%, p=0.094). The predominant site of distant relapse in the pCR cohort was CNS-only: 10/17 (58.8%) vs (9/110) 8.2% in non-pCR, p<0.001. The second most frequent site of distant relapse in pCR-cohort was liver (n=5/17, 29.4%) without significant difference vs non-pCR (n= 29/110, 26.4%). Baseline characteristics of patients who developed CNS-only relapse as first event did not differ between pCR and non-pCR cohorts and were as follows: median age 51 years (range 34-72), stage III 52.6%, nodal involvement 73.7%, Grade 3 94.1%, median TILs 13% (IQR 2-25).

Conclusions: In patients with TNBC achieving pCR after NAT, CNS relapse without extracranial disease is the predominant first relapse site. Identifying factors predicting this dismal event in an otherwise low-risk population is urgently needed, as these patients could participate in in targeted follow-up programs and clinical trials investigating more aggressive therapeutic approaches after NAT. Our data also challenge the appropriateness of systematic avoidance of CNS staging in early TNBC at diagnosis, especially in patients at increased risk.

PS14-10: Effects of trastuzumab deruxtecan (T-DXd) on health-related quality of life (HRQOL) & neurological function in patients (pts) w/ HER2+ advanced/metastatic breast cancer (mBC) with or without brain metastases (BM): DESTINY-Breast12(DB-12) results

Nadia Harbeck, Eva Ciruelos, Guy Jerusalem, Volkmar Müller, Naoki Niikura, Giuseppe Viale, Rupert Bartsch, Christian Kurzeder, Michaela J Higgins, Michelino De Laurentiis, Joëlle Collignon, Toshinari Yamashita, Manoj Prahladan, Helen Bridge, Rajee Antony, Nancy U Lin

Background: In DB-12 (NCT04739761), a prospective Phase 3b/4, single-arm, open-label study, T-DXd exhibited substantial and durable overall and intracranial clinical activity in HER2+ mBC, including pts with BM. BM cohort 12-month (mo) progression-free survival (PFS): 61.6% (95% CI 54.9, 67.6); 12-mo CNS PFS: 58.9% (95% CI 51.9, 65.3). CNS objective response rate: 71.7% (95% CI 64.2, 79.3); 79.2% (95% CI 70.2, 88.3) in stable and 62.3% (95% CI 50.1, 74.5) in active BM. Efficacy in the non-BM cohort was consistent with previous reports. No new safety signals were identified (Harbeck N, et al. Nat Med. 2024). BM and local therapies for BM (eg radiotherapy) can impact HRQOL and neurological function. Here, we report T-DXd effect on HRQOL and neurological function in pts with and without BM.

Methods: Adults with HER2+ mBC and progression on ≤2 prior lines of therapy were enrolled in the BM cohort (stable / active [untreated/treated progressing] BM not requiring immediate local therapy; dexamethasone ≤3 mg daily use or equivalent allowed for symptom control) or non-BM cohort. Design did not allow cross-cohort comparison. Pts received T-DXd 5.4 mg/kg intravenously every 3 weeks. HRQOL was assessed as proportion of pts with clinically meaningful deterioration (change from baseline [BL]: ≤−4 for cognitive functioning, ≤−8 for Global Health Status [GHS], ≤−10 for pain and physical functioning) using EORTC QLQ-C30. Neurological function was assessed as change from BL score to worst score (at any point during treatment) using the NANO scale, and clinically meaningful change (±10 points) from BL for the MDASI symptom diary (brain tumor-specific outcomes; BM cohort only).

Results

Median total treatment duration in the BM cohort (N=263): 11.5 mo; 118 pts were still receiving T-DXd at data cutoff (DCO). EORTC QLQ-C30, NANO, and MDASI compliance: >81.0% at BL and >78.3% overall. For EORTC QLQ-C30, the number (%, time to deterioration [TTD] 25th percentile) of pts with BL values who had clinically meaningful deterioration was 101/223 (45.3, 2.1 mo) for cognitive functioning (CF); 131/223 (53.2, 0.8 mo) for GHS/QOL; 99/224 (44.1, 2.0 mo) for pain; and 99/224 (44.1, 2.7 mo) for physical functioning. Median TTD was not calculated (NC) for any domain. For NANO, 220/254 (86.6%) pts had neurological stability as BL score; of these, 140 had neurological stability and 80 had neurological progression as worst score at any point during treatment. Of 25 (9.8%) pts with neurological progression as BL score, 18 had neurological progression and seven had neurological stability as worst score at any point during treatment. No clinically meaningful mean changes were observed in brain tumor-specific MDASI symptom diary

items (including difficulty concentrating, speaking, and understanding; irritability; seizures; vision).
Median total treatment duration in the non-BM cohort (N=241): 12.0 mo; 95 pts were still receiving T-DXd at DCO. Four pts developed new symptomatic CNS metastasis (incidence rate 0.017 [95% CI 0.00452, 0.04250]) during the study. EORTC QLQ-C30 and NANO compliance: >85.9% at BL and >80.5% overall. For EORTC QLQ-C30, 93/207 (44.9, 2.7 mo) pts had clinically meaningful deterioration of CF; median TTD was NC. For NANO, 217/236 (91.9%) pts had neurological stability as BL score; of these, 172 had neurological stability and 45 had neurological progression as worst score at any point during treatment. Of 16 (6.8%) pts with neurological progression as BL score, ten had neurological progression and six had neurological stability as worst score at any point during treatment.
Conclusion
Overall, HRQOL and neurological function were preserved in most pts with HER2+ mBC, with and without BM, receiving T-DXd.

PS15-01: Utilization of weight management treatment and subsequent cardiovascular events among patients with breast cancer

Margaux Wooster, Ling Chen, Melissa K. Accordino, Claire Sathe, Jason D. Wright, Dawn L. Hershman

Background: Previous studies have suggested that overweight and obese breast cancer (BC) survivors have an increased risk of cancer recurrence along with a higher all-cause mortality including from cardiovascular disease (CVD). CVD is the primary cause of death among patients with BC and CVD risk factors, such as obesity and metabolic disorders, may be more prevalent among BC survivors compared to the general population as BC and CVD share common risk factors. Weight loss medications and bariatric surgery have proven to effectively reduce weight and cardiovascular events (CVE) in the patients who are obese or overweight. We assessed the use of weight modifying agents following a BC diagnosis and evaluated the rates of CVE in these patients.
Methods: We conducted a retrospective cohort study using the MarketScan Commercial Claims and Encounters and Medicare Supplemental Database. Eligibility included aged 18-95 years, overweight or obese per ICD 9 and ICD 10 coding, with a diagnosis of invasive BC between 1/1/2009 – 12/31/2021, who were treated with lumpectomy or mastectomy. Patients who underwent bariatric surgery within one year prior to index date, or had a secondary breast cancer or gastrointestinal cancer prior to surgery were excluded. Patients were categorized by weight status (overweight, obesity class I/II/unspecified, or obesity class III) and by use of weight management treatment (WMT) (yes/no) including nutrition counseling, weight loss medications (Bupropion Hydrochloride/Naltrexone Hydrochloride, Liraglutide, Orlistat, Phentermine Hydrochloride/Topiramate, Semaglutide, and Setmelanotide) and bariatric surgery. We utilized descriptive statistics and conducted a univariate analysis for factors associated with receipt of WMT and rates of CVE by group, defined as cardiovascular complications or myocardial infarction on the same day of

surgery or within 1 year after surgery using ICD-9 or -10 codes. We fit a multivariable logistic regression model to determine factors associated with receipt of WMT.
Results: We identified 35,206 eligible patients, 18.8% (n=6,631) were overweight, 53.7% (n=18,919) were obese class I/II/unspecified, and 27.4% (n=9,656) were obese class III. Of these, 5.3%, 6.4%, and 9.6% received WMT within 1 year of surgery, respectively (p<0.001). Among the 2,484 patients who received WMT, types of therapy utilized were: 72.7% nutritional counseling, 26.7% weight-loss medication, and 4.9% bariatric surgery. Over the years 2009 to 2021, the incidence of WMT significantly increased from 3.7% to 11.3% (p < 0.001), and the use of weight-loss medication increased from 0.3% to 5.1% (p <0.001). In multivariable analysis, young age, 19-40 years old (aOR 2.72 95%CI 2.10-3.52), obesity class III (aOR 1.66 95%CI 1.44-1.90), lumpectomy (aOR 1.14 95%CI 1.04-1.90), more recent year of surgery (aOR 3.04 95%CI 2.22-4.17, referent 2009), comorbidity score of two or greater (aOR 1.24 95%CI 1.09-1.41), and WMT before surgery (aOR 13.56 95%CI 12.19-15.07) were associated with receipt of WMT within 1 year after surgery compared to older age (71-95 years old), overweight classification, mastectomy, earlier year of surgery, comorbidity score of zero, and no prior WMT, respectively. Across all patients, there were 457 CVE within 1 year of surgery; 438 of these patients had not received WMT and 19 patients had received WMT. Patients who received at least one type of WMT had a lower cumulative incidence of CVE, 0.8% compared to 1.3% (p 0.02) in patients who did not receive WMT.
Conclusions: Among newly diagnosed patients with BC, WMT and specifically, weight loss medication use, has increased over time. Among those who received WMT, there was a lower incidence of CVE. Given the known risk of obesity and cardiovascular disease in BC survivors, more work is needed to determine the optimal weight management strategy in this vulnerable population.

PS15-02: Genome-wide association study (GWAS) of aromatase inhibitor musculoskeletal toxicity (AIMT) among early-stage breast cancer (BC) survivors.

Pietro Lapidari, Youenn Drouet, Emilie Thomas, Jérémie Jacquemin, Maria Alice Franzoi, Martina Pagliuca, Sophie Laurent, Chayma Bousrih, Maryam Lustberg, Olivier Tredan, Anne-laure Martin, Catherine Gaudin, Christelle Jouannaud, Marion Fournier, William Jacot, Marina Rousseau, Jean Francois Deleuze, Alain Viari, Ines Vaz-Luis, Antonio Di Meglio

Background: More than half of patients with early BC on aromatase inhibitors (AI) experience AIMT. Inflammatory traits linked with treatment-related estrogen depletion have been associated with AIMT. A potential role for germline variants in genes regulating inflammation, bone turnover, estrogen metabolism and AI pharmacokinetics has also been suggested (Reinbolt 2018, Stearns 2024, Lintermans 2016, Wang 2016, Hertz 2017). Yet study were relatively small and results inconsistent or not validated. Therefore, the understanding of the biological and potential genetic underpinnings of AIMT is still limited. We aimed to comprehensively explore the association of genetic variants with AIMT in

order to identify targets for impactful interventions.

Methods: We included postmenopausal patients with stage I-III BC treated with adjuvant AI from the longitudinal CANTO cohort (NCT01993498). AIMT was evaluated at month 3-6, year (Y) 1, Y3 and Y5 of AI treatment and defined as presence of any grade [G] articular or muscular pain by CTCAE v4.0. All germline variants were assessed on blood samples obtained at BC diagnosis. We performed a GWAS between 1,894,475 single nucleotide polymorphisms (SNPs) (Illumina InfiniumExome24 / Illumina GSA24) and AIMT, using multivariable logistic regressions. Each model was adjusted on pre-specified clinical and behavioral factors, including age, socio-economic status, comorbidities, tumor and treatment-related variables (including type of AI), and patient-reported health outcomes, all assessed at BC diagnosis. Missing data was handled by multiple imputation with a set of 15 complete datasets. The study had approximately 80% power to detect associations with AIMT at Y3 at suggestive GWAS significance alpha level of 10-6 targeting variant with minor allele frequency (MAF) of 0.25 and odds ratio (OR) of 1.5. Therefore, our primary outcome of interest was AIMT at Y3. Given the exploratory nature of these analyses, we report relevant associations at an alpha threshold of 10-4. Genes harboring significant top SNPs were annotated to identify potential explicatory biological pathways.

Results: Overall 4854 patients treated with AI were included. Of these, 3847 had available genetic data. Mean age was 63.9 years (SD 7.2), mean BMI was 27.0 (5.6). 63% patients reported history of articular disease, 41% received chemotherapy. 55% received letrozole, 40% anastrozole and 5% exemestane as first AI. 65% of patients reported AIMT at Y3 (of whom G3 9%), while 86% patients reported AIMT overall (at any time point; of whom G3 18%). Patients with AIMT at Y3 were generally younger, with higher BMI, had previous history of articular or muscular disease, and reported more frequently anxiety or depression at diagnosis. The GWAS identified 9 SNPs as associated with AIMT at Y3: rs4096589 (MAF 0.39; OR 1.36 [95% CI 1.21-1.53]), rs983495 (MAF 0.46; OR 0.76 [0.68-0.85]), rs12964962 (MAF 0.25; OR 0.73 [0.64-0.84]), rs348780 (MAF 0.42; OR 0.77 [0.69-0.86), rs72485589 (MAF 0.13; OR 0.67 [0.56-0.81]), rs2559854 (MAF 0.42; OR 0.78 [0.69-0.87]), rs895876 (MAF 0.16; OR 0.72 [0.61-0.83]), rs2926866 (MAF 0.17; OR 1.40 [1.20-1.66]), rs2240027 (MAF 0.08; OR 1.58 [1.28-1.96]). rs2926866 was also associated with AIMT at Y1 (1.22 [1.05-1.41]), Y5 (1.36 [1.12-1.66]), and overall (1.48 [1.24-1.76]). Relevant molecular functions that were associated with the identified SNPs included protein homodimerization activity (rs4096589), identical protein binding (rs895876), actin- and actin-filament binding (rs2240027).
Conclusions: This was an exploratory study aimed to assess associations between genetic variants and AIMT in postmenopausal patients with early BC. Results of this relatively large prospective cohort identified several SNPs that might be involved in AIMT. Further analyses are warranted for model validation and to better elucidate the mechanistic role of the described genetic variants from a functional perspective.

PS15-03: Retrospective study of GLP-1 Receptor Agonists in Breast Cancer Survivors: Weight Loss and Patient Outcomes

Jasmine Sukumar, Akshara Raghavendra, Sarah Pasyar, Roland Bassett, Debu Tripathy, Carlos H Barcenas, Karen Basen-Engquist, Banu Arun

Background: Obesity in breast cancer (BC) survivors is associated with higher BC recurrence risk and mortality, and weight loss in an important tenet of health promotion. Glucagon-like peptide-1 receptor agonists (GLP1-RA) are incretin mimetics with favorable metabolic effects and approved for type 2 diabetes (DM2) or weight loss. While drug utilization is increasing, the implications in cancer survivors are not well elucidated. This study evaluated treatment patterns of GLP1-RA, weight loss trends, and patient outcomes in a cohort of BC survivors. Methods: We retrospectively analyzed patients with non-metastatic (DCIS or invasive stage I-III) BC treated at MD Anderson Cancer Center (MDACC) who received at least 3 months of GLP1-RA from 2005 - 2024. Data was obtained from the MDACC BC and pharmacy databases. Linear regression models estimated the association between weight change and clinical factors. After excluding patients with DCIS, propensity score matching (1:2 ratio) was used to match patients who received GLP1-RA with those who did not, based on baseline body mass index (BMI), DM2, age, clinical stage, and BC receptor status. Kaplan-Meier estimates and log-rank tests estimated and compared overall survival (OS) and disease-free survival (DFS) between patients who received GLP1-RA and those who did not. Results: In total, 1,022 patients met inclusion criteria. Median age was 54 years (23-86) years, and 56.9% were postmenopausal; 79.0% had DM2. Most (91.4%) had stage I-III invasive BC and 8.6% had DCIS; 80.2% had hormone receptor positive BC and 65.9% received adjuvant endocrine therapy with an aromatase inhibitor (AI) or tamoxifen. GLP1-RA was started following definitive BC therapy (chemotherapy, surgery, radiation) in 87.6%; the median time from BC diagnosis to GLP1-RA initiation in these patients was 4.7 (0.0-34.0) years. The median duration of GLP1-RA use was 1.2 (0.3-8.1) years. Median BMI at BC diagnosis was 33.5 (20.1-56) kg/m2. Baseline median weight and median BMI at GLP1-RA initiation (within 90 days prior) was 86.8 (47.2-175.0) kg and 33.6 (18.9-61.8) kg/m2, respectively. In patients (n=442, 43.2%) who received the drugs approved for weight loss (semaglutide or tirzepatide), median weight loss at 3 (+/- 45 days), 6 (+-/45 days), and 12 (+/- 60 days) months was -1.9% (-13.2%-14.9%), -3.1% (-20.2%-19.0%), and -2.6% (-27.8%-11.5%), respectively. On multivariate regression analysis, no significant association was observed between the 6 month change in weight and clinical factors (DM2, metformin use, endocrine therapy use, duration of GLP1-RA, clinical stage); however, the 12 month change in weight was significantly associated with clinical stage (invasive BC was associated with more weight loss vs DCIS, $p<0.01$) and endocrine therapy (tamoxifen or AI use was associated with weight gain, $p=0.019$). Patients who received endocrine therapy experienced, on average, a 2.83 kg weight gain at 12 months compared to those who did not, after adjusting for other variables in the model. In those with invasive BC (DCIS excluded); there was no significant difference in DFS but there was a significantly improved OS in patients who received GLP1-RA compared with controls (median survival not reached (0-30.9) vs 27.0 years (0-57.3), $p<0.0001$). Conclusion: This is the largest study describing

real world patterns of GLP1-RA use in BC survivors. These medications were associated with modest weight loss; however, endocrine therapy may decrease this impact. An improved all-cause survival was observed, but there was no difference in DFS. Clinical trials are needed to investigate the role of these agents for weight loss as an adjunct to lifestyle interventions in cancer survivors. Further exploration of potential anti-cancer biological effects for BC risk reduction and cancer control may also be warranted.

PS15-04: Impact of a dietitian and nurse-led survivorship clinic utilizing ePRO collection on body composition and muscle strength in early-stage breast cancer: Results from the Linking You to Support and Advice (LYSA) Randomized Control Trial

Katie E Johnston, Kate O'Connell, Naoimh Flynn, Veronica McSharry, Laia Raigal-Aran, Aoife M Ryan, Brendan Palmer, Darren Dahly, Josephine Hegarty, Samantha J Cushen, and Roisin M Connolly

Background: Breast cancer history and adjuvant endocrine therapy use are associated with unfavorable body composition alterations, including increased body weight and adipose tissue mass and decreased muscle mass and strength. Qualitative research highlights that breast cancer survivors are unlikely to receive optimal support to manage these alterations. We evaluated the impact of a dietetic intervention utilizing electronic patient reported outcomes (ePROs) on body composition in a randomized control survivorship trial.
Methods: LYSA (n=200) was a multisite randomized control trial with parallel arms (experimental and active comparator) which assessed the feasibility of a complex survivorship intervention incorporating ePROs in early-stage hormone receptor (HR)-positive breast and gynecologic cancer (NCT05035173, DOI: 10.1200/JCO.2024.42.16_suppl.1505). Amongst those with HR-positive breast cancer (n=168), endocrine therapy use (n=163) included aromatase inhibitors (55%, n=90), tamoxifen (36%, n=59) and ovarian function suppression combinations (8%, n=14). Although not powered to assess between arm differences, a secondary outcome of the trial explored the impact of a dietetic intervention on body composition. Body composition assessments were conducted at baseline and 12 months in both arms, including lean body mass and adipose tissue mass via bioelectrical impedance analysis; muscle strength via handgrip strength, waist circumference and body mass index. The experimental arm completed ePROs bi-monthly from baseline to 12 months including body weight and weight gain concern. ePROs triggered a nurse and dietitian-led personalized symptom management pathway.
Results: In the experimental arm, 63 breast cancer participants initiated 211 dietetic consultations through ePROs. At baseline, weight gain concern was reported by 67% (n=55, active comparator) and 66% (n=52, experimental). At 12 months, weight gain concern increased to 72% (n=56) in active comparator arm but reduced to 52% (n=39) in experimental arm. In the experimental arm, there was a consistent numerical decrease in weight gain concern over the study period: 55% (n=43) at month 2 versus 46% (n=32) at

month 10. Weight remained stable in both arms at 12 months (p=0.057, -1.12 [95% CIs -2.27 to 0.03]). There were non-significant increases in lean tissue mass in the experimental arm versus the active comparator arm at 12 months (35kg [range: 26-60] vs 34kg [22.5 to 49], p=0.718 [95% CI -1.08 to 0.75]). Handgrip strength decreased over 12 months in both arms. However, the experimental arm maintained more muscle strength versus the active comparator arm at 12 months (24kg [11-41] vs 23kg [6.5 to 35.5], p=0.126 [95% CI -0.23 to 1.86]). In all arms, an exploratory analysis showed that participants with stronger handgrip strength were likely to have a higher lean tissue mass.
Conclusion: A dietetic intervention, within a randomized survivorship trial incorporating ePRO collection, appeared to reduce weight gain concern in patients with HR-positive breast cancer. Impact on changes in weight and lean tissue mass should be explored in future trials powered to detect a difference in these endpoints.

PS15-05: Breast Cancer Patients with High-Risk Disease Characteristics have Proportionately Higher Risk of Mortality from Non-Breast Cancer Related Causes in both Non-Metastatic and Metastatic Disease

Varsha Gupta, Vinit Singh, Karan Yagnik, Gurtesh Singh, Shipra Gandhi

Background: Breast Cancer (BC) is the most common cancer among females with significant improvement in survival in both metastatic (mBC) and non-metastatic (nmBC) setting. Prolonged survival increases the risk of acquisition of other comorbidities which may or may not be linked to primary BC, and results in non-breast cancer related mortality (NBCRM). The purpose of this study is to quantify the causes of NBCRM and identify related high-risk disease characteristics.
Methods: Patients with BC diagnosed as first primary between 2010-2019 were identified from SEER 17 registries database 2023, with last follow up till 12/31/2021 and with at least 1-month survival. Demographic and clinical data were extracted. Cause of mortality was based on death certificates of the patient and were extracted from SEER database. We calculated BC related mortality (BCRM) and NBCRM, separately for nmBC and de-novo mBC. Multivariate cox proportional hazard model was used to identify high-risk disease characteristics (based on tumor histology, biomarkers, stage and demographics of the patients) and quantify its association with cause-specific mortality.
Results: 457,655 patients with BC (4.73% de-novo mBC) were identified. 83,797 patients died during the study period with 15,130 (18.05%) death in the mBC. The median OS for mBC was 34 months (95% CI 33-35). Median OS not reached for nmBC. Proportion of BCRM was significantly higher in mBC (87.76%) compared to nmBC (43.44%, p-value < 0.05). Risk of BCRM was higher for older adults (Age >65 Years) (mBC HR 1.47, p <0.05; nmBC HR 1.72, p <0.05) compared to age < 50 years, Non-Hispanic African American (NHAA) (mBC HR 1.32; nmBC HR 1.43, p <0.05) compared NH-White, Triple Negative (mBC HR 2.81, p <0.05; nmBC HR 2.47, p <0.05) compared to HR+/Her2-, Stage II (HR 4.03, p <0.05) and Stage III (HR 14.90, p <0.05) compared to Stage I. Compared to ductal histology, Lobular histology had lower risk of BCRM for nmBC (HR 0.90, p <0.05) and no difference

were seen for mBC (0.99, p 0.94). For NBCRM, risk was higher for older adults (nmBC HR 10.83, p <0.05, mBC HR 3.27, p <0.05) and age group 51-65 years (nmBC HR 2.57, p <0.05, mBC HR 1.64, p <0.05) compared to age ≤ 50 years. TNBC (nmBC HR 1.42, p <0.05; mBC HR 2.26, p <0.05) had higher risk compared HR+/Her2-, and higher risk for Stage II (HR 1.61, p <0.05) and Stage III (HR 2.81, p <0.05) compared to Stage I. Lobular histology had lower risk of NBCRM for nmBC (HR 0.84, p <0.05) and no difference were seen for mBC (HR 0.93, p ~ 0.27). Patient who received radiation had both lesser risk of BCRM (nmBC HR 0.60, p <0.05, mBC HR 0.94, p <0.0003) and NBCRM (nmBC HR 0.54 p <0.05, mBC HR 0.81, p <0.05). Similarly, patients who received chemotherapy had lesser risk of BCRM (nmBC HR 0.94, p <0.05, mBC HR 0.66, p <0.0003) and NBCRM (nmBC HR 0.48 p <0.05, mBC HR 0.52, p <0.05). Cardiovascular (30.76%) and subsequent malignancies (19.62%) were the most common causes of NBCRM for nmBC. For mBC, subsequent malignancies (30.24%) and Cardiovascular (24.78%) were the 1st and 2nd most common causes.
Conclusions: With the rising number of BC survivors, it is imperative to identify high-risk disease characteristics which can lead NBCRM. TNBC, ductal histology (for nmBC), and late stage confers higher risk for both BCRM and NBCRM and conveys need for better treatment strategies. Cardiovascular death and subsequent malignancies are significant irrespective of stage of diagnosis and so adherence to preventative health guidelines and lifestyle modifications is crucial. Our study reflects the need to focus on survivorship specifically for older adults and NHAA.

PS15-06: Ability to comply with placebo predicts overall survival in randomized trial

Tara Sanft, Jieling Miao, Allison Meisner, Shay Bellasea, William E. Barlow, Mariana Chavez-MacGregor, Lajos Pusztai

Background: Poor compliance with medications has been linked to inferior health outcomes. Inability to complete therapy is often attributed to adverse effects from the treatment or its financial burden. However, other less easily measurable factors (e.g. trust in the recommendation, fear of future adverse events, nocebo effect, misinformation, convenience, competing life priorities, etc.) can also influence patients' willingness and ability to follow medical recommendations. In this study, we compared the survival of patients who completed versus not the everolimus placebo pill assigned in the control arm of the S1207 randomized trial.
Methods: The S1207 trial compared 1 year of adjuvant everolimus versus 1 year of placebo added to standard of care adjuvant endocrine therapy. No benefit of everolimus was seen for invasive disease-free (IDFS) or overall survival (OS1. Treatment completion rates were 48% in the everolimus arm and 73% in the placebo arm. In this exploratory analysis, we assessed in the control arm if iDFS and OS differed between patients who could complete 1 year of placebo versus those who could not. The Kaplan-Meier method was used to estimate survival from 1 year (i.e. end of treatment period) and the log rank test to compare the groups. Multivariable Cox regression model included age, performance status, and

prognostic risk group1 as covariates.
Results: This 1-year OS landmark analysis included 823 patients in the placebo arm. Median age was 54 years, 86% were White, 32% premenopausal, and 80% were in prognostic risk groups 3 (i.e. ≥ 4 positive nodes at diagnosis) and 4 (≥ 1 positive nodes after neoadjuvant chemotherapy). Two hundred and twenty-one patients (18%) did not complete placebo defined as taking < 75% of total planned placebo pills. Grade 1-2 adverse events (AE) were reported in 77% (515 out of 670) of the patients in the completer cohort and in 63% (133 out of 211) ($p < 0.0001$) of the non-completer cohort. Grade ≥3 AEs were reported in 5% and 13% ($p < 0.0001$) respectively. After placebo discontinuation, endocrine therapy continued for 89% of patients in the completer and 85% of patients in the non-completer cohort (p=0.30). The 1-year iDFS landmark analysis included 782 patients in the placebo arm. The estimated 5-year iDFS rates from 1-year were similar, 76.4% and 78.2% respectively (HR=0.95, 95% CI: 0.64 –1.41, p=0.81). At median follow-up of 74 months, the 5-year OS rate from 1-year among placebo completers and non-completers was 88.6% and 67.4%, respectively (HR=0.32, 95%CI: 0.22-0.44, p<0.0001). In multivariable analysis, only completer status was associated with improved OS (HR=0.31, 95%CI 0.22-0.44, p<0.0001).
Conclusion: Patients who were not able to complete the assigned placebo drug in the control arm of the randomized S1207 trial had significantly lower OS compared to those who completed the assigned placebo treatment.

PS15-07: Late effects of chemotherapy on patient-reported falls among older breast cancer survivors

Inimfon Jackson, Kaiping Liao, Susan K. Peterson, Liang Li, Daria Zorzi, Holly M. Holmes, Mariana Chavez Mac Gregor, Sharon H. Giordano

Introduction: It is unknown whether adjuvant chemotherapy increases the risk of falls in older breast cancer (BC) survivors. We evaluated the long-term impact of chemotherapy receipt on patient reported balance problems and falls among older BC survivors.

Methods: Using the Texas Cancer Registry (TCR)-Medicare linked data, BC survivors aged 65 years and older at diagnosis, with local/regional disease, and diagnosed between 2012–2013 were identified. Self-administered questionnaires collected information on patient-reported outcomes (including treatment side effects), demographic and clinical variables between April 2018 and October 2019. Rao-Scott Chi-square tests were used to examine the association between chemotherapy receipt after initial cancer diagnosis and patient-reported falls in the 12 months prior to survey completion, balance problems and receipt of fall prevention interventions (such as assistive devices or physical therapy). Multivariable logistic regression models were used to evaluate the factors associated with patient-

reported falls and balance problems.

Results: Of the 1,493 BC survivors who completed the survey, majority were non-Hispanic white (83.8%), with a history of hormone receptor positive (HR+) BC (77.1%) and localized stage disease (76.6%). 28.3% received adjuvant chemotherapy, and 89% of those received a taxane. Patients who received chemotherapy were more likely to report severe numbness/tingling (12.3% vs 5.1% p <0.0001). However, falls in the past 12 months (32.0% vs 32.9%, p = 0.77), and balance problems (50.3% vs 49.8%, p = 0.86) were similar between chemotherapy vs non-chemotherapy treated groups. In adjusted analysis, taxane use was not significantly associated with falls (aOR: 1.15; 95% CI 0.87–1.52), but older age and higher comorbidity scores were. Patients treated with a taxane were more likely to report problems with balance and walking than those who did not receive chemotherapy (aOR: 1.36; 95% CI 1.04–1.78). Black (aOR: 1.64; 95% CI 1.00–2.69) and Hispanic (aOR: 1.69; 95% 1.14–2.50) BC survivors were more likely to receive an intervention from their health care provider to prevent falls or treat balance problems compared to White survivors.

Conclusion: Chemotherapy use is associated with persistent numbness/tingling more than 5 years after treatment in older BC survivors and patients treated with taxanes are more likely to report balance and walking problems than survivors who did not receive chemotherapy. However, these persistent symptoms and chemotherapy use were not associated with a higher risk of falls among older breast cancer survivors.

PS15-08: Factors and trends associated with alcohol intake in late survivorship for patients with breast cancer

Sanjna Rajput, Robert A Vierkant, Nicole L. Larson, Daniela L. Stan, Dawn M. Mussallem, Shawna L. Ehlers, Stacy D. D'Andre, Fergus J. Couch, Janet E. Olson, Ciara C. O'Sullivan, Kathryn J. Ruddy

Background: Alcohol intake (AI) has consistently been shown to increase the risk of breast cancer (BC), and AI during survivorship may impair prognosis. The American Cancer Society, American Institute for Cancer Research, and National Comprehensive Cancer Network guidelines recommend that female survivors abstain from or limit AI to no more than 1 drink per day. Yet many US cancer survivors self-report regular AI, including some who display excessive drinking behaviors. As AI is potentially modifiable, a better understanding of factors associated with AI in BC survivors may inform public health strategies to reduce risk of recurrence. This study aimed to describe sociodemographic and treatment-related predictors of AI near the time of BC diagnosis, and approximately four years after the same.
METHODS:
Adult patients newly diagnosed (within 1 year prior) with BC (stage I-III) and seen at Mayo Clinic Rochester were invited to enroll in the Mayo Clinic Breast Disease Registry. Those

who consented to participate between 12/4/2014 and 4/16/2018 (N=3252) were asked to complete self-reported questionnaires at baseline and at four years after diagnosis. These questionnaires included questions about weekly AI, education, and other demographic factors. Respondents reported weekly AI as follows: none, 1-4, 5-9, 10-14, 15-19, 20-29, 30-39, or 40+ drinks per week, with one drink defined as 5 ounces of wine, 12 ounces of beer or 1 ounce of liquor. Three patients with recurrences were excluded (N=734). Clinical data were abstracted from medical records by a trained nurse abstractor. Questionnaire data from year 2 were used to understand how posttraumatic symptoms, assessed by the Impact of Event Scale (IES-R), as well as depression, assessed by the PHQ-2, might be associated with later AI. Univariate models were used to assess which factors were associated with higher AI (5+ drinks per week) at year 4. Associations of AI with variables of interest were assessed using Cochran Mantel Haenszel tests for trend. This longitudinal cohort study was approved by the institutional review board.

Results: Among 734 participants who reported their weekly AI at both timepoints (mean age 58.5 years, 98.9% female, 97% white), 176 (24%) and 137 (18.7%) reported AI of ≥5 drinks weekly at baseline and year 4, respectively. Higher AI at baseline was strongly associated with higher AI at year 4 ($p<0.001$). There was a decrease in total AI over time across the cohort ($p=0.003$). In univariate models, younger age at cancer diagnosis ($p<0.001$), not having received radiotherapy ($p=0.05$), and carrying a known deleterious BRCA mutation ($p=0.05$) were associated with greater AI at year 4. Smoking was associated with greater AI at both baseline and year 4 ($p<0.001$). More minutes of moderate intensity exercise (described as “not exhausted”, example fast walking) and mild intensity exercise (described as “minimal effort”, example easy walking), higher Godin activity scores, and greater physical health at baseline and year 4 were also associated with increased AI. The IES-R total score at year 2 was strongly positively associated with high AI at year 4 ($p<0.001$), as were IES-R subscale scores for intrusion ($p=0.008$), avoidance ($p=0.006$), and hyperarousal ($p<0.001$). Higher depression scores at year 2 also were linked to greater AI at year 4 ($p=0.04$). Financial stability, educational status, having received chemotherapy, having received endocrine therapy, tumor stage and type of surgical treatment pursued were not associated with AI at year 4.

Coclusion: While overall AI decreased over time in this cohort of BC survivors, AI at baseline was still associated with AI at 4 years. Young patients and those with deleterious BRCA1/2 mutations, as well as those who reported posttraumatic distress and depressive symptoms at year 2, were more likely to report AI at year 4 after a BC diagnosis. These findings may inform targeted public health interventions to mitigate AI and improve BC outcomes.

PS16-01: Longitudinal validation in the UK Biobank of a breast cancer risk assessment tool that combines a polygenic score for all ancestries with traditional risk factors

Timothy Simmons, Elisha Hughes, Srikanth Jammulapati, Dmitry Pruss, Eudora Hu, Ryan Bernhisel, Allison Kurian, Holly J. Pederson, Pat Whitworth, Sarah Ratzel, Jeff Jasper, Katie Johansen Taber, Alexander Gutin

Background: Polygenic risk scores (PRS) have been shown to improve predictive accuracy when incorporated into traditional breast cancer (BC) risk assessment tools. However, most PRS have demonstrated suboptimal performance among women of non-European ancestry. We improved a previously reported multiple-ancestry PRS (MA-PRS) to create a second-generation MA-PRS consisting of 56 ancestry-informative and 329 BC-associated single-nucleotide polymorphisms (SNPs). MA-PRS achieved accuracy for diverse populations by characterizing genetic ancestry at each BC SNP and applying ancestry-specific SNP risks and frequencies. Here, we present longitudinal validation of a combined risk score (CRS) that integrates the second-generation MA-PRS with Version 8 of the Tyrer-Cuzick (TC) model using data from the UK Biobank (UKBB).
Methods: The study cohort comprised 198,872 female participants from the UKBB with no history of cancer at the time of study enrollment. Data was dispensed on September 20, 2023. The primary outcome was the time from enrollment to diagnosis of invasive BC or censoring. CRS calibration was assessed by comparing observed (O) to expected (E) incident BCs. The ability of CRS and TC to discriminate between women diagnosed with BC versus women who were unaffected throughout study follow-up was measured by Cox proportional hazards models adjusted for age and ten genetic principal components. We used Kaplan-Meier analysis to examine BC incidence for patients classified as high-risk or low/moderate-risk according to a 5% 10-year risk threshold. Analyses were conducted in both the full cohort and in a subset of 11,563 female participants of self-reported non-White ancestry.
Results: After a median follow-up of 11.8 years, 7,127 (3.6%) participants from the overall cohort and 315 (4.4%) non-White participants were diagnosed with invasive BC. The CRS was well calibrated in the overall cohort (O/E 1.00; 95% CI 0.97-1.02) and in the non-White sub-cohort (O/E 0.91; 95% CI 0.81-1.02). The incorporation of MA-PRS led to significantly improved discriminatory accuracy of CRS compared to TC in both the overall cohort (p=8.2´10^-320) and in the non-White sub-cohort (p=3.1´10^-04). More participants were identified as high risk by CRS (13.0%) than by TC alone (8.4%). Among those classified as high risk by TC, 39.3% were low/moderate risk by CRS, and of those classified as low/moderate risk by TC, 8.6% were high risk by CRS. In cases where CRS and TC classifications disagreed, CRS was more accurate in predicting incident BC.
Conclusion: The CRS, incorporating a second-generation MA-PRS, was well-calibrated in predicting BC and significantly improved upon a traditional risk factor model in UKBB participants unaffected with BC at the time of enrollment. Clinical use of CRS has the potential to improve BC survival through more accurate identification of individuals at high risk.

PS16-02: Polygenic risk score as an aid for risk stratification in benign breast disease

Kush R Lohani, Stacey J Winham, Bryan McCauley, Robert A Vierkant, Tanya L Hoskin, Matt Jensen, Jessica Fischer, Denice Gehling, Christine Schmelzer, Lori Denison, Laura Pacheco-Spann, Lisa Seymour, Derek C Radisky, Mark E Sherman, Celine M Vachon, Amy C Degnim

Background: Pathologic diagnoses of benign breast disease (BBD), subclassified by histologic impression as non-proliferative disease (NP), proliferative disease without atypia (PDWA) and atypical hyperplasia (AH), predict increasing breast cancer risk (BC) in populations; however improved methods to predict individual risk are needed. Research has established that a polygenic risk score (PRS) based on variation in 313 single nucleotide polymorphisms (SNPs) predicts breast cancer (BC) risk in the general population, but data among women with BBD are limited. Thus, we evaluated a PRS in a large single institutional study to assess associations with BBD subtype and BC risk.

Methods: With IRB approval, we evaluated 3,943 subjects in our institutional BBD cohort with existing genotyping data or germline buccal DNA that was genotyped with Illumina's Global Screening Array; these comprised a sample from the underlying BBD cohort of 20,380 women from years 1967-2013, for whom followup data were available on later BC events.

PRS was computed using 261 of the published 313-PRS SNPs that were commonly available across all datasets. The PRS was a weighted linear combination of the genotypes and odds ratios from the largest BC genome-wide association study (GWAS) to date. PRS was standardized within genotyping platform and evaluated per one standard deviation. BBD histologic impression was based on pathology review as NP, PDWA, or AH. Odds ratios (OR) and 95% confidence intervals (CI) for the PRS and histologic impression were calculated using logistic regression, adjusted for age and genotyping platform. Models were examined for histologic impression alone, PRS alone, and the two factors combined. Also, associations between PRS and histologic impression were assessed as well as potential interactions between the two variables on BC risk.

Results

Of the 3,943 women with BBD and PRS data, 857 were cases (i.e., developed BC after BBD) and 3086 were controls. Across the entire sample, histologic impression was NP in 56%, PDWA in 35%, and AH in 9%. The PRS scores after normalizing by platform across the 3,943 women in the sample had a mean of -0.007 with a standard deviation of 1.001 and a range of -3.67 to 3.94. In multivariable models estimating risk of BC based on a referent of NP and mean PRS, factors associated with risk included: PRS (per-SD OR=1.52, 95% CI: 1.39-1.66); PDWA (OR=1.63, 95%CI: 1.35-1.97) and AH (OR=1.71, 95%CI: 1.26-2.30), all significant at $P<0.001$. An interaction term between BBD histologic impression and PRS was not statistically significant ($p>0.70$).

Conclusions: Our analysis suggests that both BBD histologic subtype and PRS are independently associated with BC risk; thus, PRS information may be helpful for personalizing risk assessment in the setting of BBD.

PS16-03: Isoform-level analyses of breast cancer and its subtypes uncover extensive genetic risk mechanisms undetected at the gene-level

Taylor Head, Yung-Han Chang, Tabitha Harrison, Yao Yu, Chad D. Huff, Bogdan Pasaniuc, Sara Lindström, Arjun Bhattacharya

Integrating genome-wide association studies (GWAS) and transcriptomic datasets can identify potential mediators for germline genetic risk of breast cancer. However, traditional methods have been largely unsuccessful at most loci because of an overreliance on total gene expression. These approaches overlook alternative splicing, which can produce multiple isoforms from the same gene, each with potentially different effects on cancers. Here, we integrate genetic and multi-tissue isoform-level expression from the Genotype Tissue-Expression Project (GTEx, N = 838) with publicly available European-ancestry GWAS summary statistics to identify both isoform- and gene-level risk associations with overall breast cancer and estrogen receptor-positive (ER+) and -negative (ER-) subtypes. We employ our recently developed isoform-level Transcriptome-Wide Association Study (isoTWAS) framework that jointly models germline genetic variation, all isoforms of a gene, and phenotypic associations to identify transcriptomic mediators of genetic risk loci. Directly modeling isoform expression substantially increases discovery of transcriptomic mechanisms underlying genetic associations, compared to traditional methods leveraging total gene expression.

Across the 3 indications, isoTWAS identified 2,304 more unique genes than TWAS, reflecting an 34.3% increase (jackknife SE = 3.8%) in effective sample size. In total, we find that isoTWAS-prioritized genes are enriched for pathways involved in DNA repair and damage responses, apoptosis, DNA and transcription factor binding, and cell cycle regulation. In addition, these genes are enriched for transcription binding sites of oncogenic transcription factors, like RUNX2, ESR1, and MYC. Critically, isoTWAS is able to pinpoint an isoform-specific mediation of the ESR1 and FOXA1 loci using isoform expression of non-cancerous breast tumor.

Next, isoTWAS associations are enriched for genes that are evolutionary constrained and showing intolerance to protein-truncating variation (pLI score 0.90), prioritizing 587 constrained genes compared to 153 by TWAS (P = 2.8 x 10-9). This result suggests that isoform associations capture more likely disease signal. Of the 309 independent GWAS loci across the 3 indications, isoTWAS tagged 42% additional GWAS loci with transcriptomic associations (221 loci with isoTWAS, 156 with TWAS, 124 in common). Relatedly, the cis-genetic component of isoform expression (20.8 ± 7.3%) mediates an estimated 92.4% more of cancer risk SNP heritability compared to that of gene expression (10.8 ± 2.6%), using Mediated Expression Score Regression. Lastly, we highlight several salient and novel isoTWAS associations that exhibit isoform but not gene expression colocalization, including BABAM1 and FDPS, associated with overall breast cancer risk, and L3MBTL3 and CASP8, associated with ER- breast cancer risk.

Our results strongly demonstrate that modeling isoform expression is crucial to maximize discovery of genetic risk mechanisms for breast cancer that are testable and actionable.

PS16-04: Differences in breast cancer phenotype by germline TP53 variant functional classification.

Renata L. Sandoval, Michele Bottosso, Miki Horiguchi, Natalia Polidorio, Anh Le, Brittany L. Bychkovsky, Benjamin Verret, Alessandra Gennari, Sophie Cahill, Alison Schwartz-Levine, Olivier Caron, Marion ImbertBouteille, Catherine Noguès, Pauline Rochefort, Kara N. Mawell, Maria Isabel Achatz, Fabrice Andre, Judy E. Garber

Introduction: TP53 is a multi-functional tumor suppressor gene, with several important roles in tumorigenesis. Females who harbor germline TP53 pathogenic/likely pathogenic variants (GPV) have a very high lifetime risk of developing breast cancer (BC), especially hormone receptor positive and HER2 positive tumors. Specific TP53 variants have different functional consequences for molecular pathways and somatic aberrations in cancers, leading to the hypothesis that the type of TP53 GPV could modulate breast tumor phenotype.
Objective: To examine differences in TP53 GPV and their predicted functional impact on age at first BC diagnosis and BC subtype (ER and HER2 status).
MATERIAL AND METHODS: This multicenter international cohort was comprised of female TP53 GPV carriers diagnosed with any invasive BC (non-metastatic or de novo metastatic). We included TP53 variants classified as GPV in ClinVar, or classified as GPV by at least one major laboratory, or truncating variants. Carriers of a second GPV in other BC genes and carriers of TP53 GPV downgraded to a variant of uncertain significance by the TP53 ClinGen-VCEP were excluded. Clinical data were abstracted from medical records. TP53 GPV were classified according to mutation type: nonsense, frameshift, missense affecting the DNA binding domain (Missense_DBD) or the tetramerization domain (Missense_TD), variants affecting splicing, and copy number variations. For this report, functional classification was performed using Fortuno's classification based on two germline TP53 databases from commercial labs. Functional classification categories included: missense variants with dominant negative effect (Missense_DNE) and without DNE (Missense_notDNE), truncating and hotspots variants. The bivariate association between tumor phenotype and each of the variables (mutation type and Fortuno's functional classification) was assessed using two-sample Wilcoxon test for continuous and Fisher's exact test for nominal categorical variables.
Results: Among 301 females who met study criteria,mean age of BC diagnosis was 37.0 years (SD 10.46), 187 (62.1%) met Li-Fraumeni syndrome clinical criteria (revised Chompret or Classic criteria), and 41 (13.6%) had bilateral synchronous BC. The distribution of BC subtypes was: 108 (35.9%) ER+/HER2-, 79 (26.2%) ER+/HER2+, 62 (20.6%) ER-/HER2+, 20 (6.6%) ER-/HER2-, and 32 (10.6%) ER unknown and/or HER2 unknown. Most TP53 GPV were missense variants (n=217; 141 Missense_DBD, 76 Missense_TD). In comparison to Missense_TD, Missense_DBD carriers had a younger age at BC diagnosis (35.7 vs 42.3, p<0.01), lower rates of ER+ disease (63.1% vs 80.3%, p<0.01), and higher rates of HER2+ disease (48.9% vs 27.6%, p<0.01). When considering ER and HER2 subtypes, Missense_TD carriers had more ER+/HER2- BC (51.3% vs 34.8%, p=0.02) and Missense_DBD carriers had more ER-/HER2+ tumors (22.0% vs 5.3%, p=<0.01).

According to Fortuno's classification, 89 (29.6%) TP53 GPV were Missense_notDNE, 59 (19.6%) Missense_DNE, 80 (26.6%) truncating, 49 (16.3%) hotspots variants, and 24 (8.0%) variants unclassified by the method. Among all these categories, Missense_notDNE variants were associated with older ages of BC diagnosis (51.7% above 40 years; $p<0.001$), higher rates of ER+ disease (79.8%; $p<0.001$), lower rates of HER2+ tumors (29.2%; $p<0.001$), and lower rates of bilateral synchronous BC ($p=0.003$).
CONCLUSIONS: These findings suggest that TP53 GPV functional status can influence age at breast cancer presentation and tumor ER/HER2 status which can potentially improve targeted treatment strategies and inform risk prediction and risk reduction strategies.

PS16-05: Primary breast cancer prevention using oral endoxifen

Per Hall, Stephen Nash, Magnus Bäcklund, Jenny Bergqvist, Mattias Hammarström, Mikael Eriksson, Steven Quay, Kamila Czene

Estrogens play a crucial role in regulating the growth and differentiation of glandular cells in the breast. Tamoxifen blocks the effect of estrogens through binding to the estrogen receptor thereby altering downstream signaling. Tamoxifen was approved by the U.S. Food and Drug Administration (FDA) in 1977 for the treatment of breast cancer. In 1997 the FDA accepted tamoxifen for prevention of breast cancer. Theapproval for prevention was based on results from several large randomized controlled trials targeting women aged 35 years or older with a 5-year breast cancer risk of 1.67% or higher.
Despite tamoxifen's success in reducing the recurrence risk of breast cancer, its systemic side effects have led to generally low acceptance. Also, the effect is heterogeneous because tamoxifen acts as a pro-drug that needs to be metabolization in the liver, primarily via the CYP2D6 enzyme. The most potent metabolite is endoxifen.
Recent studies have shown that breast cancer patients who are poor or ultrarapid metabolizers have a worse outcome than intermediate and normal metabolizers. Poor metabolizers have too low endoxifen levels, while ultrarapid metabolizers often discontinue therapy due to unacceptable side effects. Additionally, common medications, such as selective serotonin reuptake inhibitors, influence CYP2D6 activity, altogether leading to a heterogeneity in tamoxifen efficacy. Endoxifen has been proposed as an alternative, not needing activation and not influenced by drug interactions.
It has been shown that tamoxifen-induced mammographic density decrease is strongly associated with tamoxifen therapy response. Thus, a change in mammographic density could be used for evaluating the effect of endoxifen and / or tamoxifen. A density decrease could also theoretically be used to increase the sensitivity of a mammogram since density influences the ability to identify breast cancer on a mammogram.
The ATOS-016R trial is a phase 2, randomized, double-blinded, placebo-controlled, study of oral (Z)-endoxifen (2 mg, 1 mg, and placebo; 80 women in each arm) in premenopausal women with measurable breast density. The trial invited women aged 40-55 years from three hospitals in Stockholm, Sweden.
The primary objective is to determine if six months of daily (Z)-endoxifen can lead to a relative reduction in mammographic breast density area (cm^2). The secondary objective is

to assess the safety and tolerability of daily oral (Z)-endoxifen. The exploratory objectives are to: i) determine if daily oral (Z)-endoxifen for a maximum of six months results in at least a one-category reduction in the BI-RADS scale, ii) study the durability of (Z)-endoxifen effect on breast density response at 24 months post-standard of care screening mammogram, and iii) evaluate the levels of endoxifen over time and correlate endoxifen values to density change.
Standard of care mammograms was used for the screening mammogram. Two study mammograms (each equivalent to the radiation dose of half a normal mammogram) was performed at 3 and 6 months. Clinical labs, vital signs, adverse events, and responses to questionnaires was used to assess safety and tolerability.
The study was launched in December 2021, and the end of follow-up for the last of the 240 women is scheduled for June 14, 2024. Early results are expected in the fall of 2024.
The ATOS-016R trial is a follow-up study to the KARISMA Low Dose Tamoxifen trial presented at SABCS in December 2023. In that trial, we showed that substantially lower doses of tamoxifen (2.5 mg) reduced mammographic density to the same extent as the established 20 mg dose. Severe side effects were reduced but reports of menopausal-like side effects associated with tamoxifen exposure were still substantial.

PS16-07: Quantitative breast density measures and radiomic parenchymal phenotypes improve breast cancer risk prediction among Black and White women undergoing mammography screening

Anne Marie McCarthy, Stacey Winham, Christopher Scott, Aaron Norman, Walter C. Mankowski, Alex Nguyen, Sarah Ehsan, Matthew Jensen, Eric A. Cohen, Hannah Horng, Andrew D. A. Maidment, Kathleen Brandt, Emily F. Conant, Karla Kerlikowske, Despina Kontos, Celine M. Vachon

Breast parenchymal patterns identified on mammograms are associated with breast cancer risk. Breast density, which is clinically and visually assessed based on the BI-RADS lexicon, is a well-recognized risk factor for breast cancer that has modest reproducibility. Black women have, on average, lower BI-RADS categorized density than White women, despite having higher volumes of dense breast tissue when density is measured quantitatively. Beyond breast density, we recently identified and validated six parenchymal phenotypes, based on 390 radiomic texture features extracted from 2-D full-field digital mammograms performed from 2011 through 2014 from a racially diverse population of 30,000 women. The six phenotypes were also significantly associated with breast cancer risk after adjusting for BI-RADS density among Black and White women. The purpose of this study was to evaluate whether the combination of quantitative breast density measures (dense volume and volumetric percent density) with the parenchymal phenotypes improves breast cancer risk prediction, particularly among Black women. Eligible women were aged ≥35 with no prior history of breast cancer who underwent routine screening mammography at two large academic medical centers. Invasive breast cancer cases were identified and matched to controls in a 1:3 ratio based on age within 5 years, race, timing of images, and

mammogram site. The six phenotypes were estimated on the 1055 invasive breast cancer cases and 2764 controls, of whom 144 cases and 390 controls were Black and 875 cases and 2298 controls were White. BI-RADS density was clinically assessed according to the 4th or 5th edition lexicon. Dense volume (DV) and volumetric percent density (dense volume / total breast area, VPD) were estimated using Volpara software. Conditional logistic regression was used to estimate the associations of BI-RADS density, quantitative density, and radiomic parenchymal phenotypes with breast cancer risk, adjusted for age and BMI. Area under the receiver operating curve (AUC) was also calculated for each model. Both dense volume and radiomic phenotypes were significantly associated with breast cancer risk among both Black and White women ($p<0.05$). Among White women, age and BMI adjusted models including BI-RADS density (AUC=0.600), volumetric percent density (AUC=0.596), and dense volume (AUC=0.601) yielded similar AUCs. For Black women, BI-RADS density had higher AUC (0.630) than VPD (AUC=0.599) or dense volume (AUC=0.607). The addition of parenchymal phenotypes to the models increased discrimination to a greater extent for Black women (BI-RADS + radiomics AUC=0.679, 95%CI=0.632-0.725, VPD + radiomics 0.666, 95%CI=0.619-0.713, and DV + radiomics 0.679, 95%CI=0.632-0.725) than for White women (BI-RADS + radiomics AUC=0.609, 95%CI=0.589-0.629, VPD + radiomics AUC=0.607, 95%CI=0.588-0.627), and DV + radiomics AUC=0.623, 95%CI=0.603-0.643). The model containing age, BMI, BI-RADS density, radiomic parenchymal phenotypes yielded significantly higher AUC among Black women (AUC=0.692, 95% CI 0.646-0.737) compared with White women (AUC= 0.625, 95%CI=0.606-0.645). These results suggest that incorporation of parenchymal phenotypes based on radiomic features improves breast cancer risk prediction and that the addition of quantitative breast density measures further improves risk prediction particularly among Black women.

PS16-08: Trends in LCIS Incidence from 2000-2020 Mirror USPSTF Screening Guidelines: A SEER Registry Analysis

Anna C Beck, Madhuchhanda Roy, Ashley A Woodfin, Benjamin W Weber, Meeghan A Lautner, Nicci Owusu-Brackett, Laura Bozzuto, Heather Neuman, Lee G Wilke, Mai A Elezaby

Introduction: Lobular carcinoma in situ (LCIS) is a proliferative breast lesion that is associated with an increased risk of developing breast cancer. The United States Preventative Task Force (USPSTF) screening mammography guidelines have had a significant impact on screening practice. This is especially true for women aged 40-49 who were recommended screening in the 2002-2009 guidelines but not in the 2009 guideline. The incidence and population level impact of LCIS has not been characterized in association with imaging utilization, specifically changes in the USPSTF screening mammography guidelines. We sought to determine if variations in the incidence of LCIS in the US population correlated with changes in mammographic screening guidelines.

Methods: Utilizing the Surveillance, Epidemiology and End Results (SEER) 22 Registries

2000-2020, we identified all diagnoses of LCIS from 2000-2020 using the ICD-0-3 Hist/behave code 8520/2. Patients <20 years of age and those with a prior breast cancer diagnosis were excluded. Age adjusted incidence per 100,000 was analyzed for trends over the study period. Simple linear regression models were used to determine significance in trend with set at 0.05. Joinpoint version 5.0 was utilized to evaluate the average annual percent change (APC) in age-adjusted incidence over time. Inflection points were set at the years USPSTF screening mammography guidelines changed (2002 and 2009) to evaluate temporal trends before and after the change in guidelines.

Results: 71,588 documented cases of LCIS were identified within the SEER database between 2000-2020. Since 2000, the age-adjusted incidence of LCIS increased from 2.8 per 100,000 to 3.0 per 100,000 in 2020 (p=0.006), with the highest incidence recorded in 2009 at a rate of 3.7 per 100,000. Between 2002 and 2009, during which time USPSTF guidelines recommended starting screening mammography at age 40, joinpoint analysis identified a significantly increased rate of LCIS diagnosis with an APC of 3.6 (confidence interval [CI] 2.2-4.7, p<0.01). Prior to this change in guidelines, from 2000-2002, APC of LCIS incidence was 0.06 (CI -5.5-2.8, p=0.84). Following 2009, when the USPSTF guidelines recommended against routine screening for women ages 40–49 and the reduced screening frequency for women ≥50, APC was -1.2 (CI –[1.8-0.31], p<0.01). Subset analysis was performed separating patients by age group given the differences in screening recommendations by age over the study period. From 2002-2009, the incidence of LCIS was found to increase the greatest in women age 40-49 (APC 5.6, CI 4.8-7.1, p<0.01), although the incidence also increased in women age 50-59 (APC 2.5, CI 1.1-3.3, p<0.01) and those aged 60-69 (APC 0.65, CI -0.01-1.6, p=0.052). From 2009-2020, however, the incidence of LCIS declined in women age 50-59 (APC -1.5, CI –[2.1-0.51], p<0.01) and age 60-69 (APC -2.0, CI –[2.5-1.7], p<0.01), while the incidence of LCIS was unchanged in women age 40-49 (APC -0.39, CI -1.1-0.28, p=0.22).

Conclusions: Incidence of LCIS has increased from 2000 to 2020 with rate of change mirroring changes in USPSTF screening guidelines, with higher incidence identified when guidelines recommended initiating screening at age 40. This suggests that early initiation of screening may lead to diagnosis of LCIS at a younger age, which may allow for earlier initiation of risk-reducing interventions. Given the recent USPSTF guideline changes recommending screening mammography initiation at age 40, we anticipate a future increase in the incidence of LCIS diagnoses in screened populations and subsequently increased opportunity and demand for education, tailored supplemental screening, and risk management for these individuals with LCIS.

PS16-09: A decision support intervention to promote the use of preventive therapy among women at high risk for invasive breast cancer

Inimfon Jackson, Lisa Lowenstein, Parijatham S. Thomas, Therese Bevers, Viola Leal, Jurnie Hinde, Robert J. Volk, Abenaa M. Brewster Background: Clinical trials have reported

significant breast cancer risk reduction with preventive therapy among women at high risk for invasive disease, but these medications remain underutilized. We developed risk communication and decision support tool comprised of an educational video and graphic display of benefits of preventive therapy for providers to use during patient consultations. The primary aim was to increase the uptake of preventive therapy among high-risk women.
Methods: Women aged 35–69 years with a history of lobular carcinoma in situ (LCIS) or atypical hyperplasia (AH) receiving care at MD Anderson Cancer Center, Houston, Texas, were eligible to participate. After cognitive testing, a field test was performed on two patient populations before (pre-implementation) and after incorporating the tool into clinical practice (implementation). Study participants completed self-administered questionnaires including knowledge about preventive therapy, treatment preferences, decisional conflict, shared decision-making process and Ottawa acceptability scales; physicians completed surveys on their experiences with the decision support tool. Descriptive analyses and standard tests of association were performed.
Results: Of the 48 female participants who completed surveys, 21 were in the implementation group. Majority of the participants were non-Hispanic (80.8%), White (75%), with a college degree or more (63.8%) and mean age of 53 years. Most participants had good knowledge about the role of preventive therapy but only 10% pre-implementation and 15% in the implementation group correctly identified that taking preventive therapy can reduce the risk of breast cancer by up to 50%. Overall, 65.2% of participants were leaning towards taking preventive therapy. Compared to those in the implementation group, women in the pre-implementation group were more likely to be unsure about their decision (34.6% vs 20.0%, p=0.088). Participants in the implementation group were less likely to take preventive therapy (57.1% vs 70.4%, p=0.428). Decision making process scores were high (3.26 vs 3.65, p=0.122) and decisional conflict was low in both groups (12.9 vs 16.1, p=0.498). While participants in the implementation group agreed that the amount of information provided by the tool was just right (80%), they found the materials slanted towards taking preventive therapy (75%). Using a psychometric assessment, physicians gave high ratings for acceptability (mean 4.1, SD 0.6), feasibility (mean 4.4; SD 0.60) and appropriateness (mean 4.2, SD 0.6) of the tool and were satisfied/very satisfied (83.3%) with the tool.
Conclusion
Although study participants had good health literacy, the majority were unaware of the significant benefit of preventive therapy in reducing breast cancer risk. A greater percentage of women in the pre-implementation group were unsure about their decision compared to women who received the tool but after receiving the tool, women in the implementation group were less likely to agree to preventive therapy. These findings suggest that the decision support tool might reduce the proportion of patients uncertain about preventive therapy but increase preference for not starting treatment. The next steps are to enhance provider discussions on the benefits of preventive therapy, test the decision support tool in less educated and underrepresented minority populations, and track adherence to preventive therapy in patients who receive the tool.

PS17-01: Spatial transcriptomics identifies molecular patterns predictive of response to neoadjuvant chemotherapy in triple-negative breast cancer

Isobelle Wall, Jelmar Quist, Sarah Pinder, KCL Biobank, Sheeba Irshad, Cheryl Gillet, Victoria Seewaldt, David Frankhouser, Shankar Subramanium, Maddy Parsons, and Anita Grigoriadis

Background: Triple-Negative Breast Cancer (TNBC) is a highly aggressive subtype of breast cancer and only ~40% of TNBC patients achieve pathological complete response (pCR) following neoadjuvant chemotherapy (NACT). Since molecular heterogeneity of TNBC contributes to NACT response, we investigated their histology and spatial transcriptomics (ST) patterns.
Methods: In total, 97 core biopsies, taken prior to (n = 92) or during (n = 5) treatment, and 44 post-treatment surgical resections were collected from 96 women with TNBC receiving NACT from archival samples and the ongoing FORCE (NCT03238144) clinical trial at Guy's Hospital, London, UK. Each tissue section was H&E stained, imaged, and annotated by a pathologist. A 6-digit classifier was designed to capture the histology of each region of interest (ROI), characterising the tumour region, epithelial type and immune cell localisation, population, distribution, and abundance. The annotations were used to guide ST profiling of serial sections, using the GeoMx Digital Spatial Profiler. Tissue sections were stained with fluorescent antibodies against PanCK and CD45. Tumour and immune-enriched compartments, defined as PanCK+/CD45- and PanCK-/CD45+, respectively, were acquired. Data analysis was performed in R 4.3.1, including quality control, batch correction, differential and topographical gene expression, immune cell deconvolution and gene set enrichment analysis (GSEA). Epithelial states (ES) were defined by identifying gene modules of co-expressed genes and annotating these with enriched pathways.
RESULTS: To date, we have performed ST profiling of 120 TNBCs from 85 patients (40 Non-Responders; 45 Responders), totalling 4506 tumour or immune-cell enriched regions. Genes signatures known to predict pCR of NACT in women with TNBC were first assessed by generating a pseudo-bulk dataset produced in silico by combining gene counts from all regions. Two gene signatures, namely the PAM50 proliferation signature and the GeparSixto Immune signature, were found to be predictive (PAM50: OR = 0.12, p-value = 0.06; GeparSixto: OR= 0.19, p-value = 0.03) in our data. Seven transcriptionally distinct epithelial states (ES), each underpinning unique molecular functions, were defined by identifying gene modules of tumour-enriched regions. The relative abundance of ES2 (DNA repair mechanisms) and ES4 (deregulated ECM, increased epithelial-mesenchymal transition and TGF-b signaling) in pre-NACT core biopsies was significantly associated with pCR (OR=1.03, p-value = 0.02) and residual disease (OR = 0.98, p-value = 0.05), respectively. Within the immune compartment, seven clusters of tumour-immune microenvironments (TIMEs), were obtained by unsupervised hierarchical clustering of immune cell proportions. A high relative abundance of TIME1 (naïve CD4 T cells and plasma cells) and TIME5 (naïve CD4 T cells, naïve B cells, memory B cells and plasma cells) were significantly associated with pCR (TIME1 OR = 1.05, p-value = 0.01; TIME5 OR = 1.04, p-value = 0.05). We further investigated rates of co-occurrence between each ES and TIME, identifying combinations

that were statistically most probable to occur and identified TIME as a confounding factor in the relative risk associated with the presence of individual ES. Moreover, we identify potential ligand-receptor interactions between distinct ES and TIMEs which may provide new insights into the mechanisms driving differential responses to NACT in TNBC.

Conclusion: To date, we have collected one of the largest spatial transcriptomics data sets with detailed histological annotation. The abundance of epithelial states and tumour-immune microenvironments is predictive for pCR in NACT TNBC. The spatial location, colocalization and ligand-receptor interactions in ES and TIME provide novel insights into the molecular heterogeneity of TNBCs and mechanisms regulating responses to NACT.

PS17-02: Molecular and Immune Landscape of Metaplastic Triple Negative Breast Cancer Compared with Invasive Ductal Triple Negative Breast Cancer

Pooja Advani, Sachin Kumar Deshmukh, Sharon Wu, Joanne Xiu, Jose P. Leone, Priya Jayachandran, Matthew Oberley, Maryam Lustberg, Stephanie L. Graff, George W. Sledge Jr, Asher Chanan-Khan

Background: Metaplastic Breast Cancer is rare and aggressive form of BC with majority having triple-negative receptor status. There are no standard therapeutic approaches for MBC and patients are treated similar to invasive ductal triple negative breast cancer (ID-TNBC) but with worse outcomes in comparison to ID-TNBC. Hence, there is an urgent need for development of new drug targets and therapies to improve outcomes in these patients. Here, we characterize the molecular and immune signature of metaplastic TNBC (M-TNBC).
Methods : 455 BC samples (M-TNBC, n=91; ID-TNBC, n=364) were analyzed by next-generation sequencing (592, NextSeq; WES, NovaSeq), Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) totaled somatic mutations per tumor (high>10 mt/MB). Microsatellite-instability (MSI) was tested by IHC and NGS. Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Pathway enrichment was determined by GSEA (Broad Inst). Statistical significance was determined using chi-square and Mann-Whitney U test and p-value <0.05 was considered significant.
Results: M-TNBC had a higher frequency of PIK3CA (50.0% vs 14.5%), PTEN (16.1% vs. 8.4%), EGFR, (2.2% vs 0%), PIK3R1 (14.4% vs. 5.5%), TERT (29.7% vs. 0.5%), but lower frequency of TP53 (70.6% vs. 89.7%) compared to ID-TNBC (all p<0.05). There was no difference in the frequency of TMB-high (3.3% vs 5.2%, p=0.58), dMMR/MSI-H (2.2% vs 1.1%, p = 0.34) and PD-L1 positivity (22c3) (50.0% vs 42.6%, p=0.38) between M-TNBC and ID-TNBC. M-TNBC had lower AR protein expression (11.0% vs 24.8%) and lower frequency of fusion variant-AR (0% vs 4.9%) compared to ID-TNBC (all p < 0.05). Analysis of inferred immune cell infiltrates showed that M-TNBC had increased infiltration of M2 macrophages (3.3% vs. 2.9%) and neutrophils (5.9% vs. 2.6%) but decreased infiltration of B cells (3.9% vs. 4.5%), T regulatory cells (Treg) (1.0% vs. 1.9%), Dendritic Cells (DC) (1.7% vs. 3.2%)

and CD8 T cells (0% vs. 0.5%) (all $p < 0.05$). M-TNBC had decreased IFNγ score (-0.31 vs -0.24, $p=0.05$), but increased MAP kinase pathway activity score (0.9 vs 0.08, $p<0.05$). ID-TNBC had higher expression of immune checkpoint genes (FOXP3, IDO1; FC: 1.3-1.5), cell cycle genes (CDKN1B, E2F1, CCNE1; FC: 1.2-1.4), inhibition of apoptosis genes (BIRC3, BIRC6, BCL2; FC: 1.1-1.3), but lower expression of stem cell-related genes (CD44, ALDH1A2, KLF4, SOX2; FC: 1.2-2.3) (all $p < 0.05$). M-TNBC had gene set enrichment of epithelial to mesenchymal transition (EMT) pathway (NES: 1.5, FDR<0.25).
Conclusion: These data indicate that M-TNBC is associated with an aggressive disease biology with higher frequency of PIK3CA, PTEN, PIK3R1, TERT, EGFR and gene set enrichment of EMT pathway. Higher expression of stem cell-related gene expression in M-TNBC indicates their association with therapy resistant phenotype. Also, M-TNBC had increased infiltration of M2 macrophages and neutrophils, decreased infiltration of B cells, Treg, DC and CD8 T cells and, lower IFNγ score and MAP kinase activity score suggesting differential tumor immune microenvironment compared to ID-TNBC However, these findings warrant further validation in larger studies.

PS17-03: Real World Adjuvant Capecitabine Utilization and Patient Outcomes Among Patients With Triple-Negative Breast Cancer with Residual Disease after Neoadjuvant Chemotherapy

Ava Strahan, Qingchun Jin, Akshara Singareeka Raghavendra, Danielle Brandes Zakon, Michael Grimm, Melissa E. Hughes, Mathew Cherian, Julie Vincuilla, Tonia Parker, Paolo Tarantino, Elizabeth A. Mittendorf, Tari A. King, Vicente Valero, Debasish Tripathy, Sara M. Tolaney, Nabihah Tayob, Nancy U. Lin, Daniel G. Stover, Ana C. Garrido-Castro, Carlos H. Barcenas

Background: Residual disease (RD) after neoadjuvant chemotherapy (NAC) for patients diagnosed with triple-negative breast cancer (TNBC) identifies a high risk population with increased rates of recurrence and poor prognosis. Adjuvant therapy (AT) with capecitabine is a standard management for patients with TNBC-RD based on the CREATE-X study. Alternative approaches, such as adjuvant capecitabine for unselected patients with TNBC (GEICAM 2003-11/CIBOMA 2004-01) have not shown benefit. Real-world utilization of adjuvant capecitabine for patients with TNBC-RD and the association of capecitabine with survival outcomes remains largely unknown. To address this gap, we investigated the utilization of capecitabine and other adjuvant therapies and association with outcome in a large cohort of patients with TNBC receiving NAC in the era prior to routine use of immunotherapy.
Methods: Patients with stage I-III TNBC (including estrogen receptor and progesterone receptor <10%) who received NAC and underwent surgery between January 2016 and June 2019 were identified from databases from 3 comprehensive cancer centers. Treatment in the adjuvant setting was categorized as: capecitabine, other systemic therapy, or no AT. Propensity score methods were used to control potential confounding effects from baseline covariates (site, age at diagnosis, race, clinical stage, histology type, genetic status, residual

cancer burden/RCB class, HR at diagnosis, HER2 at diagnosis, HR at surgery, HER2 at surgery, nodal disease at surgery, neoadjuvant anthracycline/taxane receipt). Survival outcomes were estimated using Kaplan-Meier and Cox proportional hazards models.
Results: Among 977 patients with TNBC, the NAC regimen was primarily anthracycline-taxane (n=611; 62.5%), anthracycline-taxane-platinum (180; 18.4%), or taxane-platinum (39; 4.0%), while 122 (12.5%) patients received single-agent therapy or an alternate regimen. In the total population, 316/977 (32.3%) experienced pathologic complete response (pCR) while 661/977 (67.6%) had RD. Among patients with TNBC-RD, omission of AT was common: 45.1% (298/661) of patients with TNBC-RD did not receive any AT. Adjuvant therapy regimens among patients with TNBC-RD were diverse with 202/661 (30.6%) receiving capecitabine, 115/661 (17.4%) other chemotherapy, and 46/661 (7.0%) only targeted therapy. The primary objective was to evaluate survival outcomes among patients with TNBC-RD who received capecitabine versus no AT. At 3.5 years median follow-up, receipt of capecitabine was associated with significantly improved recurrence-free survival (RFS; hazard ratio/HR 0.70 95% confidence interval/CI 0.54-0.91, p=0.008), distant recurrence-free survival (DRFS; HR 0.71, 95% CI 0.54-0.93, p=0.01), and overall survival (OS; HR 0.66; 95% CI 0.49-0.90, p=0.009). As a sensitivity analysis, receipt of adjuvant capecitabine without any other chemotherapy (n=189) versus no AT demonstrated similar significant association with RFS, DRFS, and OS. Receipt of other adjuvant chemotherapy (n=109; with 67/109 single agent anthracycline, taxane, or platinum) versus no AT did not demonstrate significant association with RFS (HR 0.90, 95% CI 0.57-1.42, p=0.7), DRFS (HR 0.84, 95% CI 0.52-1.34, p=0.5), or OS (HR 0.63, 95% CI 0.37-1.08, p=0.08).
Conclusion: In this large cohort of patients with TNBC-RD, omission of adjuvant therapy was common, with less than a third of patients receiving adjuvant capecitabine. However, receipt of adjuvant capecitabine was associated with significantly improved RFS, DRFS, and OS. These results highlight the importance of evaluating adjuvant capecitabine benefit in the immunotherapy era.

PS17-04: Implications of Adjuvant Chemotherapy in Small Triple-Negative Breast Cancer

Hannah Hackbart, Swati Sikaria, Yuan Yuan, David Chan, Jin Sun Bitar

Background: The role of adjuvant chemotherapy in triple-negative breast cancer (TNBC) is critical given the absence of effective targeted therapies. Current guidelines strongly recommend adjuvant chemotherapy for patients with T1cN0 TNBC (primary tumor over 1 cm), yet the potential benefits for T1ab (up to 1 cm) TNBC remain unclear.
Methods: This study evaluates the efficacy of adjuvant chemotherapy across early stages of TNBC (T1abc) using our institution's cancer registry and survival data. We collected patients' demographics and clinical manifestations. Kaplan-Meier analysis was used for disease-free survival (DFS) and overall survival (OS). Cox multivariate analysis was used to identify independent predictors of survival outcomes.

Results: A total of 389 patients were diagnosed with stage I TNBC between 2000-2023. Clinical and survival data were available for 280 patients from the main campus, while 109 patients from the satellite site had survival data only. The median age at diagnosis was 60. Among these patients, 8 out of 48 (16.7%) with T1a, 61 out of 116 (52.3%) with T1b, and 143 out of 225 (63.6%) with T1c received adjuvant chemotherapy. Our data suggest that adjuvant chemotherapy significantly improved OS in patients with T1b and T1c TNBC ($p=0.048$ and $p<0.001$, respectively), while no difference was observed in OS for T1a TNBC. There were no significant differences in DFS in T1abc, likely due to the small number of events. Cox multivariate analysis revealed that patients older than 50 years (HR 3.53, $p=0.003$) and those with T1c stage tumors (HR 3.20, $p=0.031$) had significantly poorer OS. Conversely, adjuvant chemotherapy was associated with a marked improvement in OS (HR 0.36, $p=0.001$). Notably, patients with significant comorbidities were less likely to receive chemotherapy, potentially confounding OS outcomes.
Conclusion: Our study provides crucial insights into the potential benefits of extending adjuvant chemotherapy to small TNBC tumors. These findings advocate for further research to precisely define which early-stage TNBC patients can significantly benefit from chemotherapy, thereby refining treatment protocols and improving patient outcomes.

PS17-05: Use and benefit of neoadjuvant versus adjuvant chemotherapy in node-negative, T1 triple negative breast cancer.

Jesus D. Anampa, Alvaro Alvarez Soto, Shuwen Lin, Ana M. Bernal, Xiaonan Xue, Maja H. Oktay

Purpose: Neoadjuvant chemotherapy (NACT) is frequently used in node-positive and/or large (>2cm) triple-negative breast cancer (TNBC). However, there are scarce data about use and benefit of NACT in small size, node-negative TNBC. We examined survival differences of patients with T1N0 TNBC that were treated with NACT vs. adjuvant chemotherapy (ACT).
Methods: This is a retrospective, cross-sectional study using data from the Surveillance, Epidemiology, and End Results database of patients with T1N0 TNBC diagnosed between 2010-2020. Logistic regression analysis was used to identify factors associated with the use of NACT. Cox regression models were used to compare overall survival (OS) for ACT and NACT cohorts, adjusting for demographic, clinicopathological, treatment and socioeconomical variables. Cumulative incidence functions (CIF) and cause-specific hazard models were used to compare the risk of breast cancer death between ACT and NACT cohorts. We also evaluated pathological complete response (pCR) rate in patients treated with NACT.
Results: We found 8,146 patients treated with ACT and 1,263 patients treated with NACT. Age <50 years, mastectomy and radiation therapy were associated with higher odds of receiving NACT. Age >65 years, non-metropolitan residency, histology other than ductal, and having small tumor size were associated with lower odds of receiving NACT. When adjusted for demographic, clinicopathological, treatment, and socioeconomic covariables,

NACT was associated with worse OS (HR, 1.34; 95% CI, 1.04–1.73; p=0.023) and breast cancer specific survival (BCSS) [HR, 1.52; 95% CI, 1.11–2.08; p=0.008] than ACT. The worse OS and BCSS with NACT were mainly driven by T1a tumors as patients with T1a tumors had worse OS (HR, 9.13; 95% CI, 2.40–34.75) and BCSS (HR, 19.70; 95% CI, 3.82–101.67) when treated with NACT when compared to those treated with ACT; whereas patients with T1c tumors had no difference in OS and BCSS when treated with NACT or ACT. pCR in all T1 tumors was associated with improved OS (HR, 0.28; 95% CI, 0.15 – 0.52; p<0.001) and BCSS (HR, 0.21; 95% CI, 0.01 – 0.46).
Conclusion: Patients with T1b and T1c tumors benefit equally from the use of ACT and NACT. The reasons for worse outcome in patients with T1a tumors treated with NACT compared to ACT are unknown and need further investigation. pCR was associated with improved outcomes in patients with T1N0 TNBC who received NACT.

PS17-06: Neutrophil-to-lymphocyte ratio (NLR) predicts long-term survival in early triple negative breast cancer (TNBC) treated with neoadjuvant chemotherapy (NACT)

Gabriel Berlingieri Polho, Leticia Kimie Murazawa, Vinicius Vitor Oliveira, Victor Rocha Pinheiro, Diana del Cisne Pineda Labanda, Yumi Ricucci Shinkado, Romualdo Barroso-Sousa, Luciana Rodrigues Carvalho Barros, Laura Testa, Renata Colombo Bonadio

Introduction: Biomarkers for long-term survival in early TNBC are needed to improve neoadjuvant strategies. This study aimed to evaluate the role of neutrophil-to-lymphocyte ratio (NLR) in predicting survival after NACT.
Methods: We retrospectively reviewed our institutional database to identify patients (pts) who underwent NACT for early-stage TNBC (II-III) from 2012 and 2024 and collected data from medical records. Event-free survival (EFS) was calculated from the first cycle of NACT until an event occurred. EFS events were defined as death, disease recurrence or disease progression that precluded surgery. EFS and overall survival (OS) were estimated with the Kaplan-Meier method and Cox regression model was used to calculate Hazard Ratio (HR). Logistic regression was used to verify association between NLR and pathological complete response (pCR). NLR was calculated from the complete blood count before NACT initiation.
Results: Among the 692 pts with available information identified, 62.9% had stage III disease, 61.1% grade 3 disease and 77% ki67 >50%. Median age was 48 years and the most common NACT regimen used was AC-T (86.2%). The overall pCR rate was 28.3% and pts with NLR ≤ 2 had an increased probability of achieving pCR (32.6% vs 22.7%, p = 0.005). After a median follow-up of 59.6 months, NLR ≤ 2 was associated with improved 5-year EFS in the overall population (51% vs 66%, HR 0.59, 95 % Confidence Interval [95CI] 0.46 - 0.75, p<0.001), in pts with stage II disease (69% vs 81%, HR 0.49, 95CI 0.29 - 0.85, p=0.01), stage III (43% vs 55%, HR 0.70, 95CI 0.53 - 0.93, p=0.01), residual disease (42% vs 54%, HR 0.65, 95CI 0.50 - 0.84, p=0.001) and a trend for improved survival for pts with pCR (82% vs 92%, HR 0.45, 95CI 0.18 - 1.1, p=0.08). 5-year OS was also improved in the overall population with NLR ≤ 2 (58% vs 73%, HR 0.56, 95%, 0.42 - 0.74, p<0.01]), stage II disease

(75% vs 86%, HR 0.42, 95CI 0.22 - 0.81, p=0.009), stage III disease (50% vs 62%, HR 0.68, 95CI 0.50 - 0.93, p=0.015) and in pts with residual disease (50% vs 64%, HR 0.62, 95CI 0.46 - 0.82, p=0.001), but not in pts who achieved pCR (82% vs 91%, HR 0.50, 95CI 0.20 - 1.24. p=0.1). In multivariate analysis, including pCR status and clinical stage, NLR ≤ 2 remained statistically significant for improved OS (p= 0.002) and EFS (p=0.002).
Conclusion: NLR >2 is an independent risk factor for poorer survival in pts with TNBC who received NACT. As a readily available biomarker, NLR should be further explored in current neoadjuvant protocols for early TNBC.

PS17-07: Comparison of an Atezolizumab monotherapy window followed by Atezolizumab and chemotherapy vs. Atezolizumab and chemotherapy alone in high-risk triple-negative breast cancer (TNBC) – a subgroup analysis of the neoadjuvant neoMono trial

Hans-Christian Kolberg, Johannes Schumacher, Ramona Erber, Michael Braun, Peter A. Fasching, Eva-Maria Grischke, Christian Schem, Michael P. Lux, Mustafa Deryal, Oliver Hoffmann, Bernhard Heinrich, Georg Kunz, Kristina Lübbe, Petra Krabisch, Arndt Hartmann, Philip Raeth, Sabine Kasimir-Bauer, Cornelia Kolberg-Liedtke

Background: The neoMono trial prospectively analyzed whether the addition of a preceding Atezolizumab monotherapy window prior to Atezolizumab and neoadjuvant chemotherapy (CTX) improves pCR rates among patients with early TNBC (eTNBC). pCR rates in the investigational arm (i.e., Atezolizumab monotherapy window) were 91.5% in the PD-L1 (IC)-positive group and 56.1% in the PD-L1 (IC)-negative group, corresponding pCR rates in the control arm were 82.2% and 64.5%, respectively. In multivariate analysis of the ITT population (including tumor size, nodal status, tumor grade, age and PD-L1 status) the odds ratio (OR) for achieving a pCR was 4.77 (p< 0.001) for PD-L1-positive tumors indicating a significant impact of the PD-L1 status on pCR-rates in the neoMono trial. The goal of the following subgroup analysis was to explain the influence of different clinical risk profiles on the role of PD-L1 as a biomarker in eTNBC for efficacy of neoadjuvant ICI-containing therapy by analysis of patients with high risk (tumor size 2 cm and higher and/or N+) eTNBC.
Methods: NeoMono is a phase 2 randomized multicenter trial planned to recruit a maximum of 458 female and male pts with primary TNBC (defined as ER/PR < 10% and HER2 negative) with tumor stages cT1c – cT4d (cN0 and cN+). PD-L1 status had to be identifiable by central pathology by means of the VENTANA PD-L1 (SP142) assay and was defined by PD-L1 expression on immune cells (IC). Neoadjuvant treatment in both study arms consisted of Atezolizumab 1200 mg every 3 weeks in addition to neoadjuvant CTX (12 x Carboplatin/Paclitaxel q1w followed by 4x Epirubicin/Cyclophosphamide q3w), in arm A preceded by an Atezolizumab monotherapy window of 840 mg once two weeks prior to initiation of combination therapy. The neoMono statistical design uses Bayesian posterior probabilities (uniform prior distribution) and logistic regression. In this subgroup analysis we included only patients with a tumor size of 2 cm and higher and/or involved lymph

nodes
Results:
115 pts in arm A and 121 in arm B from 34 study sites were included in this subgroup analysis. Demographics and baseline characteristics as well as drug exposure were well-balanced in both arms. In the analysis stratified by PD-L1 (IC) status (negative: <1% versus positive: ≥ 1%), pCR rates in arm A were 88.9 % in the PD-L1 (IC)-positive group and 50.6 % in the PD-L1 (IC)-negative group, the corresponding pCR rates in arm B were 80.0 % and 59.3 %, respectively. In a multivariate analysis including therapy arm, PD-L1 status, tumor size, nodal involvement, grade 3 and age only PD-L1 (IC) status (OR 4.42; p <0.001) and grade 3 (OR 3.49; p=0.014) interacted significantly with pCR.
Conclusion:
In this analysis, the association between PD-L1 (IC) status and pCR rates could be reproduced in a subgroup of patients with =/> cT2 and/or N+ tumors. These results are in line with exploratory results of the NeoTRIP trial and the IMPASSION031 trial demonstrating an association of PD-L1 status with pCR rates after neoadjuvant Atezolizumab + chemotherapy in patients with high risk eTNBC similar to the population in this subgroup analysis. Our analysis in the largest group of patients with high risk eTNBC treated with neoadjuvant Atezolizumab + chemotherapy published to date demonstrated a significant association of PD-L1 status and pCR rates. Further investigations are needed to better understand the clinical implications of this finding.

PS17-08: Association of antibiotic exposure with pathologic complete response in patients with non-metastatic triple-negative breast cancer receiving neoadjuvant chemotherapy and pembrolizumab

Alexis Espinal, Crystal Taylor, Monika Burness, and Melissa Pilewskie

Background: Results of the KEYNOTE-522 trial established the role of immunotherapy in combination with neoadjuvant chemotherapy (NAC) for early-stage triple negative breast cancer (TNBC). In this trial, the addition of the immune checkpoint inhibitor, pembrolizumab, when used in combination with paclitaxel-carboplatin/doxorubicin-cyclophosphamide NAC achieved higher pathologic complete response (pCR) and improved event-free survival compared to NAC alone and thus, this regimen has become standard of care in this population. As the use of immunotherapy for early stage TNBC increases, it is critical to assess factors that impact treatment efficacy. Emerging data suggests antibiotic exposure may decrease rates of pCR among patients with solid cancers receiving NAC + immunotherapy, however, there is minimal data in breast cancer and there is heterogeneity in defined windows of antibiotic exposure. We therefore sought to assess the association of antibiotic exposure and window of antibiotic exposure on rates of pCR among patients with TBC treated with the KEYNOTE-522 regimen.
Methods: Patients with non-metastatic TBNC who received NAC + pembrolizumab and completed breast surgery at our institution were identified. Clinicopathologic and treatment data including patient age, BMI, clinical stage, histology, chemotherapy regimen,

receipt of antibiotics, number of pembrolizumab doses received, and final pathology details were collected. Pathologic complete response was defined as no residual invasive carcinoma in the breast or nodes (ypT0/isN0). Differences between the cohort of patients who did or did not receive antibiotics were assessed by Chi-squared tests. Rates of pCR were compared between those with antibiotic exposure vs none at the following time points: antibiotics concurrent with NAC + pembrolizumab, antibiotics within 30 days of first pembrolizumab dose, and antibiotics within 60 days of first pembrolizumab dose using logistic regression.
Results: 42 women received NAC + pembrolizumab followed by surgery for non-metastatic TNBC from 2021-2024. Patient demographics are as follows: mean age 51 years, 90% cT2-4 tumors, 50% node positive at presentation, 93% invasive ductal histology with 7% metaplastic tumors. Overall, 20 (47.6%) patients received antibiotics concurrent with NAC + pembrolizumab, 13 (31%) within 30 days of first pembrolizumab dose, and 20 (47.6%) within 60 days of first pembrolizumab dose. There were no significant differences in age, BMI, clinical stage, tumor history, or number of pembrolizumab doses received between those who did or did not receive antibiotics. The overall pCR in the cohort was 59.5%. Rates of pCR for those who did or did not receive antibiotics concurrently with pembrolizumab were 55% vs 63.6%, p=0.6, respectively. Similarly, pCR rates for those who received antibiotics within 30- or 60- days of initiation of NAC + pembrolizumab compared to those who did not were 53.9% vs 62.1%, p=0.6 and 60% vs 59.1%, p=0.95, respectively.
Conclusions: Use of antibiotics concurrently or within 30 days of initiation of NAC + pembrolizumab was associated a non-significant trend of reduced pCR among non-metastatic TNBC patients. While this series is limited due to the small patient cohort, these patterns align with data from other cancer types highlighting the need for additional study of the impact of antibiotic exposure and efficacy of immunotherapy for this high-risk patient population.

PS17-09: Immune landscape and clinical features of acquired resistance to immune checkpoint blockade in triple negative breast cancer

Veerle Geurts, M Chelushkin, M de Graaf, NF Greenwald, R Salgado, HM Horlings, KE de Visser, C Curtis, TN Schumacher, LFA Wessels, M Angelo, M Kok

Introduction: A substantial number of patients with metastatic triple negative breast cancer (mTNBC) relapse after having an initial response to immune checkpoint blockade (ICB). Our understanding of acquired resistance to ICB in solid tumors is limited and data is lacking for TNBC. Here, we present an in-depth analysis of the immune and genetic landscape of patients with mTNBC who developed acquired resistance during treatment with anti-PD1.

Methods: We identified patients with acquired resistance from the TONIC [NCT02499367] and TONIC-2 [NCT04159818] trials, in which patients with mTNBC were treated with anti-PD1 with or without a short induction treatment with low dose chemotherapy or irradiation. Acquired resistance was defined as (oligo)progression despite continuous

dosing of anti-PD1 following an initial response with a duration of at least 6 months (complete or partial response according to iRECIST1.1). Biopsies were taken at baseline, during response to anti-PD1 and at time of acquired resistance. Nine baseline tumor samples were available for whole exome sequencing (WES), bulkRNAseq and multiplexed ion beam imaging (MIBI). Paired biopsies at baseline and time of acquired resistance were available for six patients.

Results: Among 24 responders out of a total of 158 evaluable patients, we identified 14 patients with acquired resistance and 7 patients with a durable response > 1 year (median 169 weeks). Patients with acquired resistance had median tumor infiltrating lymphocyte (TIL)-levels at baseline of 14% (range 1% – 60%), and 10/14 patients had a PD-L1 positive tumor (CPS ≥10). Half of the patients had visceral metastases, predominantly lung (n=4), and only 1 patient had liver metastasis. Among patients with a durable response, median TIL-score was 10% (range 1%-80%), 4/7 patients had a PD-L1 positive tumor and only 1 patient had liver metastasis.
Our exploratory analyses revealed a decrease in infiltrating CD8+ T cells and MHC-II-related gene set expression at time of acquired resistance compared to the time of ongoing response ($p < 0.05$). In addition, we observed an increase in expression of gene MAL2 ($p < 0.05$), which is known to be involved in several processes among which endocytosis and degradation of MHC-I complexes.
In contrast to patients with progression of all tumor lesions, patients with only one progressive lesion (oligo-progression) had an increase in immune checkpoint molecules (PD-L1, PD1, CTLA4, TIM3, LAG3, TIGIT) and infiltration by T cell subsets (CD8+, helper T- and regulatory T cells) accompanied by IFN-y signaling pathway upregulation at time of acquired resistance compared to baseline. CTLA4-expression already increased during response with further increase at time of acquired resistance in this subset of patients. Newly acquired mutations related to immune escape or -invasion were not yet identified, except for a mutation in IFN-alfa16 in 1 patient at time of resistance. Analyses of MIBI-data, and a comparison between patients with acquired resistance and primary resistance is currently ongoing. Results will be presented at SABCS.

Conclusion: Our exploratory analyses based on longitudinal tumor samples suggest that patients with TNBC who develop acquired resistance to anti-PD1 might have a decreased T cell activity in the TME and hampered antigen presentation at time of acquired resistance. These findings inform novel approaches for overcoming acquired resistance, which occurs in a substantial group of mTNBC patients with initial response to anti-PD1.

PS17-10: Genomic and transcriptomic analyses of residual invasive triple-neg breast cancer after neoadjuvant chemotherapy in prospective MIRINAE trial (a randomized phase II trial of adjuvant atezolizumab + capecitabine versus capecitabine; KCSG-BR18-21)

Seock-Ah Im, Kyunghee Park, Jiwon Koh, Kyung Hae Jung, Jieun Lee, Hee Kyung Ahn, Ahwon Lee, Sung Hoon Sim, Min Hwan Kim, Jee Hyun Kim, Jee Hung Kim, Kyoung Eun Lee, Kyong Hwa Park, Moon Hee Lee, Seungtaek Lim, Han Jo Kim, Dae-Won Lee, Jae Ho Jeong, Keun Seok Lee, Joohyuk Sohn, Koung Jin Suh, Ji-Yeon Kim, Yoon Jin Cha, Sung-Bae Kim, Kabsoo Shin, Heejung Chae, Gun Min Kim, Kyung-Hun Lee, Woong-Yang Park, Yeon Hee Park, In Hae Park

Background: Neoadjuvant chemotherapy (NAC) is the preferred treatment approach for clinical stage II/III triple-negative breast cancer (TNBC). Pathologic complete response (pCR) rates ranges from 30% to 65%. The MIRINAE trial (KCSG-BR18-21) is a randomized phase II trial evaluating the efficacy and safety of adjuvant atezolizumab plus capecitabine versus capecitabine in TNBC patients who do not achieve pCR after NAC without immunotherapy (NCT03756298). This study aims to characterize residual TNBC following NAC through comprehensive tumor microenvironment (TME) and genetic analysis in a prospective multicenter trial.
Methods: After anthracycline and taxane-based NAC, surgically resected residual tumors were collected, and analyzed for stromal tumor-infiltrating lymphocytes (TILs), FoundationOne®CDx, and RNAseq. A 30% cut-off was used to classify samples into TIL-high and TIL-low. RNAseq-based molecular subtyping was performed to determine intrinsic subtype via PAM50, as well as for TNBC and TME subtypes. Immune cell deconvolution was conducted using CIBERSORTx. Fisher's exact test was used to analyze the association between TILs and molecular subtypes, with significance set at a $p < 0.05$. Differentially expressed genes were identified using glmFit function in edgeR package.
Results A total of 311 patients (median age 48; range, 28-74) were analyzed. ypTNM stages were stage I (28.0%), II (48.7%), and III (23.3%). TILs were evaluated in 299 (96.1%) samples, with 27.1% classified as TIL-high. FoundationOne®CDx was performed in 255 (82.0%) samples. The most frequently mutated genes were TP53 (87.8%), PIK3CA (19.6%), BRCA1 (8.6%), and PTEN (6.7%). Pathogenic alterations in the PI3K/AKT pathway (PIK3CA, PTEN, AKT1, and PIK3R1) were observed in 28.6%, while homologous recombination repair-related genes (BRCA1, BRCA2, and PALB2) were mutated in 12.1%. RNAseq was performed in 221 (77.8%) samples. According to the PAM50 classification, most patients (51.1%) were classified as Basal-like, 19.0% as Luminal A, 5.0% as Luminal B, 14.0% as HER2-enriched and 10.9% as Normal-like. TNBC molecular subtyping revealed that 36.7% of the tumors were categorized as mesenchymal (MES), followed by basal-like immune suppressed (BLIS) at 30.3%, basal-like immune activated (BLIA) at 20.8%, and luminal androgen receptor (LAR) at 12.8%. Among 213 patients with both RNAseq and TIL data available, we found that TIL-high group was significantly enriched with BLIA subtype (37.5%) and TME subtypes including IE (immune-enriched, 45.3%) and IE/F (immune-

enriched/fibrotic, 31.3%). Immune-suppressive subtypes D (immune-depleted, 49.7%) and F (fibrotic, 29.5%) were significantly enriched in TIL-low. CIBERSORTx immune cell deconvolution analysis showed greater proportions of plasma cells, CD8+ T-cells, CD4+ memory resting T-cells, follicular helper T-cells, activated NK-cells, and M1 macrophages in TIL-high tumors (all adjusted $p < 0.01$). TIL-high samples showed upregulation of immune cell-related genes (CD3D, CD4, CD8A, CD38, IRF4, MZB1 and GZMK). Chemokine and immune-checkpoint genes (CXCL9, CXCL13 and LAG3) were also higher in TIL-high. VEGFA, NDRG1 and IRS4 were highly expressed in TIL-low (all adjusted $p < 0.0001$). Gene sets related to immune response and interferon-gamma response were significantly enriched in TIL-high group, while TIL-low tumors showed enrichment for hypoxia related gene sets (all adjusted $p < 0.05$).
Conclusion: Residual invasive TNBC after standard NAC in the MIRINAE trial were predominantly MES and BLIS subtype with a high frequency of TP53 mutations. TIL-high tumors were associated with immune-enriched cancer including BLIA and TME subtypes. Ongoing analysis of invasive disease-free survival as the primary endpoint in each arm of MIRINAE trial and the role of atezolizumab in association with genomic features will provide deeper insights into the role of ICIs as adjuvant therapy.

PS18-01: Spatial Transcriptomics-Derived Classification of Invasive Lobular Carcinoma: Associations with Clinical, Genomic Characteristics, and Prognosis

Matteo Serra, Mattia Rediti, Laetitia Collet, Frederic Lifrange, David Venet, Nicola Occelli, Delphine Vincent , Ghizlane Rouas, Denis Larsimont, Miikka Vikkula, Francois P Duhoux, Françoise Rothé, Christos Sotiriou

Background: Invasive lobular carcinoma (ILC) is the second most prevalent histological subtype of breast cancer. This study presents four newly identified ILC subtypes associated with tumor microenvironment (TME) heterogeneity and examines their associations with clinical characteristics and prognosis.
Methods: Spatial transcriptomics (ST, Visium 10X) was performed on frozen tumor samples from 43 primary hormone receptor positive (HR+), HER2-negative (HER2-) ILCs. H&E slides were morphologically annotated, and ST spots were clustered by gene expression. By integrating morphology and sequencing data, ILCs were classified based on TME heterogeneity using the intNMF algorithm. Subtypes were annotated using morphology (image analysis), pathway enrichment analysis (GSEA), and cell type composition from single-cell deconvolution (CARD software). Gene signatures for each subtype were derived and used to retrieve the subtypes in METABRIC (ILC cohort, n = 122) and SCAN-B (ILC cohort, n = 853) microarray/bulk RNA-sequencing datasets. Statistical analyses included chi-square and Kruskal-Wallis tests to investigate associations with clinical characteristics and Cox proportional hazard models for univariate and multivariate survival analyses in both METABRIC and SCAN-B.
Results: Patient-level classification revealed four ILC subtypes, namely proliferative (P),

normal-stroma enriched (NSE), metabolic (M), and metabolic-immune enriched (MIE). In our ST cohort, the P subtype (n = 12) was enriched in tumor cells and proliferation-related pathways; NSE subtype (n = 10) was associated with more fibroblasts, carcinoma in situ, and heightened expression of EMT-related pathways; the M subtype (n = 9) was enriched in endothelial cells, metabolic-related pathways, and heightened AR gene expression; the MIE subtype (n = 10) was enriched in adipose tissue, endothelial cells, M2 macrophages, and metabolic-related pathways. All four subtypes were identified in METABRIC (NSE = 40, P = 34, MIE = 17, M = 31) and SCAN-B (NSE = 291, P = 226, MIE = 150, M = 186), with GSEA showing consistent differences at the gene expression level. In METABRIC, the P and MIE subtypes were associated with high and low cellularity, respectively ($p = 0.042$), and P was also linked to higher tumor grade ($p = 0.0187$). Notably, the P subtype exhibited more copy number aberrations (CNA) compared to other subtypes ($p = 0.0159$), but no differences in tumor mutational burden. In SCAN-B, the P and NSE subtypes were associated with larger and smaller tumors, respectively ($p < 0.001$). The P subtype was also linked to higher tumor grade ($p < 0.001$), lymph node involvement ($p = 0.02$), and high Ki67 ($p < 0.001$). In METABRIC, univariate analysis showed NSE and P subtypes to be associated with good and poor prognosis, respectively, for relapse-free interval (RFI) (HR = 0.56, $p = 0.027$, FDR = 0.055; HR = 1.8, $p = 0.019$, FDR = 0.055). Multivariable analysis confirmed NSE's association with good prognosis (HR = 0.47, $p = 0.03$, FDR = 0.12 for RFI), even when correcting for clinical features. In SCAN-B, univariate analysis revealed an association between NSE and longer RFI (HR = 0.42, $p = 0.0018$, FDR = 0.0035) and between P and shorter RFI (HR = 2.2, $p = 0.0014$, FDR = 0.0035). When correcting for clinical characteristics, NSE remained associated with longer RFI (HR = 0.54, $p = 0.035$, FDR = 0.11), while a trend was observed for P and shorter RFI (HR = 1.6, $p = 0.079$, FDR = 0.13).
Conclusions: Spatial transcriptomics revealed four ILC subtypes describing TME heterogeneity. These subtypes were successfully identified in microarray/bulk-RNA sequencing datasets and associated with different clinical characteristics. Importantly, the subtypes showed differences in disease outcomes, refining prognosis in ILC.

PS18-02: E-cadherin inactivation shapes tumor microenvironment specificities in invasive lobular carcinoma

Lounes Djerroudi, R. Mhaidly, H. Croizer, G. Gentric, A. Meng, L. Fuhrmann, M. Caly, C.Benoist, V. Renault1, F.C. Bidard3, Y. Kieffer2, A. Vincent-Salomon and F. Mechta-Grigoriou

Background: Invasive lobular carcinoma (ILC) shows distinct clinicopathological features compared to invasive breast carcinoma of no special type (IBC-NST), including specific stromal characteristics. One of them concerns the singular infiltration pattern of lobular tumor cells, which induces minimal stromal reaction. In addition, a key function of tumor microenvironment has been previously demonstrated reporting that tumor-infiltrating lymphocytes (TIL) are not associated with good prognosis in ILC, in contrast to IBC-NST. So far, the precise impact of E-cadherin inactivation in tumor cells on these stromal peculiarities remains largely unknown.

Materials and Methods: In this context, we performed an in-depth characterization of heterogeneity, function, and interactions of Cancer-Associated Fibroblasts (CAF) with both immune and tumor cells in ILC compared to IBC-NST. To do so, we leveraged a well characterized retrospective series of 251 patients, who underwent surgery at Institut Curie for a primary ILC between 2005 and 2008, for whom frozen tumor samples were available for RNA sequencing. We established tissue microarrays (TMA) for 158 ER+ ILC from this cohort and 77 primary ER+ IBC-NST from our institute. Based on the TMA cohort, we did comparative immunohistochemical analysis of specific markers of different CAF populations, in particular FAP+ CAF, and immune cells. In addition, we characterized six classical ILC by single cell RNA sequencing and we performed spatial transcriptomic analysis of 16 ILC from the retrospective series. Finally, we studied the interactions of ER+ breast cancer cell lines with CAFs and CD8 T lymphocytes in vitro, using co-culture experiments and selective inactivation of E-cadherin (in tumor cells) or some of its heterologous receptors (especially in CAFs).
Results: By combining these analyses, we found that (1) CAF content of ILC is heterogeneous, notably depending on two tumor histopathological features (ILC histological type and tumor cellularity), (2) ILC have more inflammatory CAF and less myofibroblastic CAF than ER+ IBC-NST, (3) this particular feature is dependent on a previously undescribed mechanism involving E-cadherin in CAF plasticity, (4) CAF content in ILC determines the pattern of TIL infiltration which in turn has an independent prognostic impact in this cancer and finally, (5) the lack of good prognostic value of TIL in ILC may be partly explained by a cytotoxic CD8 T cell-related immune escape mechanism associated with E-cadherin inactivation in tumor cells.
Conclusion: In conclusion, we have demonstrated for the first time that E-cadherin has a direct effect on CAF differentiation via a previously undescribed mechanism, explaining some of the morphological specificities of the ILC stroma. Furthermore, inactivation of E-cadherin determines both the spatial organization pattern of TILs and the escape of tumour cells from CD8 T cell cytotoxicity. Our data provide an unprecedented insight into the ILC stroma and E-cadherin-mediated modulation of breast cancer tumour microenvironment.

PS18-03: GeoMx DSP and CosMx single cell spatial transcriptomics for molecular characterization of invasive lobular breast cancer cells and their microenvironment

Lynda Bennett, Sunati Sahoo, Cheryl M. Lewis, Indu Raman, Guanchun Chen, Chengsong Zhu and Suzanne D. Conzen

Invasive lobular breast cancer (ILC) represents 10-15% of all breast cancer cases but remains understudied. Lack of e-cadherin is thought to be the basis for the distinct single-file growth pattern of ILC. ILC exhibits late recurrence, commonly metastasizing to the peritoneum and bone with poor outcome. Primary ER+ ILC tumor cells exhibit wide variation in nuclear GR expression, ranging from negative to strongly positive. We previously reported better patient outcome in ER+ breast cancers with high glucocorticoid

receptor (GR) expression (Pan et al 2011). We hypothesize that GR expression may also impact outcome in ILC.

Crosstalk between tumor and stromal cells leads to evolution of a tumor microenvironment (TME) favorable for growth and/or invasion. Because of the characteristic histology of ILC, we expected the TME to be unique compared to other breast cancers. We recently reported that GR+ ILC shows reduced proliferation to GR- but exhibit an enhanced metastatic phenotype (Porter et al 2023). Hence, we predicted that tumor cell-intrinsic GR expression will impact the ILC TME.

We used an integrated approach to explore in-depth the molecular profile of primary ILC and to study interactions between tumor and neighboring cells. We measured average gene and protein expression in regions of interest on primary ILC tissue sections using nanoString GeoMx DSP with whole transcriptome (WTA), protein modules and IO Proteome Atlas. We also performed single-cell spatial transcriptomics for a subset of those patients leveraging the CosMx platform.

GR+ ILC tumor cells exhibited distinct transcriptional profiles with enrichment of RNA processing, translation pathways and oxidative phosphorylation. MHC class II antigen presentation pathways were downregulated. The most significantly enriched pathways in GR- tumor cells and TME were collagen synthesis and extracellular matrix (ECM) remodeling. Sflomos et al previously reported that ILC cells contribute to their own extracellular matrix, but we were surprised to observe the magnitude of increased expression in cells without GR. Gene expression in the TME strongly suggested of a much greater presence of cancer-associated fibroblasts (CAFs) surrounding GR- ILC. Proteome assays supported the WTA data, showing more fibronectin and type I collagen in GR- tumors. Also consistent with transcriptomic data, protein DSP indicated suppression of antigen presentation in GR+ ILC evidenced by lower expression of type I and type II MHC proteins.

Next, CosMx single cell in situ transcriptomics allowed us to reaffirm observations from DSP, and to examine expression at the single cell level, assign cell types and examine interactions between cells. GR+ and GR- tumor cells were transcriptionally distinct, as shown by clustering, and the abundance of certain cell types in their surrounding microenvironment were notably different. We confirmed a higher presence of CAFs transcriptionally similar to myofibroblasts that were in close proximity to GR- tumor cells. We also observed downregulation of MHC class I and II genes at the single cell level in GR+ compared to GR- tumor cells and low representation of antigen presenting cells in the stroma.

Our combined data supports repression of antigen presentation pathways in GR+ ILC accompanied by a relative exclusion of CAFs. Evidence suggests that tumor cells as well as stromal cells contribute to the modeling of the ECM, and crosstalk between them leads to the establishment of a favorable environment to support ILC tumor cell survival, growth and invasion.

PS18-04: Tumor intrinsic and extrinsic characteristics of invasive lobular carcinomas

Lise Mangiante, Kathleen Houlahan, Cristina Sotomayor Vivas, Alvina Adimoelja, Seongyeol Park, Sophia Pribus, Brennan Simon, Zhicheng Ma, Aziz Khan, Jennifer Caswell-Jin, Christina Curtis

Background: It is now well-established that invasive lobular carcinoma (ILC) is a distinct disease with higher risk of distant recurrence after 10 years compared to invasive ductal carcinoma (IDC) (Pestalozzi et al. J Clin Oncol 2008). However, little is known about the underlying mechanisms of relapse in ILC cases. Additionally, recent large landmark studies have revealed heterogeneity at the morphological, molecular, and microenvironmental levels (Ciriello et al. Cell 2015, Michaut et al. Sci Rep 2016, Desmedt et al. J Clin Oncol 2016) suggesting that the overarching category of ILC may encompass several distinct subgroups. A more detailed understanding of the underlying genomic drivers, mechanisms of immune evasion, and evolution may inform more effective and personalized treatment. Previously, across histological types, we established a genome-driven breast cancer classification scheme that defines 11 integrative subgroups (ICs) of disease with distinct copy number aberrations (CNAs), transcriptional profiles, and clinical outcomes. Specifically, we identified four subgroups of ER+ disease (IC1, IC2, IC6, IC9) with a persistent risk of lethal distant relapse up to two decades after diagnosis, each with focal copy number drivers and two distinct subgroups of triple-negative disease (Curtis et al. Nature 2012; Rueda et al. Nature 2019). These findings nominate new therapeutic strategies, however, it is not known how mutational processes and genomic architecture differ between IDC and ILC in this context to sculpt the evolution of disease, nor how their microenvironments differ. Methods: To interrogate the genomic and immune landscape of invasive lobular carcinomas, we collected a meta-cohort of 401 primary invasive breast tumors, including 254 with whole-genome or whole-exome sequencing, 350 with whole-transcriptome sequencing, and 203 with both modalities. This meta-cohort includes the clinically curated METABRIC dataset with 20 years of clinical follow-up. Additionally, we established a single-cell spatially resolved transcriptomic meta-cohort of 54 primary ILCs, including 7 metastatic ILCs with primary and matched metastatic lesion(s). Results: Analysis of this large clinically curated dataset reveals a distinct pattern of relapse for patients with ILC tumors. Patients with ILC exhibited a higher 5 year recurrence risk (39% vs. 30%) and modestly higher cumulative recurrence risk (62% vs. 54% at 20 years) in the ER+ High-risk group, while this difference was even more striking amongst ER+ Typical-risk tumors, where ILC cases exhibited higher rates of late recurrence than IDC (55% vs. 37% at 20 years). Paradoxically, ILC tumors are enriched for the genomic stable ER+ Typical-risk subgroup that displays quiet genomes compared to other IC subgroups. In particular, ER+ High-risk and HER2+ tumors are associated with focal amplifications, extrachromosomal DNA, and coincident structural variants, whereas triple-negative tumors are characterized by global genomic instability and tandem duplications. Consistent with their quiet genomes and higher proportion of CDH1 mutations, ILC tumors demonstrated a lower proportion of whole-genome doubling, lower ploidy, lower fraction of copy number aberrations, lower

proportion of TP53 mutations and replication stress compared to IDC. Moreover, the ILC ER+ Typical-risk tumors were enriched for immune-depleted and fibrotic TMEs compared to ER+ Typical-risk IDCs tumors. Spatial transcriptomic profiling suggests an overall lower level of interaction and cell-cell communication between tumor, immune and stromal cells in ILC compared to IDC. Conclusion: Taken together, our data uncover tumor-intrinsic molecular characteristics of ILC and implicate tumor-extrinsic factors in disease aggression.

PS18-05: Clinical Management and Oncological Outcomes of Pure Pleomorphic and Florid Lobular Carcinoma in Situ of the Breast: Results from the MultiLCIS Study

Massimo Ferrucci, Daniele Passeri, Francesco Milardi, Rocco Cappellesso, Paola Del Bianco, Gian Luca De Salvo, Angelo Paolo Dei Tos, Gianluca Franceschini, Pietro Maria Ferrando, Lucio Fortunato, Matteo Ghilli, Adele Sgarella, Carla Cedolini, Francesca Catalano, Serena Scomersi, Simone Mele, Francesca Muscara, Graziano Meneghini, Eugenia Raffaeli, Donato Casella, Christian Rizzetto, Francesca Pellini, Guido Papaccio, Eleonora Meduri, Michela Stumpo, Simona Grossi, Leonardo Barellini, Alba Di Leone, Cristian Scatena, John Benson, Angela Santoro, Virginia Castagnetta, Isabella Castellano, Jacopo Cumbo, Ada Ala, MD; Gianmarco Piccolino, Chiara Anghelone, Serena Bertozzi, Martina Rapisarda, Margherita Fezzi, Moira Ragazzi, Filippo Cappello, Nicola Rocco, Giacomo Montagna, Walter Paul Weber, Alberto Marchet

Background:
Pure pleomorphic (PLCIS) and florid (FLCIS) lobular carcinoma in situ, without concurrent invasive carcinoma (IC) or ductal carcinoma in situ (DCIS), are rare and poorly understood. Their treatment is not standardized due to limited outcome data and lack of management guidelines. We aimed to gather the first large multicentric cohort of cases and analyze oncological outcomes to identify the optimal therapeutic approach.
Methods:
This international multicentric study (ClinicalTrials.gov ID NCT06133465) collected data from 23 centers. Patients diagnosed with pure PLCIS and/or FLCIS on core biopsy and/or final specimen pathology were included, with concurrent presence of classic (C-) LCIS permitted. Cases with associated (micro-) IC and/or DCIS were excluded. An internal slide review by a dedicated pathologist was required. A minimum follow-up of 2 years was guaranteed.
Results:
We collected 327 patients diagnosed with pure P-/FLCIS on core biopsy and/or on surgical specimen between 01/2004-06/2022. Of these, 58 showed P-/FLCIS only upon final histology, including 44/58 preoperative B3 lesions (17 CLCIS) and 14/58 misdiagnosed DCIS. The remaining 269 had a preoperative diagnosis of pure P-/FLCIS; of these, 82/269 cases (30.5%) upgraded on surgical specimen, with 72/82 (87.8%) to IC and 10/82 (12.2%) to DCIS ($p<0.001$). The upgrade rate to IC was 32.4% for PLCIS and 14.9% for FLCIS ($p=0.002$). Factors significantly associated with upgrade included radiological mass-like

aspect, size and multicentric distribution of the lesion, irregular margins on ultrasound, and presence of necrosis on core biopsy.
Our analysis focused on the 245 (74.9%) cases diagnosed as pure PLCIS (152/245, 62%) or FLCIS (93/245, 38%) on surgical specimen. Median age was 58 years, and 79.2% of the patients were diagnosed through screening mammogram. MRI was performed in 46% of cases, with 68% showing a non-mass-like enhancement. Median lesion size was 13 mm (IQR 7.5-22). Mastectomy was performed in 22 cases, while 223/245 (91%) patients underwent lumpectomy. Margin involvement (defined as P-/FLCIS on ink) occurred in 52/223 cases (23.3%), leading to 21 re-excisions, 4 mastectomies, and no further intervention in 27 cases. Factors significantly associated with positive margins included pleomorphic form, calcifications and architectural distortion on mammogram, a radiological mass-like aspect, and multicentric distribution. Sentinel lymph node biopsy was performed in 62/245 (25.3%) cases, with no positive lymph nodes found. Adjuvant radiotherapy was administered to 38/245 (15.5%) patients, while 50/245 (20.4%) received adjuvant endocrine therapy.
With a median follow-up of 76 months (IQR 34-91), local recurrence (LR) occurred in 35/245 (14.3%) cases, including 16 IC, 2 DCIS and 17 P-/FLCIS. Involved margin ($p<0.001$) and multicentric radiological distribution ($p=0.001$) were associated with LR. Adjuvant therapies did not influence recurrence rates (RR) in patients with clear margins ($p=0.3$), nor in those with involved margins ($p=0.06$). Among patients with positive margins, local RR was significantly higher in patients who did not have a re-excision (22/27, 81.5%) compared to those who did (2/25, 8%) ($p<0.001$). RR were similar between pure PLCIS and FLCIS cases (15.1% vs. 12.9%, $p=0.427$). The 5-year recurrence free survival was 84.6% for the entire cohort (95%CI 78.8-89%).
Conclusion:
In this cohort, yet the largest collected to date, the upgrade rate of pure P-/FLCIS to IC/DCIS was 30.5%, suggesting careful preoperative assessment. Axillary surgery should be omitted. Involved margins were associated with LR (invasive in nearly half of cases) while adjuvant therapies were not. Surgery with clear margins, and not adjuvant therapies, seem to be the mainstay of treatment for this disease.

PS18-06: Primary results and the transcriptomic analysis of PELOPS, a randomized phase II study of neoadjuvant palbociclib with or without endocrine therapy for breast cancer patients with invasive lobular carcinoma or invasive ductal carcinoma

Rinath Jeselsohn, Douglas Russo, Qingchun Jin, Patrick Kurnia, Jorge Gomez Tejeda, Kavya Prasad, Shira Sherman, Michelle K Demeo, Ying Huang, Jane Brock, Deborah A. Dillon, Tari A. King, Denise Yardley, Ingrid A Mayer, William F Symmans, Chip Stewart, Eric Winer, Nabihah Tayob, Gaddy Getz, Sara M Tolaney, Otto Metzger

Background: Invasive lobular carcinoma (ILC) is biologically distinct from invasive ductal carcinoma (IDC). Pre-clinical studies in human cell lines demonstrate that ILC has a unique

epigenetic state and estrogen receptor (ER) transcriptional axis, resulting in relative resistance to tamoxifen (T). Retrospective analyses of phase III clinical trials of adjuvant endocrine therapy (ET) (BIG 1-98, SOFT and TEXT) also support this hypothesis, with a greater difference between tamoxifen (T) and an aromatase inhibitor in ILC compared to IDC; PELOPS was designed to prospectively test this hypothesis.
Methods: PELOPS was a multi-center randomized phase II trial with both a window and treatment phase. Postmenopausal patients (pts) with early-stage ER+ breast cancer were randomized to a 2- week window of neoadjuvant letrozole (L) or T. Subsequently, pre and postmenopausal pts were randomized 2:1 to 6-cycles of neoadjuvant palbociclib (P) plus ET or ET alone. Histological subtype was among the stratification factors. Primary endpoints included 1) change in Ki67 after two weeks of T or L in the window phase within cohorts of pts with different histological subtypes, and 2) residual cancer burden (RCB) scores between arms in the treatment phase. Wilcoxon-rank sum test with two-sided alpha of 0.05 was used for both endpoints. Event-free survival (EFS) was defined as time from registration to the first event of disease progression precluding surgery, locoregional ipsilateral invasive recurrence, contralateral invasive breast cancer, distant recurrence or death from any cause. Biopsies were collected at baseline, after 2 weeks of ET and at surgery, and were subjected to RNAseq. Gene set variation analysis (GSVA) pathway analysis was performed.
Results: A total of 116 pts were evaluable for the window phase of the study (T=58, L=58). The Ki67 log-scale fold change (FC) was significantly lower with L compared to T among pts with both IDC (T: N=27, median FC=-0.121, L: N=28, median FC =-1.26, p=0.0045) and ILC (T: N=25, median FC=-0.452, L: N=25, median FC=-1.8, p=0.0161). In the treatment phase, 188 pts were evaluable (P+ET=128 and ET=60). The RCB scores in the two arms were comparable (median RCB 3.13 and 3.09, p-value = 0.9288). Median follow up was 4.65 years (IQR: 3.66 – 5.56 years), five-year EFS rate was 79.4% (95% CI: 71.2% - 88.5%) for P+ET and 80.9% (95% CI: 70.8% - 92.4%) for ET (hazard ratio 0.97 [95% CI, 0.47-2.00], p=0.926). RNAseq was completed on biopsies from a subgroup of pts highly representative of the entire population (279 biopsies from 97 pts). Most pts had luminal B breast cancers. Hierarchical clustering of baseline samples showed a distinct ILC transcriptome compared to IDC (Fisher's exact test, $p<0.001$). Pathway analysis revealed a significant reduction in expression of the cell cycle pathways after two weeks of T in IDC pts (paired T-test, $p<0.05$). In contrast, T did not suppress the cell cycle in ILC pts (lowest p=0.2). Interaction tests of GSVA changes after T treatment between ILC and IDC met significance or near significance (E2F targets p=0.051; Mitotic Spindle p=0.002; G2M checkpoint p=0.05, unequal variances t-tests). L treatment significantly decreased cell cycle pathways in both ILC and IDC, but other gene expression changes were disparate, underscoring the unique ER axis in ILC.
Conclusions: In the neoadjuvant setting, two-week treatment with letrozole achieved a superior reduction in Ki67 compared to tamoxifen in IDC and ILC, however, the addition of palbociclib to ET for 6 cycles did not improve RCB scores. Comprehensive molecular studies of biopsies from PELOPS provides the first prospective evidence of differential responses to T in ILC versus IDC. These results highlight the importance of molecular analyses in neoadjuvant ET trials and warrant trials for the optimization of ET specifically in ILC.

Additional gene expression analyses, including data from ET+/- palbociclib will be presented.

PS18-07: Differential odds of response in ILC versus IDC correlate with changes in the TIME in a phase II trial of pre-operative fulvestrant with or without enzalutamide.

Jennifer Richer, Anthony D. Elias, Alyse W. Staley, Monica Fornier, Gregory A. Vidal, Vida Alami, Sharon Sams, Nicole S. Spoelstra, Andrew Goodspeed, Peter Kabos, Jennifer R. Diamond, Elena Shagisultanova, Rosa I Gallagher, Julia Wulfkuhle, Emanuel Petricoin, Kathryn Zolman, Tessa McSpadden, Christian Rickert, Kimberly R. Jordon, Jill E. Slansky, Virginia F. Borges, Dexiang Gao

Background: The majority of ER+ breast cancers (BC) express androgen receptors (AR). In a randomized phase II trial for women with ER+/HER2- primary BC T2 or greater, neoadjuvant fulvestrant (Fulv) alone or with enzalutamide (Combo) was given for 4 months prior to surgery. A total of 59 patients were evaluable: 33 on Combo and 26 on Fulv. The addition of AR blockade to Fulv reduced residual tumor at time of surgery as measured by modified preoperative endocrine predictive index (PEPI) score. Fresh tumor biopsies were required at study entry (baseline), after 4 weeks on therapy (W5), and at surgery. The Combo arm achieved PEPI=0 more frequently (24%: 8/33) than Fulv (8%: 2/26). Interestingly, the odds of response were 4.6-fold (95% CI: 0.9-22) higher for patients with invasive lobular cancer (IDC) versus invasive ductal (IDC). Results: When examining all tumors, gene expression analyses showed significantly decreased estrogen response and cell division gene sets in tumors in both arms; however, only Combo treated tumors exhibited significant enrichment of immune activation genes sets, including interferon gamma, complement, inflammation, antigen processing, and B and T cell activation. AR protein was significantly reduced by time of surgery in the Combo arm only ($P<0.05$) as measured by immunohistochemistry. AR was also significantly lower at time of surgery in the PEPI=0 as compared to PEPI >0 ($P<0.05$) and in the Ki67 responders versus non-responders ($p<0.02$). Because of the 4.6-fold higher odds of PEPI=0 response in ILCs versus IDC, we examined phosphoproteins that changed with treatment in these two histologic groups by reverse phase phosphoprotein assay (RPPA) from frozen tumor sections. Both AR and phosphoS650 AR showed significantly more decrease from BL to W5 in ILC versus IDC. Cyclin D1, S6RP, HIF-1 alpha, ATP citrate lyase, were significantly lower in ILC than IDC, while CHK1 and ALK were higher. As would be expected with the higher odds of response in ILC, cell cycle proteins decreased significantly more with treatment in this histologic subtype, as did growth/survival and metabolism proteins. Polaris Multiplex immunofluorescence, used to study the tumor immune microenvironment (TIME), revealed that the number of tertiary lymphoid structures (TLS) per area surrounding resected tumor at time of surgery was higher in the Combo arm and was significantly higher near tumors that achieved PEPI=0 ($P<0.03$). Additionally, the average number of TLS/mm2 was higher in the ILC versus IDC ($P < 0.059$). T regulatory cells were reduced in the Combo arm

($p<0.0002$) and in Ki67 responsive tumors ($p<0.004$); however, T regs were not significantly different in ILC versus IDC. Tumor-associated macrophages decreased by time of surgery only in the Combo arm ($p<0.0001$), only in tumors that achieved PEPI=0 ($p<0.0005$) and trended towards decreased numbers in ILC vs IDC. Conclusions: AR inhibition in combination with a SERD activates the immune system in ER+ BC, particularly in ILC.

PS18-08: MDA iLobulaRx: An Advanced Clinico-Patho-Therapeutic Tool for Risk Stratification in Early-Stage Invasive Lobular Carcinoma

Jason A Mouabbi, Akshara S. Raghavendra, Sarah Pasyar, Roland L. Bassett Jr., Azadeh Nasrazadani, Carlos H. Barcenas, Amy A. Hassan, Debu Tripathy, Rachel M. Layman

Background: Invasive lobular carcinoma (ILC) is a distinct subtype of breast cancer that differs from the more common invasive ductal breast cancer (IDC) in its unique characteristics and arguably inferior prognosis. Recent studies have shown that ILC is associated with worse long-term outcomes compared to IDC. Risk stratification is essential in early breast cancer for tailoring treatment to optimize outcomes. We developed the MDA iLobular prognostic tool to incorporate clinical and pathological features to predict recurrence and survival in early-stage ILC (eILC). Recent studies suggest that the choice of adjuvant endocrine therapy (ET) significantly impacts recurrence and survival in eILC. We present an improved tool, “MDA iLobulaRx,” which includes clinical, pathological, and planned ET to enhance prognostic accuracy.
Methods: A retrospective analysis was performed on patients treated at MD Anderson Cancer Center with a diagnosis of stage I-III ILC in our prospectively collected and curated electronic database. Primary endpoints were overall survival (OS) and distant recurrence-free survival (DRFS). Univariate and multivariate Cox Proportional Hazard (PH) regression models assessed the significance of variables. Univariate Cox analysis identified prognostic factors for further multivariate analysis. Backward and stepwise multivariate Cox PH regression identified significant factors for final models. Hazard ratios and 95% confidence intervals were estimated, considering $P < 0.05$ significant. We evaluated model performance using Harrell's C-index, dividing data into two-thirds training and one-third test datasets.
Results: The study included 4,216 female patients with a median age of 56 years. The median pathological tumor size was 20 mm, and the median number of lymph nodes involved was one. Among these patients, 70% were post-menopausal. The ET used were tamoxifen (32%), non-steroidal aromatase inhibitor (NSAI) (30%), and no therapy (38%). The training cohort had 2,950 patients, and the test cohort had 1,266 patients. The best prognostic model for OS and DRFS had a Harrell's C-index of 0.727 and 0.713, respectively. The model included age, lymph nodes, tumor size, ER status, tumor grade, ILC histology, LCIS presence, and choice of adjuvant endocrine therapy data. (Table 1).
Conclusion: MDA iLobulaRx represents a significant advancement, offering the first dedicated clinico-patho-therapeutic tool for risk stratifying eILC.

PS18-09: Endocrine Response in Women with Invasive Lobular Carcinoma (TBCRC 037): A Multicenter Randomized Clinical Trial

Priscilla McAuliffe, Clark BZ, Hieken TJ, Mukhtar RA, Linden H, Nangia J, Gallagher K, Stringer-Reasor E, Bedrosian I, Feldman S, Nanda R, Boisvert M, Rothman J, Sikora MJ, Atkinson JM, Thorpe H, Tatsuoka C, Lee AV, Thompson A, Davidson NE, Oesterreich S, Jankowitz RC; on behalf of the Translational Breast Cancer Research Consortium (TBCRC)

Background: Adjuvant endocrine therapy (ET) recommendations for patients (pts) with invasive lobular carcinoma (ILC) are no different than for other breast cancer subtypes. However, due to unique differences in estrogen pathway signaling of ILC, identifying biological markers of ET sensitivity or resistance could have a major impact on its clinical management. Pre-clinical studies suggest that fulvestrant may be more effective than anastrozole or tamoxifen for ILC. Here we test reduction in the proliferation marker Ki67 as a surrogate for treatment response to ET.
Methods: This open label, randomized, controlled, multicenter phase 0 window of opportunity trial (NCT02206984) was conducted at 12 TBCRC institutions between 10/8/15 and 7/28/23. Postmenopausal women with previously untreated hormone receptor-positive (HR+), HER2 negative ILC, centrally histologically confirmed on diagnostic core needle biopsy (CNB), measuring ≥ 1 cm, were eligible. Stage IV was excluded. Pts were randomized 1:1:1 to fulvestrant (500 mg IM on days 1 and 15), anastrozole (1mg/day) or tamoxifen (20 mg/day). After 21-27 days of treatment, pts underwent operation (from which a CNB of residual tumor bed was taken) or a post-treatment image-guided CNB. The primary endpoint was change in Ki67 immunohistochemistry at post-treatment compared to baseline. Given the log-normal distribution of Ki67 measurements generally observed in this population, values were log-transformed for statistical analysis [log (post/pre)]. Group medians were compared using a quantile regression linear model adjusting for institutional-level random effects. A linear mixed model (glmmTMB R package) was fit that allowed for treatment level error variance. Post-hoc pairwise comparison of log(post/pre) were performed using Tukey adjustment for multiple comparison.
Results: 201 women were randomized, 172 completed the assigned treatment, and 138 (fulvestrant n=37; anastrozole n=49; tamoxifen n=52) had evaluable pre- and post-treatment tissue. No serious adverse events or deaths occurred. Pre-treatment demographic and tumor characteristics were well-balanced between the treatment groups. Median [range] age was 67 [48-86] years. Race was reported as Asian in 2 (1.5%), Black in 15 (10.9%), other in 4 (2.9%) and White in 117 (84.8%). Presenting clinical stage was IA in 54 (39.1%), IB in 4 (2.9%), IIA in 51 (37%), IIB in 19 (13.7%), IIIA in 4 (2.9%), IIIB in 5 (3.6%), and IIIC in 1 (0.7%). Median H-score [IQR] was ER 260 [50], PR 140 [215]. In the fulvestrant, anastrozole and tamoxifen groups respectively, pre-treatment Ki67 [IQR] was 13.8 [13.5], 13.6 [8.7], and 12.6 [11.9]; and post-treatment Ki67 [IQR] was 4.8 [5.4], 4.5 [5.6], and 5.7 [10]. A statistically significant reduction in Ki67 was found favoring fulvestrant vs tamoxifen (p=0.0419). No significant difference after adjustment was seen between anastrozole and tamoxifen (p = 0.2602) or between fulvestrant and anastrozole (p = 0.6643).

Conclusions: A greater reduction in Ki67 was seen post-treatment in CNB of pts with ILC treated with fulvestrant vs tamoxifen. Interestingly, tamoxifen treatment resulted in a reduction in Ki67 of a similar magnitude to anastrozole, despite clinical concerns about its reduced efficacy in ILC. Planned correlative studies will determine whether Ki67 reduction is associated with alterations in expression of ER and ER-regulated genes and/or in other novel pathways, potentially opening avenues for improved treatment strategies in ILC.

PS19-01: Medication Nonadherence and Financial Toxicity Among Patients with Metastatic Breast Cancer on Cyclin Dependent Kinase 4/6 Inhibitors

Claire Sathe, David DeStephano, Melissa Beauchemin, Melissa Accordino, Nadia Liyanage-Don, Ian M. Kronish, Dawn L. Hershman

Background: Existing research on adherence to breast cancer (BC) medications commonly focuses on the adjuvant treatment of early-stage BC. With the growing availability of novel oral therapies for metastatic BC (MBC), there is a gap in knowledge regarding adherence to medications for MBC. First-line treatment for hormone-positive MBC typically consists of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) combined with endocrine therapy (ET). CDK4/6i often require a complex dosing schedule, have a less favorable side-effect profile than ET alone, and can result in high patient out-of-pocket costs. These characteristics are known to affect medication adherence, yet little is known about the prevalence and drivers of nonadherence to CDK4/6i.
Methods: We identified a convenience sample of patients with MBC from the BC clinic of our urban academic medical center with at least 1 prescription for ribociclib or palbociclib between 3/2017 (FDA approval) and 5/2024. We did not include patients on abemaciclib, as it is often prescribed in the adjuvant setting. We assessed pharmacy fill adherence for both CDK4/6i (as a class) with 2 approaches to calculate the proportion of days covered (PDC): (i) using EHR-linked fill data exclusively; and (ii) integrating order data to determine the first continuous period of medication use. We followed patients from their first CDK4/6i fill or first fill after their first order for 180 days (or up until the start of a 30-day gap in orders or a 180-day gap in fills). We measured the overall prevalence of nonadherence, defined as either order or fill PDC <80% (adjusted for dosing schedule), and conducted a bivariate demographic subgroup analysis using Fisher's exact and Chi-squared tests. We examined the results of a patient-reported financial toxicity screener (2 questions from the COmprehensive Score for financial Toxicity [COST]), administered through the patient portal at appointment registration starting in 3/2021, which assesses financial certainty and financial worry. We performed a bivariate analysis of the association between nonadherence and financial toxicity.
Results:
We identified a total of 159 MBC survivors on CDK4/6i with pharmacy fills between 4/2017 and 5/2024 (mean age 66 yo; 43.4% non-Hispanic White, 13.8% non-Hispanic Black, 23.9% Hispanic). Of these, 129 (81.1%) had at least 1 palbociclib fill and 45 (28.3%) at least 1

ribociclib fill. With nonadherence defined as either order of fill PDC <80%, the overall nonadherence prevalence was 21.0% for CDK4/6i. On subgroup analysis, we did not identify any statistically significant difference in adherence prevalence by age, race, ethnicity, or language. A total of 64 patients included in our study population also responded to the financial toxicity screener. Of these, 58 (90.6%) screened positive for financial toxicity, reporting financial uncertainty (for 57 patients [89.1%]) and/or worry about finances (for 46 patients [71.8%]) due to cancer care costs. This is significantly higher than the 66.5% prevalence of financial toxicity in the overall breast oncology population at our BC clinic during this time ($p<0.001$). Of the 58 patients on CDK4/6i who reported financial toxicity, 10 (17.2%) were non-adherent based on PDC calculations. Of the 6 patients who screened negative for financial toxicity, none were nonadherent.
Conclusions:
Patients with MBC on CDK4/6i are at risk for medication nonadherence, with over 1 in 5 patients nonadherent based on fill or order data. They are also highly vulnerable to the financial toxicities of cancer treatment compared to the general breast oncology population. Further research is needed to clarify the impact of financial constraints on adherence to costly oral therapies and identify other possible drivers of nonadherence that can be targeted in future interventions.

PS19-02: Economic Impact of Concurrent Tissue and Circulating Tumor DNA Molecular Profiling In Advanced Breast Cancer Patients

Zachary Rivers, Rotem Ben-Shachar, Halla Nimeiri, Suzanne Belinson, Ira Klein, Charu Aggarwal

Background: The use of molecularly-directed targeted therapies has become a vital tool in treating advanced breast cancer patients. While solid tumor testing is standard of care for biomarker detection, the use of circulating tumor DNA (ctDNA), a noninvasive technology for molecular profiling is becoming more common. Concurrent testing, or the use of simultaneous solid tissue and ctDNA testing, has the potential to increase detection of actionable findings, as well as reduce adverse events from repeat biopsies compared to solid tissue testing alone. A large real-world study of patients tested concurrently identified an additional 20% of patients with advanced breast cancer with actionable findings which were missed by tissue-based testing alone. We use these data to assess the economic impact of concurrent testing compared to tissue-only testing in a simulation of patients with advanced Breast Cancer in the United States.
Methods: This microsimulation compares concurrent testing to solid tumor testing alone in patients with advanced breast cancer. Frequency of actionable biomarkers (BRCA1, BRCA2, ERBB2, ESR1, PIK3CA, and MSI) detected by testing modality were derived from a real-world data study of patients tested concurrently. Other model inputs, including detection rates of testing modalities, rates of rebiopsy due to inadequate tissue, and rates of adverse events were derived from literature. Total costs modeled included cost of NGS, biopsy costs, and management of adverse events due to biopsies. We assumed the cost of solid tumor and

the cost of liquid biopsy were each $2,919. The primary economic endpoint measured was the total cost per patient, while the primary clinical endpoints included percentage of patients with actionable variants identified, total biopsies performed per cohort, and serious biopsy events avoided per cohort.
Results: In a simulated cohort of 1,000 patients, real-world data suggest that 587 patients will carry an actionable variant. In the model simulations, concurrent testing identified 93 more patients with actionable findings than solid tumor testing alone (586 patients detected via concurrent testing vs. 493 patients detected by solid tumor testing), while also reducing the number of additional biopsies by 24. This reduction translates to a number needed to test (NNT) with concurrent testing to prevent one additional biopsy of 42 patients.The improved outcomes came at an increased incremental cost per patient of concurrent testing of $2,803 ($6,853 compared to $4,050 for solid tumor testing alone), $106 less than the cost of an additional liquid biopsy test.
Conclusions: Concurrent testing in advanced breast cancer identifies a higher proportion of patients with actionable variants than tissue testing alone, at a per-patient cost that is less than the actual cost of the liquid biopsy. This increased identification, coupled with a reduction in repeat biopsies, highlights a role for concurrent testing in the management of advanced breast cancer.

PS19-03: Contemporary patterns of Medicare Utilization and Spending on Herceptin and its Biosimilars in Breast Cancer

Charmi Bhanushali, Vidit Majmundar, Vaibhavi Mukhtiar, Vidhi Bhanushali, Kalaivani Babu, Srinishant Rajarajan, Kala Seetharaman

Introduction: A biosimilar is a biological product that is highly similar to and has no clinically meaningful differences from an existing FDA-approved reference product. Trastuzumab biosimilars are significant in HER2-positive breast cancer due to their cost savings and increased access to HER2-targeted therapy in early-stage and metastatic cases. The six FDA approved Herceptin biosimilars are: Ogivri, Herzuma, Ontruzant, Trazimera, Kanjinti, and Hercessi. Our objective is to analyze the trends of utilization, spending and cost of these biosimilars as compared to Herceptin (transtuzumab).
Methodology: We analyzed publicly available datasets from Centers for Medicare & Medicaid Services (CMS) within Medicare Part D. We extracted total spending, spending per claim, the number of beneficiaries, and spending per beneficiary for trastuzumab and its biosimilars. Kanjinti, Ontruzant, Trazimera were approved in 2019, so we examined changes between 2020 and 2022. All costs were adjusted for inflation and represented in 2022 US dollars. Because all data were deidentified and publicly available, the study was deemed exempt from institutional review board.
Results: From 2020 to 2022, total spending on Herceptin significantly decreased from $13,633,376 to $5,953,812, while spending on all biosimilars increased. Trazimera had the steepest increase ($70,717.28 in 2020 to $2,940,700.78 in 2022). Kanjinti had the highest spending among biosimilars in 2022 at $4,193,266.07. The total dosage units for Herceptin

decreased by 50% (from 7,184 in 2020 to 3,586 in 2022), while Trazimera saw an increase from 18 to 1,659 units.
Herceptin claims dropped by 48% (from 1,995 in 2020 to 1,044 in 2022), whereas biosimilar claims increased, with Kanjinti having the highest number in 2022 at 881 claims, and Herzuma the lowest at 38 claims. In 2022, Herceptin had the highest average spending per claim at $5,702.89, followed by Herzuma at $5,566.46. Kanjinti and Ontruzant had lower average spending per claim at $4,759.67 and $4,418.89, respectively.
The number of beneficiaries for Herceptin decreased by 44.5% (from 292 in 2020 to 162 in 2022), while it increased significantly for Kanjinti (from 34 in 2020 to 138 in 2022) and Trazimera (from 34 in 2021 to 115 in 2022). On the other hand, the beneficiaries for Ogivri fluctuated slightly (from 45 in 2020 to 58 in 2022). Average spending per beneficiary for Herceptin was $36751.93 in 2022 (vs 45299.84 in 2020). In comparison, the average spending per beneficiary in 2022 for all biosimilars was lower ($24359.03 for Ogivri; $25571.31 for Trazimera; $30385.99 for Kanjinti; $32110.63 for Ontruzant).
Conclusion: There has been a significant decline in Herceptin utilization and spending, accompanied by a shift towards biosimilars; reflecting changing trends in HER2-positive breast cancer treatments. Kanjinti and Trazimera, in particular, experienced substantial increases in spending, dosage units, claims, and beneficiaries, indicating growing acceptance and usage. Despite these increases, total spending and claims for Herceptin remain higher than for its biosimilars. The average spending per beneficiary and per claim is higher for Herceptin compared to its biosimilars. However, the decrease in these costs from 2020 to 2022 possibly indicate a favorable outcome as a result of market competition from biosimilars. The diversification provided by biosimilars has expanded patient options, potentially reduced costs and improved access to essential therapies. Continuous monitoring and analysis will be crucial to understanding the long-term impacts on healthcare costs and patient outcomes.

PS19-04: Exploring the broad societal value of pembrolizumab in triple-negative breast cancer in Canada

Kate Young Brook E, Madin-Warburton M; Wijenayake N; Mishkin K; Meilleur M-C; Davies A

Background: The impact of breast cancer is multifaceted; for each patient there are personal, social, and financial consequences which have wider societal and economic consequences. Cost-effectiveness analyses for health technology assessment (HTA) purposes are predominantly conducted from the traditional payer perspective and often do not capture these wider impacts. Pembrolizumab, a programmed death receptor-1 (PD-1)-blocking antibody indicated for the treatment of triple-negative breast cancer (TNBC), has demonstrated substantial survival benefits to patients. Our study analyzes the traditional societal and broader societal net monetary benefit (NMB) of pembrolizumab-based therapies for early TNBC (eTNBC) and metastatic TNBC (mTNBC) in a Canadian setting. We incorporate novel elements of value described in the third ISPOR Special Task Force Report alongside new elements considered relevant to the disease. METHODS: Two validated and

HTA approved cost-effectiveness models for pembrolizumab in eTNBC and mTNBC were expanded to include elements constituting the broad societal perspective. For the traditional societal perspective, this included productivity. For the broad societal perspective, the additional elements included caregiver burden, insurance value, value of hope, real option value, severity of disease, out-of-pocket expenses, and fertility treatment costs. A targeted literature review was conducted to identify inputs for each element. A standard of care comparator, consisting of chemotherapy, was generated for each indication; formed of a weighted average of the various chemotherapy comparators by indication based on market share. Canadian list prices were used for all treatment acquisition costs. An overall NMB was generated across indications by weighting individual results by prevalence and using a willingness to pay threshold of CAD$100,000. Probabilistic sensitivity analysis (PSA) and scenario analyses were implemented to analyze the robustness of results to plausible variation.

Results: The results showed that adopting a broad societal perspective resulted in more favourable cost-effectiveness results. Specifically, the overall broad societal NMB was CAD$1,113,858, almost four times greater than the traditional payer (CAD$282,644) and traditional societal NMB (CAD$279,534). For mTNBC, the NMB was positive for the broad societal perspective whereas the two traditional perspectives yielded a negative NMB. For eTNBC, pembrolizumab consistently resulted in a positive NMB for all three perspectives, however the broad societal perspective resulted in a substantially higher NMB. This was largely driven by the substantial insurance value impact on quality-adjusted life years. The next most influential element was the value of hope. PSA was consistent with deterministic results. Scenario analysis demonstrated that the choice of input source used to inform the broad elements of value had a substantial impact on NMB.

Discussion: The inclusion of broader societal elements of value resulted in a significantly higher NMB than the traditional payer perspective for both indications, indicating that society as a whole may place a substantially greater value on access to treatment than suggested from a traditional payer perspective. However, the paucity of disease-specific input data and the uncertain estimation of some of the broad societal perspective elements of value result in challenges with interpretation. Overall, the research highlights the importance of considering alternative and broader perspectives of analysis in health technology evaluation, but more research is needed to robustly parameterize novel elements of value. Notably, this study indicates that the traditional payer and societal perspectives commonly used for HTA may be missing key elements of value, and thus underestimate the value that general societal places on access to innovative therapies.

PS2-01: Dalpiciclib versus placebo in combination with letrozole or anastrozole as first-line treatment for women with HR+/HER2- advanced breast cancer: prespecified final analysis of progression-free survival of the phase 3 DAWNA-2 trial

Binghe Xu, Pin Zhang, Qingyuan Zhang, Zhongsheng Tong, Tao Sun, Wei Li, Quchang Ouyang, Xichun Hu, Ying Cheng, Min Yan, Yueyin Pan, Yuee Teng, Xi Yan, Ying Wang, Weimin Xie, Xiaohua Zeng, Xiaojia Wang, Changlu Hu, Cuizhi Geng, Hongwei Zhang, Wenxin Li, Xinhong Wu, Jincai Zhong, Jingwei Xu, Yanxia Shi, Mengzhu Yu, Xiaoyu Zhu

Background: Dalpiciclib (a highly selective and potent CDK4/6 inhibitor) plus letrozole or anastrozole as first-line treatment led to a statistically and clinically significant improvement in progression-free survival (PFS) compared with endocrine therapy alone in women with HR+/HER2- advanced breast cancer, according to the interim analysis of the DAWNA-2 trial (NCT03966898; Xu et al., Lancet Oncology, 2023). In this report, we present the prespecified final analysis of PFS and an updated safety analysis after more than one year of additional follow-up.

Methods: The DAWNA-2 study was a randomized, double-blind, multicenter phase 3 trial conducted at 42 centers in China. The DAWNA-2 trial enrolled patients aged 18–75 years, of any menopausal status, who had an ECOG performance status of 0–1 and pathologically confirmed HR+/HER2- untreated advanced breast cancer. Patients were randomly assigned in a 2:1 ratio to receive oral dalpiciclib (150 mg per day for three weeks, followed by one week off) or a matching placebo. Both groups also received continuous endocrine therapy, either 2.5 mg letrozole or 1 mg anastrozole, administered orally once daily. The primary endpoint was investigator-assessed PFS. The data cutoff for the updated analysis was March 31, 2024.

Results: Between July 19, 2019, and December 25, 2020, 456 eligible patients were enrolled and randomized into two groups: 303 in the dalpiciclib group (dalpiciclib plus letrozole or anastrozole) and 153 in the placebo group (placebo plus letrozole or anastrozole). At the data cutoff, the median follow-up duration was 40.6 months (IQR 30.3-45.1) for the dalpiciclib group and 38.9 months (IQR 27.5-44.6) for the placebo group. Post-discontinuation therapy was received by 154 (50.8%) patients in the dalpiciclib group and 101 (66.0%) in the placebo group, with endocrine therapy being the most common (32.7% in the dalpiciclib group and 49.7% in the placebo group). Disease progression or death occurred in 160 (52.8%) patients in the dalpiciclib group and 109 (71.2%) in the placebo group. Dalpiciclib plus letrozole or anastrozole significantly prolonged investigator-assessed PFS compared to placebo plus letrozole or anastrozole (median PFS: 33.4 months [95% CI 29.6-39.0] vs. 19.3 months [95% CI 16.5-22.5]; hazard ratio [HR] 0.56 [95% CI 0.44-0.72]; one-sided p <0.0001). The PFS benefit with dalpiciclib was consistent in both postmenopausal women (HR 0.54 [95% CI 0.40-0.74]) and pre- or perimenopausal women (HR 0.63 [95% CI 0.41-0.95]). Per investigator assessment, 181 patients (59.7%) in the dalpiciclib group and 76 (49.7%) in the placebo group achieved an objective response; the

median duration of response was 36.1 months (95% CI 29.4-45.8) and 16.4 months (95% CI 13.8-24.8), respectively. Dalpiciclib showed benefits beyond the initial study treatment, as indicated by the time to first subsequent chemotherapy (median not reached [NR] vs. 47.4 months [95% CI 31.4-NR]; HR 0.76 [95% CI 0.56-1.02]). As of the data cutoff date, 80 (26.4%) patients in the dalpiciclib group and 46 (30.1%) in the placebo group had died. The median overall survival (OS) was not yet mature in both groups. Serious AEs occurred in 17.5% of patients in the dalpiciclib group and 7.8% in the placebo group. Treatment discontinuation due to adverse events (AEs) was reported for 4.6% and 2.0% of patients, respectively.
Conclusion: The addition of dalpiciclib to letrozole or anastrozole continues to demonstrate PFS benefits with no new safety signals identified after prolonged follow-up, further supporting this regimen as an alternative option in the current treatment landscape for patients with HR+/HER2- advanced breast cancer, regardless of menopausal status.

PS2-02: Tibremciclib (BPI-16350) plus fulvestrant versus placebo plus fulvestrant for patients with HR+/HER2- advanced breast cancer after progressing on endocrine therapy: Updated analysis of the phase III study

Zhonghua Tao, Jian Zhang, Qiufan Zheng, Yongsheng Wang, Li Cai, Hongyan Xu, Xinhua Xu, Xiangshun Kong, Sijuan Ding, Chunfang Hao, Hao Wang, Hong Zong, Xin Jin, Xinshuai Wang, Yang Li, Xiuli Yang, Peiqi Li, Lieming Ding, Shusen Wang, Xichun Hu

Background: Tibremciclib (BPI-16350; TIB), a novel highly potent CDK4/6 inhibitor, improved progression-free survival (PFS) when combined with fulvestrant (FUL) versus placebo (PBO) plus FUL in patients with HR+/HER2- advanced breast cancer (ABC) that progressed on prior endocrine therapy in an interim analysis of a randomized, double-blind, phase III study (NCT05433480). Here, we report the updated analysis from the phase III study.
Methods: Patients with post-menopausal status (natural or artificial) who had recurred during or within 12 months from the end of neo-adjuvant or adjuvant endocrine therapy or who progressed on the first-line endocrine therapy for metastatic disease were randomly assigned to receive TIB (400 mg orally once daily) or matching PBO plus FUL (500 mg intramuscularly on days 1 and 15 of 28 days of cycle 1, then day 1 of every subsequent cycle), in a 2:1 ratio between patients with TIB and PBO. The primary endpoint was investigator (INV)-assessed PFS, and key secondary endpoints were independent review committee (IRC)-assessed PFS, INV-assessed objective response rate (ORR), disease control rate (DCR), clinical benefit rate (CBR); overall survival (OS) and safety.
Results: A total of 274 patients were randomly assigned to receive TIB plus FUL (N = 184) or PBO plus FUL (N = 90). By the data cutoff date of March 31, 2024, the median follow-up was 12.88 months for either group. The median INV-assessed PFS was significantly longer with TIB plus FUL versus PBO plus FUL (16.53 months [95% CI 12.85-16.59] versus 5.59 months [95% CI 4.53-9.20], HR 0.37 [95% CI 0.27-0.52]; $p < 0.0001$). Improvement in PFS was confirmed by the IRC analysis, with an HR of 0.37 (95% CI 0.26-0.54; $p < 0.0001$). The

INV-assessed confirmed ORR was 39.1% versus 10.0% ($p < 0.0001$), DCR was 89.1% versus 76.7% ($p=0.0053$), and CBR was 74.5% versus 42.2% ($p < 0.0001$) in the TIB group and PBO group, respectively. Median OS for the study has still not been reached (19.7% OS data maturity). Safety profiles showed no new safety signals from the interim analysis. The most common treatment-emergent adverse events (TEAEs) in the TIB group were diarrhea (79.3%; versus 13.3% for the PBO group), neutropenia (75.5%; versus 15.6%), and leukopenia (73.9%; versus 16.7%). The most common grade 3 or higher TEAE was neutropenia in the both groups (15.2% versus 5.6% for the TIB group and PBO group). The incidence for grade 3 or higher diarrhea was 4.9% in the TIB group and 1.1% in the PBO group. Serious adverse events (SAEs) occurred in 24 patients (13.0%) in the TIB group and 9 patients (10.0%) in the PBO group. TEAEs leading to dose discontinuation occurred in 4 patients (2.2%) for the TIB group and none for the PBO group. No treatment-related death in the TIB group and 1 death (1.1%) in the PBO group.
Conclusions: Tibremciclib plus fulvestrant continued to demonstrate a statistically significant and clinically meaningful improvement in PFS for patients with HR+/HER2- ABC who had progressed on endocrine therapy. Safety prolife was aligned with the previous interim analysis, with no new safety findings identified.

PS2-03: Comparative overall survival of CDK4/6is plus an aromatase inhibitor (AI) in HR+/HER2- MBC in the US real-world setting

Hope S. Rugo, Rachel M. Layman, Filipa Lynce, Xianchen Liu, Benjamin Li, Lynn McRoy, Aaron B. Cohen, Melissa Estevez, Giuseppe Curigliano, Adam Brufsky

Background: Palbociclib (PAL), the first CDK4/6i, in combination with endocrine therapy (ET) was approved for HR+/HER2- advanced/metastatic breast cancer (MBC) in 2015. Two additional CDK4/6is, Ribociclib (RIB) and Abemaciclib (ABE), were approved in 2017. CDK4/6i combination therapy has become standard of care for 1st line HR+/HER2- MBC. Randomized clinical trials (RCT) demonstrated that the 3 CDK4/6is plus ET vs ET plus placebo all significantly prolonged patients' progression free survival (PFS, primary endpoint). However, the 3 CDK4/6is have inconsistent 1st line RCT overall survival findings (OS, secondary endpoint). In the absence of head-to-head RCTs, real-world data (RWD) is an important complementary source of evidence. Several small RWD studies have evaluated the relative effectiveness between CDK4/6is, and their findings are inconsistent. Large RWD studies are needed to understand the effectiveness of the 3 CDK4/6is. This study compared OS of 1st line PAL vs RIB and ABE plus AI for HR+/HER2- MBC in routine US clinical practice.

Methods: We conducted a retrospective comparative effectiveness study of CDK4/6is plus AI in HR+/HER2-MBC using the US nationwide Flatiron Health electronic health record (EHR)-derived deidentified Panoramic database, comprised of >650k patients with breast cancer. Patients included had HR+/HER2- MBC, were ≥18 years, started index treatment (PAL+AI, RIB+AI, or ABE+AI) as 1st line therapy within 90 days of MBC diagnosis between

February 2015 and September 2023 (index period), and did not participate in clinical trials. Patients were assessed from start of index treatment to March 2024, death, or last medical activity, whichever came first. OS was defined as months from start of index treatment to death. Patients were balanced via exact 1:1 matching on age, gender, race and ethnicity, practice type, disease stage at initial diagnosis, ECOG, time from initial to MBC diagnosis, visceral disease, bone-only disease, and number of metastatic sites. Kaplan-Meier method and Cox proportional hazard regression model were used to analyze OS.

Results: Of 9770 patients eligible for the analysis, 7563, 1130, and 1077 patients received PAL+AI, RIB+AI, and ABE+AI, respectively. Median follow-up was 32.9 months for PAL+AI, 16.5 months for RIB+AI, and 21.3 months for ABE+AI treated patients. Compared with RIB and ABE groups, PAL group was 1-2 years older and had a lower proportion of patients with ECOG=0. After 1:1 matching, baseline demographics and clinical characteristics were well balanced between PAL vs RIB pairs (n=942) and PAL vs ABE pairs (n=857). In PAL-RIB pairs, 2- and 3-year OS rates were 81.3% and 67.6% for PAL group vs 79.8% and 69.7% for RIB group. In PAL-ABE pairs, 2- and 3-year OS rates were 76.8% and 63.0% for PAL group vs 75.7% and 67.4% for ABE group. Compared with PAL+AI, RIB+AI was not significantly associated with prolonged OS (unadjusted HR=0.90, 95%CI=0.80-1.02, p=0.097; matched HR=0.98, 95%CI=0.84-1.15, p=0.823). Similarly, ABE+AI vs PAL+AI was not significantly associated with prolonged OS (unadjusted HR=0.95, 95%CI=0.84-1.07, p=0.376; matched HR=0.90, 95%CI=0.77-1.06, p=0.212). Further analyses with additional follow-up, treatment duration, subsequent therapies, and time to chemotherapy will be reported.

Conclusions: Our findings suggest that there is no significant OS superiority of first-line RIB+AI and ABE +AI compared to PAL+AI for HR+/HER2- MBC patients in routine clinical practice in the US. Although the sample size precludes a formal non-inferiority analysis and short follow up may limit interpretation, this study represents the largest real-world comparative analysis of OS between the CDK 4/6is in combination with AI conducted to date.

PS2-04: Health related quality of life with first- versus second-line CDK4/6 inhibitor use in advanced breast cancer: results from the phase 3 SONIA trial (BOOG 2017-03)

Noor Wortelboer, Seamus Kent, Hedwig M. Blommestein, Annemiek van Ommen-Nijhof, Vincent van der Noort, Esther van den Pol, Cristina Guerrero Paez, Aart Beeker, Karin Beelen, Lisanne C. Hamming, Joan B. Heijns, Aafke H. Honkoop, Paul C. de Jong, Quirine C. van Rossum-Schornagel, Christa van Schaik-van de Mheen, Jolien Tol, Cathrien S. Tromp-van Driel, Suzan Vrijaldenhoven, A. Elise van Leeuwen-Stok, Gabe S. Sonke, Agnes Jager, Inge R. Konings

Background: Adding cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i) to endocrine

therapy improves outcome in patients with hormone-receptor positive, HER2-negative advanced breast cancer. The phase 3 SONIA trial randomised 1,050 patients to receive CDK4/6i in first- versus second-line in addition to aromatase-inhibitor in first- and fulvestrant in second-line. No significant difference between the strategies was observed in progression-free survival after two treatment lines (PFS2; HR 0.87; 95% CI 0.74 to 1.03) while first-line CDK4/6i use increased toxicity (74% more grade ≥3 adverse events, most often neutropenia) and costs. We now present the health-related quality of life (HRQoL) outcomes in the first- versus second-line CDK4/6i group.

Patients and methods

HRQoL was assessed using the Functional Assessment of Cancer Therapy-Breast (FACT-B) questionnaire (version 4) at baseline, 12, 24, 48 and 72 weeks on both first- and second-line treatment and at SONIA treatment discontinuation. FACT-B total scores along with subscale scores for physical (PWB), social (SWB), emotional (EWB), functional well-being (FWB) and the breast cancer subscale (BCS) were calculated for all completed questionnaires within 60 days after SONIA treatment discontinuation. Missing baseline scores were imputed using the mean baseline score. For missing post-baseline timepoints, multiple imputation was employed separately for each score and arm using the predictors age at randomisation, ECOG performance status, baseline score, progression or a serious adverse event within last 3 months and the timepoint of the questionnaire. Mixed linear regression models with a random intercept were used to compare HRQoL over time between the two arms. Response variables were FACT-B total and individual subscales scores and covariates included treatment arm, time (continuous), and baseline HRQoL. We also tested for an interaction between arm and time. A difference of 7-8 points in FACT-B total score and of 2-3 points in subscales was defined as a clinically meaningful difference.

Results: Across arms, questionnaire completion rates were high at baseline (88%), as well as over the different time points during first- (82%) and second-line treatment (73%), and at treatment discontinuation (52%). The average difference in FACT-B total and subscale scores between the two arms was close to zero (i.e. no difference) and we found no evidence of an interaction with time. Over time, the observed mean differences using CDK4/6i in second-line as reference, were -0.49 (95% CI -1.88 to 0.90) for the FACT-B total score, -0.19 (95% CI -0.58 to 0.20) for PWB, 0.40 (95% CI -0.04 to 0.83) for SWB, 0.00 (95% CI -0.34 to 0.35) for EWB, -0.05 (95% CI -0.48 to 0.38) for FWB and -0.36 (95% CI -0.77 to 0.05) for BCS.

Conclusions: Health-related quality of life, as measured by the FACT-B total score and all subscales, was comparable between the CDK4/6i-first and CDK4/6i-second group during the two protocol-defined treatment lines in SONIA. These data indicate that adding CDK4/6i in first-line compared to second-line does not result in improved HRQoL, providing further justification for deferring the use of CDK4/6i to second-line treatment.

Clinical trial registration: NCT03425838

PS2-05: PRESERVE 2: A randomized, phase 3, double-blind trial of trilaciclib or placebo in patients (pts) receiving first-line gemcitabine/carboplatin (GCb) for locally advanced or metastatic triple-negative breast cancer (mTNBC)

Shom Goel, Joyce O'Shaughnessy, Binghe Xu, Zhongsheng Tong, Shusen Wang, George Emile, Ekaterine Arkania, Gia Nemsadze, Iurie Bulat, Rodryg Ramlau, Aleksandra Grela-Wojewoda, Mafalda Oliveira, Valerii Cheshuk, Philip Lammers, Michael Danso, Hope S. Rugo, Debra Patt, Timothy Pluard, Julio Ruiz, Rajesh Malik, Antoinette R. Tan

Background: TNBC is an aggressive malignancy for which chemotherapy is a backbone of treatment. Trilaciclib is an intravenous (IV), selective, and reversible cyclin-dependent kinase 4/6 inhibitor. In a randomized phase 2 trial in pts with previously treated mTNBC, trilaciclib administered prior to GCb resulted in a clinically meaningful improvement in overall survival (OS) versus GCb alone, regardless of programed death-ligand 1 (PD-L1) status, potentially via protection and direct activation of immune function. The multinational, randomized, double-blind, placebo-controlled, phase 3 PRESERVE 2 trial (NCT04799249) was designed to further evaluate efficacy and safety of trilaciclib prior to GCb in previously untreated pts with mTNBC. Here, we report final data from pts receiving first-line therapy, regardless of tumor PD-L1 status (cohort 1).
Methods: Eligible pts had locally advanced, unresectable, or metastatic TNBC, an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0/1, received no prior systemic therapy in the advanced/metastatic setting, and were ineligible/unable to receive treatment with a programmed cell death protein-1 (PD-1)/PD-L1 inhibitor. Pts were stratified according to tumor PD-L1 status (positive vs negative), disease-free interval (DFI; ≥ 6 months and < 12 months vs ≥ 12 months or de novo mTNBC), and country, and randomized 1:1 to receive IV placebo or trilaciclib 240 mg/m2 prior to gemcitabine (1000 mg/m2) and carboplatin (AUC 2) on days 1 and 8 of 21-day cycles. Primary endpoint: OS; secondary endpoints: OS according to PD-L1 status, progression-free survival (PFS), antitumor response (including overall response rate [ORR]), quality of life measures, myeloprotection, and safety/tolerability.
Results: Overall, 187 pts from 11 countries were randomized to trilaciclib (n = 96) or placebo (n = 91) prior to GCb. Median age was 58 years (range, 30–82), and 39.6% of pts had PD-L1–positive disease (trilaciclib, 38.5%; placebo, 40.7%). DFI was < 12 months in 20.9% of pts and > 12 months (or de novo disease) in 79.1%. Pts completed a median of 6 (range, 1–41) treatment cycles. Median (95% CI) OS was 17.4 (12.4–21.3) versus 17.8 (13.3–22.5) months (hazard ratio [HR], 0.91 [95% CI, 0.62–1.33]; P = 0.884) in the trilaciclib and placebo groups, respectively, with a median follow-up of 12.1 and 14.9 months. In pts with PD-L1–positive disease, median OS with trilaciclib versus placebo was 23.1 versus 21.8 months (HR, 1.0 [95% CI, 0.51–1.96]; P = 0.923), and in pts with PD-L1–negative disease was 15.7 versus 14.9 months (HR, 0.92 [95% CI, 0.57–1.49]; P = 0.913), respectively. Median (95% CI) PFS was 6.3 (4.4–8.3) months with trilaciclib and 6.4 (5.2–8.1) months with placebo (HR, 1.17 [95% CI, 0.80–1.69]; P = 0.434), and ORR was 29.5% and 38.2%,

respectively. Overall, safety was comparable between treatment arms; 128 pts (92.3%) had an adverse event (AE), including 143 pts (78.6%) with grade ≥ 3 AEs. Trilaciclib-/placebo-related AEs were reported in 109 pts (59.9%). The most common (≥ 40% of pts) any-grade AEs, irrespective of causality, were anemia (trilaciclib, 58.1%; placebo, 62.9%) and neutrophil count decreased (trilaciclib, 40.9%; placebo, 39.3%). Compared with placebo, fewer pts receiving trilaciclib had grade 4 neutropenia (8.6% vs 25.8%), any-grade thrombocytopenia (38.7% vs 53.9%), and chemotherapy dose reductions (49.5% vs 64.0%).
Conclusions: Data from PRESERVE 2 show that compared with placebo, administering trilaciclib prior to GCb did not improve survival in pts with mTNBC. The safety profile of trilaciclib was consistent with previous studies. Some myeloprotective effects were observed, consistent with the known mechanism of action of trilaciclib.

PS2-06:First-line (1L) ribociclib (RIB) + endocrine therapy (ET) vs combination chemotherapy (combo CT) in clinically aggressive HR+/HER2- advanced breast cancer (ABC): a subgroup analysis of RIGHT Choice by intrinsic subtype & gene & signature expression

Yen-Shen Lu, Chia-Lang Hsu, Eznal Izwadi Bin Mohd Mahidin, Sudeep Gupta, Erhan Gökmen, Elena Artamonova, Huang-Chun Lien, Hamdy Azim, Yoon-Sim Yap, Yesim Eralp, Seock-Ah Im, Fei Su, Yogesh Chattar, Estelle Roux, Melissa Gao, Nagi S. El Saghir

Background: The phase 2 RIGHT Choice study showed a statistically significant median progression-free survival (mPFS) benefit with 1L RIB + ET vs combo CT (HR, 0.61; 95% CI: 0.43-0.87; P = .003) in pts with clinically aggressive HR+/HER2− ABC (Lu Y-S, et al. J Clin Oncol. Published online May 21, 2024). This exploratory analysis of the RIGHT Choice study examined efficacy of RIB + ET vs combo CT by intrinsic subtype and gene/signature expression levels.
Methods: Pre/perimenopausal pts with no prior systemic therapy for aggressive HR+/HER2− ABC were randomized 1:1 to RIB + letrozole/anastrozole + goserelin or physician's choice of combo CT. Baseline tumor samples (n = 49) from pts enrolled in the trial were microdissected and underwent gene expression profiling by NanoString nCounter BC360 and PanCancer IO 360 panels. High and low baseline gene/signature expression levels were defined as greater and less than or equal to the median level, respectively.
Results: Of the available samples from the RIB arm (n = 27), 6 (22.2%) were luminal A, 14 (51.9%) were luminal B, 6 (22.2%) were HER2E, and 1 (3.7%) was basal-like; in the CT arm (n = 22), 11 (50.0%) were luminal A, 9 (40.9%) were luminal B, and 2 (9.1%) were HER2E. The mPFS in the RIB vs CT arms was 32.5 mo vs not reached (NR) (HR, 0.88; 95% CI: 0.20-3.91) in luminal A, 38.0 vs 21.7 mo (HR, 0.64; 95% CI: 0.18-2.20) in luminal B, and 17.4 vs 8.0 mo (HR, 0.23; 95% CI: 0.03-1.66) in HER2E subtype. In the combined luminal B/HER2E set, which are known to be associated with poor prognosis, the mPFS was 38.0 vs 18.4 mo with RIB + ET vs combo CT (HR, 0.58; 95% CI: 0.21-1.62). In the RIB arm, pts with high ESR1 expression showed longer mPFS vs pts with low ESR1 expression (high vs low

expression, mPFS, HR [95% CI]; 38.0 vs 32.5 mo, 0.52 [0.16-1.66]). Pts in the RIB arm with low expression of tumor inflammation or immune-related genes/cells, such as tumor inflammatory signature (TIS; BC360 panel) and T-cell (IO 360 panel) expression, had a longer mPFS than pts with high expression of these signatures (low vs high expression, mPFS, HR [95% CI]: TIS, NR vs 11.4 mo, 0.17 [0.04-0.76]; T cells, NR vs 10.3 mo, 0.2 [0.05-0.76]). In contrast to the results in the RIB arm, pts with low expression of immune-related genes/cells in the CT arm had a shorter mPFS than those with high expression of these genes (low vs high expression, mPFS, HR [95% CI]: TIS, 15.0 mo vs NR, 2.08 [0.62- 6.93]; T cells, 12.8 vs 18.4 mo, 1.8 [0.57-5.71]). For most other immune-related genes/cells expressions and signatures, a comparable consistent trend in PFS benefit for low vs high expression levels was observed, with a higher PFS benefit for low gene expression in the ribociclib arm, and a higher PFS benefit for high gene expression in the CT arm. Conclusions: This exploratory analysis showed a trend towards PFS benefit with RIB + ET vs combo CT in pts with luminal B/HER2E intrinsic subtypes, which are associated with poor prognosis. This analysis also suggest a more pronounced trend for PFS benefit with RIB + ET in pts with low baseline expression levels of immune-related genes. Contrary results in the CT arm suggest that these signatures warrant further studies on their potential predictive value. These data are hypothesis generating and should be interpreted with caution due to small sample sizes.

PS2-07: Intrinsic Subtype at Progression to CDK4/6 Inhibitors Plus Endocrine Therapy in Hormone Receptor-Positive/HER2-Negative Metastatic Breast Cancer (MBC)

Isabel Garcia-Fructuoso, Fara Brasó-Maristany, Olga Martínez-Sáez, Raquel Gómez-Bravo, Sabrina Nucera, Elia Seguí, Oleguer Castillo, Paula Blasco, Valeria Sirenko, Angela Aguirre, Natalia Lorman-Carbó, Patricia Galván, Benjamín Walbaum, Esther Sanfeliu, Blanca Gonzalez-Farre, Tomás Pascual, Barbara Adamo, Maria Vidal, Montserrat Muñoz, Aleix Prat, Francesco Schettini

Background: Biomarkers after progression to CDK4/6 inhibitors plus endocrine therapy (CDKi+ET) are needed to guide the use of ET-based therapies versus chemotherapy (CT). Here, we explored the prognostic and predictive value of the 4 major intrinsic subtypes (IS) of breast cancer (i.e., Luminal A [LumA], Luminal B [LumB], HER2-enriched [HER2E], Basal-like [BL]) in tumor samples of patients with HR+/HER2- MBC progressing to CDKi+ET.

Methods: This retrospective/prospective observational study included 63 patients with HR+/HER2- MBC treated at the Hospital Clinic of Barcelona between 2018-2024 with at least one line after CDKi+ET and an available tumor biopsy obtained at progression from CDK4/6 inhibition. The primary objective was to determine the progression-free survival (PFS) and overall survival (OS) after CDKi+ET, according to IS determined at progression from CDKi+ET. PFS and OS within luminal (Lum) vs. non-Lum IS according to type of therapy was explored. A paired biopsy (before starting CDKi+ET and at progression to

CDKi+ET) was available in 39 (61.9%) cases. IS was assessed using a research-based PAM50 assay on the nCounter platform. Survival analyses were conducted with the Kaplan-Meier method and Cox regression models. Significance was established at p≤0.05.

Results: The median age was 57.6 years. Overall, CDKi+ET had been administered in 1st, 2nd and ≥3rd line in 65.1%, 14.8% and 20.1% cases, with 54.0% patients progressing to ribociclib as CDKi and 57.1% progressing to letrozole as ET. Median PFS to CDKi+ET was 13.6 months (95% CI 10.2-19.2). In tumor samples obtained at CDKi+ET progression, 27 (42.9%) were Lum (LumA+LumB) and 36 (57.1%) non-Lum (HER2E+BL+normal-like). With a median follow-up of 35.2 months (95% CI 22.5-53.3) after progressing to CDKi+ET, PFS was 5.5 months (95% CI 3.8-7.9), and OS was 21.3 months (95% CI 16.8-28.7). Subtypes at progression to CDKi+ET were prognostic for PFS (p<0.001) and OS (p=0.004) with LumA tumors displaying the best median PFS (7.9 months) and OS (43.3 months), followed by LumB (5.4 and 23.8 months), HER2E (4.8 and 21.4), and BL (4.6 and 10.3). The PFS and OS hazard ratios (HR) between LumA versus others, adjusted for post-CDKi treatment, were 0.39 (p=0.032) and 0.49 (p=0.202), respectively. Patients with non-Lum tumors received more CT +/- targeted therapy (63.9% vs 18.5%) and less ET-based therapies (25.0% vs 66.6%) than patients with Lum tumors (p<0.01). Type of therapy (CT-based versus ET-based) was not found significantly associated with PFS (p=0.585) and OS (p=0.516). However, CT-based therapies within non-Lum disease showed better PFS compared to ET-based therapies (HR=0.44, p=0.039). No difference in OS was observed (p=0.266). Within Lum disease no difference in PFS and OS was observed according to therapy. Finally, in 39 paired tumor samples, subtype switching occurred in 61.9% of the cases. Tumor samples obtained at progression to CDKi+ET were significantly enriched in HER2E disease (51.3% vs 35.9%) and showed less Lum IS (41.0% vs 56.4%), with a consistent increase in the HER2E PAM50 score (p=0.005) and mRNA levels of genes associated to proliferation or HER2E biology, e.g. MKI67 (p=0.009) and FGFR4 (p=0.035), despite no ERBB2 mRNA levels' changes (p=0.841). Similar findings were observed in a subgroup of baseline Lum tumors shifting to HER2E.

Conclusions: Subtype switching towards less ET-sensitive IS, especially the HER2E, occurs under CDKi+ET and has prognostic value. Post-CDKi LumA disease showed the best outcomes, regardless of treatment type. This group of patients might be the ideal group to be treated with ET-based therapies. Non-Lum IS performed better with CT-based approaches. Overall, these findings suggest the necessity to profile tumor samples at progression to CDKi+ET to better tailor treatments.

PS2-08: Association of MammaPrint® with gene expression pathways predictive of resistance to cyclin-dependent kinase inhibition

Adam Brufsky, VK Gadi, Aisha Ahmed, Preethi John, Beth Seiling, Josien Haan, Harshini Ramaswamy, Nicole Stivers, Andrea Menicucci, William Audeh, Joyce O'Shaughnessy

Background: Cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i) have become a first-line targeted treatment in combination with endocrine therapy for patients with recurring HR+HER2- breast cancer (BC) and have recently been added to the adjuvant setting for the treatment of clinically high-risk early-stage BC. Trials have demonstrated that approximately 30% of advanced stage breast cancers are resistant to CDK4/6i, but no biomarkers exist to inform which patients are least likely to respond. The commercially available MammaPrint genomic signature, characterizing risk of distant recurrence (UltraLow, Low, High 1, and High 2) in early-stage BC, has demonstrated utility in predicting treatment response to chemotherapy as well as targeted immunotherapies. We investigated the utility of MammaPrint in identifying tumor subtypes that predict resistance to CDK4/6 pathway inhibition, using gene expression patterns driven by cellular proliferation pathways that bypass CDK4/6 function.
Methods: All patients with early-stage HR+HER2- tumors enrolled in the ongoing prospective, observational FLEX Trial (NCT03053193), were included in this study (N = 5657). Correlation of 'Rbsig' genomic signature, measuring Retinoblastoma (Rb) loss-of-function and subsequent E2F-dependent cell proliferation, to MammaPrint Risk groups was performed. MammaPrint Risk groups were then correlated to an 11-gene signature profile that measures absence of CDK4 phosphorylation, corresponding to Rb loss-of-function and, therefore, predictive of resistance to the CDK4i, Palbociclib. Differences in clinical characteristics were evaluated by Chi-Squared test or Fisher's exact test. The association of MammaPrint and 'Rbsig' was assessed using Spearman's rank correlation. Differences in 11-gene signature predicted resistance within MammaPrint groups were assessed using Fisher's exact test.
Results: Patients with HR+HER2- EBC included in this analysis had a mean age of 60 (SD ± 12) and were more likely to be post-menopausal (74.4%). Nearly 31% of patients had T2 stage or larger, 19% of patients had nodal involvement, and 17% had Grade 3 tumors. Among all HR+HER2- tumors, 14.6% were classified as UltraLow, 38.1% Low, 37.4% High 1, and 9.9% High 2 Risk. A linear correlation was observed with increasing MP Risk and increasing 'Rbsig' scores ($p < 0.001$), suggesting MammaPrint High 2 tumors demonstrate highest probability of loss of Rb function. The 11-gene signature comparison demonstrated MammaPrint High 2 as having the highest proportion of tumors predicted to have CDK4 driven loss of Rb function (43.0%), in comparison to UltraLow (0.1%), Low (0.5%), and High 1 (1.8%) tumors ($p < 0.001$).
Conclusion: These data identify High 2 tumors as least likely to respond to CDK targeted inhibition compared to other MammaPrint Risk groups. The increasing scores of Rb loss-of-function signature, 'Rbsig,' was closely correlated with MammaPrint High 2. The 11-gene signature profile, defined by absent CDK phosphorylation and high cellular proliferation, was significantly more likely to be associated with MammaPrint High 2 Risk tumors. These data support previous studies demonstrating that increasing MammaPrint index is closely associated with Cyclin E (CCNE1 and CCNE2) and 8q22-24 (CCNE2, MTDH, TSPYL5) genomic expression, that are hypothesized to identify tumor proliferation driven by activity downstream CDK4/6 function in HR+ BC. To our knowledge, MammaPrint is the only clinically used genomic signature that may identify patient subgroups potentially resistant

to CDK4/6 inhibitors. Further research is warranted to distinguish which clinically high-risk, non-High 2 breast cancers are most likely to benefit from CDK4/6i treatments.

PS2-09: Liquid biopsy DNADX assay in advanced ER+/HER2-negative breast cancer after progression on CDK4/6 and aromatase inhibitors: a correlative analysis from the PACE phase II randomized trial

Guilherme Nader-Marta, Rosario Vega-León, Guillermo Villacampa, Reshma Mahtani, Cynthia Ma, Angele DeMichele, Sandra Cobo, Francisco Pardo, Massimo Cristofanilli, Jane Meisel, Kathy D. Miller, Yara Abdou, Elizabeth C. Riley, Ashka Patel, Melissa E. Hughes, Fara Brasó-Maristany, Oleguer Castillo, Patricia Galván, Rubina Qamar, Priyanka Sharma, Laia Paré, Marina Gómez Rey, Judit Matito, Sonya Reid, Michelle DeMeo, Patricia Villagrasa, Charles M. Perou, Joel S. Parker, Ana Vivancos, Yuan Liu, Eric Gauthier, Harold J. Burstein, Sara M. Tolaney, Rinath Jeselsohn, Aleix Prat, Erica L. Mayer

Background: DNADX, a novel machine learning-based approach, utilizes DNA copy-number aberration (CNA) data from plasma ctDNA to identify clinically relevant phenotypic tumor features and classify breast cancer into 5 groups (Nat Comm 2023). This study evaluates the ability of DNADX to predict prognosis and treatment benefit in advanced ER+/HER2- breast cancer after progression on CDK4/6 and aromatase inhibition.

Methods: DNADX was centrally evaluated in available baseline tumor plasma from the PACE trial (NCT03147287), a multicenter phase 2 clinical trial that randomized 220 patients (pts) with HR+/HER2- advanced breast cancer after progression on AI and CDK4/6 inhibitor to receive fulvestrant alone (F), F and palbociclib (F+P), or F+P and avelumab (F+P+A) in a 1:2:1 ratio. Shallow whole genome sequencing was performed on ctDNA, identifying 5 DNA-based groups through unsupervised analysis of 150 breast cancer signatures (Luminal-high, Proliferative, Basal-related, CNA-flat, and a group with tumor fraction [TF] < 3% [TF-low]). The primary objective was to evaluate the association of DNADX subtypes with progression-free survival (PFS). Secondary objectives included assessing the association of DNADX subtypes and TF with treatment benefit from palbociclib or avelumab. Uni- and multivariable Cox regression models were used.

Results: DNADX was evaluated in baseline plasma samples from 149 pts (67.7%). PFS across arms in this subset was similar to the original study population. DNADX in the pooled population identified 39 (26.2%) cases with TF-low, 4 (2.7%) with CNA-flat, 61 (41.0%) with Luminal-high disease, 30 (20.1%) with Proliferative disease, and 15 (10.0%) with Basal-related disease. The DNADX 5-group classification at baseline was significantly associated with PFS in both univariate (p=0.0298) and multivariable (p=0.012) analyses, adjusted by treatment arm and age. Compared to pts with TF-low, those with Luminal-high disease had inferior PFS (adjusted hazard ratio=1.96, 95% CI 1.19-3.24, p=0.008). The addition of palbociclib to F+/-A significantly improved PFS in the DNADX Luminal-high group (hazard ratio [HR] 0.45, 95% CI 0.22-0.92, p=0.029; interaction test p=0.081). The

addition of avelumab to F+/-P showed a nonsignificant trend towards PFS benefit in the DNADX TF-low group (HR 0.49, 95% CI 0.18-1.34, p=0.164; interaction test p=0.667). Similarly, DNADX plasma TF above the median was associated with a significant PFS benefit from the addition of palbociclib (HR 0.37, 95% CI 0.19-0.74, p=0.004; interaction p=0.025), whereas DNADX plasma TF below the median was associated with a nonsignificant trend towards PFS benefit from the addition of avelumab (HR 0.54, 95% CI 0.28-1.02, p=0.0576; interaction p=0.283).

Conclusions: In the PACE trial population, the liquid biopsy-based DNADX assay reveals substantial biological heterogeneity after progression on CDK4/6 and AI which impacts prognosis in advanced ER+/HER2- breast cancer. With further validation, DNADX may help identify a patient population that may derive benefit from continuation of CDK4/6 inhibition after progression.

PS2-10: Integrating ctDNA and Tumor Fraction Features for Deciphering Molecular Response and Resistance Mechanism to Endocrine Therapy and CDK4/6 Inhibition in Advanced HR-positive Metastatic Breast Cancer

Hao Liao, Haoran Tang, Yaxin Liu, Xiaoran Liu, Hanfang Jiang, Cancan Jia, Shidong Jia, Huiping Li

Introduction: Hormone receptor (HR)-positive breast cancer is the most common type of breast cancer and is frequently diagnosed among women worldwide. Treatments involving CDK4/6 inhibitors and endocrine therapies, such as aromatase inhibitors (AIs), have significantly improved patient outcomes. However, the risk of disease progression persists. This study employs a circulating tumor DNA (ctDNA) Next-Generation Sequencing (NGS) assay to profile gene variations in patients with advanced HR-positive breast cancer, aiming to identify gene biomarkers relevant to treatment.
Methods: In this retrospective study, 136 patients with advanced HR-positive breast cancer were recruited, and plasma samples were collected from these patients prior to first-line treatments. Of the cohort, 31 patients received CDK4/6 inhibitors with endocrine therapies, 21 received endocrine monotherapies, and 84 received chemotherapies. Among those treated with endocrine therapies, 36 were treated with AI combined with Fulvestrant. The study used PredicineCARE, a targeted NGS liquid biopsy assay, to detect somatic alterations in ctDNA from plasma. The median follow-up period until disease progression was 10 months, ranging from 1 to 60 months.
Results:
Among the 136 patients, the ctDNA assay identified 247 somatic mutations and 311 gene copy number variations. The most frequently mutated genes (prevalence ≥10%) were PIK3CA (37%), TP53 (35%), ATM (19%), FGFR1 (18%), RB1 (12%), ERBB2 (11%), PTEN (10%), ESR1 (10%), and GNAS (10%). Patients with variations in ATM (mPFS 7 vs. 11 months, p<0.001), TP53 (mPFS 7 vs. 12 months, p=0.002), and PTEN (mPFS 7 vs. 11 months, p=0.036) had significantly poorer median progression-free survival (mPFS).

Similar trends were seen for FGFR1 (mPFS 8 vs. 11 months, p=0.055) and PIK3CA (mPFS 8.5 vs. 12 months, p=0.068), though not statistically significant.
Among the 31 patients treated with CDK4/6 inhibitors, significant PFS benefits were observed (mPFS 22 vs. 8.5 months, p<0.001). Within this group, patients with ATM variations had significantly poorer PFS (mPFS 15 vs. 34 months, p<0.001), while other gene variations showed no significant prognostic value. The 36 patients treated with AI therapies showed no overall significant PFS benefit. However, within this group, those with ESR1 variations had significantly poorer PFS (mPFS 2.5 vs. 8 months, p=0.004).
Additionally, tumor fraction (TF) levels identified by the ctDNA assay showed significant prognostic value across various therapies. The median TF was 9.4%, ranging from 0.5% to 88.2%. Using a 1% cut-off, patients with higher tumor fractions had significantly poorer PFS (mPFS 9.4 vs. 15.7 months, p=0.002).
Conclusion: The sensitive ctDNA NGS assay effectively identified gene variations and tumor fraction levels as prognostic markers in advanced HR-positive breast cancer, demonstrating significant implications for personalized treatment.

PS3-01: Tislelizumab plus sitravatinib and nab-paclitaxel in patients with untreated locally recurrent or metastatic triple negative breast cancer (TNBC): updated efficacy and safety results

Xiyu Liu, Ying Xu, Xiuzhi Zhu, Wenjuan Zhang, Linxiaoxi Ma, Xi Jin, Songyang Wu, Han Wang, Shen Zhao, Yi Xiao, Li Chen, Min He, Wei Zhu, Zhigang Zhuang, Fengyi Hou, Ayong Cao, Genhong Di, Jiong Wu, Keda Yu, Guangyu Liu, Xin Hu, , Yizhou Jiang, Zhonghua Wang, Lei Fan, Zhiming Shao

Background: The PD-(L)1 inhibitor-chemotherapy combination has established efficacy as first-line treatment for PD-L1 positive metastatic TNBC, but novel treatment regimens are still needed to improve the clinical outcomes for the whole population of TNBC in the first-line setting. Emerging evidence indicates that the combination of anti-angiogenic therapies and PD-(L)1 blockade may act synergistically, thereby potentiating enhanced antitumor activity. Sitravatinib (Sitra) is a spectrum-selective tyrosine kinase inhibitor that could potently inhibit split kinase receptors and TAM receptors. SPARK study was a multi-cohort, two-stage design, phase II trial (NCT04734262) to evaluate the efficacy and safety of tislelizumab (Tisle) plus Sitra, with or without nab-paclitaxel (nab-P), for locally recurrent or metastatic TNBC. We previously reported that the triplet combination of Tisle, Sitra and nab-P (cohort C) yielded encouraging anti-tumor activity in the first-line treatment setting (Lei Fan, et al. Cancer Res (2024) 84 (9_Supplement): PO1-06-12). Here, we report the updated results of this cohort.
Methods: Eligible patients with untreated locally recurrent or metastatic TNBC were enrolled in the Tisle+Sitra+nab-P cohort to receive Tisle (200 mg, iv, day 1, Q3W) plus Sitra (70 mg, po, qd) and nab-P (100mg/m2, iv, days 1 and 8, Q3W) until disease progression or intolerable toxicity. The primary endpoint was ORR. Secondary endpoints were DCR, PFS, DOR, 1-year OS rate and safety/tolerability. Based on Simon's two-stage design, > 9

responders were required in stage 1 (n=18) to continue the study, and ＞19 responders were needed by the end of study (N=35) to demonstrate superiority with Tisle+Sitra+nab-P (assumed to be around 65%) to a historical control of 46% (1-sided alpha of 0.1, power of 80%). The stage 1 criterion was met to complete the full enrollment.
Results: Between September 9, 2022, and June 2, 2023, a total of 37 patients were enrolled, with a median age of 49 years. 15 (40.5%) patients had CD8+ disease defined as CD8 IHC staining ≥10%, 20 (54.1%) had CD8- disease, and the CD8 status was unavailable in 2 patients. After a median follow-up of 14.7 months (range: 2.8-20.1) (data cut-off: May 31, 2024), the Tisle+Sitra+nab-P cohort met its primary endpoint with 26 out of the first 35 efficacy-evaluable patients achieving objective response per RECIST v1.1. In the total of 37 efficacy-evaluable patients, the confirmed ORR was 75.7% (28/37; 95% CI: 58.8%-88.2%), including 7 CRs and 21 PRs. DCR was 97.3% (95% CI: 85.8%-99.9%). As of the data cut-off date, the median PFS was 10.3 months (95% CI 7.9-14.0). The median PFS was 12.9 months in patients with CD8+ disease, and 8.7 months in patients with CD8- disease. The median OS was not reached; 1-year OS rate was 90.5% (95% CI: 73.3%-96.9%). TRAEs occurred in 36 (97.3%) patients, of which 15 (40.5%) experienced grade ≥3 TRAEs. SAEs were reported in 11 (29.7%) patients. No new safety concerns were detected.
Conclusions: The triplet combination of Tisle, Sitra, and nab-P demonstrated clinically meaningful ORR and PFS with acceptable safety profile as first-line treatment for patients with untreated locally recurrent or metastatic TNBC. Notably, patients with CD8+ expression achieved impressive PFS, indicating that CD8 status might be a biomarker for efficacy prediction. Continued follow-up is being conducted to assess long-term survival and safety.

PS3-02: Induction of Cisplatin/abraxane/pembrolizumab followed by pembrolizumab ± Olaparib Maintenance in triple-negative Metastatic breast cancer patients (COMPLEMENT) – A Randomized, Open-label, Phase II Study

Xichun Hu, Chengcheng Gong, Zhonghua Tao, Biyun Wang, Leiping Wang, Jun Cao, Mingchuan Zhao, Jian Zhang, Jian Huang

Background: Triple negative breast cancer (TNBC) is a hard-to-treat disease requiring continuous administration of drugs, necessitating further exploration of optimal maintenance strategy. KEYNOTE-355 has proved that pembrolizumab (pembro) plus chemotherapy (chemo) significantly improved PFS than chemo alone as first-line treatment in PD-L1 positive with a combined positive score (CPS) ≥10. The PARP inhibitor olaparib is established as maintenance therapy for platinum-sensitive populations regardless of BRCA status in the setting of ovarian cancer. Moreover, both preclinical and clinical data supported olaparib and pembro have a synergistic effect, suggesting that the doublet might be a promising maintenance strategy. COMPLEMENT study is a randomized, open-label, phase II study, seeking to investigate if olaparib plus pembro will maintain the clinical benefit achieved after induction therapy with cisplatin and nab-paclitaxel (AP) regimen plus

pembro in CPS≥1 mTNBC patients (pts).
Methods: Eligible pts with locally advanced, recurrent or metastatic PD-L1 CPS ≥1 TNBC that had not been treated with chemo for the advanced disease received induction therapy of pembro (200 mg day, Q3W) + AP regimen (nab-paclitaxel 125 mg/m2 on day 1, 8 and cisplatin 75 mg/m2 on day 1, Q3W) for 4-6 cycles. Pts who have achieved CR, PR, SD based on the RECIST 1.1 criteria were eligible for maintenance period and were randomized to receive either pembro (200mg Q3W) plus olaparib (300mg po bid) group or pembro mono group until disease progression or withdrawal of consent. Pts were stratified by response status (CR or PR vs SD), genomic tumor status (BRCAm vs BRCAwt) and visceral metastases (yes vs no). The primary end point was PFS. And the key second endpoints were ORR, OS and safety signals.
Results: At the May 31, 2024 data cutoff, 52 pts have been enrolled. 20 pts (38%) were PD-L1 CPS ≥10 while 32 pts (62%) were PD-L1 CPS <10. 4 pts (8%) carried germline BRCA 1/2 mutation. 41 pts (78.8%) had TNBC at initial diagnose while 11 pts (21.2%) did not but conversed to TNBC in the recurrent lesions. At the induction stage, the overall response rate was 86.5%, the median depth of response was 60% and the median time to response was 1.5 months. A total of 29 pts (28 PR and 1CR) were randomly assigned to pembro mono group (n=15) or combo group (n=14) for maintenance treatment. 9 pts were not randomized due to disease progression and 14 pts were still at the induction stage. In pts with a follow-up time more than 12 months, the 12-month PFS rate was 72.7% (8/11). Preliminary results showed pts with conversion to TNBC obtained less clinical benefit from this maintenance strategy than pts without conversion (6.6 vs. 12.3 months). Immune-related AEs were reported in 11 (21.2%) pts, of whom 5 (9.6%) pts experienced hypothyroidism, 2 (3.8%) pts experienced pneumonitis, 2 (3.8%) pts experienced hepatitis, 1 (2%) pt experienced adrenal insufficiency and hypophysis, 1 (2%) pt experienced nephritis, and 1 pt (2%) experienced severe skin reaction. Treatment-related AEs were reported in all the pts, while grade ≥3 treatment-related AE occurred in 32 pts (61.5%) including neutrophil count decreased (52%), thrombocytopenia (4%), anemia (13%) and ALT/AST increased (8%).
Conclusions: Preliminary data indicated that induction therapy with pembro + AP was a highly potent regimen in the first-line treatment of TNBC with no new safety signal, and pts with conversion to TNBC seemed to benefit less from this regimen. More efficacy and safety data between two groups will be shared in the future.

PS3-03: Vaccination with MUC-1-targeting tecemotide improves Survival of patients receiving neo-adjuvant chemotherapy for early breast cancer: Results from the Prospective Randomized ABCSG 34 Trial

Christian F. Singer, Dominik Hlauschek, Georg Pfeiler, Daniel Egle, Rupert Bartsch, Christoph Suppan, Angelika Pichler, Edgar Petru, Richard Greil, Margaretha Rudas, Michael Seifert, Gregor Huber, Andreas Petzer, Florian Fitzal, Zsuzsanna Bago-Horvath, Martin Filipits, Lidija Soelkner, Christian Fesl, Michael Gnant

Background: The synthetic lipopeptide tecemotide (liposomal BLP25, Stimuvax®) is an investigational cancer vaccine designed to induce a cellular immune response to cancer cells that express the glycoprotein MUC1. Aberrant MUC1 is widely over-expressed in malignancies such as lung, breast, and colorectal cancer. The aim of the prospective randomized two-arm multicenter phase-II ABCSG 34 trial was to investigate the efficacy and safety of tecemotide in 400 patients with early BC when given concomitantly with neoadjuvant systemic Standard-of-Care (SoC) chemotherapy or neo-endocrine therapy. The study was accompanied by an extensive translational program which included immune response parameters such as MUC1 and PD-L1 expression, TILs, monocyte and ctDNA.
Patients and Methods:
400 patients with HER2- early BC were randomized 1:1 to receive neo-adjuvant SoC systemic therapy with or without 12 concomitant tecemotide vaccinations. Postmenopausal women with luminal A tumors received letrozole 2.5mg od for 24 weeks as SoC. TNBC patients and patients with luminal B tumors, in whom chemotherapy was considered to be SoC, received 4 x epirubicin/cyclophosphamide and 4 x docetaxel q3w. MUC1 protein expression on tumor cells was analyzed by immunohistochemistry. Invasive disease-free survival (IDFS), distant recurrence free survival (DRFS) and overall survival (OS) were analyzed with Cox regression models.
Results:
Seven years after surgery, follow-up (FU) data were collected retrospectively and available for 289 women. Of these, 236 had received chemotherapy, while 53 had received neo-endocrine letrozole. 141 had been randomized to receive concomitant tecemotide, while 148 had been randomized to SoC only. Patient and tumor characteristics in the FU group were highly representative of the overall study population, and clinical-pathological characteristics in the two randomization arms were well balanced.
After a 7 year FU, patients who had received SoC + tecemotide had an IDFS of 69.1% vs 60.5% in the SoC alone group (HR 0.75, 95% CI 0.51–1.10, p=0.141). DRFS of patients who had received SoC + tecemotide was 80.8% vs 64.7% (HR 0.53, 95% CI 0.34-0.83, p=0.005); OS in the SoC + tecemotide was 83.0% vs 68.2% (HR for OS 0.53, 95% CI 0.33-0.85, p=0.008). Participants who had received chemotherapy + tecemotide had a particularly favorable outcome with an IDFS of 71.3% vs 59.8% (HR 0.69, 95% CI 0.45–1.05, p=0.084), a DRFS of 81.9% vs 65.0% (HR 0.50, 95% CI 0.31–0.83, p=0.007), and an OS of 83.6% vs 67.8% (HR 0.51, 95% CI 0.30–0.88, p=0.016). Sensitivity analysis adjusting for T-stage, Nodal status, KI67, cancer type, and age at randomization were consistent with the primary results and confirmed the robustness of the analysis.
MUC1 protein data were available for 278 pts at baseline and 199 pts at surgery. MUC1 was expressed in 97.9% of baseline samples and in 98.5% of the surgical samples in which pCR was not achieved. Expression was high (i.e. detected in >80% of tumor cells) in 72.1% and 74.5%, respectively. While MUC1 expression levels were neither prognostic nor associated with pCR, tecemotide-treated patients with high MUC1 protein expression in their surgical sample showed a particularly good outcome with an improved IDFS (HR 0.57, 95% CI 0.34–0.98), DRFS (HR 0.38, 95% CI 0.20-0.72), and OS (HR 0.35, 0.17–0.71), when compared to SoC alone. Subgroup analysis and additional biomarker analyses will be presented at the

meeting.
Conclusions: Tecemotide, when given concomitantly with neoadjuvant SoC systemic therapy, profoundly improved IDFS, DRFS and OS in a follow-up analysis of this prospective Phase II trial. The improved long-term outcome was particularly evident in patients whose tumors expressed high levels of MUC1. While long-term outcome is an exploratory objective, this is the first study in which a therapeutic cancer vaccine has resulted in a statistically significant and substantial long-term survival benefit in breast cancer patients.

PS3-04: Overall Survival Results of Bria-IMT Allogenic Whole Cell-Based Cancer Vaccine

Saranya Chumsri, Chaitali Nangia, Minal Barve, Kendrith Rowland, Ralph Boccia, John George Knecht, Blaise Bayer, Marcela Salgado, Tamar Aghajanian, William Williams, Charles Wiseman, Giuseppe Del Priore, Carmen Calfa

Background: Despite advances in metastatic breast cancer (MBC), patients encounter challenges from resistance or intolerance. Bria-IMT is a combination immunotherapy using an allogeneic whole-cell cancer vaccine (SV-BR-1-GM) combined with checkpoint inhibitors (CPIs). Irradiated SV-BR-1-GM breast cancer cells, engineered to secrete GM-CSF, present tumor-associated antigens on HLA-I and HLA-II molecules, directly stimulating anti-tumor immunity. The addition of anti-PD1 CPI further potentiates the activity of SV-BR-1-GM to overcome the immune-suppressive tumor microenvironment. Methods This phase I/II study evaluated the Bria-IMT regimen consisting of low-dose cyclophosphamide (Day –2) followed by SV-BR-1-GM and CPI (pembrolizumab or retifanlimab), then low-dose local peg-interferon α, all given every 3 wks. In the phase II study, patients were randomized 1:1 to start CPI immediately at cycle 1 or delayed start at cycle 2. There were 2 formulations of SV-BR-1-GM with or without IFNγ incubation. Cancer-associated macrophage-like cells (CAMLs), circulating tumor cells (CTCs), and PD-L1 expression scores on these cells were monitored as biomarkers. A Candida skin test assessed anergy status before cycle 1, while a delayed-type hypersensitivity (DTH) skin test was done at each cycle with a small SV-BR-1-GM dose before the full dose. Results A total of 54 patients were enrolled with 22 patients in phase I and 32 in phase II. 11 patients were treated with pembrolizumab and 44 patients with retifanlimab (1 patient received pembrolizumab and later retifanlimab). Median age was 61 (38-81) years; median prior regimen was 6 (2-13). 39(72%) patients were ER+/PR+/HER2-; 3(6%) HER2+, and 12 (22%) triple-negative (TNBC). The Bria-IMT regimen was well tolerated, with no drop-outs attributable to Bria-IMT. The majority of adverse events (67%) were grade 1-2, with few (13%) cases > grade 3, including pulmonary embolism, dehydration, and increased lipase. In the entire cohort, the median overall survival (OS) was 9.9 (1.8-28.5) months. Patients who received the SV-BR-1-GM phase 3 formulation (without IFNγ incubation) (n=37) had a significant increase in both PFS (3.6 vs 2.6 months, P 0.01) and OS (13.4 vs. 6.9 months, P 0.04), an objective response rate (ORR) of 9.5% and a clinical benefit rate (CBR) was 55%. Among randomized patients receiving phase 3 formulation (n=21) median OS not yet reached. In ER+/PR+/HER2-, OS was 13.3

(1.8-28.5) months, HER2+ 11.9 (7.2-11.9) months, and TNBC 8.5 (2.1-15.6) months. There was a significant difference in PFS but not OS among patients who received immediate vs. delayed start of CPI (PFS 3.6 vs. 2.6 months, P 0.02; OS 9.9 vs. 11.9 months, P 0.45). Among 36 patients with post-dose CAML/CTC data, patients with post-dose CTC count < 5 had a significantly improved OS compared with a CTC count > 5 (13.4 vs. 5.5 months, P 0.01). Patients with positive DTH had significantly improved PFS (3.5 vs. 2.4 months, P 0.001) and OS (11.9 vs. 5.5 months, P 0.002).

Conclusions: In heavily pretreated MBC patients, the Bria-IMT regimen demonstrated promising results across all subtypes of breast cancer with favorable safety profiles. There was no significant difference in OS among patients treated with immediate vs. delayed CPI. However, superior outcomes were observed in patients receiving SV-BR-1-GM without IFNγ incubation. This formulation has advanced into the ongoing clinical trials. Patients with post-dose CTC count < 5, and positive DTH had significantly improved outcomes. Based on these promising findings, the randomized phase III trial comparing the BRIA-IMT regimen to the treating physician's choice is currently ongoing (NCT06072612). Trial information: NCT03328026.

PS3-05: Evaluation of the safety and efficacy of ivonescimab in combination with chemotherapy as first-line (1L) treatment for triple-negative breast cancer (TNBC)

Xiaojia Wang, Quchang Ouyang, Can Tian, Xiying Shao, Jian Huang, Zhanhong Chen, Yongsheng Wang, Tao Sun, Tienan Yi, Xufang Yu, Zhongmin Wang, Baiyong Li, Michelle Xia.

Background: Locally advanced unresectable or metastatic TNBC is highly aggressive and has a poor prognosis. Ivonescimab, a tetravalent bispecific antibody targeting PD-1 and VEGF, has the potential to produce synergistic anti-tumor effects through both pathways via cooperative binding. This study aimed to evaluate the safety and efficacy of ivonescimab in combination with chemotherapy in locally advanced unresectable or metastatic TNBC.
Methods: This was an open-label, multicenter phase II study in patients (pts) with locally advanced unresectable or metastatic TNBC. Pts received ivonescimab at 20 mg/kg Q2W and paclitaxel at 90 mg/m2 or nab-paclitaxel at 100 mg/m2 on the 1st, 8th, and 15th day of each four-week treatment cycle. The primary endpoints were safety and objective response rate (ORR) by RECIST1.1. The secondary endpoints included duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS).
Results: As of May 31, 2024, a total of 30 pts with locally advanced unresectable or metastatic TNBC were enrolled. The median age was 54.0 years (range, 35.4-73.3), 53.3% of pts had ECOG of 1, 80% of pts had a PD-L1 combined positive score (CPS) <10, and 60% of pts had previously received taxane-based neoadjuvant or adjuvant therapy. The median follow-up was 10.12 months (range: 2.66+, 15.77). A total of 53.3% (16/30) of pts experienced at least one ≥Grade 3 treatment-related adverse event (TRAE), but none led to treatment discontinuation or deaths. The most common ≥Grade 3 TRAEs with a frequency

≥10% included neutrophil count decreased (16.7%) and white blood cell count decreased (16.7%). Twenty-nine pts had at least one post-baseline tumor assessment; the ORR by investigator assessment was 72.4% (21/29) and the DCR was 100% (29/29). The ORRs of PD-L1 CPS ≥10 and PD-L1 CPS <10 were 83.3% (5/6) and 69.6% (16/23), respectively. The median PFS was 9.3 month (95% CI: 6.24, NE), the 9-month PFS rate was 56.6% (95% CI: 32.2, 75.1). In the PD-L1 CPS ≥10 population, the median PFS was not reached (95% CI: 5.36, NE), the 9-month PFS rate was 60% (95% CI: 12.6, 88.2). In the PD-L1 CPS <10 population, the median PFS was 9.3 month (95% CI: 5.55, NE), the 9-month PFS rate was 52.6% (95% CI: 22.5, 75.8). The median DoR was 7.49 month (95% CI:3.91, NE). In the PD-L1 CPS ≥10 population, the median DoR was not reached (95% CI: 3.58, NE). In the PD-L1 CPS <10 population, the median DoR was 7.49 month (95% CI: 3.91, NE). The median OS was not yet mature.
Conclusion: Ivonescimab in combination with chemotherapy showed promising anti-tumor activity and acceptable tolerable safety as 1L treatment of TNBC. Further trials to confirm the results are warranted.

PS3-06: A prospective phase 2 study on efficacy and safety of AK105, anlotinib combined with nab-paclitaxel (nab-P) as a first-line therapy in patients(pts) with advanced triple-negative breast cancer (TNBC)

Tao Sun, Liang Zhang, Xiujie Cui, Li Man, Zhaohui Li, Li Cai, Fangyuan Dong, Ying E, Yujun Jiang, Hui Cao, Yangyang Duan, Huan Li, Xiaorui Li, Zhichao Gao, Lei Jiang, Cui Jiang, Yufeng Jia, Dan Lv

Background: PD-1/PD-L1 inhibitor plus chemotherapy have shown tolerability and significant clinical benefits in pts with advanced TNBC. Antiangiogenic agent could remodel tumor blood vessels and increase the response to immune-checkpoint inhibitors (ICIs). AK105, an anti-PD-1 antibody, can effectively prevents PD-1 from binding to PD-L1 and PD-L2, and avoid immune evasion of tumor cells. Anlotinib is a novel antiangiogenic, multi-target tyrosine kinase inhibitor which inhibits VEGFR, FGFR, PDGFR, c-KIT, c-RET and MET. This investigator initiated trial (IIT) (NCT05244993) aims to investigate the efficacy and safety of AK105, anlotinib combined with nab-P as a first-line therapy in pts with advanced TNBC.
Methods: In this multicenter, prospective, single arm, phase 2 study, eligible pts were female aged 18-75 years, with ECOG PS 0-1, who had locally advanced or recurrent/metastatic triple-negative (estrogen receptor-, progesterone receptor- and HER2-) breast cancer. Eligible pts were treated with intravenous AK105 (200 mg on day 1), oral anlotinib (12 mg once daily on days 1-14) and intravenous nab-P (125 mg/m2 on days 1 and 8) . The triplet combination regimen repeated every 21 days until disease progression, death or intolerable toxicity. The primary endpoint is overall response rate (ORR), and the secondary endpoints are disease control rate (DCR), progression-free survival (PFS), overall survival (OS)and safety.
Results: From July 2022 to March 2024, 33 patients have been enrolled in this study.

Median follow-up was 6.54 months (95% CI 2.68-11.43). Of all the patients whose efficacy could be evaluated (26/33), 1(3.85%) patient achieved complete response (CR); 20(76.92%), 4(15.38%) and 1(3.85%) patients got partial response (PR), stable disease (SD) and progression disease (PD), respectively. ORR was 80.77 % (95% CI 60.65-93.45) and DCR was 96.15% (95% CI 80.36-99.90). The overall median PFS was 11.14 months (95% CI 8.34-18.04) , the median OS have not reached. The 6-month OS rate and 12-month OS were 95.83% (95% CI 73.92-99.40) and 80.90% (95% CI 50.05-93.72), respectively. The most common adverse events (AEs) were grade 1 or 2. The grade 3 AEs (incidence ≥ 10%) included were neutropenia (33.33%), leukopenia (12.12%) and elevated AST (12.12%). There were two case of grade 4 neutropenia and one case of grade 4 hypertriglyceridemia. One death (from hepatitis) was considered by the investigators to be related to the trial regimen.
Conclusion: The combination of AK105, anlotinib and nab-P showed better treatment response and tolerable toxicity in the treatment of first-line patients with TNBC. Further studies enrolling more patients are still needed.

PS3-07: SHR-A1811 as Neoadjuvant Treatment in Patients with HR-Positive, HER2-low Breast Cancer: The first-stage results from an open-label, single-arm, two-stage, phase II clinical trial

Zhenzhen Liu, Jianghua Qiao, Chengzheng Wang, Xianfu Sun, Min Yan, Lianfang Li, Xiuchun Chen, Jiujun Zhu, Jianfei Wang

Background: Patients with Hormone receptor (HR)-positive, human epidermal growth factor receptor 2(HER2)-negative breast cancer exhibit lower rates of achieving pathologic complete response (pCR) to neoadjuvant chemotherapy or endocrine therapy, with pCR rates of 10% and 5% respectively. HER2-low breast cancers are enriched in HR-positive breast cancers, but HER2-low patients had significantly lower pCR than those with HER2-0. The anti-HER2 ADC drug T-Dxd has demonstrated anti-tumor activity in HR+/HER2-low advanced breast cancer, based on the DESTINY-Breast 06 study. SHR-A1811, a novel anti-HER2 ADC, has also shown activity in HER2-low advanced breast cancer. Here we conducted this clinical trial to investigate the efficacy and safety of SHR-A1811 as a neoadjuvant treatment in patients with HR+/HER2-low breast cancer.
Methods: This was an open-label, single-arm, phase II clinical trial based on Simon's two-stage design. A total of 66 subjects were required for enrollment, with 35 subjects included in the first stage. If 18 or more patients having response, the trial would proceed to the second stage, enrolling an additional 31 subjects. Main inclusion criteria include: aged 18-70 years, treatment-naïve, histologically confirmed invasive breast cancer, cT2-3/N0-2M0, HR+/HER2-low and Ki67>14%. Eligible patients received SHR-A1811 (6.4 mg/kg IV q21 days) for eight cycles. The primary endpoint was objective response rate (ORR). Secondary endpoints included safety, residual cancer burden (RCB) 0-1 and pCR.
Results: As of June 17, 2024, 34 out of 35 patients in the first stage successfully received the study regimen and finished the operation on schedule. Of all patients, 74.3% (26/35) had

node-positive disease, 85.7% (30/35) with stage IIA/IIB, 14.3% (5/35) with stage IIIA at baseline. 74.3% (26/35) patients had baseline HER2 expression of IHC 2+, 25.7% (9/35) were IHC 1+. Our primary endpoint of the first stage was met, with 74.3% (26/35) of patients achieving an ORR, including 26 partial responses and 9 stable diseases. None of the patients achieved pCR. Treatment-related adverse events (TRAEs) were reported in all 35 patients, and the incidence of grade ≥3 TRAEs was 65.7% (23/35), the most common grade ≥3 TRAEs including neutropenia (48.6%,17/35), leukopenia (28.6%,10/35), anemia (22.9%, 8/35), diarrhea and platelet count decreased (11.4%, 4/35). Primary G-CSF prophylaxis was administered to 13 patients, and no grade 3 or higher neutropenia was reported. No interstitial lung disease (ILD) and treatment-related deaths were reported. Conclusions: SHR-A1811 has demonstrated promising anti-tumor activity and an acceptable safety profile as neoadjuvant treatment for patients with HR+/HER2-low breast cancer. The second stage is ongoing, Clinical trial information: NCT05911958.

PS3-08: Interim Overall Survival of Patients with Locally Advanced or Metastatic Triple-Negative Breast Cancer treated with First Line PM8002/BNT327 in Combination with Nab-Paclitaxel in Phase Ib/II Study

Jiong Wu, Jian Zhang, Zhongsheng Tong, Qingyuan Zhang, Yongsheng Wang, Qiao Cheng, Xin Chen, Zhihua Li, Yongmei Yin, Yiqun Du, Yanchun Meng

Background: PD-L1 and VEGF play important roles in immune evasion and tumoral angiogenesis, promoting cancer growth and metastasis. PM8002/BNT327 is an investigational bispecific antibody targeting PD-L1 and VEGF-A, in development for the treatment of solid tumors. We conducted a Phase Ib/II study of PM8002/BNT327 in combination with nab-paclitaxel in pts with locally advanced or metastatic triple-negative breast cancer (LA/mTNBC) in China. We provide updated results including interim overall survival (OS) since initial reports at SABCS 2023 and ESMO 2024.
Methods: 42 Pts with previously untreated LA/mTNBC were enrolled till 11 Apr 2023 to assess the safety and efficacy of PM8002/BNT327 in combination with nab-paclitaxel. All patients received PM8002 at 20 mg/kg (Q2W) and nab-paclitaxel at 100 mg/m2 on the 1st, 8th, and 15th day of each 28-day cycle until unacceptable toxicity or disease progression were observed. Efficacy was assessed every 8 weeks. Primary objectives were safety per CTCAE 5.0 and objective response rate (ORR) per RECIST v1.1 by investigator assessment, with progression free survival (PFS) and overall survival (OS) as secondary objectives.
Results: As of 13th Sep 2024, with a median follow-up time of 18.1 months (95% CI 16.9, 19.7), median duration of treatment was 10.0 months (range 2.0-22.0) with 9/42 patients still on treatment. The confirmed ORR (cORR) was 73.8% with a disease control rate (DCR) of 95.2%. The median time to response (TTR) was 1.9 months (95% CI 1.8, 2.0), the median duration of response (DOR) was 11.7 months (95% CI 7.2, 17.3). The matured median PFS was 13.5 months (95% CI 9.4, 18.1) for the ITT population. The median OS was not reached, while the matured 12-month OS rate was 80.8% (95% CI 65,3, 89.9), the matured 15-month OS rate was 78.1% (95% CI 62.1, 88.0) and the nearly matured 18-month OS rate was

72.2% (95% CI 55.2, 83.7). 38 pts had available PD-L1 expression results tested with E1L3N assay. cORR was 76.9% in 13 pts with PD-L1 combined positive score (CPS) < 1 and 72.0% in 25 pts with PD-L1 CPS ≥1. All 9 pts with PD-L1 CPS ≥10 achieved PR. All pts experienced treatment-related adverse events (TRAEs), 59.5% were Grade 3 or 4, no Grade 5 TRAEs were observed. The most common (≥30%) TRAEs included neutropenia, leukocytopenia, anemia, proteinuria, alopecia, hypertriglyceridaemia, hypercholesterolaemia, epistaxis and asthenia. 31.0% of pts experienced immune-related adverse events (irAEs), 9.5% were Grade 3, no Grade 4 or 5 irAEs were observed. The most common irAEs included hyperthyroidism, hypothyroidism and rash. The most common AEs typically associated with VEGF inhibition were hypertension (23.8%) and proteinuria (64.3%) which were mostly Grade 1 or 2.
Conclusions: In pts with LA/mTNBC, first-line therapy with PM8002/BNT327 combined with nab-paclitaxel showed clinically meaningful survival outcomes and antitumor activity regardless of PD-L1 status, together with a manageable safety profile. No new safety signals were observed beyond those typically described for anti-PD-1/PD-L1 and anti-VEGF therapies and nab-paclitaxel. A randomized controlled Phase III clinical trial (NCT06419621) of first-line treatment of TNBC in China and a global Phase II trial (NCT06449222) are ongoing in TNBC.
Acknowledgements: We would like to thank the pts and their families for their contribution to this trial. This trial was sponsored by Biotheus Inc. PM8002/BNT327 is jointly developed by Biotheus and BioNTech
Trial Registration: ClinicalTrials.gov: NCT05918133.
Ethics Approval: This study was approved by the Ethics Committee for Drug Clinical Trials, Fudan University Shanghai Cancer Center.

PS4-01: Predictor of benefit from dose-dense paclitaxel chemotherapy for patients with hormone receptor-positive HER2-negative breast cancer. A GEICAM/9906 sub-study

Miguel Martin, Alvaro Rodriguez-Lescure, Lourdes Calvo, Eveline Chen, Manuel Ruiz-Borrego, Cesar A. Rodriguez, Noelia Martinez-Jañez, Emilio Alba, Kevin Tran, Ignacio Pelaez Fernandez, Isabel Alvarez, Miguel Angel Segui, Alberto de la Cruz, Vicente Valero, Antonio Anton-Torres, Raquel Andres, Kepa Amillano, Jose J. Ponce-Lorenzo, Severina Dominguez Fernandez, Jesus Herranz, Raul Rincon, Rosalia Caballero, Ana Santaballa Bertran, Angel Guerrero-Zotano, W. Fraser Symmans

Background: SETER/PR index is a genomic test designed to measure endocrine transcriptional activity that is related to estrogen receptor (ER) and progesterone receptor (PR), but not proliferation. Higher values of SETER/PR index indicate greater endocrine transcriptional activity in the cancer. It was previously reported that levels of SETER/PR index below 0.75 predicted benefit from dose-dense (q2-week), versus conventional (q3-week) anthracycline-paclitaxel chemotherapy for patients (pts) with hormone receptor-positive (HR+) lymph node-positive breast cancer (BC) in the CALGB 9741 trial (Metzger et

al, 2022, ASCO). Since that was the first report of a test that could predict benefit from a dose-dense taxane-based chemotherapy in HR+ BC, we sought to independently test its predictive validity. Therefore, we tested the SETER/PR assay at this predefined cutoff point in pts with HR+/HER2- lymph node-positive BC from the phase III GEICAM/9906 trial to predict benefit from weekly paclitaxel treatments after three cycles of q3-week anthracycline chemotherapy (FEC+P) compared to three additional anthracycline treatments (FEC).

Methods

We conducted a blinded independent validation study in 647 HR+/HER2- tumor RNA samples from GEICAM/9906 BC pts (51.9% of the trial's cohort). GEICAM translational laboratory sent the de-identified tumor RNA samples to the MDACC laboratory for blinded testing with results returned to the GEICAM statistician. Predefined cutoff point was SETER/PR index <0.75. Clinical endpoints were distant recurrence-free interval (DRFI) and overall survival (OS, secondary endpoint). Multivariable Cox proportional hazards models including SETER/PR index, treatment arm and their interaction term were used to calculate hazard ratios with 95% confidence interval (HR, 95%CI) and two-sided 0.05 as predefined level of significance.

Results

Of 647 HR+/HER2- tumor samples, 567 (87.6%) passed quality control for the SETER/PR assay, with 279 from the FEC+P and 288 from the FEC treatment arm. SETER/PR index was below 0.75 in 92/567 tumors (16.2%), 44 (47.8%) in the FEC+P arm and 48 (52.2%) in the FEC treatment arm. Overall, there were 149 distant recurrence events and 144 deaths. There was significant interaction between SETER/PR status and treatment arm on DRFI (P=0.046), but not OS (P=0.352). For patients with SETER/PR below 0.75, treatment with FEC+P significantly improved DRFI (HR 0.46; 95%CI, 0.22–0.95, P=0.035), even when adjusted for menopausal status and ≤3 versus ≥4 nodes involved (HR 0.48; 95%CI, 0.24–1.00, P=0.049), but there was no difference between treatments benefit when SETER/PR index was ≥0.75 (HR 1.02; 95%CI, 0.70–1.47, P=0.931).

Conclusion

In this GEICAM/9906 trial retrospective analysis, patients with node-positive HR+/HER2- BC that has low endocrine transcriptional activity (SETER/PR index <0.75) benefited from inclusion of weekly paclitaxel in their adjuvant chemotherapy. This result provides independent confirmation that SETER/PR index predicts benefit from dose-dense paclitaxel-containing chemotherapy.

Clinical trial information: NCT00129922.

PS4-02: Patient-derived Xenografts (PDX) Allow Deconvolution of Combination Chemotherapy Response

Jonathan Lei, Lacey E. Dobrolecki, Chen Huang, Ramakrishnan R. Srinivasan, Suhas Vasaikar, Alaina N. Lewis, Christina Sallas, John D. Landua, Chang In Moon, Yuxing Liao, Na Zhao, Jin Cao, Susan G. Hilsenbeck, C. Kent Osborne, Mothaffar F. Rimawi, Matthew J. Ellis, Varduhi Petrosyan, Bo Wen, Kai Li, Alexander B. Saltzman1, Antrix Jain1, Anna Malovannaya1,

Gerburg Wulf3, Shunqiang Li4, Daniel C. Kraushaar1, Elisabetta Marangoni5, Tao Wang1, Senthil Damodaran6, Xiaofeng Zheng6, Funda Meric-Bernstam6, Bryan E. Welm7, Alana L. Welm7, Xi Chen6, Gloria V. Echeverria1, Meenakshi Anurag1, Bing Zhang1, Michael T. Lewis1

Introduction: Triple-negative breast cancer (TNBC) patients frequently receive combination chemotherapy treatment, including most recently taxane/platinum combinations. However, treatment is not biomarker-guided. As such, it is not known which patient will respond to one or the other agent, or indeed which patients actually require the combination for the most effective treatment. We hypothesized that optimization of chemotherapy may be possible if molecular mechanisms and biomarkers underlying response to individual treatments can be identified. We evaluated this hypothesis in a preclinical trial using a cohort of 50 patient-derived xenograft (PDX) models of TNBC treated with either single-agent docetaxel or carboplatin, or their combination.
Methods: 50 TNBC PDXs were evaluated for response to four weekly treatments with either single agent docetaxel (20 mg/kg), or carboplatin (50 mg/kg); 42 of these were also treated with their combination. Multi-omics profiling (genomics, transcriptomics, proteomics) was conducted before treatment. Gene level associations by treatment type were used to construct consensus gene sets by integrating our data with external TNBC PDX and patient cohorts which were then used to build XGBoost models to predict treatment-specific responses. Pathway analysis was performed using signed -log10 p-values from gene level results as input for Gene Set Enrichment Analysis.
Results: Direct comparison of responses to carboplatin, docetaxel, and their combination showed that combination treatment was largely ineffective at generating enhanced responses over the best single agent. Only 13% of the 42 PDX showed enhanced responses in combination, with a comparable percentage (12%) showing antagonism between docetaxel and carboplatin, a phenomenon observed previously in vitro.
Proteogenomic profiles revealed distinct genes associated with responses to each agent and their combination, suggesting different molecular mechanisms underlying each treatment response. A substantial number of genes linked to single-agent and combination treatments were validated in multiple independent PDX and patient cohorts receiving platinum and taxane-containing neoadjuvant therapy, confirming the clinical relevance of our PDX panel. Chemotherapy-specific predictors for pathological complete response (pCR)/CR achieved AUROCs of 0.79, 0.67, and 0.70 for platinum, taxane, and combination treatments, respectively. The single-agent platinum model was the most effective in predicting platinum response, with a similar trend for taxane and platinum+taxane predictors. These findings reinforce the observation that distinct gene sets are linked to responses to different chemotherapy treatments. Since the predictors used treatment-associated genes found in both PDX and clinical samples, these results suggest biomarker combinations for translation and clinical development to select TNBC tumors that may respond to specific regimens. In PDXs responsive to any treatment, several basal cytokeratins were among the top upregulated proteins compared to PDXs resistant to all treatments. KRT5 was validated by IHC in PDX tumors, achieving an AUROC of 0.83 for predicting responsiveness, indicating its potential as a future chemoresponse marker in TNBC. PDXs refractory to all treatment arms

had higher levels of mitochondrial and cancer stem-cell-related pathways. Treatment with romidepsin, an HDAC inhibitor that targets these pathways and increases DNA damage, enhanced carboplatin response in a chemoresistant PDX model with high abundance of HDAC proteins.
Conclusion: Proteogenomic characterization identifies molecular mechanisms and putative biomarkers for stratifying TNBC tumors for single or combination chemotherapy treatments, suggests targeted therapies to augment chemotherapy response, and provides a valuable resource for researchers and clinicians.

PS4-03: Calcium Channel Blockers Enhance Efficacy of TROP2-ADC in Overcoming Resistance in Advanced Triple-Negative Breast Cancer

Jieer Luo, Qun Lin, Yu Shi, Zhuxi Duan, Jinpeng Luo, Xiaolin Fang, Chang Gong

The TROP2-directed antibody-drug conjugate (TROP2-ADC) has been approved for treating advanced triple-negative breast cancer (TNBC) that has progressed after chemotherapy. Recent findings from the ASCENT trial indicated that sacituzumab govitecan (SG), compared with standard chemotherapy, significantly prolongs median progression-free survival and overall survival in patients with advanced or refractory TNBC, reducing the risk of disease progression by 59% and the risk of death by 52%. However, approximately 20% of patients exhibit primary resistance to SG, experiencing disease progression within 3 months. Therefore, exploring the molecular mechanisms underlying TROP2-ADC resistance is crucial for reversing drug resistance and improving the prognosis of patients with advanced TNBC.
In this study, we retrospectively observed that advanced TNBC patients with hypertension who were co-treated with SG and nifedipine displayed better survival times compared to advanced TNBC patients without hypertension who were treated with SG alone. Based on these findings, we constructed TNBC patient-derived xenografts (PDXs) that were either sensitive or insensitive to TROP2-ADC. We found that combining calcium channel blockers (CCBs) with TROP2-ADC significantly improved anti-tumor efficacy and maintained a manageable safety profile in TROP2-ADC insensitive models, both in vivo and in vitro. High-throughput sequencing of TNBC patients treated with TROP2-ADC revealed that pathways related to vesicle trafficking, calcium ion binding, and cell membrane processes were highly enriched in resistant patients. Mechanistically, excess intracellular calcium activated PKC and PACSIN2, leading to increased caveolae-mediated endocytosis. This resulted in defective plasma membrane localization of TROP2, contributing to TROP2-ADC resistance. In conclusion, our results provide insight into the potential mechanisms of TROP2-ADC resistance and suggest that combining CCBs with TROP2-ADC may offer a new therapeutic strategy for patients resistant to TROP2-ADC.

PS4-04: MammaPrint® and BluePrint® predict pathological response to neoadjuvant chemotherapy in patients with HR+HER2- early-stage breast cancer enrolled in FLEX

Joyce O'Shaughnessy, Priyanka Sharma, Cynthia R C Osborne, Gregory Vidal, Pond Remsen Kelemen, Suzanne Hoekstra, Harshini Ramaswamy, Nicole Stivers, Andrea Menicucci, William Audeh, FLEX Investigators' Group

Background: For patients with hormone receptor-positive (HR+), HER2-negative early-stage breast cancer (EBC), pathological Complete Response (pCR) rates to neoadjuvant chemotherapy (NCT) are low. However, NBRST and I-SPY2 trials report that MammaPrint risk of distant recurrence and BluePrint molecular subtyping signatures can more accurately identify which HR+HER2- EBC patients are likely to achieve pCR. Here, MammaPrint and BluePrint as biomarkers for predicting pCR and residual cancer burden (RCB) class, was evaluated among patients with HR+HER2- tumors enrolled in FLEX.
Methods: Patients with HR+HER2- tumors treated with NCT with available pCR and/or RCB data enrolled in the ongoing prospective, observational FLEX Trial (NCT03053193), were included in this study (N = 457). Tumors were characterized as MammaPrint UltraLow (UL), Low (LR), High 1 (H1) or High 2 (H2) Risk. BluePrint subtypes were classified as either Luminal A, Luminal B, HER2, or Basal. pCR and Pathological Response (PR= pCR + minimal residual cancer burden [RCB-I]) were the study endpoints. Differences in clinical characteristics and response rates were evaluated by Chi-Squared test or two-sided proportional Z-test. The association between MammaPrint, BluePrint, and PR was assessed using multivariate logistic regression and was adjusted for menopausal status, T stage, and N stage.
Results: MammaPrint classified 2% as UL, 8% as LR, 56% as H1, and 34% as H2. Nearly 60% of patients in this study had clinical lymph node (LN) positive disease. Higher tumor stage and grade were significantly more likely to be associated with higher MammaPrint Risk. Age, menopausal status, race, and LN status were comparable among MammaPrint groups. All UL and LR tumors were Luminal A, most H1 tumors were Luminal B (98%), while 45% of H2 tumors were Luminal B and 54% were Basal (1% were HER2). pCR rates were significantly higher in H2 Basal (39.8%), followed by H2 Luminal B (15.7%), H1 Luminal B (7.4%), and lowest in UL and LR, Luminal A (4.5%) ($p<0.001$). Among H2 Luminal B tumors, LN negative tumors had a pCR rate of 21.0% whereas LN positive tumors had a pCR rate of 12.5%. Rates of RCB-I were significantly higher among H2 tumors (26.9%) than H1 tumors (7.3%), or UL and LR tumors (0%) ($p=0.026$). Among H2 tumors, PR rates measured higher than rates of pCR alone in Basal tumors (43.4% vs 39.8%) and more prominently in Luminal B tumors (21.4% vs. 15.7%). Multivariate analysis revealed that MammaPrint H2 was significantly associated with likelihood of PR (OR=12.6, 95% CI 2.43 – 23.28, $p=0.016$), whereas menopausal status, T stage, and N stage were not associated with PR.
Conclusion: MammaPrint and BluePrint predict chemosensitivity to NCT in HR+HER2- EBC. Patients with MammaPrint H2 tumors, including Luminal B and Basal subtypes, are more likely to achieve pCR or PR to NCT, compared to UL, LR, and H1 groups. Additionally, pCR

rates trended lower among LN positive disease, possibly due to the increased difficulty of clearing disease in LNs with systemic therapy. We observed very high rates of RCB-I in H2 Luminal B tumors. These findings should be confirmed in other studies. The very high rates of PR observed in this study suggest that MammaPrint H2 identifies a subset of patients with HR+HER2- disease that benefit from NCT, which may enable surgical downstaging efforts and translate to improvements in outcomes.

PS4-06: HER2DX ERBB2 mRNA Score in First-Line Metastatic HER2-Positive Breast Cancer Treated with Docetaxel, Trastuzumab and Pertuzumab: Correlative Analysis from CLEOPATRA Phase III Trial

Javier Cortés, Fara Brasó-Maristany, Guillermo Villacampa, Eva Ciruelos, Mercedes Marín-Aguilera, Patricia Galván, Sanne de Haas, Eleonora Restuccia, Mahesh Shivhare, Laia Paré, Wesley Buckingham, Joel S. Parker, Ana Vivancos, Charles M. Perou, Patricia Villagrasa, Julia Maués, Aleix Prat, and Sandra Swain

Introduction: In first-line HER2-positive (HER2+) metastatic breast cancer (MBC), the standard regimen of taxane-trastuzumab-pertuzumab (THP) faces increasing competition from new therapies. This shift highlights the need for precise biomarkers to guide treatment decisions. Two previous real-world evidence studies in HER2+ MBC have shown that, compared to HER2DX ERBB2-low/med groups, the HER2DX ERBB2-high group is associated with better progression-free survival (PFS) and overall survival (OS) following THP in the first-line setting (Bayona et al. ESMO Breast 2024) and following T-DM1 monotherapy in the second-line setting or beyond (Brasó-Maristany et al. JNCI 2022). Here, for the first time, we evaluated the ability of the HER2DX ERBB2 mRNA score to predict long-term outcomes in the pivotal trial that established THP in the first-line setting.
Methods: We analyzed available formalin-fixed paraffin-embedded (FFPE) tumor RNA from participants in the CLEOPATRA phase III trial (Baselga et al., NEJM 2012; Swain et al., Lancet 2020; NCT00567190) who were randomized to THP (docetaxel, trastuzumab, and pertuzumab). Standardized HER2DX assay was conducted at Reveal Genomics' central lab (Barcelona, Spain) blinded from clinical data. The HER2DX ERBB2 score, evaluated both as a continuous variable (1 to 99) and as pre-defined groups (low, medium, and high), was correlated with overall response rate (ORR), PFS, and OS in an exploratory analysis using logistic regression and Cox proportional hazards models. The significance level for all statistical analyses was set at a two-sided alpha of 0.05.
Results: In this CLEOPATRA subpopulation, representing 53% of the original cohort (214 out of 402 patients randomized to THP), the median PFS was 18.7 months (95% confidence interval [CI]: 16.2-22.8) and the median OS was 59.5 months (95% CI: 49.3-83.5). These survival outcomes are similar to the original trial cohort. The assay success rate was 96.8% (214/221). The HER2DX ERBB2-low, -medium, and -high groups distribution was 13.5% (n=29), 8.9% (n=19), and 77.6% (n=166), respectively. The HER2DX ERBB2 score, analyzed as a continuous variable, demonstrated an association with PFS (hazard ratio [HR] per 10-unit increment=0.90; 95% CI: 0.83-0.97) and OS (HR per 10-unit increment=0.91; 95% CI:

0.83-1.00), after adjusting for IHC status (IHC 0+, 1+, 2+ versus 3+). Patients with ERBB2-high tumors showed superior median PFS (20.3 months, 95% CI: 18.2-26.4) compared to those with ERBB2-low (10.4 months, 95% CI: 8.4-12.7) and ERBB2-medium (18.7 months, 95% CI: 16.6-36.9) disease. Similarly, a better median OS was observed in patients with ERBB2-high tumors (72.7 months, 95% CI: 51.8-102.1) compared to those with ERBB2-low (40.3 months, 95% CI: 28.8-59.5) and ERBB2-medium (56.5 months, 95% CI: 37.1-59.5) disease. The ERBB2 score, as a continuous variable, was not associated with the ORR (odds ratio per 10-unit increment=1.11, 95% CI: 0.95-1.31).
Conclusion: The HER2DX ERBB2 mRNA score is strongly associated with long-term survival outcomes in metastatic HER2+ breast cancer treated with first-line THP. Notably, HER2DX identified patients with ERBB2-low disease, as the subgroup with the poorest outcomes in both PFS and OS. Further analyses will be presented at the conference.

PS4-07: Residual disease after HER2 inhibition is driven by a primary tumor subpopulation expressing an ERBB2-low associated transcriptional program

Sheheryar Kabraji, Weihua Wang, Yali Zhang, Johann Bergholz, Tao Jiang, Vittal Kurisetty, Maia Homsi, Jianmin Wang, Jean J. Zhao

Background: In HER2+ breast cancer (BC), residual disease (RD) after neoadjuvant HER2 inhibition is associated with increased risk of recurrence. However, the genetic and non-genetic resistance mechanisms underlying RD remain incompletely characterized. Here we used single nuclei (sn) RNA and DNA sequencing to profile genetic and transcriptional changes in growing, residual, and recurrent tumors from an inducible mouse tumor model of HER2+ breast cancer. Methods: We used mammary tumors / tumor bed (n=2-3/time point) from female MMTV-rtTA; TetO-ERBB2 mice at 9 weeks DoxOn (HER2on), 7 days DoxOff (HER2off) and 12-21 weeks Doxoff (recurrent). Samples were snap frozen and single nuclei isolation was performed. snRNAseq was performed using 10X 5' v2 kits for library preparation and sequencing. snDNAseq was performed using a custom amplicon panel targeting the mouse genome and human ERBB2 locus via the MissionBio Tapestri platform. Results: For snRNAseq analysis, tumor cell clusters were identified by Epcam and ERBB2 gene expression. Tumor cells were further subclustered into 18 unique clusters that separated by ERBB2 expression. Seven subclusters of HER2on tumor cells were characterized by low ERRB2 expression: 1.38 vs 2.94 (median normalized log counts) in HER2on-ERBB2high cells. Top 5 differentially expressed genes (DEG) per condition (log2 fold change >1.5, adjusted p value < 0.05) were: HER2on: Erbb2, Csn3, Lcn2, Csn2, Wfdc18; HER2on-ERBB2high: Csn3, Igfbp5, Csn2, Lcn2, Trf; HER2on-ERBB2low: Lars2, Gm47283, Cmss1, Gm42418, Neat1; HER2off: Lars2, Hexb, Cmss1, Gphn, Gm42418; Recurrent: Capza2, Vim, Lgals1, Crabp1, S100a6. HER2on-ERBB2low cells were more closely related in transcriptional space to HER2off residual tumor cells than HER2on-ERBB2high tumor cells. Trajectory analysis suggested that HER2off RD evolved from HER2on-ERRB2low cells and formed the basis of recurrent disease. To determine clonal evolution over time, we used

common top 10 DEGs between HER2on vs HER2off vs HER2low snRNAseq data and intersected that set with significantly enriched single nucleotide variants (SNVs) from our snDNAseq data. We identified 16 clones containing at least 1 SNV at >1% frequency across all samples. We observed clonal persistence, relative enrichment and extinguishment between HER2on, HER2off and recurrent samples but without clonal dominance.
Conclusion: Time-series analysis of genetic and transcriptional evolution in a mouse model of HER2+ BC RD suggests that a tumor cell subpopulation characterized by an ERBB2low-associated transcriptional program drives RD after HER2 inhibition. Further functional analysis will be presented at the conference.

PS4-08: The tumor heterogeneous overexpressed CD155 promotes treatment resistance in HER2-positive breast cancer through immune microenvironment modulation

Yi Zhang, Bingqiu Xiu, Qi Zhang, Jiong Wu

Purpose: HER2-positive breast cancer is characterized by high malignancy and frequent recurrence. The combination of immunotherapy with HER2-targeted therapy necessitates a deeper understanding of the immuno-oncology of HER2 breast cancer. CD155, an immune checkpoint highly expressed on tumor cells, promotes tumor growth and interacts with its inhibitory ligand TIGIT to form an immunosuppressive microenvironment. This study investigated the tumor heterogeneous overexpressed CD155 promotes treatment resistance in HER2-positive breast cancer.
Methods: We collected 10 untreated human HER2-positive breast cancer scRNA-seq datasets to explore the expression pattern of CD155 and used GSEA and GSVA to characterize epithelial cells expressing high levels of CD155. In addition, 3 paird HER2+ scRNA-seq samples before and after neoadjuvant therapy were also incluced. Based on bulk RNA-seq of HER2 breast cancer from TCGA, we conducted gene co-expression analysis and WGCNA to define the expression network of CD155. To uncover the relationship between CD155 and HER2-targeted therapy resistance, we collected patient tissue microarrays and paired pre/post-treatment samples for IHC. In vitro and in vivo studies were conducted to verify the molecular mechanism of CD155 expression in HER2 breast cancer.
Results: Through scRNA-seq from patient samples, we found a strong negative correlation between CD155 and ERBB2 expression in breast cancer cells, with heterogeneous expression further verified in our multiplex IHC of patient samples. To further verify the CD155 high cells are enriched after anti-HER2 treatment, we use neoadjuvant cohorts to evaluate these markers through IHCs and found the upregulation of CD155 post treatment. In addition, based on the TCGA database, CD155 correlates with a worse prognosis only in the HER2-enriched subtype. The relevance between CD155 and worse prognosis was demonstrated in our 200-patient tissue microarray IHC. In scRNA-seq, clusters bearing high expression of CD155 exhibited more vigorous metabolic features. In the cell lines SKBR3

and HCC1954, knockdown CD155 showed a decline in proliferation and increased sensitivity to HER2-targeted therapy. Moreover, Cibersort analysis revealed that CD155 is negatively correlated with the infiltration of activated NK cells in the tumor microenvironment, a major force of the ADCC effect induced by trastuzumab.
Conclusion: CD155 plays a critical role in HER2 heterogeneity and mediates immune evasion. Blocking CD155 could be a potent treatment option to overcome resistance to HER2-targeted therapy while preventing NK cell exhaustion and eliciting robust anti-tumor immunity.

PS4-09: Spatial Omics Analysis Uncovers Microenvironmental Remodeling and Immune Dynamics in T-DXd Resistant Metastatic Breast Cancer

Glori Das, Matthew Vasquez, Jeffrey Zhang, Ji-Hoon Lee, Yuan Gao, Jilun Zhang, Jenny Chang, Xiaoxian Li, Hong Zhao, Stephen T.C. Wong

Trastuzumab deruxtecan (T-DXd) is the standard of care for HER2+ or HER2 low metastatic breast cancer (mBC). However, approximately 20% of patients exhibit resistance to T-DXd therapy. As the development of more antibody-drug conjugate (ADC) therapies progresses, understanding ADC resistance mechanisms is critical. Our study aims to elucidate the etiology of ADC resistance, such as characterizing molecular changes and identifying novel biomarkers in tumor-immune interactions between T-DXd responsive (R) and non-responsive (NR) patients with mBC.
We employed Nanostring's GeoMX spatial proteomics and transcriptomics profiling technology to analyze 29 metastatic tissue sections (15R, 14NR) from heavily pre-treated patients with HER2+/low mBC, prior to T-DXd treatment. For each section, 6-8 circular regions of interest (ROIs) with a diameter of 300μm were chosen by researchers blinded to T-DXd R vs. NR outcomes and HER2 scores. ROIs were selected to capture spatially diverse tumor-dense and tumor-sparse regions. Immune markers, stromal markers, and HER2 expression levels were quantified for each ROI.
Consistent immune and stromal features related to T-DXd resistance were identified across various metastatic sites, including brain, bone, liver, lymph node, chest wall, and lung. NR tumors were characterized by relative immunosuppression and a disorganized immune response, with consistent upregulation of fibronectin and, surprisingly, granzyme B. Local immune response significantly varied based on HER2 expression. Organ-specific characteristics were also observed:
Bone metastases showed an increased correlation between various immune markers and fibronectin in NR, suggesting that fibronectin may modulate immune infiltration and promote a supportive microenvironment for tumor growth.
In contrast, chest wall metastases showed loss of correlation between various immune markers and smooth muscle actin in NR. This suggests that a remodeled, less dense smooth muscle environment might reduce physical barriers, potentially allowing better immune cell infiltration and activity in responsive tumors.

Furthermore, a subset of these patient samples was selected for spatial whole transcriptomic analysis to gain deeper insights.

PS4-10: TNBC-DX Genomic Test Predicts High pCR in Triple-Negative Breast Cancer with sTILs ≥30% Treated with Neoadjuvant Docetaxel-Carboplatin with/without Pembrolizumab

Shane Stecklein, S.R. Stecklein, M. Martín, G. Villacampa, M. Del Monte-Millán, R. Yoder, H. Pathak, S. Cobo, F. Brasó-Maristany, E.L. Álvarez, I. Echavarría, C. Bueno-Muiño, Y. Jerez, M. Cebollero, O. Bueno, J.Á. García-Saenz, F. Moreno, H. Gómez, T. Massarrah, B. Herrero, L. Paré, S. López-Tarruella, P. Villagrasa, A.K. Godwin, R. Salgado, A. Prat, P. Sharma

Background: Stromal tumor-infiltrating lymphocytes (sTILs) and the novel 15-gene TNBC-DX test, which integrates immune, proliferation, tumor size, and nodal status markers, are predictors of pathologic complete response (pCR) in triple-negative breast cancer (TNBC) treated with neoadjuvant chemotherapy (NACT), with or without pembrolizumab. This study aimed to evaluate the complementary role of TNBC-DX pCR score and sTILs in predicting pCR in patients receiving NACT ± pembrolizumab.
Methods: sTIL quantification and TNBC-DX genomic testing were performed on pretreatment tumor samples from 401 stage I-III TNBC patients undergoing NACT in two clinical trials: MMJ-CAR-2014-01 (NCT01560663; n=292), where patients received 6 cycles of carboplatin plus docetaxel (TCb), and NeoPACT (NCT03639948; n=109), where patients received 6 cycles of TCb + pembrolizumab (TCb+P). sTILs were centrally evaluated. Pre-established cut-offs defined TNBC-DX pCR-low, -medium, and -high groups. Logistic regression models assessed the association of TNBC-DX and sTILs with pCR.
Results: In the TCb-treated group, the pCR rate was 49%, with both TNBC-DX pCR score and sTILs associated with pCR (OR per 1-unit increase=1.20, p<0.001 for TNBC-DX; and OR per 1-unit increase=1.01, p<0.001 for sTILs). In the TCb+P group, the pCR rate was 58%, with both TNBC-DX pCR score and sTILs as predictors (OR=1.46, p=0.001 for TNBC-DX; OR=1.27, p=0.001 for sTILs). The correlation between TNBC-DX pCR score and sTILs was weak (r=0.26-0.32). The distribution of TNBC-DX pCR-low, medium, and high groups was approximately one-third for each category across both trials. For TCb, pCR rates in TNBC-DX high, medium, and low groups were 66%, 58%, and 25%, respectively (OR=5.81 for high vs. low; p<0.001). For TCb+P, pCR rates in these groups were 78%, 66%, and 33%, respectively (OR=7.25 for high vs. low; p<0.001). In the sTILs ≥30% and 5-29% subgroups, TNBC-DX was significantly associated with pCR. In the sTILs ≥30% subgroup, the pCR rates for TNBC-DX high, medium, and low were 70%, 65%, and 29%, respectively, for TCb (OR=5.80; p=0.010) and 91%, 79%, and 33%, respectively, for TCb+P (OR=21.0; p<0.001). In the sTILs 5-29% subgroup, the pCR rates for TNBC-DX high, medium, and low were 67%, 60%, and 26% for TCb (OR=5.83; p<0.001) and 64%, 56%, and 14% for TCb+P (OR=21.0; p=0.003). In the sTILs <5% subgroup, the pCR rates for TNBC-DX high, medium, and low were 43%, 44%, and 24% for TCb (OR=2.40; p=0.300) and 33%, 29%, and 40% for TCb+P (OR=0.75; p=0.826). Bivariate analyses showed that both sTILs and TNBC-DX were

associated with pCR with TCb+P treatment (sTILs OR=1.23, p=0.005; TNBC-DX OR=1.36, p=0.006), while only TNBC-DX was associated with pCR with TCb treatment (sTILs OR=1.01, p=0.143; TNBC-DX OR=1.18, p<0.001). Overall, tumors with sTILs ≥5% and TNBC-DX pCR med/high scores represented 55-57% of the study population.
Conclusions: The TNBC-DX genomic test effectively predicts pCR to neoadjuvant TCb ± pembrolizumab in TNBC. Notably, the TNBC-DX pCR-high group identifies patients with high sTILs who have a pCR rate exceeding 90% when treated with TCb+P. This study confirms that gene expression and sTILs provide distinct and potentially complementary information for pCR prediction in TNBC.

PS5-01: The association between pembolizumab and risk of venous thromboembolism in patients with breast cancer

Cho-Han Chiang, Junmin Song, Nutchapon Xanthavanij, Kuan-Yu Chi, Yu-Cheng Chang, Yu Chang, Chieh-Lien Hsiao, Yuan Ping Hsia, Shuwen Lin

Background: Patients with cancer are at an increased risk of venous thromboembolism (VTE) due to the underlying cancer biology or chemotherapeutic treatment. The use of immune checkpoint inhibitors (ICIs) further increases the risk of thrombosis. Pembrolizumab has recently been approved for breast cancer treatment, but data on its impact on VTE are limited. We aimed to investigate the incidence and risk of VTE associated with pembrolizumab use in breast cancer patients.
Methods: We performed a retrospective, propensity score-matched cohort study using the TriNetX Analytics Network database, which includes de-identified electronic health records from over 70 healthcare organizations and 101 million individuals. We included adult female breast cancer patients treated with pembrolizumab from November 2020 to June 2023. We excluded patients who received endocrine or HER2-targeted therapies. We further excluded patients with a prior history of VTE, atrial fibrillation, and those who received prior therapeutic anticoagulation. The comparator cohort comprised patients who received pembrolizumab and chemotherapy while the control cohort comprised patients who received chemotherapy only. The primary outcome was VTE, which was defined as a composite of pulmonary embolism (PE) and deep venous thrombosis (DVT). The secondary outcomes included individual components of PE and DVT. All outcomes were captured within 1 year following the start of ICI therapy.
Results: We identified 11,620 eligible patients, of whom 1,832 received pembrolizumab and chemotherapy, and 9,788 received chemotherapy only. After propensity score matching, 1,322 patients in each cohort were well balanced for demographics, breast cancer-directed therapy, underlying comorbidities, and medication use. The mean age for the pembrolizumab-chemotherapy and chemotherapy-only cohorts were 55.5 ± 13.8 and 55.6 ± 13.9 years, respectively. Both groups received similar cancer treatments, including mastectomy (both 6.4%) and radiation treatment (7.6% vs. 6.6%). The chemotherapy regimen between the two groups were similarly distributed, including taxanes (71.7% vs. 71.9%), platinum compounds (67.9% vs. 69.0%), anthracyclines (21.6% vs. 23.9%), and

cyclophosphamide (21.3% vs. 23.3%). Over a median follow-up of 12 months, the incidence of VTE was higher in the pembrolizumab-chemotherapy cohort (4.6 events per 100 patient-years) compared to the chemotherapy-only cohort (2.6 events per 100 patient-years). Patients who received pembrolizumab and chemotherapy had a 72% higher risk of VTE (Hazard ratio (HR), 1.72 [95% CI: 1.13-2.60]) than those who received chemotherapy only. In terms of individual VTE outcomes, the incidence of PE and DVT was higher in the pembrolizumab-chemotherapy cohort (2.7 and 2.4 events per 100 patient-years) compared to the chemotherapy-only cohort (1.3 and 1.7 events per 100 patient-years). Patients who received pembrolizumab and chemotherapy had a higher propensity to develop PE (HR, 2.10 [95% CI: 1.17-3.71]) and a higher trend towards DVT (HR, 1.41 [95% CI: 0.83-2.40]) than those who received chemotherapy only.
Conclusion: The use of pembrolizumab is associated with a higher risk of VTE among breast cancer patients. Further studies are needed to stratify patients at higher risk of developing ICI-associated VTE in this population.

PS5-02: The incidence and risk of cardiovascular events associated with pembrolizumab in patients with breast cancer

Cho-Han Chiang, Xiaocao “Haze” Xu, Junmin Song, Nutchapon Xanthavanij, Kuan-Yu Chi, Yu-Cheng Chang, Yu Chang, Chieh-Lien Hsiao, Yuan Ping Hsia, Cho-Hung Chiang, Shuwen Lin

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment. However, ICIs have been linked to serious immune-related cardiovascular adverse events. Pembrolizumab has recently been approved for breast cancer treatment, but data on its impact on immune-related cardiovascular adverse events are limited. We aimed to investigate the incidence and risk of cardiovascular events associated with pembrolizumab use in breast cancer patients.
Methods: We conducted a retrospective, propensity score-matched cohort study using the TriNetX Analytics Network database, which includes de-identified electronic health records from over 70 healthcare organizations and 101 million individuals. We included adult female breast cancer patients treated with pembrolizumab from November 2020 to May 2023. Patients who received endocrine or HER2-targeted therapies were excluded. We compared patients who received pembrolizumab and chemotherapy with those who received chemotherapy alone. The primary outcome was major adverse cardiovascular events (MACE), including myocarditis, pericarditis, myocardial infarction, heart failure, ischemic stroke, and cardiac arrest. Secondary outcomes included individual MACE components and other cardiovascular events such as atrial fibrillation and conduction disorders. All outcomes were captured within one year following the start of ICI therapy.
Results: We identified 9,913 eligible patients, of whom 1,834 received pembrolizumab and chemotherapy, and 8,079 received chemotherapy alone. After propensity score matching, 1,294 patients in each cohort were well balanced for demographics, cancer therapy, comorbidities, and cardiovascular medication use. The mean age for the pembrolizumab-chemotherapy and chemotherapy-only cohorts were 54.7 ± 13.4 and 54.7 ± 13.2 years,

respectively. The background prevalence for hypertension (24.4% vs 23.8%) and hyperlipidemia (19.3% vs 18.0%) were similar between the two groups. Both groups received similar cancer treatments, including mastectomy (5.0% vs. 5.3%), radiation treatment (6.3% vs. 6.2%), taxanes (73.6% vs. 72.5%), platinum compounds (70.4% vs. 69.7%), anthracyclines (22.2% vs. 23.7%), and cyclophosphamide (21.6% vs. 23.2%). Over a median follow-up of 12 months, the incidence of MACE was higher in the pembrolizumab-chemotherapy cohort (9.9 events per 100 patient-years) compared to the chemotherapy-only cohort (4.5 events per 100 patient-years). The pembrolizumab-chemotherapy cohort had an approximately 2.2-fold higher risk of MACE (Hazard ratio (HR), 2.18 [95% CI: 1.60-2.98]). There were five cases of myocarditis in the pembrolizumab-chemotherapy cohort, while no cases were detected in the chemotherapy-only cohort. Furthermore, pembrolizumab was associated with a significantly increased risk of heart failure (HR, 3.58 [95% CI: 1.89-6.78]), atrial fibrillation/flutter (HR, 3.78 [95% CI: 1.82-7.87]), conduction disorders (HR, 2.81 [95% CI: 1.37-5.76]), and cardiac arrest (HR, 4.80 [95% CI: 1.05-21.90]). Patients on pembrolizumab also showed a higher tendency to develop pericarditis (HR, 1.80 [95% CI: 0.96-3.37]) and myocardial infarction (HR, 1.64 [95% CI: 0.75-3.58]). Conclusion: The use of pembrolizumab is associated with more than a two-fold increased risk of MACE among breast cancer patients. Further studies are needed to optimize the detection and management of ICI-associated cardiovascular events in this population.

PS5-03: Incidence and Risk Factors of Immune-Related Adverse Events in Early-Stage Breast Cancer Patients: Findings from a Multi-Institutional Study

Alexis LeVee, Saya Jacob, Samantha Fisch, Carolyne Face, Madhuri Chengappa, Saliha Chaudhry, Nikita Baclig, Andrew Soliman, Nora Ruel, Megan Wong, Karen Tsai, Irene Kang, Laura Huppert, Laura Quintal, Michelle Melisko, Melanie Majure, Jo Chien, Melissa Lechner, Dame Idossa, Anne Blaes, Kelly McCann, Hope S. Rugo, Joanne Mortimer

Introduction: With the addition of immune checkpoint inhibitors (ICIs) to the neoadjuvant/adjuvant treatment regimen in early-stage breast cancer, an increasing number of patients (pts) with breast cancer are developing immune-related adverse events (irAE). Identifying risk factors and biomarkers predictive of irAE in pts with early breast cancer is critical to prevent and mitigate irAE and improve ICI outcomes. The aim of this study is to report the incidence and identify predictive biomarkers of irAE in a large cohort of pts with early-stage breast cancer.
Methods: We identified pts with stage I-III breast cancer who received ICI at four academic institutions between 2014-2024. Pts were excluded if currently receiving ICI. Charts were reviewed for any grade irAE during or after ICI therapy. The chi-square and Wilcoxon rank-sum tests were used to compare baseline and treatment characteristics. Uni- and multivariate logistic regression was performed to determine factors predictive of severe (grade ≥3) irAE including age at ICI treatment, menopausal status, breast cancer subtype, race/ethnicity, BMI, menopausal status, smoking history, co-morbidities, and baseline

laboratory values.
Results: Of the 423 pts with early breast cancer included in the analysis, 307 (72.6%) pts developed any grade irAE and 80 (18.9%) pts developed ≥1 grade 3-4 irAE. No deaths (grade 5) due to irAE occurred. Of the 307 pts that developed any grade irAE, 180 (58.6%) pts developed 1 irAE, 97 (31.6%) developed 2 irAE, and 30 (9.8%) developed 3+ irAE. Of the 80 pts that developed severe irAE, 73 (91.3%) pts developed 1 severe irAE, and 7 (8.8%) developed 2 severe irAE. Among the 437 any grade irAE, the most common were thyroiditis (24.3%), rash (23.0%), colitis (14.5%), hepatitis (10.6%), and adrenal insufficiency/hypophysitis (7.6%). Among the 87 severe irAE, the most common were adrenal insufficiency/hypophysitis (20.7%), rash (19.5%), hepatitis (12.6%), colitis (11.5%), and autoimmune diabetes mellitus (8.0%). Patients with irAE received fewer cycles of ICI compared to patients without irAE, with a median number of ICI cycles of 7 (IQR 4-15) and 11 (4-17), respectively (p=0.006). Similarly, patients with severe irAE also received fewer ICI cycles compared to patients without severe irAE, with a median number of ICI cycles of 4 (IQR 3-9) and 9 (4-17), respectively (p<0.0001). Multivariate logistic regression demonstrated that older age (age ≥50y vs. age <50y) [OR 1.69; 95% CI, 1.00-2.86; p=0.05] and the presence of CKD (OR 4.93; 95% CI, 1.59-15.3; p=0.006) were predictive of severe irAE.
Conclusion: In this cohort of pts with early-stage breast cancer treated with ICI, the incidence of any and severe irAE was 72.6% and 18.9%, respectively. Pts were more likely to develop severe irAE if they were older and had CKD. Further studies to identify risk factors and biomarkers of irAE in pts with early breast cancer are needed to prevent irAE and reduce the associated long-term complications.

PS5-04: Anti-RANKL bone resorptive therapy increases immune-related adverse events (irAE) in breast cancer patients (pts) treated with pembrolizumab

Alexis LeVee, Esther Peluso, Melissa Lechner, Nora Ruel, Joanne Mortimer, Irene Kang, Karen Tsai

Introduction: Immune-related adverse events (irAE) occur in approximately 33.5% patients (pts) with early TNBC and 26.5% of pts with advanced TNBC treated with pembrolizumab plus chemotherapy. Severe irAE (grade 3+) occur in approximately 5.3-12.9% of pts, which often lead to serious symptoms resulting in hospitalization, treatment discontinuation, organ dysfunction, and/or death. Bone-modifying agents (BMAs) are frequently used in early breast cancer to treat osteoporosis and to decrease disease recurrence in postmenopausal women, while advanced breast cancer pts with bone metastases are treated with BMAs to reduce skeletal-related events. Preclinical studies demonstrate that anti-RANKL therapy can have immunomodulatory effects through dysregulation of T cell negative selection and disruption of Treg function. We recently showed that pre-treatment with anti-RANKL therapy prior to receiving an immune checkpoint inhibitor (ICI) significantly increased the rate of endocrine irAE in a mouse model. Here, we report the

incidence of severe irAE in a cohort of breast cancer pts treated with pembrolizumab in combination with BMAs.
Methods: We identified female pts with breast cancer who started treatment with pembrolizumab between December 2017 to January 2024. Pts were categorized according to BMA received: zoledronic acid (ZA), denosumab (Dmab), or none (no BMA). BMA therapy was considered received within a dose interval prior to ICI (12 months for ZA; 6 months for Dmab), during ICI therapy, or within 1 month of last ICI cycle. Pts who received both ZA and Dmab were excluded. Severe irAE data according to CTCAE v5.0 were collected. Clinical characteristics and outcomes were compared using chi-square or Kruskal-Wallis tests among pts who received ZA, Dmab, and none.
Results: Our cohort consisted of 430 female breast cancer pts treated with pembrolizumab with 56 (13%) pts who received Dmab, 31 (7.2%) who received ZA, and 343 (79.8%) who received no BMA. A total of 148 (34.4%) pts had early-stage breast cancer, while 282 (65.6%) had late-stage disease. The median number of pembrolizumab cycles received was 8 (IQR 4-15), and the median duration of ICI therapy was 6.9 months (IQR 2.8-12.2). After a median follow-up of 19.4 months (95% confidence interval, 17.5-20.8), the incidence of severe irAE was 54/430 (12.6%) overall. Severe irAE occurred in 12/56 (21.4%) pts who received Dmab plus pembrolizumab, compared to 3/31 (9.7%) pts who received ZA plus pembrolizumab and 39/343 (11.4%) pts who received pembrolizumab alone. The median time from pembrolizumab initiation to onset of irAE was 2.3 months (IQR 1.1-6.9), which was not significantly different among the three groups (p=0.8). Of the 54 pts who developed severe irAE, the most common irAE included hepatitis (24%), pneumonitis (16.7%), colitis (13.0%), rash (13.0%), and hypophysitis (7.5%).
Conclusion: In breast cancer pts treated with pembrolizumab, Dmab had the highest rates of severe irAE compared to those who received ZA and those who received neither BMA. This study is consistent with higher rates of irAE seen in melanoma and lung cancer pts and in preclinical studies that combined ICI and anti-RANKL therapy. Given the expanding indication of ICIs in breast cancer treatment, further studies are needed to validate these results and to identify mechanisms to optimize the antitumor response while mitigating irAE.

PS5-05: Late-onset immune toxicity incidence & risk factors in breast cancer: a multi-institutional study

Saya Jacob, Samantha Fisch, Carolyne Face, Kelly Blum, Madhuri Chengappa, Saliha Chaudhry, Alexis LeVee, Nikita V. Baclig, Andrew Soliman, Laura Huppert, Zoe Quandt, Laura Quintal, Dame Idossa, Michelle Melisko, A. Jo Chien, Mi-Ok Kim, Joanne Mortimer, Kelly McCann, Anne Blaes, Hope S. Rugo

Background: Immune checkpoint inhibitors (ICI) have improved outcomes in patients (pts) with breast cancer. Late-onset immune-related adverse events (irAE) have been observed. Prior analyses of late-onset irAE have focused on pts with non-breast cancers as well as breast cancer within a single institution. However, the incidence of late onset irAE in larger

groups of pts with breast cancer is unknown.

Methods: We identified pts with stage I-IV breast cancer receiving ICI at four institutions between 2014-2024. Delayed irAE were defined as occurring >90 days after ICI start, post-treatment irAE were defined as occurring >60 days after ICI discontinuation, & early toxicity was defined as an on-treatment irAE occurring <90 days after ICI start. Events were categorized as irAE if provider documentation indicated that the toxicity was related to ICI. Logistic regression was performed to determine predictors of delayed & post-treatment irAE.

Results: 700 pts with breast cancer, 424 metastatic & 276 early stage, 539 (80%) with triple negative disease, underwent treatment with ICI of which 434 (62%) developed irAE at any time point, 240 (34%) developed delayed irAE (177 early stage (ES), 62 metastatic), 60 (9%) had post-treatment irAE (46 ES, 14 metastatic) & 257 (37%) had an early toxicity. 67 pts (28%) with delayed & 20 pts (33%) with post-treatment also had early irAE. All pts with a post-treatment toxicity also had a delayed toxicity.[HR1] [JS2] The median number of ICI cycles for delayed & post-treatment groups was 10 & 5. Of the pts with early toxicity, 91 (35%) discontinued ICI < 90 days after start. In the delayed & post-treatment groups respectively, 200 (83%) & 49 (82%) pts had triple negative disease (similar to the overall population at 539 (80%)). Median time to onset of delayed toxicity & post-treatment toxicity was 205 days from start of ICI (range 90-1961) & 116 days from end of ICI (60-1144), respectively. The most frequent toxicities in both groups was thyroiditis (93; 39% & 18; 30% in the delayed & post-treatment groups), colitis (41; 17% & 11; 18%), dermatitis (46; 19% & 5; 8%), & adrenal insufficiency/hypophysitis (36; 15% & 13; 22%). The most common grade ≥3 irAE was adrenal insufficiency/hypophysitis (17; 7% & 7; 12%)[HR3] [SJ4] . Pts with metastatic disease were less likely to develop delayed toxicity (Odds ratio {OR} 0.48, p=0.0002) & post-treatment toxicity (OR 0.40, p=0.0008). Logistic regression analyses of potential risk factors one at a time, adjusted for metastatic disease & treatment site, demonstrated that pts were more likely to develop delayed toxicity with increasing cycles of ICI (OR 1.08, p<0.0001) & less likely to develop delayed toxicity if they had early toxicity (OR 0.44, p<0.0001) & HR+ disease (OR 0.58, p=0.0217). The lower likelihood of developing delayed toxicity after an early toxicity remained true even after adjusting for those patients that discontinued ICI due to early toxicity (OR 0.53, p=0.0008). When multiple factors including baseline labs, BMI, age, subtype, early toxicity & number of cycles are evaluated for their adjusted effects after accounting for the effects of the rest of factors & metastatic disease & treatment site, pts were more likely to develop delayed toxicity if they had increased baseline eosinophil count (OR 3.46, p=0.0484) or increased number of ICI cycles (OR 1.10, p<0.0001 in metastatic setting, OR 1.04, p=0.0269 in early-stage setting) & less likely if they experienced early toxicity (OR 0.46, p=0.0001).

Conclusions: Immune toxicities occurred in 62% of patients with breast cancer treated with ICI. Delayed & post-treatment toxicity is common, occurring in 34% & 9% of pts in this dataset respectively, in particular thyroiditis. Early-stage disease, higher baseline eosinophil

count, higher number of cycles of ICI & lack of early toxicity were risk factors for development of delayed toxicity.

PS5-06: Osteonecrosis of the jaw (ONJ) in patients with metastatic breast cancer treated with denosumab in a randomized phase III trial comparing 4 vs. 12 weekly administration (REDUSE, SAKK 96/12)

Andreas Müller, Arnoud J Templeton, Stefanie Hayoz, Ursina Zürrer, Ursula Hasler-Strub, Michael Schwitter, Tilly Nothelfer, Konstantin Dedes, Khalil Zaman, Marc Küng, Lorenzo Rossi, Alexander Schreiber, Mathias Fehr, Ulrich Güller, Marcus Vetter, Razvan Popescu, Patrik Weder, Roman Inauen, Catrina Uhlmann Nussbaum, Claudine Egger, Corinne Cescato, Bettina Seifert, David R. Thorn, Corinne Schär, Silke Gillessen, Roger von Moos

Background: While reducing skeletal-related events in patients with bone metastases, bone-modifying agents such as bisphosphonates and denosumab have adverse events. One major adverse event of these agents is osteonecrosis of the jaw (ONJ), which often significantly impacts quality of life. The risk of ONJ increases with treatment duration and can reach cumulative rates of up to 10%. Here we report ONJ rates in a randomized phase III non-inferiority trial investigating the optimal dose schedule of denosumab (DN).
Methods: Patients with bone metastases from breast cancer (mBC) were randomized 1:1 to receive DN every 4 weeks (q4w) (arm A, standard schedule) versus every 12 weeks (q12w) (arm B, experimental schedule) after a 3-month induction phase with q4w therapy for both arms. Incidence of ONJ is a secondary endpoint of the study, while the primary endpoint is time to first symptomatic skeletal event (SSE). An oral inspection at baseline as well as before each application of DN was mandatory. In patients with risk factors for ONJ, a prophylactic dentist visit was recommended. Data from patients who received at least one dose of DN and who were randomized at least one year before data cut-off (December 11, 2023) were included in this interim safety analysis. Since the differentiation between ONJ and tooth abscess (the term according to CTCAE v5.0 is tooth infection) can be difficult, we report these two outcomes separately as well as combined.
Results: 725 patients from 50 centers with a median follow-up time of 3.4 years were evaluated for ONJ. The median number of administered DN-doses was 25 doses in arm A and 11 doses in arm B, the treatment duration was 108 weeks in arm A versus 99 weeks in arm B. During the 3-month induction phase (in which both arms had the same q4w DN-schedule) 1/725 (0.1%) patients experienced an ONJ. After this phase, when the schedules of DN begin to differ 27/333 (8.1%) patients in arm A and 17/328 (5.2%) in arm B experienced an ONJ. For tooth infections (tooth abscess) the numbers during the induction phase were 3/725 (0.4%), then after induction 30/333 (9.0%) for arm A and 15/328 (4.6%) for arm B. For the combined endpoint ONJ and/or tooth infection (tooth abscess) the numbers during the induction phase were 4/725 (0.5%), after induction 50/333 (15.0%) for arm A and 29/328 (8.8%) for arm B.Time to first ONJ differs with an advantage for the 3-month arm (HR 0.66; 95% CI 0.36 - 1.2). For the combined endpoint time to first ONJ and/or tooth infection the difference is even more pronounced (HR 0.63; 95% CI 0.4 - 0.98).

The median time to either event has not been reached for both endpoints.
Conclusions: The observed ONJ rate of 8.1% in the standard arm is in line with the literature for patients who received DN q4w for more than two years (6.0% to 9.8%). Administration of DN q12w reduces the risk of ONJ and/or tooth infections substantially. This risk reduction is clinically relevant with an absolute difference of 6.2% for ONJ and/or tooth infection after a median follow-up of 3.4 years. This suggests that DN given q12w has a more favorable long-term safety profile in terms of ONJ and/or tooth infection compared to DN q4w.Efficacy data for time to first symptomatic skeletal event (SSE) (the primary endpoint of this trial) is not yet mature and will be reported later.

PS5-07: Financial difficulty over time in young adults with breast cancer

Sara Myers, Yue Zheng, Kate Dibble, Elizabeth A. Mittendorf, Tari A. King, Kathryn J. Ruddy, Jeffrey M. Peppercorn, Lidia Schapira, Virginia F. Borges, Steven E. Come, Shoshana M. Rosenberg, Ann H. Partridge

Introduction: Although young adults (YA) aged 18-39 represent the minority of breast cancer diagnoses, they are particularly vulnerable to financial hardship. Factors contributing to sustained financial hardship are incompletely understood. Arm morbidity, one such understudied factor and key source of expense, may be particularly salient for YAs given that a high proportion of this demographic presents with aggressive tumor subtypes requiring comprehensive axillary management (a known risk factor for treatment-related lymphatic injury). In this study, we leverage a multi-institutional prospective cohort of YAs to identify patterns of financial hardship over time and characterize factors associated with discrete trajectories hypothesizing that treatment-related arm morbidity would be among the factors predicting long-term financial difficulty.

Methods: This analysis utilized data from women ≤ 40 years with newly diagnosed stage 0 to III breast cancer enrolled in The Young Women's Breast Cancer Study (YWS), a multi-institutional prospective cohort study enrolling from 2006 and 2016 at Dana-Farber Cancer Institute and 12 other academic and community hospitals in the United States and Canada. Patient, disease, and treatment information was obtained from surveys serially collected through 10 years post-diagnosis. Arm morbidity was assessed by asking patients about the degree to which they experienced upper extremity swelling and/or functional limitations using two Likert-scale response items (range: 0-4). Medical record review was used to gather supplemental clinical data. The primary outcome of interest, perceived financial difficulty, was assessed serially using a single Likert-scale response item (range: 0-4) from the CAncer Rehabilitation Evaluation System (CARES) scale. Group-based trajectory modeling classified patterns of financial difficulty from baseline through 10 years post-diagnosis. Multinomial logistic regression identified patient, disease, and treatment

characteristics associated with each trajectory.

Results: 1008 (78%) of 1297 participants were included. Median age at diagnosis was 36 years (IQR 33-39). The majority of individuals were non-Hispanic (95%), White (88%), college graduates (83%), partnered at baseline (76%), parous (64%), and without comorbidities at enrollment (90%). Patients' tumors were primarily stage I-II (86%), ER/PR-positive (75%), and HER2-negative (68%). Patients were more frequently treated with mastectomy than breast conservation ($p<0.001$). Receipt of radiation (62%), chemotherapy (75%), and endocrine therapy (63%) were common. 72% (N=727) of patients reported arm symptoms within 2 years of surgery. Three distinct financial trajectories emerged: 54% had low financial difficulty (Trajectory 1), 30% had mild difficulty that improved (Trajectory 2), and 17% had moderate/severe difficulty peaking several years after diagnosis before improving (Trajectory 3). BMI ≥ 25, undergoing bilateral mastectomy, Hispanic ethnicity, being unemployed at both baseline and 1 year, and arm symptoms were predictive of Trajectory 2 and/or 3 (more financial difficulty). Having a college degree or being partnered were predictive of Trajectory 1 (low financial difficulty). CONCLUSION: This study of YAs with breast cancer identified a subset of patients who experienced a high degree of financial difficulty that persisted into early survivorship before it improved. Targeted interventions to mitigate financial toxicity, including those focused on modifiable factors such as arm symptoms and employability/return to work after cancer, are needed.

PS5-08: Effects of Cryotherapy on Objective and Subjective Symptoms of Taxane Induced Neuropathy in Patients with Early Breast Cancer: A National, Multicenter, Prospective, Randomized, Controlled Trial.

Maria Elisabeth Lendorf, Margrethe B Bille, Sebastian M Krog, Axel V Lendorf, Hella Danø, Freja L Kruse, Ann Knoop, Steffen Birk, Anders Bonde Jensen

Background: Due to well-proven survival benefit taxane-based chemotherapy regimens are first-line treatment in both the adjuvant and neoadjuvant setting of early-stage breast cancer. Chemotherapy-induced peripheral neuropathy (CIPN) is a frequent and disabling side effect from taxane treatment. CIPN is experienced in up to 64% of cancer patients receiving docetaxel and up to 81% receiving paclitaxel. Treatment options are limited. So far, no evidence-based strategy exists for the prevention of CIPN.
We conducted a randomized controlled trial to evaluate the efficacy and safety of cryotherapy as a prevention strategy for CIPN.

Method: Patients with early-stage breast cancer starting treatment with docetaxel or paclitaxel between January 2021 and July 2023 at four oncology departments in Denmark were eligible. Patients were randomized (1:1) to receive either cryotherapy or usual care. Cryotherapy was applied as frozen gloves and socks on all four extremities from 15 min before taxane infusion until 15 min post-infusion at every cycle. Primary endpoint was

incidence of peripheral neuropathy at End of Treatment (EoT); CIPN was assessed using the Total Neuropathy Score (TNS) 3 weeks after completion of the last cycle of docetaxel or paclitaxel and compared to baseline. A TNS score ≥ 2 was considered an event. Secondary end points included level of experienced peripheral neuropathy using Common Terminology Criteria for Adverse Event (CTCAE), patient-reported outcomes (EORTC Quality of Life Questionnaire EORTC (QLQ)-CIPN20) and EORTC (QLQ)-C30) and Quantitative sensory testing (QST).

Results: A total of 268 patients were randomized (cryotherapy 133 patients; usual care 135 patients), of which 51 dropped out before or during taxane treatment, leaving 217 patients for the final analyzes. The cryotherapy group N=123 and the usual care group N=94. There was no significant difference in CIPN assessed with TNS between the cryotherapy and usual care group 3 weeks after taxane treatment ($p = 1.0$). Nor did we find a significant difference in the incidence of CTCAE grade ≥ 2 sensory ($p = 0.2$) or motor peripheral neuropathy ($p = 0.2$). However, when using EORTC QLQ CIPN20 subscales the analyses showed that patients in the cryotherapy group experienced reduced tingling in hands($p=0.0005$) and feet ($p=0.04$), reduced numbness in hands($p=0.02$) and feet ($p=0.00002$) and less trouble opening a jar or bottle due to loss of strength in hands ($p=0.002$) compared with the usual care group. Concerning patient reported QoL or global health status no difference was found ($p=0.5$). QST revealed reduced tactile disturbance development($p=0.006$) but no difference in thermosensory disturbance($p=0.433$) in the cryotherapy arm. No difference in mean dose, dose reductions or premature cessation of the chemotherapy was observed. Data revealed a compliance with cryotherapy of 67% and no serious side effects were associated with cryotherapy.

Conclusions: This is so far the largest randomized controlled trial (n=217) evaluating the preventive effect of cryotherapy on taxane induced CIPN. No significant difference in incidence of CIPN at EoT was seen. However, an important benefit of cryotherapy was observed as patients reported significantly fewer sensory symptoms. Furthermore, a better result from monofilament testing of tactile sensitivity was seen in the cryotherapy treated group. Cryotherapy did not influence the administered dose of the cytotoxic drug. The benefits of cryotherapy regarding sensory symptoms will be further investigated in the present study as long-term follow-up are planned.
Clinical Trial Registration: ClinicalTrials.gov: NCT05928429

PS5-09: Feasibility of an Interactive Care Plan for Self-Management of Toxicity Symptoms and Surveillance for Non-Metastatic Disease in Breast Cancer Survivors

Marcia Venegas Pont, Aparna Kaur, Samatha Mannion, Jennifer L. Ridgeway, Summer Allen, Lisa Ahlberg, Kathryn J. Ruddy, Stephanie Lindeen, Sarah Jenkins, Tufia C. Haddad, Daniela L. Stan

Purpose: To assess the feasibility of an app-based interactive care plan (ICP), a self-management and surveillance tool, in breast cancer (BC) survivors, after completion of active medical treatments.

Methods: A single arm feasibility trial of patients who recently completed active BC treatments was conducted. ICP tasks were delivered for 12 months, and included: (1) daily "Be active at least 20 minutes today" activity reminders; (2) monthly assessments of four treatment-related toxicity symptoms: fatigue, insomnia, sexual dysfunction, and hot flashes (Likert scale 0-10); (3) monthly surveillance questionnaires assessing for symptoms of recurrence; and (4) quarterly quality of life (QOL) PROMIS 29 s (scored on a T-score metric with 50 being the mean of a general US adult reference population, 10 is the standard deviation and higher scores denote more of the tested outcome). On-demand education was available for the four self-reported toxicity symptoms. Positive answers to recurrence assessments and high anxiety and depression subscale scores of the PROMIS questionnaires escalated through decision trees embedded in the ICP to nurses who contacted the patient. The primary outcome was feasibility defined as 75% ICP tasks completion rate and <1 escalation/participant. Secondary outcomes were changes in toxicity symptom burden and in QOL. PROMIS scores were assessed between baseline and 6-months using paired t-tests tests.

Results: 101 patients were enrolled between August 2020 and May 2022, and the intervention was completed on May 2023. Three withdrew during the study period. Mean participant age was 56 years (range 30-78) and 97% were white. Of the daily "Be active" reminders, a median of 26.6% were checked (53.3% at month 1 decreasing to 6.7% at month 12). Similarly, 53.8% of the monthly toxicity and surveillance symptoms questionnaires were answered (84.7% at baseline to 6.1% at month 12) and 40.0% of the quarterly QOL questionnaires were answered (66.3% at baseline and 18.4% at month 12). The care team received 251 messages over the 1 year intervention, of which 90 (0.9/participant) were escalations related to symptoms worrisome for recurrence (68) and to anxiety or depression (22). The remainder 161 messages were related to restarting the ICP after dismissal from a hospital admission (52) and the need to discontinue the ICP at the completion of the intervention (106).
Among the treatment-related symptoms assessed at baseline, hot flashes was most frequently endorsed (48.2%), followed by fatigue (34.9%), insomnia (22.9%), and sexual dysfunction (13.3%). At baseline, 34.9% of participants noted treatment-related fatigue (average intensity of 4.6 on a 0-10 point scale), and this endorsement was near 30% for the first few months before dropping gradually. Among those reporting fatigue at baseline, 54% of them requested additional information to help better understand and manage the symptom. Similar trends were observed for the other treatment related symptoms.
At baseline, the PROMIS T-scores were generally near the population average of 50. Comparing baseline to month 6 among 24 participants with complete data at both time points, the average physical function T-score increased from 47.9 to 50.5 ($p=0.03$),

depression T-score decreased from 49.3 to 46.0 (p=0.006), and social roles/activities T-score increased from 53.7 to 56.3 (p=0.02).

Conclusion: Implementation of an app-based ICP in BC survivors was feasible although engagement decreased over time. The impact of escalation messages to the care team was minimal, therefore clinical implementation of the ICP is acceptable. Findings were difficult to compare over time due to a drop in response rate for the monthly surveys. Further improvement of the ICP with patient input is needed, to increase engagement and interest.

PS6-01: The PARP inhibitor rucaparib is a strong radiosensitizer in women with residual triple-negative breast cancer treated concurrently with adjuvant radiotherapy

Atif Khan, Alice Ho, Jacqueline Bromberg, Julia Ah-Reum An, Christopher Gareth Smith, Mike Bernstein, Amy Xu, Diana Roth Obrien, Richard Gewanter, Erin Gillespie, Marsha Reyngold, Zhigang Zhang, Mark Robson, Pedram Razavi, Simon N Powell

Purpose/objectives: Women with triple-negative breast cancer (TNBC) who have residual disease after neoadjuvant chemotherapy (NAC) have worse outcomes, including higher local-regional failure. ~50% of TNBCs have a high rate of homologous recombination repair defects (HRD). HRD cells are uniquely sensitive to PARP inhibitors (PARPi) through synthetic lethality. Radiation therapy (RT) also induces DNA lesions requiring PARP for repair. We hypothesized that the combination of RT and PARPi could improve outcomes. Materials/Methods: From June 2018 - June 2022, we enrolled 30 evaluable patients to a phase 1 trial of concomitant rucaparib with adjuvant RT using a TITE-CRM design with a target DLT rate of 30%. RT was delivered to 50 Gy in 25 fractions with a mandatory 10 Gy boost in lumpectomy cases (optional in mastectomy). Oral rucaparib was started at a dose of 400 mg bid, with 2 escalations to the target dose of 600 mg bid and one de-escalation to 300 mg bid. The drug was taken concurrently during RT and then for 4-5 weeks after RT for a total of 10 weeks. Non-hematologic DLTs included moist desquamation exceeding 25 cm2, delay of radiotherapy exceeding 5 business days, or any other grade 3 non-hematologic toxicity by CTCAE v4.03. The primary objective was to identify the maximum tolerated dose (MTD) of concurrent rucaparib and RT. Plasma was collected at baseline (pre-RT), during- (week 3), and post-RT (week 10), to evaluate circulating tumor DNA (ctDNA) using a personalized assay targeting multiple tumor-specific variants (RaDaR). Results: Median age of enrolled patients was 50 (range 31-75). Median clinical tumor size before NAC was 5 cm (range 1.3-8) and 19 patients were clinically node positive. Fourteen women had lumpectomy while the remainder had mastectomies, of which all but 5 had reconstructions. Two patients were enrolled at 400 mg bid of which one had a DLT (skin). Five patients were enrolled at a dose of 300 mg bid of which 3 had a DLT (2 skin and one neutropenia). Based on our observed DLTs, we amended the study to introduce lower dose levels: 200 mg bid, 300 mg qd and 200 mg qd. Three patients were enrolled at the

lowest dose of 200 mg qd without DLT. Three additional patients were enrolled at 300 mg qd with one DLT (skin). The dose was escalated to 200 mg bid in two patients, with one DLT (neutropenia). The dose was again reduced to 200 mg qd for 3 patients without DLT. The final 12 patients were treated at a dose of 300 mg qd, with 2 DLTs observed (skin), and this was declared to be MTD. Two patients progressed during the study period. With a median follow-up of 31 months, there were 2 local-regional recurrences (LRR, 1 isolated) and 13 distant metastases. 6/14 lumpectomy patients had fair or poor physician rated cosmesis (43%). For the 26 patients with at least one plasma collection for ctDNA, 22 had available tumor tissue for sequencing and 19 had a successful custom ctDNA panel created and used on plasma samples from at least one time point. 18 had a baseline result, 13 had on-RT, and 9 had at least one post-RT result at any time. Four of the 9 patients with a post-RT sample had ctDNA detected, and all four recurred. Lead times were 48, 91, 207, and 427 days. The other 5 patients were ctDNA negative and did not recur, indicating 100% accuracy. Of note, ctDNA detection at any post-surgery timepoint, regardless of timing relative to RT, was associated with recurrence (7/7 patients recurred). Two of 12 patients without ctDNA detected developed a clinical relapse, though sampling was limited in one.
Conclusions: When combined with adjuvant breast/chest wall radiotherapy, the MTD of rucaparib was 300 mg daily, corresponding to one-fourth of the approved monotherapy dose. The majority of DLTs seen were skin desquamation events (6/8 DLTs). We conclude that rucaparib is a very potent radiosensitizer, possibly leading to improved LRR, but poorer cosmesis in BCT patients. ctDNA detection associated with ultimate recurrence, but numbers were small and validation is required.

PS6-02: Association of VMAT versus 3D-CRT Radiotherapy Treatment Technique with Acute Toxicity of Regional Nodal Irradiation: A Secondary Analysis of the SAPHIRe Phase III Randomized Clinical Trial

Chelain Goodman, Melissa P. Mitchell, Saleh Ramezani, Simona F. Shaitelman, Rensi F. Zacharia, Isidora Y. Arzu, Elizabeth Bloom, Clifton D. Fuller, Melissa M. Joyner, Lauren L. Mayo, George H. Perkins, Jay Reddy, Puneet Singh, Michael C. Stauder, Eric A. Strom, Valerie K. Reed, Pamela J. Schlembach, Wendy A. Woodward, Benjamin D. Smith, Karen E. Hoffman

Background: Regional nodal irradiation (RNI) improves breast cancer survival but is associated with treatment-related toxicity. Volumetric Modulated Arc Therapy (VMAT)/Intensity Modulated Radiation Therapy (IMRT) treatment technique has been shown in other disease sites to improve dose homogeneity while reducing side effects compared to 3-Dimensional Conformal Radiation Therapy (3D-CRT). To evaluate the association of radiotherapy (RT) treatment technique with acute toxicity for patients receiving RNI, we performed a secondary analysis of the Shortening Adjuvant Photon Irradiation to Reduce Edema (SAPHIRe) trial, a Phase III trial evaluating conventional (CFx) vs. hypofractionation (HFx). We hypothesized that VMAT technique would be associated with reduced acute toxicity compared to 3D-CRT.

Methods: Patients with clinical or pathologic T0-3 N0-2a/3a invasive breast cancer dispositioned to receive comprehensive RNI were randomized to CFx vs. HFx (50Gy/25Fx or 40.05Gy/15Fx). Nodal target volumes included the axilla, infraclavicular and supraclavicular nodal basins, and internal mammary chain. Acute RT-related toxicity was graded utilizing the NCI CTCAE v4.0 scale at the end of RT. Associations between treatment technique with clinicopathologic and treatment variables, dosimetric data, and toxicity endpoints were determined using the Fisher's Exact, Mann-Whitney U, and Kruskal-Wallis tests. Univariate analysis and multivariable binomial logistic regression were performed to calculate adjusted odds ratios (OR) for factors associated with Grade 2+ toxicity at the end of RT.
Results: A total of 645 patients with available RT variables and end of RT toxicity assessments were enrolled from 2017-2024 (median follow-up, 20 months [IQR, 7-35]). Patients treated with VMAT technique were balanced across randomization arm (CFx vs HFx) as well as clinicopathologic and treatment variables but had significantly higher body mass index (BMI) (30 [25-34] vs. 28 [24-33], p=0.004) and were more likely to undergo plastic surgery reconstruction (40% vs. 21%, p<0.001).
Patients treated with VMAT technique experienced significantly reduced Grade 2+ toxicity at the end of RT treatment compared to 3D-CRT (38% vs. 51%, p=0.002), including Grade 2+ dermatitis (32% vs. 47%, p<0.001), Grade 1+ fatigue (50% vs. 60%, P=0.03), Grade 1+ pruritus (40% vs. 49%, p=0.02), and Grade 1+ breast edema (0.4% vs. 3.9%, p=0.02). VMAT technique was associated with significantly reduced volume of the body receiving ≥105% (V105%) of the prescription dose (72cc vs. 351cc), V107% (2cc vs. 186cc), and V110% (0cc vs. 77cc; all p<0.001), as well as the maximum percentage dose (Dmax) to the nodes (106% vs 120%, p<0.001). 3D-CRT technique was associated with significantly increased dose to the ipsilateral lung (V20Gy [CFx]/V16Gy [HFx]>35% = 12% vs. 1%, p<0.001) as well as mean heart dose (MHD>4Gy [CFx]/3.2Gy [HFx] = 6% vs. 1%, p=0.007). V105% to the body and Dmax to the nodes were significantly associated with increased rates of acute dermatitis (p=0.004 and p=0.01, respectively) and breast edema (p=0.02 and p=0.005, respectively) while V107% was associated with significantly increased fatigue (p=0.02). On multivariable analysis, increased BMI (OR [95% CI]=1.04 [1.00-1.07], p=0.03) was significantly associated with increased rates of Grade 2+ toxicity at the end of RT while hypofractionation (OR=0.28 [0.19-0.42], p<0.001), VMAT treatment technique (OR=0.38 [0.21-0.68], p=0.001), and absence of boost (OR=0.38 [0.15-0.87], p=0.03) were associated with significantly decreased rates of Grade 2+ toxicity at the End of RT.
Conclusion: In this secondary analysis of a prospective randomized clinical trial, patients treated with RNI utilizing VMAT technique compared with 3D-CRT experienced significantly decreased rates of acute treatment-related toxicity, including any Grade 2+ toxicity, in the setting of improved dose homogeneity.

PS6-03: Post-Mastectomy Proton Therapy Imparts Increased Risk of Capsular Contracture in Reconstructed Breast Cancer Patients

Mehmet Murat Zerey, Omer Gal, Joseph Panoff

Background: The rising utilization of post-mastectomy proton therapy (PMPT) in the setting of breast reconstruction has raised concerns about increased complication rates. There is some limited data indicating PMPT may increase the risk of capsular contracture (CC) when compared with photon therapy. We examined the capsular contracture rate in the largest number of PMPT patients in the literature to date. This study aims to evaluate capsular contracture rates following PMPT and assess the relationship between CC and patient demographics and treatment characteristics.
Methods: An IRB approved retrospective study was conducted on breast cancer patients who underwent two stage tissue expander/implant (TE/I) or direct-to-implant (DTI) breast reconstruction and received PMPT between January 2018 and January 2023 at the Miami Cancer Institute, Baptist Health South Florida. Descriptive statistics were used to analyze patient demographics and treatment characteristics. Binary logistic regression was employed to assess the impact of patient and treatment factors on CC development. The Kaplan-Meier method was utilized to evaluate time to CC development.
Results: The study cohort comprised 89 patients with 89 reconstructed breasts. The median age was 50 years (24-78). Patient characteristics included 67.4% Hispanic, 10.1% African American, and 68.5% left sided breast cancer. 56.2% underwent total mastectomy, 32.6% had nipple sparing mastectomy, and 11.2% had skin sparing mastectomy. 59.5% of patients had TE at time of PMPT and 40.5% had permanent implant. Tumor characteristics were 89.9% invasive ductal carcinoma, 64% hormone receptor (HR) positive HER2 negative, 15.7% HR positive HER2 positive, 11.2% HR negative HER2 positive, and 9% triple negative. The majority of patients (88.8%) received 50.4 Gy/28 fractions of PMPT (45-56 Gy/25-28 fractions), and 62.9% received neoadjuvant chemotherapy. CC was observed in 51.7% of patients (46 patients), with a mean time to development of 15 months (0.4-152) post-PMPT. Of these 46 patients, 34 underwent surgical intervention, although all were advised to do so. Acute toxicity was observed in 81% of patients, with 62.9% developed grade 2 dermatitis and 5.6% developed grade 3 dermatitis. Logistic regression analysis revealed that DTI significantly increased CC rates compared to TE (OR 3.5, 95% confidence interval 1.4-8.5, p=0.007). No other patient factors were significantly associated with CC development. The mean follow-up was 36 months. At the time of last follow-up, 95.5% of patients were alive and 3.7% have experienced locoregional tumor recurrence.
Conclusion: This study demonstrates that breast cancer patients who underwent TE or DTI and received PMPT had an increased risk of CC when compared with photons in the existing literature (50% vs 20%). DTI was associated with a significantly higher risk of CC compared to TE. In the context of PMPT, careful consideration of breast reconstruction modalities and patient discussion is crucial with regard to complication rates. We plan to perform a matched case control study to compare proton vs photon PMRT to further elucidate the CC rate difference. We expect prospective clinical trials to illustrate the increased risk of CC.

PS6-04: Eliminating breast surgery for invasive, hormone-positive breast cancers with an exceptional response to endocrine therapy and ablative radiotherapy: a single-arm, phase 2 trial

Simona Shaitelman, Savitri Krishnamurthy, Gaiane M. Rauch, Yu Shen, PhD, Yan H. Lin, Benjamin D. Smith, Melissa P. Mitchell, Karen E. Hoffman, Chelain R. Goodman, Vicente Valero, Helen M. Johnson, Wendy A. Woodward, Henry Kuerer,

Objective(s): To define pathologic response rates to endocrine therapy and ablative radiotherapy, with omission of breast surgery, for early-stage, hormone receptor (HR)+ breast cancer in a prospective, phase II trial (NCT02945579). Methods: Twenty eligible patients with HR+, HER2-, clinical stage I, unicentric, non-lobular breast cancers with no lymphovascular space invasion, Oncotype ≤25 and age ≥50 were accrued to an IRB approved-protocol. Enrolled patients received three months of endocrine therapy followed by restaging ultrasound and ablative radiotherapy, 37.5Gy/5 fractions every other day. MR LINAC was used when feasible. After radiotherapy, patients continued on endocrine therapy and underwent percutaneous vacuum-assisted, image-guided core biopsy (VAIGCB) of the tumor 6-12 months following radiation, with a minimum of 12 9G cores. Near complete response (nCR) was defined as Miller-Payne 4 and pCR as 5. Patients with a pathologic complete response (pCR) were followed every 6 months with imaging; those without a pCR were recommended for standard-of-care surgery. Miller-Payne score was evaluated on core biopsy and surgical specimens. Co-primary endpoints are pCR on VAIGCB and tumor control at 3 years. We report here the former co-primary endpoint of pCR along with the 95% credible interval (CI). Results: 19 of 20 (95%) of patients underwent VAIGCB; 1 declined and elected continued observation. Of the 19 biopsies, 10 (52.6%) demonstrated pCR (Miller-Payne 5), 7 (36.8%) nCR (Miller-Payne 4) and 2 (10.5%) Miller-Payne 3. Of patients who had a VAIGCB 6 months after radiotherapy, 5/11 (45.4%, 95% CI 18.9%-71.5%) had pCR; of those with VAIGCB 12 months after RT, 5/8 (62.5%, 95% CI 27.4%-86.6%) had pCR. 7/9 patients with residual disease (Miller-Payne <5) underwent surgery, one of whom had pCR in the surgical specimen, consistent with complete removal at VAIGCB. There were no postoperative complications. Two patients with nCR declined surgery: one underwent cryoablation and one continued endocrine therapy and underwent repeat biopsy 4 months later with pCR. In total, 17/19 pts who underwent VAIGCB (89.5%) had pCR or nCR. The 1 patient who declined VAIGCB has no residual disease on imaging 2 years after RT. Median follow-up time for all patients who did not have surgery is 26 (range 18 to 38 mo months), with none (0/12) experiencing progression or recurrence. Conclusion: This is the first study to demonstrate a high rate of VAIGCB pCR and nCR following endocrine therapy and ablative radiotherapy for early stage, HR+, HER2- breast cancers. This may be an appealing approach for patients with breast cancer interested in non-surgical approaches to definitively treat their tumors and highlights the efficacy for non-surgical candidates.

PS6-05: First report of clinicopathologic characteristics and surgical outcomes of patients in the Avoid axillary Sentinel Lymph node biopsy After Neoadjuvant chemotherapy (ASLAN) trial (KBCSG-28)

Han-Byoel Lee, Jai Min Ryu, Ji-Jung Jung, Wonshik Han, Sung Gwe Ahn, Hee Jeong Kim, Hyung Seok Park, Ji Soo Choi, Haeyoung Kim, Won Kyung Cho, Jeong Eon Lee,

Background: With advances in neoadjuvant systemic therapy (NST), response to treatment and pathologic complete response (pCR) rates have increased considerably, producing de-escalation of surgery strategies. Multiple trials are ongoing to demonstrate the oncologic safety of omitting breast or axillary surgery. The ASLAN trial (NCT04993625) is a prospective, multicenter, single-arm non-inferiority trial with a target accrual of 178 patients that aims to demonstrate the oncologic safety of omitting axillary surgery in patients with a pathologic complete response in the breast after NST for cT1-3, cN0-1 triple-negative, human epidermal growth factor 2 (HER2)-positive, or low-estrogen receptor (ER) breast cancer. Patients with excellent response to NST on physical examination and radiologic imaging (≤2cm mass on mammogram, breast ultrasound, and MRI or ≤4cm non-mass enhancement on MRI) who are planning to undergo breast-conserving surgery (BCS) were screened for eligibility. After BCS without axillary surgery, patients with a pCR defined as no residual invasive cancer were enrolled in the trial and avoided axillary surgery. Those with residual invasive cancer received additional sentinel lymph node biopsy (SLNB) and/or axillary lymph node dissection (ALND) and were registered into a prospective registry. We aimed to investigate the clinicopathologic characteristics and surgical outcomes of the patients in the ASLAN trial.
Methods: The ASLAN trial screened 254 patients who met the inclusion criteria from September 2021 to December 2023. A total of 245 patients who received BCS were included for analysis. Clinicopathologic variables, including the pCR status of the breast and axillary lymph nodes (LNs), were analyzed.
Results: Most patients had cT2 (217/245, 88.6%) and cN0 (189/245, 77.1%) disease before NST. Among 56 (22.9%) cN1 patients, a fine-needle aspiration was performed on the suspicious LNs in 37 (66.1%) and 24 (42.9%) had LN metastasis. 130 (53.1%) were TNBC, 113 (46.1%) were HER2-positive, and 2 (0.8%) were low-ER. After BCS, a breast pCR was confirmed in 182 (74.3%) patients, two of whom were dropped from enrollment due to refusal of radiation therapy or lost to follow-up resulting in 180 patients with ongoing follow-up. Among 63 (25.7%) patients with a breast non-pCR, SLNB only was performed in 60, SLNB followed by ALND in one, and no axillary surgery in two (patients refused). 95.1% (58/61) of patients who received axillary surgery had no LN metastasis, and two had micrometastasis in one LN. Patients with a non-pCR had more ER-positive disease (p=0.002), lower Ki67 (p=0.025), larger post-NST size on ultrasound (p=0.006), and no difference in the proportion of cN1 patients (p=0.824).
Conclusion: The ASLAN trial completed screening of 245 patients by performing BCS of the breast and enrolled 182 patients who were confirmed to have a pCR on BCS and were omitted axillary surgery. Axillary surgery on cN0-1 patients with excellent radiologic response to NST had LN metastasis in less than 5%. This trial will be the first prospective

trial to determine the oncologic safety of avoiding axillary surgery in exceptional responders to NST. Data lock is expected in December 2028.

PS6-06:Upstage of N-Stage by Diagnostic Axillary Lymph Node Dissection in Patients w/ Isolated Tumor Cells or Micrometastases in Sentinel/Target Lymph Node after Neoadjuvant Chemotherapy - Results from the Prospective Multicenter AXSANA / EUBREAST 3 Study

Thorsten Kuehn, Maggie Banys-Paluchowski, Nina Ditsch, Elmar Stickeler, Oreste David Gentilini, Jana de Boniface, Michael Hauptman, ldeniz Karadeniz , Markus Hahn, Marc Thill, Rosa Di Micco, Toralf Reimer, Sarah Frohlich, Esther Schmidt, Kristina Wihlfahrt, Tomasz Berger, Timo Basali, Franzsika Ruf, Angelika Rief, Michael Patrick Lux, Hans-Christian Kolberg, Isabel Rubio Rodriguez, Maria Luisa Gasparri, Michaelis Kontos, Eduard-Alexandru Bonci, Laura Niinikoski, Dawid Muraw, David Pinto, Florentina Peintinger , Ellen Schlichting , Nina Heldion, Hagigat Valiyeva Qanimat, Marian Vanhoeji, Pamela Rebaza, Bilge Aktas Sezen, Katharina Jursik, Geeta Kadayaprath, Lukas Dostalek, Ashutosh Kothari, Andraz Perhavec, Tsvetomir Ivanov, Douglas Zippel, Sarun Thongvitokomarn , Meryem Gunay Gurleyik, Annette Lebeau, Steffi Hartmann

Introduction: The role of completion axillary lymph node dissection (cALND) in patients with low volume residual disease in the sentinel (SLN) or target lymph node (TLN) after neoadjuvant chemotherapy (NACT) is a matter of controversial debate. While increasing evidence suggests no therapeutic benefit from cALND, additional lymph node surgery is also performed for diagnostic purposes to identify patients for post-neoadjuvant systemic treatment or regional radiotherapy.
Material and Methods: We analyzed the conversion rate of patients with isolated tumor cells (ITCs) or micrometastases in the SLN or TLN to a higher nodal (N)-stage by cALND from the prospective multicenter AXSANA trial (NCT04373655), which compares different axillary surgical staging procedures (ALND, SLN biopsy (SLNB) and targeted axillary dissection (TAD)) after NACT in patients with initially positive axillary lymph nodes.
Results: 5,328 patients from 291 study sites in 26 countries were included in the AXSANA study between June 2020 and March 3rd, 2024. Of these, 2,193 had completed surgery including SLNB or TAD at the time of analysis. All datasets were monitored. 51 out of 2,193 patients (2.3%) were ypN0(i+)(sln/tln) stage and 153 out of 2,193 (7.0%) were ypN1(mi)(sln/tln). cALND was performed in 16/51 patients (31.4 %) with isolated tumor cells (ITC) and 71/153 (46.4 %) women with micrometastases in the SLN or TLN.
Among 16 patients with a ypN0(i+)(sn/tln) stage who underwent cALND, 3 (18.8 %) had further non-SLN/TLN involvement including 2 with additional ITCs and 1 with macrometastatic lymph node involvement. 8 out of 16 patients (50%) achieved complete response in the breast (breast-pCR). The only macrometastasis was found in a patient with a non-pCR in the breast. Overall, 1 out of 16 patients with ypN0(i+)(sln/tln) stage was upgraded to ypN1 (6.25 %) by cALND. Among patients with a breast-pCR, no patients' N-stage increased to a higher stage.

Among 71 patients with a ypN1(mi)(sln/tln) stage who underwent cALND, 28 women (39.4 %) had further non-SLN/TLN involvement, 1 (1.4 %) had additional ITCs, 17 micrometastatic (23.9 %) and 10 (14.1 %) macrometastatic non-SLN/TLN disease. 18 out of 71 patients in this subgroup (25.4 %) achieved breast-pCR. Of these, 7 patients had additional micro- and 1 patient macrometastatic non-SLN/TLN involvement (38.9 % and 5.6 % respectively). One patient converted to a ypN1-stage (5.6 %) and no patient to a ypN2/3-stage. Among 53 patients without breast-pCR, 10 women had further micrometastatic and 9 patients additional macrometastatic involvement (18.9 % and 17.0 %). Overall, 9 out of 53 patients (17 %) with a ypN1(mi)(sln/tln)-status and non-pCR in the breast were upgraded to a higher ypN-stage (3 to ypN1, 5 to ypN2, and 1 to ypN3) (22.6 %, 15.1 %, and 1.9 %, respectively).
Conclusion: An upgrade of nodal stage in ypN0(i+)(sln/tln) patients is a rare event. cALND for diagnostic purposes is not justified in this group and should be discouraged, especially in patients with a breast-pCR.
Also for patients with a ypN1(mi)(sln/tln)-stage, an upgrade to a higher N-stage is also rare if breast-pCR is achieved. In patients with non-pCR in the breast, cALND is associated with a higher risk for an upgrade of the nodal stage, so that diagnostic cALND may be indicated in selected patients with potential therapeutic implications. Provided that further research confirms no therapeutic benefit from cALND, additional axillary surgery for diagnostic purposes can be omitted in most patients with initially positive lymph nodes and a low tumor burden in the SLN or TLN after NACT.

PS6-07: Clinical and patient reported outcomes in women offered oncoplastic breast conserving surgery as an alternative to mastectomy: 12-month results of the UK ANTHEM multicentre prospective cohort study

Shelley Potter, Charlotte Davies, Leigh Johnson, Carmel Conefrey, Nicola Mills, Patricia Fairbrother, Chris Holcombe, Lisa Whisker, William Hollingworth, Joanna Skillman, Paul White, Douglas MacMillan, Charles Comins

Background: Oncoplastic breast conserving surgery (OPBCS) may be a better option than mastectomy for many women, but high-quality comparative evidence is lacking. The UK ANTHEM study (ISRCTN18238549) aimed to explore the clinical and patient-reported outcomes (PROs) in a multicentre cohort of women offered OPBCS as an alternative to mastectomy +/- immediate breast reconstruction (IBR).
Methods: Women aged >18 with invasive breast cancer or DCIS who were offered OPBCS with either volume displacement (therapeutic mammaplasty, TM) or replacement (chest wall perforator flap, CWPF) techniques to avoid mastectomy were recruited prospectively. Demographic, operative, oncological and 3- and 12-month (m) complication data were collected. The rate of successful breast conservation and the numbers of additional procedures required to achieve clear margins were explored.
Participants completed the validated BREAST-Q at baseline, 3 and 12m post-operatively. Questionnaires were scored according to the developers' instructions and scores compared

across timepoints in each group.
Results: 362 women from 32 UK breast units participated in the study. Of these 294 (81.2%) had OPBCS as their first procedure with the remainder opting for mastectomy with (n=35) or without (n=33) IBR. Women undergoing IBR were significantly younger (p=0.005) with bilateral surgery performed more frequently in the TM and IBR groups (TM n=81, 38.0%; IBR n=9, 25.7% p<0.001).
Of the 255/294 patients opting for OPBCS in whom post-operative margin status was reported, 210/255 (82.4%) had clear margins following their initial operation. Of the remainder, 28 (62.2%) patients achieved clear margins after one additional procedure and 20% (n=10) with two or more additional operations. The overall rate of successful BCS was 95.7% with only 10 women (3.9%) having completion mastectomy +/- IBR. No differences were seen in the final histology, recommendation for adjuvant chemotherapy or time to receipt of adjuvant treatment between the groups. Radiotherapy was more frequently recommended after OPBCS (256/284, 90.1% vs 39/78, 50.0%, p<0.001).
A total of 96 (26.5%) women experienced a post-operative complication at 3 months of whom 22 (6.1%) had a major complication requiring readmission or re-operation. No difference in total complications was observed between groups, but major complications were higher after IBR (IBR=22, (25.0%), OPBCS n=12 (4.9%), mastectomy only n=0, IBR=22, p<0.001).
At least one BREAST-Q scale was completed by 329 (90.9%), 279 (77.1%) and 273 (75.4%) participants at baseline, 3m and 12m respectively. There were clinically meaningful and statistically significant increases in both the 'Satisfaction with Breasts' and 'Psychosocial Well-being' scores from baseline to 3m that were sustained at 12m in the TM group whereas 'Satisfaction with Breasts' decreased from baseline to 3m in the mastectomy only group with no improvement at 12m. Both OPBCS groups reported significant decreases in 'Physical Well-being-Chest' scores from baseline to 3m with further decreases in scores between 3 and 12m in the CWPF group. No other significant changes in any other BREAST-Q scale were seen in any patient group over the study period.
Conclusions: OPBCS successfully allowed over 95% of women to avoid mastectomy with lower major complication rates than IBR and improved patient-reported outcomes, especially in women having therapeutic mammaplasty. OPBCS should be offered as an alternative to mastectomy in all women in whom it is technically feasible.

PS6-08: Quality of life following total mastectomy, breast-conserving surgery, and immediate breast reconstruction in patients with breast cancer: A multicenter cross-sectional study

Hirohito Seki, Maho Kato, Takako Komiya, Nobuko Tamura, Yoshihiro Sowa, Hirotsugu Isaka, Yutaka Nishida, Jyunji Takano, Miho Saiga

Background: The development of various treatment modalities has led to improved prognosis for patients with breast cancer. The diversity of individual values and lifestyles must be considered when deciding on a surgical approach. However, there is a paucity of reports assessing postoperative health-related quality of life (HR-QOL) in these populations from multiple perspectives. Therefore, this study aimed to identify differences in the HR-QOL and the impact on postoperative life for each surgical procedure using patient-reported outcomes in Japanese patients with breast cancer.
Patients and Methods: This multi-institutional cross-sectional study included patients with primary breast cancer who underwent total mastectomy (MT), breast-conserving surgery (BCS), or immediate breast reconstruction (IBR) between August 2013 and July 2021. Data were collected using a questionnaire administered postoperatively between October 2022 and March 2024 to patients who provided consent. BREAST-Q was administered to investigate postoperative HR-QOL and satisfaction. An ad-hoc questionnaire was used to investigate the effects on postoperative life. The BREAST-Q scores and impacts of the three surgical procedures on postoperative life were compared. One-way ANOVA was used to compare the differences in BREAST-Q scores among these groups. Multiple regression analysis was performed to evaluate the relationship between BREAST-Q scores, clinical factors, and social backgrounds. The differences in the impact on postoperative life among these groups were compared using the chi-square test.
Results: The questionnaire response rate was 90.2% (577/640). The analysis included 194 patients with MT, 185 with BCS, and 194 with IBR, with mean ages of 58.1, 54.8, and 48.2 years, respectively ($p < 0.001$). The rates of clinical tumor size (T) ≥ 3 ($p < 0.001$), clinical nodal stage (N) ($p = 0.003$), axillary lymph node dissection ($p < 0.001$), and adjuvant chemotherapy ($p < 0.001$) were significantly higher in the MT group than in the BCS and IBR groups. Additionally, the frequency of Grade ≥ 3 complications was significantly higher in the IBR group than in the MT and BCS groups ($p < 0.001$). Of the 198 patients in the IBR group, implant reconstruction was performed in 72.2% of patients, nipple-sparing mastectomy in 39.9%, and one-stage reconstruction in 21.7%. Significant differences were observed in satisfaction with the breasts (SB), psychosocial well-being (PSW), and sexual well-being (SW) using the BREAST-Q among the groups. The SB scores for the MT, BCS, and IBR groups were 46.7, 66.7, and 60.5, respectively ($p < 0.001$). The PSW scores were 53.3 (MT), 62.9 (BCS), and 61.5 (IBR) ($p < 0.001$). The SW scores were 31.6 (MT), 44.5 (BCS), and 41.3 (IBR) ($p < 0.001$). Multiple regression analysis indicated that procedures (SB: MT vs. BCS or IBR, $p < 0.001$; PSW: MT vs. BCS, $p = 0.001$; MT vs. IBR, $p = 0.027$; SW: MT vs. BCS, $p = 0.005$; MT vs. IBR, $p = 0.041$) and age (SB, $p = 0.006$; PSW, $p < 0.001$; SW, $p = 0.016$) were significant factors affecting the patients' quality of life. When comparing the impact on postoperative life between procedures, the proportion of women who did not experience any negative impact on their postoperative lives was the highest in the BCS group ($p < 0.001$), whereas the proportion of women who developed clothing issues was the highest in the MT group.
Conclusions: Surgical procedure and age may have significant impacts on postoperative HR-QOL in women with breast cancer. Women with breast cancer who underwent BCS or IBR

had a significantly high aesthetic breast satisfaction and psychosocial and sexual well-being. Postoperative life was significantly less affected in patients who underwent BCS.

PS7-01: Efficacy of RLY-2608, a mutant-selective PI3Kα inhibitor in patients with PIK3CA-mutant HR+HER2- advanced breast cancer: ReDiscover trial

Cristina Saura, Sarah L. Sammons, Milana Bergamino, Anne Schott, Antoine Italiano, Kari B. Wisinski, Pablo Tolosa, Lucia Sanz Gomez, Antonio Marra, Steven J. Isakoff, Komal Jhaveri, Veronique Debien, Angel I. Guerrero Zotano, Rita Nanda, Jordi Rodon Ahnert, Jennifer Segar, Alexander I. Spira, Santiago Ponce-Aix, Alison M. Schram, Jason T. Henry, Cesar A. Perez, Victor Moreno, Erika P. Hamilton, Julia E. McGuinness, Erika Puente-Poushnejad, Ashley M. Wagner, Jinshan Shen, Gege Tan, Florence (Tianhui) Ramirez, Alison Timm, Eunice L. Kwak, Beni B. Wolf, Andreas Varkaris, Giuseppe Curigliano

Background Oncogenic PIK3CA mutations constitutively activate PI3Kα and drive approximately 40% of HR+HER2- breast cancer (BC); however, the toxicity (hyperglycemia, rash, diarrhea, stomatitis) of non-selective inhibitors (i) limits their tolerability and efficacy. RLY-2608 is the first oral, mutantselective, allosteric PI3Kαi designed to overcome these limitations. We report efficacy and safety of RLY-2608 + standard-dose fulvestrant (F) in pts with PIK3CA-mutant, HR+HER2- BC treated in the FIH study, ReDiscover (NCT05216432). Methods Previously treated adult pts with advanced HR+HER2- BC and PIK3CA mutation per local assessment were eligible. Key objectives were investigator-assessed efficacy per RECIST 1.1 and adverse events (AEs) per CTCAE v5.0. Safety was assessed in all pts, and efficacy in pts without detectable PTEN/AKT co-alterations treated at the RP2D. Results As of 24JUN24, 116 pts received RLY-2608 (100-1000 mg BID) + F. All pts received prior endocrine therapy and CDK4/6i with 51% having 2 prior systemic therapies for advanced disease including 57% with prior F/SERD and 22% with prior chemotherapy or antibody-drug conjugate. Treatment-related AEs (TRAEs) were generally low-grade, manageable and reversible, most commonly hyperglycemia (42% any grade; 2% Gr 3), nausea (40%; 1% Gr 3), creatinine increased (34%; 0 Gr 3), fatigue (32%; 7% Gr 3), and diarrhea (28%; 1% Gr 3). There were no grade 4/5 TRAEs. Sixty-two pts (30 kinase, 24 helical, 8 other) were treated at the 600 mg BID RP2D which provided exposure in the target therapeutic range and rapid decline in mutant PIK3CA ctDNA. Treatment was ongoing in 34/62 (55%) and discontinued in 28 (22 due to PD and 2 due to TRAE). Of 52 pts without PTEN/AKT alterations, mPFS was 9.2 months (95% CI 5.5-12.4), 18/26 (69.2%) evaluable for response had radiographic tumor reduction and 8 achieved an objective response (30.8%, 95% CI 14.3-51.8) with median time-to-response 8 weeks. Conclusion RLY-2608 demonstrates durable initial efficacy and favorable safety/tolerability across PIK3CA genotypes in heavily pretreated pts previously exposed to CDK4/6i with advanced PIK3CA-mutant HR+HER2- BC without concurrent PTEN/AKT alterations. These data validate RLY-2608 as the first allosteric pan-mutant selective PI3Kαi and warrant pivotal clinical development.

PS7-02: First-in-human results of STX-478, a mutant-selective PI3K alpha inhibitor, in HR+ breast cancer and advanced solid tumor patients

Dejan Juric, Antonio Giordano, Komal Jhaveri, Pamela Munster, Jordi Rodón Ahnert, Patricia LoRusso, Douglas Orr, Jorge Bartolomé, Antoine Italiano, Gennaro Daniele, Maria de Miguel, Anthony Elias, Aixa Soyano, Robert Wesolowski, Bernard Doger, Joyce O'Shaughnessy, Timothy Pluard, Tatiana Hernández, Cristina Saura, Stefani Corsi-Travali, Courtney Ewert, Ming Lin, Fiona Xu, Simon Roberts, Bill Bradley, Dave St. Jean, Leonard Buckbinder, Mark Chao, Alberto J. Montero

Background: PI3Kα is commonly mutated in cancer, most frequently in breast and gynecologic cancers. PI3Kα inhibitors have shown clinical benefit in hormone receptor positive (HR+), HER2- breast cancer (BC) in Phase 3 studies, but are limited by toxicities from wild-type (WT) PI3Kα inhibition. STX-478 is an oral, allosteric, CNS-penetrant, mutant-selective PI3Kα inhibitor designed to improve efficacy while sparing WT toxicities. Preclinically, STX-478 alone and in combination with fulvestrant and CDK4/6 inhibitors led to deep and sustained tumor regression without causing metabolic abnormalities in both PIK3CA kinase and helical domain mutant BC xenografts. Here, we report the initial Phase 1 trial results of STX-478 monotherapy in BC and other solid tumors.

Methods: This first-in-human, Ph1/2 study is evaluating STX-478 alone or in combination with fulvestrant and fulvestrant + CDK4/6 inhibitors in patients with advanced PIK3CA-mutant solid tumors and/or HR+HER2- BC. Dose escalation occurred per 3+3 design followed by expansion. Patients were required to have a PIK3CA mutation, measurable disease and HbA1c less than 7%. Patients with pre-diabetes, or Type 2 diabetes controlled on medications (including insulin) and those intolerant to PI3K pathway inhibitors were permitted.

Results: As of June 21st, 2024, 61 patients (29 HR+/HER2- BC, 32 other solid tumors) were treated at STX-478 monotherapy doses of 20 mg to 160 mg daily. In patients with HR+/HER2- BC, median age was 64 (range 37-81) and median prior lines of therapy in the metastatic setting was 3 (range 1-7). All patients received prior endocrine therapy, 97% received a prior CDK4/6 inhibitor and 66% received at least one line of chemotherapy. Additionally, 48% of patients were pre-diabetic/diabetic and 41% had a prior PI3K pathway inhibitor. STX-478 was well-tolerated with a MTD of 100 mg daily. For all 61 patients (all tumor types), treatment-related adverse events (AEs) of 15% or higher and AEs of interest included fatigue (30%), hyperglycemia (23%), nausea (20%), diarrhea (15%), rash (10%) and neutropenia (0%). PI3Ka WT AEs (hyperglycemia, diarrhea, and rash) were all grade 1/2. No patient discontinued due to an AE. STX-478 exposure was dose proportional up to the MTD and reached steady state by day 15. At doses of 40 mg and higher, STX-478 achieved target coverage several fold higher than other PI3Ka inhibitors. In 22 HR+/HER2- BC patients with measurable disease, the confirmed/unconfirmed ORR was 23% with 68% of patients exhibiting radiographic tumor reductions. Objective responses were seen in both kinase and helical domain mutant tumors. Multiple responses deepened over time on therapy, including one patient with durable PR on therapy for over one

year. Responses have been observed in patients with other solid tumors with a similar ORR (19%) to that in patients with HR+/HER2- BC. PIK3CA-mutant variant allele frequency, as measured by ctDNA, markedly decreased on therapy in the majority of assessed patients. Conclusions: In heavily pre-treated patients, STX-478 was well tolerated, with infrequent Grade 1/2 PI3Ka WT-associated toxicities in a high-risk patient population including diabetic patients and those intolerant to PI3K pathway inhibitors. STX-478 was active in HR+ BC and other solid tumors, with a monotherapy ORR generally exceeding historical comparisons to other PI3K inhibitors. Efficacy was observed in both PIK3CA kinase and helical domain mutations, which comprise of 80-90% of all PI3Ka mutations. These data support STX-478 as a potential best-in-class mutant selective PI3Ka inhibitor. Enrollment is ongoing with combination cohorts with STX-478 + fulvestrant and STX-478 + fulvestrant + CDK4/6 inhibitors.

PS7-03: A first-in-human phase 1a/b trial of LOXO-783, a potent, highly mutant-selective, brain-penetrant, allosteric PI3Kα H1047R inhibitor in PIK3CA H1047R-mutant advanced breast cancer and other solid tumors: Results from the PIKASSO-01 study

Komal Jhaveri, Takako Eguchi Nakajima, Antonio Giordano, Dejan Juric, Cynthia Ma, Nisha Unni, Matthew P. Goetz, Shigehisa Kitano, Sherene Loi, Hope Rugo, François-Clément Bidard, Cristina Saura, Elgene Lim, Patrick Neven, Joyce O'Shaughnessy, Manali Bhave, Tira J. Tan, Philippe L. Bedard, Hélène Vanacker, Ruth O'Regan, Nick C. Turner, Javier Cortes, Stephen Chia, Mario Campone, Vincent Chau, Matthew P. Hanley, Lin Du, Aurelie Lombard, Monica Ramstetter, Shawn Estrem, Funda Meric-Bernstam.

Background: Phosphoinositide 3-kinase alpha (PI3Kα) H1047R mutations occur in ~15% of breast cancers (BC). Approved treatments for PI3Kα mutant-driven BC include inhibitors of the PI3K/AKT pathway; these block signaling from mutant PI3Kα but also inhibit wild-type PI3Kα leading to dose-limiting toxicities (DLTs) that include hyperglycemia, rash, and GI side effects. Thus, there is a need for novel PI3Kα inhibitors with improved therapeutic indices. LOXO-783 is an oral, brain-penetrant allosteric PI3Kα inhibitor, highly selective for H1047R that induces tumor regressions in ER+, HER2- PI3Kα H1047R-mutant BC models without increasing plasma insulin or C-peptide. Here we present clinical data from PIKASSO-01, a global, first-in-human phase 1a/b trial of LOXO-783 as monotherapy and in combination with other anticancer therapies in patients (pts) with PIK3CA H1047R-mutant advanced BC (aBC) and other solid tumors (NCT05307705).
Methods: Phase 1a (ph1a) evaluated LOXO-783 dose escalation (mTPI-2 design) in pts with PIK3CA H1047R-mutant solid tumors (excluding colorectal cancers). Phase 1b (ph1b) included the evaluation of LOXO-783 plus (+) endocrine therapy (ET: fulvestrant [F] / aromatase inhibitor [AI]), or LOXO-783 + paclitaxel (P) in PI3Ki-naïve/intolerant pts with PIK3CA H1047R aBC. Key objectives included safety, tolerability, PK, and antitumor activity (objective response rate, ORR and clinical benefit rate, CBR per RECIST v1.1). Serial plasma samples were collected for ctDNA analysis and glucose metabolism markers.

Results: As of 14 June 2024, 149 pts were enrolled: 43 pts (35 aBC [30 HR+ HER2-, 5 TNBC], 8 other solid tumors) into ph1a and 106 pts with aBC (90 HR+ HER2-, 16 TNBC) into ph1b. Median age was 58 years. In ph1a, pts received monotherapy doses from 200 – 600 mg BID or 500 – 600 mg QD. Median prior regimens was 3 (1-5) including prior PI3K/AKT/mTORi (28%). DLTs occurred in 4 pts, 1 each at: 500 mg QD (grade [G] 3 fatigue), 600 mg QD (G3 ALT, AST, and G1 bilirubin elevation), 400 mg BID (G3 sepsis and enterocolitis), and 600 mg BID (G2 photosensitivity). In ph1b, pts received LOXO-783 (200 – 400 mg BID or 300 – 600 mg QD) in doublet therapy: + ET (n=86; 6 + AI; 80 + F) or + P (n=20). Median prior regimens for aBC was 2 (1-7).
Across all treated pts in the monotherapy or doublet therapy cohorts, diarrhea was frequently observed (84% any grade [G], 7% G ≥3) and was more common/severe (G ≥3) at higher doses (≥400 mg QD and BID dosing). Overall, 37% of pts who experienced diarrhea required a dose modification. Other frequent (any G/G ≥3) treatment-emergent AEs with LOXO-783 +/- ET included fatigue (32%/2%) and nausea (31%/2%); + P included neutrophil decreased (65%/45%), anemia (40%/20%), fatigue (35%/0%), and WBC decreased (30%/25%). Treatment-related AEs led to discontinuation of any study treatment in 4% and 10% of pts who received LOXO-783 +/- ET and + P respectively. No treatment-related hyperglycemia was observed.
Preliminary PK analyses showed dose-dependent and time-dependent nonlinear increases in LOXO-783 exposure across all doses (reaching H1047R IC90 from 200 mg BID + ET); tmax ~2 h and half-life ~19 h; and no combination drug-drug interactions.
Minimal activity was observed with LOXO-783 monotherapy (ORR/CBR in evaluable pts: 3%/17% [n=29]). In doublet therapy cohorts, ORR/CBR was 5%/19% + ET (n=77) and 19%/25% + P (n=16). Most (80%; 85/106) evaluable pts had a decrease (any) in PIK3CA H1047R variant allele frequency at C1D15 compared to baseline.
Conclusions: LOXO-783 demonstrated proof of concept of mutant selectivity by entirely sparing hyperglycemia in the clinic, but exhibited high rates of diarrhea, limiting ability to achieve the optimal preclinical dose of LOXO-783.

PS7-04: BBO-10203, a first-in-class, orally bioavailable, selective blocker of the PI3Kα:RAS interaction inhibits tumor growth alone and in combination with standard of care therapies in breast cancer models without inducing hyperglycemia

Kerstin Sinkevicius,): James Stice, Erin Riegler, Siyu Feng, Cathy Zhang, Daniel J. Czyzyk, John-Paul Denson, Yue Yang, Sofia Donovan, Ming Chen, Cindy Feng, Brian P. Smith, Lijuan Fu, Ken Lin, Felice C. Lightstone, Anna E. Maciag, Keshi Wang, Dwight V. Nissley, Dhirendra K. Simanshu, Eli M. Wallace, Rui Xu, Frank McCormick, Pedro J. Beltran

Aberrant activation of the PI3Kα pathway is one of the most frequent oncogenic events across human cancers and leads to promotion of tumor cell growth, survival, glucose metabolism, and acute resistance to numerous standard of care cancer therapies. While small molecule inhibitors of the kinase activity of PI3Kα have been approved for the

treatment of HR+ HER2- breast cancer patients with PI3Kα mutations, a large medical need remains to increase their safety profile due to dose-limiting on-target hyperglycemia. This toxicity may limit target coverage, the number of eligible patients, and the duration of treatment which could result in suboptimal efficacy. An alternative novel strategy is to block RAS-mediated activation of PI3Kα, a signaling event prevalent mostly in malignant cells. Previous elegant preclinical studies have established that RAS activation of PI3Kα is important in tumor cells but may not be involved in normal cell types controlling glucose metabolism because insulin activation of PI3Kα does not depend on RAS. Here, we report on a novel first-in-class covalent small molecule designed to block the PI3Kα:RAS protein-protein interaction and inhibit RAS-mediated activation of the AKT pathway via PI3Kα without the resultant hyperglycemia associated with direct inhibition of PI3Kα kinase activity. BBO-10203 covalently and selectively binds PI3Kα on cysteine 242 in the RAS binding domain, which prevents the interaction of PI3Kα with KRAS, HRAS, and NRAS. BBO-10203 shows potent cellular target engagement with an IC50 of 1.4 nM and full target engagement achieved at 10 nM in ER+ HER2amp breast cancer BT-474 cells, which harbor a PIK3CAK111N mutation. BBO-10203 potently inhibits phosphorylated AKT (pAKT) across a diverse panel of 18 human breast cancer cell lines with amplification of HER2 or mutations in PI3Kα with a mean EC50 of 3.2 nM. Transcriptional and post-translational cellular changes driven by treatment with BBO-10203 are consistent with PI3Kα-specific inhibition. BBO-10203 displays excellent drug-like properties and oral bioavailability. Single dose treatment of BT-474 tumor bearing mice with increasing doses (10 to 100 mg/kg) of BBO-10203 results in dose and time dependent inhibition of pAKT. In the BT-474 xenograft model, BBO-10203 daily oral dosing of 100 mg/kg results in 88% tumor growth inhibition. Importantly, BBO-10203 does not induce hyperglycemia or hyperinsulinemia during an oral glucose tolerance test in fasted male C57BL/6 mice, demonstrating independence of insulin receptor signaling from RAS. Since activation of AKT provides acute resistance to multiple cancer therapies, BBO-10203 has the potential to enhance the long-term responses in combination with targeted and conventional anti-cancer agents in multiple settings. In vitro and in vivo studies show that BBO-10203 significantly enhances the anti-tumor activity of the HER2-targeted antibody trastuzumab in the BT-474 (ER+, HER2amp, and PIK3CAK111N) and MDA-MB-453 (ER-, HER2+, and PIK3CAH1047R) breast cancer models. In addition, BBO-10203 also significantly enhances the anti-tumor activity of the SERD fulvestrant or the CDK4/6 inhibitor palbociclib in the MCF7 (ER+, HER2-, and PIK3CAE545K) breast cancer model. All of these combinations induce tumor stasis or regression through direct effects on tumor cells and are well tolerated. In conclusion, BBO-10203 blocks RAS-mediated activation of PI3Kα and strongly inhibits pAKT signaling in tumor cells without affecting glucose metabolism. BBO-10203 has entered phase 1 clinical trials and may provide clinical benefit without the limiting toxicities that have restricted the use of PI3Kα inhibitors.

PS7-05: Impact of prior treatment, ESR1 mutational (ESR1m) landscape, and co-occurring PI3K pathway status on real-world (RW) elacestrant outcomes in patients (pts) with hormone receptor-positive (HR+)/HER2-negative advanced breast cancer (aBC)

Maxwell Lloyd, Azka Ali, Caroline M. Weipert, Sheila R. Solomon, Jayati Saha, Marla Lipsyc-Sharf, Erika P. Hamilton, Kevin Kalinsky, Adam Brufsky, Aditya Bardia, Nicole Zhang, Seth A. Wander

Background: Elacestrant is the first oral selective estrogen receptor degrader FDA-approved as endocrine therapy (ET) in pts with ESR1m HR+/HER2- aBC, based on results from the EMERALD trial which demonstrated improved progression free survival (PFS) compared to standard-of-care ET. Here, we used a large clinical-genomic database to assess RW use and the impact of prior treatment, the type/number of ESR1m, and co-occurring PI3K pathway alterations on pt outcomes.
Methods: Pts with HR+/HER2- aBC were identified via the GuardantINFORM database; pts with ESR1m detected on circulating tumor DNA (ctDNA) testing done within 6 months prior to elacestrant initiation and treated with elacestrant after FDA approval in January 2023 were included. Real-world time to treatment discontinuation (rwTTD) and time to next treatment (rwTTNT) were analyzed as proxies for PFS (measured in months). Pts were required to have >28 days of follow-up after the first elacestrant claim to be included in outcomes analysis. For rwTTD/rwTTND, non-adjusted Kaplan-Meier (KM) curves were generated with 95% confidence intervals (CI) and Cox-Regression hazard ratios (HR) adjusted for patient age, gender, year of ctDNA result and line of therapy were used. Oncogenic alterations in AKT1, PTEN, and PIK3CA were included as PI3K pathway alterations.
Results: A total of 1,015 aBC pts received elacestrant post-FDA approval, 772 of whom had a ctDNA test 6 months prior to treatment start, with a median age of 63 years. The most common ESR1m were D538G (69%), Y735S (51%), Y537N (20%), and E380Q (10%). 45% of pts had >1 ESR1m (2: 24%, 3: 10%, 4: 5%, 5+: 6%). Of 758 pts eligible for outcomes analysis, the overall rwTTD was 4.57 months (95% CI 4.03 - 5.4 months) and rwTTNT was 6.53 months (95% CI 5.60 - 8.10 months). There were no significant differences in rwTTD or rwTTNT based on specific ESR1m (D538G vs Y537S and Y537S vs other ESR1m), prior exposure to an aromatase inhibitor or fulvestrant (vs no prior exposure), or elacestrant line of therapy (2 vs 3 vs 4+). Pts with >4 ESR1m (but not 2-3 ESR1m) had significantly worse rwTTD compared to those with 1 ESR1m (3.73 mos vs 5.27 mos, p=0.01, HR 1.69; 95% CI 1.23 - 2.33); rwTTNT was numerically shorter but did not reach statistical significance (5.17 mos vs 7.67 mos, p=0.145, HR 1.47, 95% CI 1.03 - 2.11). Pts with oncogenic PI3K pathway alterations detected (210/758) had significantly worse rwTTD and rwTTNT compared to those without (rwTTD: 3.97 mos vs 5.27 mos, p<0.0001, HR 1.55, CI 95% 1.25-1.93; rwTTNT: 4.60 mos vs 7.57 mos, p=0.0003; HR 1.58, CI 95% 1.24-2.00).
Conclusions: Using a large clinical-genomic database, we demonstrate robust RW outcomes in a cohort of over 700 pts with ESR1m aBC treated with elacestrant. Pt treatment

outcomes, as measured via rwTTD and rwTTNT, exceeded the PFS reported in the EMERALD trial. This may be due to multiple factors impacting patient selection and restaging protocols, which can differ in prospective trials versus routine clinical care. Treatment outcomes did not significantly differ by specific ESR1m, prior ET exposure, or elacestrant line of therapy. Pts with >4 ESR1m had significantly worse rwTTD and numerically worse rwTTNT compared pts with 1 ESR1m, suggesting a possible relationship between complex ESR1m polyclonality and response to ET. Oncogenic PI3K pathway co-mutations had a negative prognostic impact on treatment duration. Given the availability of multiple targeted therapies for pts with aBC, including two drugs targeting the PI3K pathway, these results suggest that additional biomarker analysis may help elucidate optimal therapy selection, including combination therapy and drug sequencing, in the post-CDK4/6 inhibitor treatment landscape.

PS7-06: Elacestrant combinations in patients with estrogen receptor-positive (ER+), HER2-negative (HER2-) locally advanced or metastatic breast cancer (mBC): Update from ELEVATE, a phase 1b/2, open-label, umbrella study

Hope S. Rugo, Sara M. Tolaney, Nancy Chan, Erika Hamilton, Marina N. Sharifi, Kristine J. Rinn, Wassim McHayleh, Rinat Yerushalmi, Neelima Vidula, Joyce O'Shaughnessy, Giuseppe Curigliano, Javier Cortés, Paula Muñoz Romero, Bartomeu Piza Vallespir, Kathy Puyana Theall, Alessandro Paoli, Monica Binaschi, Tomer Wasserman, Virginia Kaklamani

Background: Endocrine therapy (ET) + CDK4/6i is the mainstay in 1L ER+/HER2- mBC; however, ET resistance develops. Intrinsic resistance mechanisms include PI3K/AKT/mTOR or cell cycle pathway alterations; acquired resistance mechanisms include ESR1-mut during ET in mBC. In EMERALD, single-agent elacestrant significantly improved PFS vs standard of care (SOC) ET (ESR1-mut tumors: HR = 0.55; 95% CI, 0.39-0.77; P = 0.0005; all patients: HR = 0.70; 95% CI, 0.55-0.88; P = 0.0018) with manageable safety in patients with ER+/HER2- mBC previously treated with ET+CDK4/6i (Bidard 2022). In those with prior ET+CDK4/6i ≥12 months and ESR1-mut tumors, median PFS (mPFS) with elacestrant was 8.6 vs 1.9 months (HR = 0.41; 95% CI, 0.26-0.63) with SOC ET (Bardia 2022). To address various resistance mechanisms, ELEVATE (NCT05563220) evaluates elacestrant in combination with everolimus, alpelisib, capivasertib, ribociclib, palbociclib, or abemaciclib.
Methods: Eligible patients have ER+/HER2- mBC. Phase 1b objective is to identify the recommended phase 2 dose (RP2D) of each combination. ELECTRA (NCT05386108) evaluated the RP2D of elacestrant + abemaciclib. Phase 2 primary objective is to evaluate PFS in patients receiving elacestrant combined with each of the other study drugs at the RP2D. This analysis reports updated safety from the phase 1b portion for the following combinations: everolimus, alpelisib, ribociclib, and palbociclib. Preliminary phase 1b efficacy is reported for the elacestrant + everolimus combination; efficacy evaluation for additional combinations is ongoing.

Results: As of July 2024, 23 patients have been enrolled in the elacestrant (258-345 mg) + everolimus (5-10 mg) cohorts. The most common (≥30%) treatment-emergent AEs (TEAEs) were nausea (n=13, 57%; 4% Gr ≥3), stomatitis (n=12, 52%; 9% Gr ≥3), diarrhea (n=10, 43%; 9% Gr ≥3), and fatigue (n=10, 43%; 9% Gr ≥3). mPFS was not yet reached after a median 0.8 to 12.3 months of follow-up across cohorts. Preliminary efficacy in response evaluable patients (n=16) for the elacestrant + everolimus combination demonstrated a CBR at 24 weeks of 81% and ORR of 25%. The elacestrant (258 mg) + alpelisib (250-200 mg) cohort enrolled 9 patients. The most common TEAEs (≥30%) were nausea (n=8, 89%; 11% Gr ≥3), rash (n=4, 44%; 22% Gr ≥3), vomiting (n=4, 44%; 0 ≥G3), dry mouth, stomatitis, and dizziness (n=3, 33%; 0 Gr ≥3). Elacestrant (86-258 mg) + ribociclib (400-600 mg) cohorts enrolled 18 patients. The most common (≥30%) TEAE was neutropenia (n=7, 39%; 28% Gr ≥3). Elacestrant (258-345 mg) + palbociclib (100 mg) cohorts enrolled 12 patients. The most common (≥30%) TEAEs were neutropenia (n=5, 42%; 17% Gr ≥3) and nausea (n=4, 33%; 0 Gr ≥3). Phase 1b of the capivasertib combination is currently ongoing to determine the RP2D. Updated data will be presented.
Conclusion: The phase 1b combinations of elacestrant with either everolimus, ribociclib, or palbociclib demonstrated a manageable safety profile consistent with previously reported data for each compound. The elacestrant + everolimus combination shows favorable efficacy. The phase 1b combinations with ribociclib, palbociclib, or capivasertib are ongoing. The phase 1b combination with alpelisib is under evaluation. The elacestrant + everolimus and elacestrant 345 mg QD + abemaciclib 150 mg BID (RP2D determined in ELECTRA trial) combinations are currently enrolling patients in phase 2. Elacestrant has the potential to become the ET backbone with targeted therapies, to enable all-oral combinations as a treatment option that can replace fulvestrant-based combinations and delay chemotherapy or ADC-based regimens.

PS7-07: Elacestrant plus abemaciclib (abema) combination in patients (pts) with estrogen receptor-positive (ER+), HER2-negative (HER2-) advanced or metastatic breast cancer (mBC)

Hope S. Rugo, Sara M. Tolaney, Nancy Chan, Erika Hamilton, Eva Ciruelos, Ji-Yeon Kim, Elena López-Miranda, Elia Seguí, Neelima Vidula, Joyce O'Shaughnessy, Giuseppe Curigliano, Javier Cortés, Alessandro di Sanzo, Paula Muñoz Romero, Bartomeu Piza Vallespir, Manuel Domínguez-Lizarbe, Kathy Puyana Theall, Alessandro Paoli, Monica Binaschi, Tomer Wasserman, Virginia Kaklamani

Background: Endocrine therapy (ET) plus a CDK4/6 inhibitor (CDK4/6i) is the primary first-line treatment for ER+/HER2- mBC; however, resistance eventually develops. In the EMERALD trial, single-agent elacestrant significantly prolonged progression-free survival (PFS) vs standard-of-care (SOC) ET with manageable safety in pts with ER+/HER2-, mBC previously treated with ET+CDK4/6i (ESR1-mut tumors: HR = 0.55; 95% CI, 0.39-0.77; P = 0.0005; all pts: HR = 0.70; 95% CI, 0.55-0.88; P = 0.0018). In those with prior ET+CDK4/6i ≥12 months and ESR1-mut tumors, median PFS with elacestrant was 8.6 vs 1.9 months with

SOC ET. Combining elacestrant + abemaciclib (abema) may overcome additional resistance mechanisms, improve efficacy, and enable an all-oral treatment option that can replace fulvestrant-based combinations and delay chemotherapy or ADC-based regimens. Elacestrant + abemaciclib combination is being evaluated in the phase 1b/2 ELECTRA (NCT05386108) and ELEVATE (NCT05563220) trials. Here, we present a pooled analysis of efficacy and safety.
Methods: Eligible pts were treated for ER+/HER2- mBC in ELECTRA and ELEVATE trials. Pts must have previously received ET in mBC, including ≥1 line of ET, CDK4/6 inhibitors, or chemotherapy (ELECTRA only). Safety was evaluated in all patients who received elacestrant + abemaciclib. The efficacy evaluable population included pts who had measurable disease (ie, ≥1 target lesion) at baseline and ≥1 post-baseline RECIST assessment.
Results: As of July 2024, 55 pts have received elacestrant + abemaciclib, the majority with 1-2 lines of prior ET (91%), prior CDK4/6i (95%), and visceral metastases (66%); 25% received prior chemotherapy. The most common all-grade AEs (≥20%) were diarrhea (n=37, 67%; 2% Gr ≥3), nausea (n=34, 62%; 6% Gr ≥3), neutropenia (n=17, 31%; 27% Gr ≥3), vomiting (n=16, 29%; 2% Gr ≥3), fatigue (n=12, 22%; 2% Gr ≥3), anemia (n=11, 20%; 4% Gr ≥3), and decreased appetite (n=11, 20%; 0 Gr ≥3). No Grade 4 AEs were observed. In all efficacy-evaluable pts (n=27), mPFS was 8.6 mo. In the ESR1-mut population (n=11), mPFS was 8.7 mo. In ESR1-mut not detected (n=13), mPFS was 7.2 mo. In patients with only 1-2 lines of prior ET in mBC (n=23), mPFS was 8.7 mo. Median PFS according to dose level was 8.6 mo (elacestrant 258 mg QD + abema 100 mg BID, n=8), 7.5 mo (elacestrant 345 mg QD + abema 100 mg BID, n=7), and 8.7 mo (elacestrant 345 mg QD + abema 150 mg BID, n=12). Elacestrant 345 mg QD + abema 150 mg BID was determined as the recommended phase 2 dose (RP2D) for both ELECTRA and ELEVATE Phase 2 arms. Updated safety and efficacy will be reported.
Conclusion: The RP2D dose combination of elacestrant 345 mg QD + abemaciclib 150 mg BID shows favorable efficacy with a manageable and predictable safety profile. Elacestrant has the potential to become the ET backbone for combination regimens. The Phase 2 portions of both studies are currently enrolling.

PS7-08: Results from SERENA-1 Parts K/L: A Phase 1 study of the next-generation oral selective estrogen receptor degrader (SERD) camizestrant (AZD9833) in combination with ribociclib in women with ER-positive, HER2 negative advanced breast cancer

Richard Baird, Manuel Ruiz-Borrego, Ivan Victoria Ruiz, Christos Vaklavas, Anne Armstrong, Begoña Bermejo de las Heras, Mafalda Oliveira, Nicholas Turner, Irene Moreno, Peter Kabos, Chris Twelves, Jason Incorvati, Maria Borrell, Alberto Indacochea Cusirramos, Jennifer Diamond, Gabriel Funingana, Alejandro Falcón González, Cristina Hernando, Ciara O'Brien, Jorge Ramon-Patino, Mei Wei, Maxine Ajimi, Carmela Ciardullo, Teresa Klinowska, Justin P O

Lindemann, Patricia Martin Romano, Alastair Mathewson, Christopher J Morrow, Andy Sykes, Ewa Warwick, Jincheng Yang, Bairu Zhang

Background: SERENA-1 (NCT03616587) is a Phase 1, multi-part, open-label study of camizestrant in women with ER+/HER2− advanced breast cancer. Study parts examining camizestrant as monotherapy and in combination with palbociclib, abemaciclib, and capivasertib have been presented previously. Here, we present the data from Parts K and L, which examined camizestrant in combination with ribociclib.
MethodsThe primary objective was to determine the safety and tolerability of camizestrant 75 mg once daily (QD) in combination with intermittent ribociclib 400 mg or 600 mg QD (21 days on, 7 days off). Objectives included assessment of the anti-tumor response and pharmacokinetics (PK). Patients were women with advanced breast cancer, and premenopausal women were required to receive ovarian function suppression. Prior treatment with ≤2 lines of chemotherapy in the advanced setting was permitted, with no limit on prior endocrine treatment lines; previous treatment with CDK4/6 inhibitors (CDK4/6i) and/or fulvestrant was also permitted.
Results: As of April 26, 2024, 58 patients (median age 57 (range [31–80]) were enrolled; 26 and 32 patients received camizestrant 75 mg in combination with ribociclib 400 or 600 mg, respectively. Overall, patients were heavily pre-treated in the advanced setting; 17/58 (29%) patients had received prior chemotherapy, 40/58 (69%) prior CDK4/6i, and 28/58 (48%) prior fulvestrant. 35/58 (60%) patients had visceral metastases.
Steady state ribociclib exposure in combination with camizestrant 75 mg was comparable to simulations from a published ribociclib monotherapy population PK (popPK) model. Exposure to camizestrant 75 mg in combination with ribociclib 400 or 600 mg is comparable to a popPK simulation exposure of monotherapy camizestrant 150 mg.
Visual effects and bradycardia, causally related to camizestrant (per investigator's opinion), were reported in 20/58 (35%) and 15/58 (26%) patients, respectively; all grade 1. The most common ribociclib-related adverse events (AEs) were neutropenia (24/58; 41%), nausea (15/58; 26%), and fatigue (14/58; 24%). 17/58 (29%) patients reported ribociclib-related AEs that led to ribociclib-only interruptions (most commonly neutropenia [n=13] and QT prolongation [n=3]); 6/58 (10%) patients reported AEs related to both camizestrant and ribociclib leading to interruption of both treatments (most commonly QT prolongation [n=2]). One patient discontinued both camizestrant 75 mg and ribociclib 600 mg due to grade 4 QTc prolongation, which resolved 7 days after cessation of dosing. There were no patients with AEs leading to camizestrant-only interruptions.
At Cycle 1, Day 1, 20/58 (34%) patients had a detectable ESR1 mutation (ESR1m) by ctDNA and an evaluable Cycle 2 Day 1 (C2D1) result; 85% of these patients experienced ESR1m reduction of >50% at C2D1, including 50% of patients where ESR1m was cleared.
While the median duration of exposure to camizestrant and ribociclib at this data cut was 4.5 months, median progression-free survival has not yet been reached, with 40% (23/58) experiencing a progression event to date. Updated data will be presented at the meeting.
Conclusion: Camizestrant 75 mg in combination with ribociclib 400 or 600 mg was well tolerated, consistent with data for each drug individually, and resulted in ESR1m ctDNA suppression in 85% of patients with ESR1m at baseline. This combination is included in the

ongoing Phase 3 SERENA-6 trial (NCT04964934) of camizestrant combined with CDK4/6i versus an aromatase inhibitor plus CDK4/6i in patients with detectable ESR1m during first-line therapy, which will further clarify the role of camizestrant in the treatment of patients with ER+/HER2− advanced breast cancer.

PS8-01: ZN-1041, a potential best-in-class BBB Penetrable HER2 Inhibitor, has high antitumor activity in patients with Breast Cancer with CNS Metastases

Di Zhu, Fei Ma, Yiqun Li, Herui Yao, Jingfen Wang, Quchang Ouyang, Jing Cheng, Xiaoyan Li, Xiao-Xiao Dinglin, Gongsheng Jin, Huan Zhou, Xinshuai Wang, Yuee Teng, Yongsheng Wang, Qi Dang, Jin Yang, Hui Hua Xiong, Weihong Zhao, Li Cai, Tingting Fu

Background: An estimated 50% of patients with HER2-positive metastatic breast cancer will develop brain metastases (BCBM). BCBM is associated with shortened overall survival and disruption of quality of life, representing an area of investigation for newer and more effective treatments. Previous studies, including Phase 1a and 1b, have demonstrated that ZN-1041, a HER2 TKI designed to penetrate the blood-brain barrier (BBB) with high selectivity and a broad safety margin, exhibits promising antitumor activity both as monotherapy and in combination with trastuzumab and capecitabine. This abstract presents the Phase 1c data to evaluate the safety and efficacy of the combination when treating HER2-positive BCBM and extracranial disease.
Methods: The phase 1 multicenter open-label study ZN-1041-101 (NCT04487236) includes dose escalation of ZN-1041 monotherapy (Phase 1a) in patients with HER2-positive solid tumors, with or without brain metastases, followed by dose escalation (Phase 1b) and expansion (Phase 1c) of ZN-1041 with capecitabine (1000 mg/m^2 bid for 14 days, followed by 7 days off) and trastuzumab (8 mg/kg loading dose, followed by a 6 mg/kg maintenance dose iv q3wks) in HER2-positive BCBM. The primary objective was to evaluate safety and tolerability and determine the RP2D for the subsequent study, while secondary objectives included pharmacokinetics and antitumor response rate (RR) per RECIST 1.1 and RANO-BM criteria.
Results: A total of 40 TKI-naïve, HER2-positive BCBM pts were enrolled in phase 1c with ZN-1041 1000 mg bid combined with capecitabine and trastuzumab, and all patients tolerated the treatment well. Grade 3 or higher treatment-related adverse events (>5%) included hyperbilirubinemia (20%), GGT increase (17.5%), white blood cell decrease (15%), ALT increase (5.7%), AST increase (7.5%), and weight decrease (7.5%), headache (7.5%). The incidence of diarrhea was 37.5 % for all grades, with no patients experiencing Grade 3 or higher diarrhea.
Among the 34 BCBM pts who met the tumor assessment criteria,t The median duration of follow-up was 13.9 months, the confirmed overall response rate (RR) was 79.4% (95% CI: 62.10–91.30), the intracranial RR was 75.0% (95% CI: 56.6–88.5), and the disease control rate (DCR) was 100%. Kaplan-Meier analysis estimated the median progression-free survival (PFS) at 14 months (95% CI: 9.13-17.94), with a median duration of response

(DOR) of 12.6 months (95% CI: 6.7-16.59). The 12-month PFS rate was 56.4% (95% CI: 37.76-71.45). Subgroup analysis of 32 patients with measurable brain lesions indicated benefit from the regimen, with a median PFS of 17.4 months (95% CI: 8.74-19.61) and a median duration of intracranial response (DOIR) of 14.7 months (95% CI: 6.51–NR). As of May 22nd, 2024, 10 patients were still in treatment, the longest duration of which being 22.8 months.
Conclusions: Encouraging preliminary efficacy and tolerability were observed for ZN-1041 either as monotherapy or combined with capecitabine and trastuzumab in TKI naïve, HER2+ BCBM patients. Further development of ZN-1041 combination therapies in a larger population is warranted, including the ongoing ZN-1041-101-US study which is evaluating the safety and efficacy of ZN-1041 in combination with trastuzumab deruxtecan and with trastuzumab and pertuzumab in a larger population across the US, EU, UK, Australia, and New Zealand.

PS8-02: A Phase 1 study Evaluating the Safety, Efficacy and Pharmacokinetics of TL938 in HER2-Positive Patients with Advance Solid Tumors

Yuankai Shi, Lin Gui, Xinrui Chen, Hongming Pan, Wei Jin, Jiping Sun, Liqun Zou, Yongsheng Wang, Yuyao Yi, Chang Tan

Background: Patients with human epidermal growth factor receptor 2 positive (HER2+) breast cancer (BC) who develop brain metastasis (BM) often have a poor prognosis. The treatment options for HER2+ BCBM is limited due to the presence of the blood–brain barrier (BBB). TL938 is an oral HER2 inhibitor capable of crossing the BBB, demonstrated by a brain-to-plasma partition coefficient (Kp, uu,brain) of over 400% in rat. This suggests TL938 has significant potential for the treatment of HER2+ BCBM.
Methods: Cancer patients with advanced HER2+ solid tumors (overexpression, amplification, or mutation) confirmed by histology or cytology were treated with TL938. Seven dose levels of TL938 were investigated: 50 mg, 100 mg, 150 mg, 200 mg, 250 mg, 300 mg, and 350 mg. TL938 was administered orally once daily. The study followed a 3 + 3 design. The primary endpoints were the maximum tolerated dose (MTD), recommended phase 2 dose (PR2D) and safety of TL938. Secondary endpoints included Investigator-assessed (RECIST v1.1) objective response rate (ORR), duration of response (DoR), disease control rate (DCR), progression free survival (PFS), and pharmacokinetics.
Results: As of the cutoff date of May 17, 2024, TL938 has been administered to 44 patients. No dose-limiting toxicities (DLTs) were observed, and the MTD was not reached.
The most common treatment related adverse events (TRAEs) (>20%) were diarrhea (75.0%), followed by increased blood creatine phosphokinase (38.6%), increased aspartate aminotransferase (36.4%), increased blood creatinine (31.8%), increased α-hydroxybutyrate dehydrogenase (27.3%), increased alanine aminotransferase (22.7%), proteinuria (22.7%), decreased lymphocyte count (22.7%), vomiting (22.7%), and increased blood creatine phosphokinase MB (20.5%). Grade 3 or higher TRAEs included

diarrhea (18.2%), increased blood creatine phosphokinase (11.4%), and upper abdominal pain (2.3%). Three subjects (6.8%) experienced dose reduction due to TRAEs, including diarrhea (2.3%) and increased blood creatine phosphokinase (4.5%), and three subjects (6.8%) had dose interruption due to TRAEs, increased blood creatine phosphokinase (4.5%), vomiting (2.3%), gastritis (2.3%), upper abdominal pain (2.3%), and gastroesophageal reflux disease (2.3%).
Among the 41 patients with tumor assessments, a total of 7 cancer types were represented, with the most common being BC (44%), lung cancer (22%), and salivary gland cancer (12%). Of the 18 BC patients who had tumor assessments at least once, a 50.0% overall response rate (ORR) and an 83.3% disease control rate (DCR) were observed. Notably, for the BC patients treated at a dose of 200 mg (N=10), an ORR of 70.0% and a DCR of 100.0% were achieved, including 1 patient who achieved a complete response.
TL938 demonstrated intracranial disease control in five (including one with BC) patients with brain metastasis, who had previously undergone surgery, chemotherapy, and HER2-antibody-drug conjugate therapy. Among these patients, two achieved significant regressions in intracranial target lesions with reductions of 60% and 41%, respectively.
After a single oral dose of TL938, the maximum plasma concentration (Cmax) was reached at a median time (Tmax) of 6-8 hours in most dosage groups. After 15 consecutive once-daily oral doses, minimal fluctuation of plasma concentrations around the average levels was observed across all dose cohorts, with fluctuation percentages below 30% for doses ranging from 100 to 250 mg. This indicates relatively stable exposure with repeated dosing.
Conclusions:
TL938 has demonstrated preliminary efficacy as a single agent therapy in HER2+ metastatic breast cancer patients with good tolerance. The most common TRAE observed was diarrhea, which is consistent with other similar tyrosine kinase inhibitors.

PS8-03: Exploratory biomarker analysis of Trastuzumab deruxtecan (T-DXd) vs Trastuzumab emtansine (T-DM1) efficacy in human epidermal growth factor receptor 2–positive (HER2+) metastatic breast cancer (mBC) in DESTINY-Breast03 (DB-03)

William Jacot, Seock-Ah Im, Sherene Loi, Thomas Bachelot, Sara Hurvitz, Srinivasan Madhusudan, Hiroji Iwata, Giuseppe Curigliano, Javier Cortés, Anton Egorov, Vinit Kumar, Aislyn Boran, Yusuke Kuwahara, Erika Hamilton

Background: This is the first exploratory biomarker analysis from DB-03 (NCT03529110), which showed a 22-mo improvement in median progression-free survival (mPFS) with T-DXd vs T-DM1 in patients (pts) with HER2+ mBC previously treated with trastuzumab and taxane.
Methods: This analysis assessed the impact of genomic alterations (alt) on efficacy (objective response rate [ORR] and mPFS), at baseline (BL) and alt emerging at progression. Genomic alt from the GuardantINFINITY panel of >700 genes were examined in circulating tumor DNA (ctDNA) samples collected at BL from 204 pts and 217 pts, and at end of

treatment due to disease progression (DP) for 67 pts and 141 pts, treated with T-DXd and T-DM1, respectively. Data cutoff was July 25, 2022. Median follow-up was 28.4 mo and 26.5 mo in the T-DXd and T-DM1 arms, respectively.
Results: The DB-03 genomic landscape largely recapitulated that of HER2+ BC, with most frequent alt (single nucleotide variants, amplifications [amp], and indels) observed in TP53 (73%), HER2 (ERBB2; 61%), CDK12 (52%) and PIK3CA (48%).
HER2 genomic status
Detection rate of HER2 amp in ctDNA was relatively low: 56% (235/420) detected, including aneuploidy and focal HER2 amp. HER2 plasma copy number (CN; adjusted for ctDNA tumor fraction) was higher in the subgroup of pts with HER2 IHC3+ vs IHC2+ tumors. Efficacy was comparable in the T-DXd arm regardless of high/low median HER2 plasma CN at BL, whereas numerically shorter PFS and lower ORR were observed in the T-DM1 arm with lower HER2 plasma CN at BL.

T-DXd: HER2 CN high (n = 62 [30.4%]) vs CN low (n = 59 [28.9%]) vs not detected (ND; n = 83 [40.7%])

ORR, % (95% CI): 87.1 (76.1-94.3) vs 81.4 (69.1-90.3) vs 77.1 (66.6-85.6)
mPFS, mo (95% CI): 23.9 (18.0-not estimable [NE]) vs 21.1 (12.3-NE) vs 37.3 (26.2-NE)

T-DM1: HER2 CN high (n = 56 [25.8%]) vs CN low (n = 59 [27.2%]) vs ND (n = 102 [47.0%])

ORR, % (95% CI): 50.0 (36.3-63.7) vs 35.6 (23.6-49.1) vs 31.4 (22.5-41.3)
mPFS, mo (95% CI): 9.7 (6.8-25.7) vs 5.4 (3.0-6.8) vs 8.1 (4.4-10.9)

No difference in response based on BL HER2 activating mutation (mut) status was observed in either arm. Data to be presented.
PI3K pathway
T-DXd efficacy was comparable irrespective of PI3K pathway mut status. In contrast, a trend towards reduced efficacy was observed in pts with PI3K mut in the T-DM1 arm.

T-DXd: PI3K mut (n = 87 [42.6%]) vs ND (n = 117 [57.4%])

ORR, % (95% CI): 80.5 (70.6-88.2) vs 82.1 (73.9-88.5)
mPFS, mo (95% CI): 27.6 (15.0-NE) vs NE (22.1- NE)

T-DM1: PI3K mut (n = 87 [40.1%]) vs ND (n = 130 [59.9%])

ORR, % (95% CI): 33.3 (23.6-44.3) vs 40.0 (31.5-49.0)
mPFS, mo (95% CI): 4.4 (3.2-6.8) vs 9.7 (6.8-12.1)

Homologous recombination deficiency (HRD) and BRCA1/2 alt status
ORR was similar regardless of HRD status in the T-DXd arm and numerically lower in the HRD+ subgroup of the T-DM1 arm. mPFS tended to be shorter in both arms with HRD+ status.

T-DXd: HRD+ (n = 23 [11.3%]) vs ND (n = 181 [88.7%])

ORR, % (95% CI): 82.6 (61.2-95.0) vs 81.2 (74.8-86.6)
mPFS, mo (95% CI): 12.4 (6.8-NE) vs 37.3 (23.7-NE)

T-DM1: HRD+ (n = 27 [12.4%]) vs ND (n = 190 [87.6%])

ORR, % (95% CI): 14.8 (4.2-33.7) vs 40.5 (33.5-47.9)
PFS, mo (95% CI): 2.8 (1.4-4.3) vs 7.1 (5.7-9.7)
m
Similar trends were observed based on BRCA1/2 alt status. Data to be presented.
Conclusions
Genomic alt at BL were not significantly associated with response to T-DXd vs T-DM1. T-DXd maintained superior activity to T-DM1 regardless of the presence of detectable BL genomic alt. T-DXd was comparably active in pts with PI3K pathway mut whereas T-DM1 activity appeared lower. T-DXd outperformed T-DM1 regardless of HRD+/- or BRCA1/2 alt status, although HRD+ status and BRCA1/2 alt were poor prognosticators for PFS in both arms. Mutational analysis at DP will be presented.

PS8-04: Targeting clinically advanced breast cancer with conjugated and unconjugated HER2 antibodies: Does copy number matter?

Nicole Odzer, Pusztai L, Chen KT, Jin DX, Sisoudiya S, Schrock A, Ross J, Sokol ES, Lustberg M

Background: HER2-targeted therapy is broadly used in advanced breast cancer (aBC). For HER2+ aBC (HER2 IHC 3+ or 2+/ISH+), 1L standard of care includes unconjugated HER2 antibodies trastuzumab and pertuzumab (HP) in combination with chemotherapy. In the 2L+ setting, antibody drug conjugate trastuzumab deruxtecan (T-DXd) can be used for HER2 low (IHC 1+, 2+/ISH-) patients with significant benefit seen in DESTINY Breast 04 relative to physicians' choice chemotherapy. For some targeted therapies, including MET inhibitor capmatinib, the magnitude of genomic copy number (CN) gains predict benefit. Here, we examined a real-world cohort of aBC patients (pts) treated with HER2 antibody therapies to determine if HER2 genomic CN ratio predicts outcomes.
Methods: This study used the US nationwide de-identified Flatiron Health (FH) and Foundation Medicine Inc. (FMI) clinico-genomic database including patient-level structured and unstructured retrospective longitudinal clinical and genomic data from approximately 280 cancer clinics (approximately 800 care sites) in the United States and included patients who underwent tissue comprehensive genomic profiling

(FoundationOne®/FoundationOne®CDx) after 2014. HER2 CN ratio was defined as ratio of modeled absolute CN to specimen ploidy.

Results: 121 pts with HER2+ aBC were treated with HP + chemotherapy in 1L and received genomic profiling before start of 2L. HER2 CN ratio was generally high (median HER2 CN ratio of 10; IQR 2.8-17.8). Pts with a HER2 CN ratio of >5 (equivalent to CN 10 in a diploid tumor) had significantly better TTD (median 8.4 v 5.3 mo, HR = 0.55, 95% CI 0.36-0.84, p = 0.006), and OS (median 76 v 31mo, HR = 0.33 95% CI 0.18-0.61, p <0.001) than pts with a HER2 CN ratio of ≤5, and comparable trends were observed for PFS (median 13v 9mo, HR = 0.81 (95% CI 0.52-1.26), p = 0.35). Similar benefit was seen for pts with a HER2 CN ratio of 5-10, 10-15, 15-20, and 20+ relative to HER2 ratio ≤5.
For 95 pts with HER2 low BC treated with T-DXd in the 2L or 3L setting, HER2 CN ratio was generally low (median ratio of 1, IQR 1-1) with a maximum HER2 CN ratio of 2.5 in the cohort. Across HER2 CN levels, outcomes were similar with the exception of pts with a HER2 CN ratio of ≤0.5 (11/95; 12%) who had significantly worse PFS (median 2.5 v 6.1 mo, HR = 0.37, 95% CI 0.17-0.79 p = 0.01) and OS (median 6.5 v 25.2 mo; HR =0.32, 95% CI 0.14-0.75; p=0.008) than pts with a HER2 CN ratio of >0.5, with similar trends for TTD (median 1.6 v 4.8 mo, HR = 0.52, 95% CI 0.26-1.06 p = 0.07).
Conclusions: In a cohort of real-world aBC pts treated with HER2 antibody therapies, HER2 CN ratio was significantly associated with clinical outcomes. For unconjugated antibodies, pts with a HER2 CN ratio of <5 had significantly shorter TTD, PFS and OS. Future work should explore whether these pts may benefit from therapy escalation (e.g. use of conjugated HER2 antibodies) and/or increased surveillance. For the HER2 conjugated antibody T-DXd, pts with HER2 low BC with a hemizygous or deep deletion in HER2 (HER2 CN ratio ≤0.5) had significantly worse outcomes, consistent with partial or complete target loss. These results suggest potential additional predictive value of an NGS-based HER2 CN quantitative biomarker that could be deployed in conjunction with the currently employed qualitative IHC status biomarker to identify pts for whom an alternative therapy may be more efficacious. For pts with a ratio of >0.5, benefit was seen across the range of HER2 CN ratios suggesting that even low levels of HER2 are enough for activity of T-DXd, consistent with the high payload:antibody ratio and bystander effect for T-DXd. Prospective or observational studies should be performed to validate these findings.

PS8-05: ACE-Breast-08: a phase I study of ARX788, a novel anti-HER2 antibody-drug conjugate, in patients with TKI pretreated HER2 positive advanced breast cancer

Xiaojia Wang, Zefei Jiang, Weimin Xie, Xinshuai Wang, Wei Li, Tao Sun, Xinhong Wu, Yongsheng Wang, Fei Xu, Xiaohua Zeng, Wenyan Chen, Ruizhen Luo, Enfeng Zhao, Min Yan.

Background: Anti-HER2 TKI-resistant, advanced breast cancer has a poor prognosis with limited treatment options. ARX788 is a next-generation antibody-drug conjugate (ADC) of HER2 monoclonal antibody site-specifically conjugated with a potent cytotoxic tubulin inhibitor (AS269). This phase Ⅱ study aimed to evaluate the efficacy and safety of ARX788 in patients with HER2 positive advanced breast cancer previously treated with trastuzumab and anti-HER2 tyrosine kinase inhibitor (TKI).
Methods: This multicenter, open and single-arm study was conducted in 13 centers in China. Eligible patients were aged between 18 and 75 years, had an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1, had HER2 positive (FISH+ or IHC3+) unresectable or metastatic breast cancer pretreated with trastuzumab and anti-HER2 TKI, and had at least one measurable lesion per Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST 1.1). All patients were received ARX788 1.5mg/kg, administered by intravenous infusion every 3 weeks. Primary endpoint was independent review committee (IRC)-assessed confirmed objective response rate (cORR) per RECIST 1.1 in all patients.
Results: Between February 9, 2022 and April 30, 2024, totally 138 patients were enrolled and received ARX788 at lease one dose. At baseline there were 8.8% (12/138) of patients with brain metastasis and 76.8% (106/138) with visceral metastasis. The median prior lines of therapy in the metastatic setting were 3 (1, 9). In the intent-to-treat population, IRC-assessed cORR was 44.9% (95%CI: 36.5- 53.6) with a complete response (CR) seen in 3 patients and partial responses (PR) in 59 patients. cORR assessed by investigators was 42.0% (95%CI: 33.7-50.7) with 3 patients of CR and 55 patients of PR. With the median follow-up time of 14.78 months, the IRC-assessed progression-free survival (PFS) was 5.68 months (95%CI: 5.49-8.25), while investigators-assessed PFS was 6.90 months (95%CI: 5.45-7.89). The median duration of response was 13.86 months (95%CI: 6.87-NR). The median OS was not reached and 1-year OS rate was 81.3%. The incidence of treatment-emergent adverse events of any grade occurred in 99.3% (137/138) patients. The most common treatment-related adverse events (>30%) were aspartate aminotransferase increased (65.9%), dry eye (52.9%), alanine aminotransferase increased (44.9%), blurred vision (36.2%), interstitial lung disease (ILD, 35.5%), platelet count decreased (32.6%) and hypokalemia (31.2%). 10.1% of patients had adverse events requiring treatment discontinuation and 27.5% had grade ≥3 adverse events of special interest, mainly containing blurred vision (10.9%), ILD (5.8%), dry eye (7.2%) and keratitis (3.6%). 1 case diagnosed with ILD was reported of treatment-related death. Overall, adverse events were consistent with the known safety profile with low incidence of hematological and gastrointestinal toxicity in the previous studies.
Conclusions: ARX788 showed encouraging efficacy and manageable toxicities in patients with HER2-positive advanced breast cancer previously treated with trastuzumab and anti-HER2 TKI.

PS8-06: A randomized, open-label phase III study comparing disitamab vedotin (an anti-HER2 monoclonal antibody-MMAE conjugate) with lapatinib plus capecitabine in patients with HER2-positive, advanced breast cancer with liver metastasis

Jiayu Wang, Quchang Ouyang, Weimin Xie, Zhaofeng Niu, Qingyuan Zhang , Xi Yan, Yue'e Teng, Jianying Chang, Ying Cheng, Hongyan Xu, Jingfen Wang, Herui Yao, Zhuangqing Yang, Tao Sun, Zhongsheng Tong, Xinhong Wu, Yongsheng Wang, Enxiang Zhou, Xiangshun Kong, Xujuan Wang, De Zeng, Shanshan Gu, Dandan Gao, Zerui Qu, Chenran Han, Jianmin Fang, Binghe Xu

Background: The prognosis of patients (pts) with HER2-positive, advanced breast cancer with liver metastasis is poor and there is no standard therapy recommended for this pts population. RC48-C006 is a randomized, multicenter, phase II/III clinical trial to compare disitamab vedotin (DV) versus lapatinib+capecitabine (L+C) in HER2-positive locally advanced or metastatic breast cancer in phase II part and in HER2-positive advanced breast cancer with liver metastasis in phase III part (ClinicalTrials.gov Identifier: NCT03500380). Here, we first report the phase III data.
Methods: Key inclusion criteria were histologically/cytologically confirmed breast cancer with radiologically confirmed liver metastasis, HER2-positive (defined as IHC 3+ or FISH+), and prior treatment with trastuzumab and taxanes. Pts were randomized at 1:1 (stratification factors: prior lines of chemotherapy [≤1 or 2], and lung metastasis [yes or no]) to receive DV (2.0 mg/kg IV) every 2 weeks or lapatinib (1250 mg, orally daily) + capecitabine (2000 mg/m2, orally daily on days 1-14) every 3 weeks until occurrence of disease progression or unacceptable toxicity. Pts in L+C group were allowed to cross over to receive DV after disease progression. Tumor was assessed every 6 weeks (±7 days) as per RECIST v1.1. The primary endpoint was IRC (Independent Review Committee)-assessed progression-free survival (PFS); secondary endpoints included investigator-assessed PFS, OS, ORR, and DoR. The data cutoff date for this analysis was December 31, 2023.
Results: As of the cutoff date, 104 pts from 39 sites in China were randomly assigned (53 in DV group and 51 in L+C group). At a median follow-up of 15.38 months for DV and 19.35 months for L+C, DV significantly improved IRC-assessed PFS vs L+C (median: 9.86 vs 4.90 months; HR: 0.561 [95%CI: 0.350-0.897]; P=0.0143), consistent with investigators' assessment (HR: 0.621 [95% CI: 0.392-0.985], nominal P=0.0418). OS was immature with 25 events to data cutoff (median: not evaluable [NE] vs 25.92 months for DV vs L+C; HR: 0.563 [95% CI: 0.246-1.289]); after adjusting for crossover (21 pts) using the two-stage method, the HR was 0.410 (95% CI: 0.189-0.944). Per IRC, ORR was 58.5% vs 54.9%, and median DoR was 11.20 vs 6.97 months for DV and L+C groups, respectively. Among all treated pts, 22 (41.5%) of 53 in DV and 20 (40.0%) of 50 in L+C experienced grade ≥3 treatment-emergent adverse events (TEAEs), mostly (incidence ≥5%) neutrophil count decreased (18.9% vs 10.0%), gamma-glutamyltransferase increased (9.4% vs 0.0%), white blood cell count decreased (5.7% vs 4.0%), hypertriglyceridemia (5.7% vs 4.0%), hypokalemia (3.8% vs 8.0%), hand-foot syndrome (0.0% vs 10.0%), and diarrhea (0.0% vs

6.0%). No TEAEs led to death in either group.
Conclusion: DV is the first HER2-targeting ADC that demonstrated significant PFS benefit vs L+C and an acceptable safety profile in pts population with HER2-positive breast cancer with liver metastasis. It provides a potential new standard treatment option for these pts.

PS8-07: Efficacy and Safety of GQ1005, a Promising HER2-ADC, in Patients with Metastatic HER2-Positive Breast Cancer

Biyun Wang, Jian Zhang, Yuping Sun, Ting Deng, Jing Liu, Bo Yang, Hongwei Yang, Jingfen Wang, Rongbo Lin, Jia Wei, Xian Wang, Qiao Cheng, Wu Zhuang, Caicun Zhou.

Introduction: GQ1005 is a novel HER2 antibody-drug conjugate (ADC) designed using advanced Ligase-Dependent Conjugation (iLDC) technology. This ADC features a highly stable linker, an improved safety profile, and an expanded therapeutic window. Here, we present the latest findings from the ongoing phase I clinical trial of GQ1005, focusing on the cohort with HER2-positive metastatic breast cancer (MBC).(NCT06154343)

Methods: Participants aged 18 years and older with locally advanced or metastatic HER2-positive MBC (IHC 3+; IHC 2+ and FISH positive) were enrolled. These patients had previously received and progressed on standard therapies and had measurable disease per RECIST v1.1 criteria. The primary objectives were to assess the safety, tolerability, pharmacokinetics, and antitumor efficacy of GQ1005. The drug was administered intravenously at doses of 2, 4, 6, 7.2, and 8.4 mg/kg every three weeks until intolerable toxicity or disease progression was observed.

Results: As of May 10, 2024, 60 HER2-positive MBC patients (6 mg/kg n=3; 7.2 mg/kg n=57) were enrolled, with a median age of 53 years. These patients had undergone multiple previous treatments, with a median of four prior anti-tumor therapies (range 1-11). All participants had received chemotherapy, 93.3% had received trastuzumab, 86.7% had received HER2 TKIs (nearly all received pyrotinib), and 63.2% had received other HER2 ADCs (including T-DM1, FS-1502, A-166, etc.). No dose-limiting toxicities (DLTs) were observed, and the maximum tolerated dose (MTD) was not reached. Adverse effects were manageable, mainly involving gastrointestinal toxicity, bone marrow suppression, and elevated transaminases. Grade 3 or higher treatment-related adverse events (TRAEs) occurred in only 5 patients (8.3%), including leukopenia (3.3%), hypokalemia (1.7%), and anemia (1.7%). Treatment was temporarily suspended in 2 patients due to grade 1 interstitial lung disease (ILD). In the 7.2 mg/kg group, no subjects experienced TRAEs necessitating dose reduction, permanent discontinuation, trial withdrawal, or resulting in death.

Efficacy assessments were conducted in 49 subjects (6 mg/kg n=3, 7.2 mg/kg n=46). The overall response rate (ORR) was 65.3% (95% CI: 50.36-78.33), with a confirmed ORR of

51.0% (95% CI: 36.34-65.58). The disease control rate (DCR) was 95.9% (95% CI: 86.02-99.50), with a confirmed DCR of 75.5% (95% CI: 61.13-86.66). The median progression-free survival (PFS) was 8.87 months (95% CI: 5.55-NA), and the median duration of response (DoR) was 7.52 months (95% CI: 4.37-NA). The median time to response (TTR) was 1.41 months (95% CI: 1.35-2.73), and the median follow-up time for overall survival (OS) was 4.21 months, with median OS not yet reached. In the 7.2 mg/kg group, ORR was 63.0%, DCR was 95.7%, median PFS was 10.91 months (95% CI: 5.55-NA), and the 9-month PFS rate was 69.14% (95% CI: 41.82-85.54%). OS was not reached.
Conclusion: GQ1005 demonstrates robust anti-tumor activity and a favorable safety profile in patients with heavily pretreated HER2-positive MBC. Notably, GQ1005 exhibits significantly superior safety profiles, attributable to its higher linker stability and minimal payload shedding in circulation. These promising results warrant further investigation in randomized, controlled phase III studies. (sponsored by GeneQuantum Healthcare (Suzhou) Co., Ltd.)

PS8-08: Efficacy and safety of SHR-A1811, an anti-HER2 antibody-drug conjugate (ADC), in 391 heavily pretreated multiple solid tumors with HER2-expression or mutations: a global, multi-center, first-in-human, phase 1 study

Herui Yao, Min Yan, Zhongsheng Tong, Xinhong Wu, Yongmei Yin, Min-Hee Ryu, John J. Park, Tao Dai, Yiming Zhao, Jee Hyun Kim, Shouman Wang, Yahua Zhong, Mark Voskoboynik, Jian Zhang, Andreas Kaubisch, Caigang Liu, Yu Chen, Seock-Ah Im, Lingying Wu, Yingbin Liu, Vinod Ganju, Minal Barve, Hui Li, Guangyu Yao, Lequn Bao, Kaijing Zhao, Yu Shen, Shangyi Rong, Xiaoyu Zhu, Erwei Song

Background: SHR-A1811, an anti-HER2 ADC comprising trastuzumab, a cleavable linker, and the topoisomerase I inhibitor payload SHR169265, has shown substantial tumor response and a manageable safety profile in heavily treated multiple solid tumors with HER2 expression or mutations (Yao. et al., JCO, 2024). Here we present for the first time the progression-free survival (PFS) analysis results of SHR-A1811 and updated safety results, including an additional 1-year of follow-up and an expanded cohort from 307 to 391 patients.
Methods: Patients eligible for this study had HER2-expressing or mutated unresectable, advanced, or metastatic solid tumors and were refractory or intolerant to standard therapies. SHR-A1811 was administered intravenously at doses ranging from 1.0 to 8.0 mg/kg every 3 weeks. Primary endpoints included dose-limiting toxicity, safety, and the recommended phase 2 dose.
Results: Between Sep 7, 2020 and Jan 12, 2024, 391 patients received SHR-A1811 treatment, including 136 HER2-positive breast cancers, 110 HER2 low-expressing breast cancers, 42 biliary tract cancers, 39 urothelial carcinomas, 22 gynecological cancers, 14 colorectal cancers (CRC), 13 gastric or gastro-esophageal junction adenocarcinomas (GC/GEJ), 4 non-small cell lung cancers (NSCLC), and 11 other types of solid tumor. These

patients had undergone a median of 3 (IQR 2–5) prior treatment regimens for metastatic disease. Of these, 261 (66.8%) had an ECOG performance status of 1, 196 (50.1%) had liver metastasis, and 186 (47.6%) had lung metastasis. As of data cutoff (Feb 29, 2024), the median follow-up for HER2-positive breast cancer, HER2-low breast cancer, and non-breast tumor was 13.4, 9.5, and 6.3 months (mo), respectively. The adverse events remained consistent with previous findings in terms of frequency, severity, and specificity. No new safety signals were identified. Grade ≥3 treatment-related adverse events (TRAEs) were reported in 247 patients (63.2%) and 26 patients (6.6%) discontinued treatment due to TRAEs. Incidence of interstitial lung disease was limited, occurring in only 10 patients (2.6%), predominantly at grade 1–2. Of the patients whose tumor responses were evaluable, the confirmed objective response rate (ORR) was 79.1% (95% CI 71.2–85.6) in HER2-positive breast cancer, 62.0% (95% CI 52.2–71.2) in HER2-low breast cancer, and 40.0% (95% CI 31.5–49.0) in non-breast tumor. Responses were durable, with median duration of response (DoR) of 23.6 mo (95% CI 15.6–NE), 12.2 mo (95% CI 7.3–NE), and 15.2 mo (95% CI 9.9–20.9), respectively. Median PFS was 20.0 mo (95% CI 15.1–NE) in HER2-positive breast cancer, 11.0 mo (95% CI 8.2–13.7) in HER2-low breast cancer, and ranged 3.4–8.5 mo in various non-breast tumor types. In breast cancer patients with liver metastasis, the median DoR and PFS (HER2-positive: not reached for DoR, 20.0 mo for PFS; HER2-low: 10.8 mo for DoR, 10.9 mo for PFS) were consistent with the total breast cancer population. Similarly, for breast cancer patients with visceral metastasis, the median DoR and PFS (HER2-positive: 23.7 mo for DoR, 21.9 mo for PFS; HER2-low: 9.9 mo for DoR, 9.8 mo for PFS) also aligned with the overall breast cancer population. Additionally, patients with HER2-positive non-breast tumors showed a trend of better efficacy compared to the overall non-breast tumor cohort in terms of ORR (45.1%), DoR (median 15.2 mo), and PFS (median 7.9 mo).
Conclusions: This updated analysis reaffirms the manageable safety profile and promising efficacy of SHR-A1811 in heavily pretreated multiple solid tumors with HER2 expression or mutations. Pivotal study results are highly expected in HER2-positive breast cancer, HER2-low breast cancer, CRC, GC/GEJ, and NSCLC.

PS8-09: Zanidatamab in combination with evorpacept in HER2-positive and HER2-low metastatic breast cancer: Results from a phase 1b/2 study

Alberto Montero, Kari B. Wisinski, Bruno Fang, Kelly E. McCann, Sara Hurvitz, Kay T. Yeung, Ritesh Parajuli, Jorge Chaves, Adam Brufsky, Peter A. Kaufman, Manish R. Patel, Timothy Pluard, Bob Salim, Kavita V. Shah, Shanhong Guan, Athanasios C. Tsiatis, Sophia Randolph, Funda Meric-Bernstam

Background: Patients (pts) with HER2-expressing breast cancer (BC) are in need of novel therapies, including chemotherapy-free treatments and more options post-progression on available therapies, such as trastuzumab deruxtecan (T-DXd). Zanidatamab (zani) is a HER2-targeted bispecific antibody that binds two domains on HER2, leading to crosslinking of adjacent HER2 molecules and multiple mechanisms of action, including inhibition of

growth signaling, complement-dependent cytotoxicity, antibody-dependent cellular cytotoxicity, and antibody-dependent cellular phagocytosis (ADCP). Evorpacept (evo) is a high-affinity CD47-blocker with an inactive IgG Fc region designed to enhance ADCP. Here, we report results from a phase 1b/2 trial of zani + evo in advanced HER2-expressing cancers.

Methods: This two-part, open-label, multicenter study (NCT05027139) included pts with previously treated, inoperable, locally advanced, or metastatic (m) HER2-expressing (by local or central assessment) cancers. Part 1 evaluated safety/tolerability and established the recommended dose (RD) for Part 2. The primary objective in Part 2 was to evaluate the antitumor activity by cORR per RECIST 1.1 in HER2-positive (HER2+) mBC (cohort 1), HER2-low mBC (IHC1+ or IHC2+/ISH negative; cohort 2), and other HER2-overexpressing advanced tumors (cohort 3). DCR, DOR, PFS, OS, and safety were secondary endpoints. Prophylactic treatment for infusion-related reactions (IRRs) was mandatory. Based on the IRR rate in the first 25 pts enrolled, the protocol was amended to reverse the dosing order to zani followed by evo.

Results: As of March 27, 2024, enrollment was complete with a total of 52 pts; 44 at the RD (cohort 1, n=21; cohort 2, n=15; cohort 3, n=8). Median age (range) was 59 (34-81) yrs; 15 pts (29%) had a history of brain metastasis, and 15 pts (29%) had de novo metastatic disease. By central HER2 assessment, 9/21 (43%) pts in cohort 1 had HER2+ mBC and 14/15 (93%) pts in cohort 2 had HER2-low mBC. The median number of prior systemic regimens in the metastatic setting was 6 in cohort 1, 5 in cohort 2, and 3.5 in cohort 3. All pts in cohort 1 and 5 pts in cohort 2 had prior T-DXd. Median follow-up was 7 months, with 8 pts on treatment at data cutoff.

In Part 1, there were two dose-limiting toxicities, both grade 3 IRRs that resolved following treatment discontinuation. The Part 2 RD was zani 1200 mg (pts <70 kg) or 1600 mg (pts ≥70 kg) + evo 30 mg/kg IV Q2W.

Among all 52 pts, treatment-related (zani or evo) adverse events (TRAEs) of any grade occurring in ≥20% of pts were diarrhea (62%), fatigue (31%), nausea (27%), and IRRs (21%). Grade 3 TRAEs occurring in ≥2 pts were diarrhea (6%) and IRRs (4%). There were no grade 4 or 5 TRAEs. Three (6%) pts had serious TRAEs (dyspnea, GGT increase, and IRR; 1 pt each). TRAEs of special interest included 1 (2%) pt with a grade 2 LVEF decrease and 12 (23%) pts with IRRs, 11 of whom had the event before the dosing order was reversed. No non-infectious pulmonary toxicities occurred. TRAEs led to treatment discontinuation and dose reductions in 2 pts (4%) each.

Among response-evaluable pts treated at the RD, in cohort 1 (n=19) the cORR (95% CI) was 37% (16, 62) and the DCR (95% CI) was 74% (49, 91). The median DOR (range) was not reached (2-22 months). In the 9/19 pts in cohort 1 with centrally confirmed HER2+ mBC, the cORR (95% CI) was 56% (21, 86) and the DCR (95% CI) was 78% (40, 97). For cohort 2 (n=15), the cORR (95% CI) was 20% (4, 48) and the DCR (95% CI) was 40% (16, 68). The median DOR (range) was 6 (4-7) months. Additional efficacy results (including PFS) will be presented at the congress.

Conclusions: Zani + evo showed a manageable safety profile and promising antitumor

activity, particularly in pts with heavily pretreated HER2+ mBC, including prior exposure to T-DXd. Further development of this novel chemotherapy-free regimen is warranted.

PS9-01: Actionable Genomic Alterations in Localized Hormone Receptor Positive (HR+) Breast Cancer and Impact on Clinical Outcomes: Results from Comprehensive Whole Exome Sequencing (WES) and Tumor-Informed circulating tumor DNA (ctDNA) analysis.

Marla Lipsyc-Sharf, Samer Alkassis, Kasey Fitzsimmons, Arielle J. Medford, Emily L. Podany, Caterina Gianni, Maurice Berkowitz, Rena D. Callahan, Brian DiCarlo, Nimmi S. Kapoor, Aashini K. Master, Kelly McCann, Juliet Penn, Mina S. Sedrak, Samuel Rivero-Hinojosa, Janie Fielder, Ekaterina Kalashnikova, Angel A. Rodriguez, Minetta C Liu, Andrew A. Davis, Massimo Cristofanilli, Aditya Bardia

Background: The development of targeted therapies directed towards particular tumor genomic alterations has revolutionized the treatment of HR+ breast cancer in the metastatic setting, yet little is known about whether these agents have utility in the early-stage setting. Here, we conducted a comprehensive analysis using data from tumor-informed minimal residual disease (MRD) testing to identify actionable genomic alterations and ctDNA dynamics in localized HR+ breast cancer and evaluate the impact on clinical outcomes.
Methods: Actionable genomic alterations were analyzed in tumors from 1639 women in the United States with early-stage (stage I-III) HR+/HER2- breast cancer who had ctDNA testing via a clinically-validated, personalized, tumor-informed 16-plex PCR-NGS ctDNA assay (Signatera™, Natera, Inc.). Targetable alterations, including somatic mutations in PIK3CA, AKT, PTEN, BRCA1/2, ESR1, and ERBB2, were assessed via whole exome sequencing (WES) of tumor tissue performed for generation of patients' personalized plasma MRD assays. All tests were ordered in the real-world clinical setting. For a subset of patients, distant recurrence-free survival (DRFS) events (including distant relapse and date of either last follow up or death) were obtained by review of electronic medical records. DRFS was evaluated by the presence or absence of actionable genomic alterations as well as MRD status (ctDNA + vs -). Timing of MRD testing was divided into three discrete categories of 0-2 years, 2-5 years, and >5 years after primary breast cancer surgery.
Results: 1639 patients with early-stage HR+ HER2- breast cancer and tumor-informed ctDNA testing were included in the analytical dataset. Included patients had a median of 5 ctDNA tests performed (range: 1-33). The first ctDNA test was performed within 2 years after surgery for 900/1639 (54.9%) patients, between 2-5 years for 467/1639 (28.5%), and after 5 years for 272/1639 (16.6%) patients. 287/1639 (17.5%) had >1 positive ctDNA (ctDNA+) test. Of patients with ctDNA+, 127/287 (44.2%) had at least 1 targetable genomic alteration including PIK3CA (99/287, 34.5%), AKT (14/287, 4.9%), PTEN (9/287, 3.1%), BRCA1/2 (1/287, 0.3%), ESR1 (5/287, 1.7%), and ERBB2 (10/287, 3.5%). Of ctDNA+ patients with PIK3CA mutations, 32/99 (32.3%) first were ctDNA+ 0-2 years post-surgery, 34/99 (34.3%) between 2-5 years and 33/99 (33.3%) >5 years. DRFS data were available for 205 patients. In the patients with ctDNA+ 0-2 years after surgery, the median DRFS was

34.7 months vs not reached in the ctDNA- patients. For patients with ctDNA+ testing 0-2 years post-surgery, stratifying by PIK3CA status, those with PIK3CA-mutated tumors had a median DRFS of 23.67 months vs 34.72 months in PIK3CA WT (reference: ctDNA- patients; PIK3CA mutated/ctDNA+: HR=36.9; PIK3CA WT/ctDNA+: HR=16.3). The 5 year DRFS in patients with ctDNA+ was 25% vs 92% in ctDNA-. In patients with PIK3CA mutation and ctDNA+, the 5 year DRFS was 20% vs 29% in those with PIK3CA WT.
Conclusions: To our knowledge, this is the first analysis incorporating comprehensive WES data with tumor-informed ctDNA analysis to evaluate the impact of targetable genomic alterations on ctDNA detection and DRFS in early-stage HR+ breast cancer. Overall, 44% of patients with ctDNA+ had at least one targetable genomic alteration. Among patients with early ctDNA positivity, those with PIK3CA mutated tumors tended to have worse early DRFS than those with PIK3CA WT tumors. Overall, this analysis provides the landscape of actionable genomic alterations in localized HR+ breast cancer and guides future therapeutic interception trials to potentially improve outcomes for patients with high recurrence risk due to MRD.

PS9-02: Serial circulating tumor DNA (ctDNA) assessment to predict treatment response and identify genomic evolution in patients with metastatic breast cancer (mBC)

Laura Linville, Talia Haller, Faith Too, Alexandra Lombardo, Jui Malwankar, Resham Mawalkar, Meron Haile, Lily Zandi, Vidya Babu, Ruizhe Chen, Derek W Brown, Chang Xu, Patrick J Boyle, Lincoln W Pasquina, Cesar A. Santa-Maria

Background: Next generation sequencing of ctDNA can provide a comprehensive assessment of a tumor's genomic landscape. ctDNA is non-invasive, enabling serial liquid biopsies to monitor for clinical response and resistance over time. The Individualized Molecular Analyses Guide Efforts in Breast Cancer (IMAGE) II study evaluated clinical utility of serial ctDNA assessment in patients (pts) with mBC.
Methods: IMAGE II (NCT02965755) is a prospective, multi-center trial for pts with mBC of any subtype planning to initiate a new line of therapy (LOT). Plasma samples from baseline, 1-2 weeks after next LOT initiation, first restaging, and progression underwent comprehensive genomic profiling (CGP) by Foundation Medicine. Baseline plasma CGP and clinical tumor tissue sequencing results were reviewed in real time by the Johns Hopkins Genetic Alteration In Tumors With Actionable Yields (GAITWAY) Tumor Board to provide treatment recommendations. ctDNA tumor fraction (TF) was calculated using FoundationOne®Liquid CDx. Maximum variant allele frequency (max VAF) was calculated by filtering out variants with VAF 40-60% or >90% and variants in genes commonly associated with clonal hematopoiesis (CH). We examined TF and maxVAF dynamics vs clinical response at first restaging as extracted from clinical documentation and dichotomized into stable/responding versus progressing. We also identified alterations that were emerging (not detected at baseline, detected subsequently), disappearing (present at baseline, not detected later), or persistent (present throughout). Statistical

significance was assessed by χ-squared analysis.
Results: Enrollment was 197 pts: 136 ER/PR+ and HER2-, 21 HER2+, and 40 ER/PR- and HER2-. Most (193) were women, and median age was 57 years (range 27-86). Median prior metastatic LOT was 2 (44 pts with 4+ prior LOT). TF was estimated for 84 samples at baseline and 107 at week 1-2. At time of first restaging, 44% of patients who had a clinical response had a decrease in TF at week 1-2 by 90% from baseline, compared to only 9% of patients who had clinical progression (p=0.028). MaxVAF was estimated for 178 baseline samples and106 at week 1-2. A decrease in maxVAF at week 1-2 by 90% compared to baseline was not associated with clinical response first restaging (23% vs. 12%, p=0.2715). A total of 5566 alterations were detected in 397 baseline and serial samples. Of the 958 alterations not classified as variants of unknown significance (non-VUS) detected in 122 patients with plasma from more than one time point, 408 (43%) were emerging, 165 (17%) were disappearing, 268 (28%) were persistent and 117 (12%) were intermittently detected. Genes most commonly identified as having non-VUS emerging mutations were DNMT3A (39 alterations), TP53 (26), BRCA2 (22), ATM (20), and PALB2 (18) whereas non-VUS disappearing mutations occurred inTP53 (31), ESR1 (23), PIK3CA (19), PALB2 (14), and BRCA2 (12). When restricting analysis to only oncogenic alterations in clinically actionable genes in breast cancer (AKT, BRCA1, BRCA2, ERBB2, ESR1, PIK3CA, PTEN), 33 pts (27%) had emerging mutations, most frequently in BRCA2 and ESR1, while 35 pts (27%) had disappearing mutations, most frequently in ESR1 and PIK3CA. Emerging mutations were most often first detected at progression, while disappearing mutations were most often lost at week 1-2.
Conclusions: Decrease in TF, but not maxVAF, at 1-2 weeks after starting next therapy is correlated with clinical response at time of restaging and can provide an early assessment of treatment response. Genomic evolution with both emerging and disappearing alterations, including in genes clinically actionable in breast cancer as well as genes likely associated with CH, was frequently identified by serial liquid biopsies, both at time of progression and while on treatment.

PS9-03: Circulating tumor DNA (ctDNA), dormant disseminated tumor cells (DTCs) and recurrence outcomes in breast cancer survivors on the SURMOUNT Study

Eleanor Taranto, Nicholas J. Seewald, Lauren J. Bayne, Emma Walinsky, Shannon Deluca, Natalie NC. Shih, Pauleen Sanchez, Isoris Nivar, Bana Ambasager, Clodagh Murray, Amber Chevalier, Christopher G. Smith, Igor Makhlin, Killian Rohn, Brooke L. Goodspeed, Jessica Savage, Paul Wileyto, Jianping Wang, George Belka, Elizabeth Chislock, Lindsay R Berry, Don Berry, Anupma Nayak, Michael Feldman, Amy S. Clark, Lewis A. Chodosh, Angela DeMichele

Background: Recurrence after early-stage breast cancer (BC) is a challenge, occurring in ~30% of patients (pts). Recurrences may arise from reactivation of disseminated tumor cells (DTCs) persisting in a dormant state after primary treatment. The presence of minimal residual disease (MRD) as bone marrow DTCs and/or circulating tumor DNA (ctDNA) in the

blood increases the risk of BC recurrence/death. It remains unclear which pts with DTCs will have these reactivate or develop detectable ctDNA before clinical relapse. We evaluated the association and temporal relationship of ctDNA with DTCs in a population of high-risk BC survivors, and the relationship of these markers with subsequent metastatic recurrence.
Methods: "PENN SURMOUNT" is a single center, prospective, longitudinal cohort study examining MRD biomarkers among pts within 5 years (y) of BC diagnosis who completed all curative treatment except endocrine therapy. Eligible pts must have had: 1) TNBC, or 2) HER2+ or HR+ BC with positive LN and/or residual disease after neoadjuvant therapy, or 3) HR+ BC with a 21-gene Recurrence score >25 and/or high risk Mammaprint. Pts had annual bone marrow aspirate (BMA) for DTCs by immunohistochemistry (using methods of Naume et al.). DTC+ pts went on therapeutic trial; DTC- pts had up to 5y of annual BMA and blood testing. ctDNA was retrospectively assessed using the RaDaR assay, which targets pt-specific somatic mutations identified by whole-exome sequencing (WES) of primary tumor tissue.
Results: Of 184 pts enrolled from 2016 – 2021, 121 had tissue available; 114/121 (94%) had successful WES. A total of 338 plasma samples from 96 pts (median 2 timepoints each, range 1-12) have been successfully tested by RaDaR to date. Overall, ctDNA was detected in 11 samples from 9/96 pts (9.3%) with a median eVAF of 0.009% (range 0.002-0.084%). Two pts were ctDNA+ at baseline (BL), and 7 became positive on surveillance. 87/96 (90.6%) were ctDNA- across all timepoints. 34/96 pts (35%) were DTC+, either at BL (n=24, 25%) or after (n=10, 10%). Considering all timepoints, concordance was 64%. Of 34 ever-DTC+ pts, 4 (12%) were ctDNA+ (of whom 3/4 recurred) and 30 remained ctDNA- (with 1/30 who recurred). Among the 62 pts who remained DTC-, 5 (8%) were ctDNA+ (with 5/5 who recurred), and 57 remained ctDNA- (of whom 5/57 recurred). All ctDNA positivity in DTC+ pts occurred at the time of or after DTC positivity. Over median follow-up (f/u) of 65 months (m), BC recurrence occurred in 14/96 pts (15%), with 2 locoregional-only and 12 distant +/- locoregional recurrences (involving the bone, liver, lung/pleura, and brain); 8/14 pts (57%) were ctDNA+ prior to relapse. 7/12 (58%) with distant recurrences were ctDNA+ prior to metastatic diagnosis, at a median lead time of 15 m (range 0 – 25). Overall, ctDNA+ pts experienced a median lead time from ctDNA positivity to recurrence of 13 m (range 0 – 25). Only 1 of 9 ctDNA+ pts has not recurred; this pt was DTC+ and went on therapeutic trial, without evidence of recurrence over 20 m f/u. 30/34 DTC+ pts (89%) who went on therapeutic trial have not had ctDNA detected during f/u and have not recurred. Overall, ctDNA status was significantly associated with relapse ($p<0.01$), with a PPV of 89% and NPV of 93%. Of the 24 BL DTC+ pts, 2 became ctDNA+ at subsequent timepoints, an average of 18 m after DTC assessment, and both relapsed (3 and 5 m from ctDNA detection, respectively).
Conclusions: In this surveillance study of high-risk BC pts, DTC+ pts were identified who subsequently developed detectable ctDNA and clinical relapse. Where there were discordant results, the timing of DTC and ctDNA positivity revealed a window of opportunity for intervention. A strategy combining both markers for surveillance and intervention to prevent metastatic disease may be of value.

PS9-04: Evaluating racial genomic differences in de novo metastatic breast cancer utilizing ctDNA: results from a large multi-center consortium

Emily Podany, Lorenzo Foffano, Arielle J. Medford, Lorenzo Gerratana, Katherine Clifton, Shaili Tapiavala, Marko Velimirovic, Marla Lipsyc-Sharf, Carolina Reduzzi, Annika Putur, Letizia Pontolillo, Foluso O. Ademuyiwa, Fabio Puglisi, William J. Gradishar, Cynthia X. Ma, Aditya Bardia, Massimo Cristofanilli, Andrew A. Davis

Background: Prior studies have shown that Black patients (pts) are more likely to present with de novo metastatic breast cancer (mBC) compared to White pts and have worse survival outcomes. Our prior research demonstrated some somatic differences in circulating tumor DNA (ctDNA) mutation profiles between Black and White pts with mBC (Podany et al., SABCS 2023). However, there remains a research gap in exploring somatic differences between Black and White pts with de novo versus recurrent mBC.
Methods: This retrospective cohort study included pts with mBC who underwent genomic profiling using the commercially available Guardant360 ctDNA assay. All pts were treated at Washington University in St. Louis, Massachusetts General Hospital, or Northwestern University. Race was pt reported and ancestry data were not available. Clinical and pathologic data were obtained through electronic medical record review. We performed descriptive analysis of clinical variables and pathway variants in Black and White pts with de novo mBC, then performed univariate, multivariate, and multinomial analyses to evaluate single gene mutations and pathway variants within the entire cohort and the estrogen receptor positive, HER2 negative (ER+/HER2-) subpopulation. We then performed a logistic regression to determine clinical and genomic differences between Black pts with de novo mBC versus recurrent mBC.
Results: 274 of 1134 pts (24.2%) had de novo mBC in the overall cohort, 33 of whom self-identified as Black (12.0%) and 210 as White (76.6%). 26.2% of pts had ctDNA collection prior to any therapy, 24.0% after 1st line therapy, and the remaining pts after 2 or more lines of therapy. In the ER+/HER2- population, there were 193 pts (193/855, 22.6%) with de novo mBC, of whom 29 were Black (15.0%). ctDNA results from Black pts with de novo mBC showed a higher frequency of CCND1 copy number variants (cnv) (OR 4.08, CI 1.49-11.15, p=0.006) and GATA3 single nucleotide variants (snv) (OR 3.11, CI 1.10-8.78, p=0.032) on univariate analysis when compared to White pts with de novo mBC. The CCND1 cnv remained significant (OR 3.64, CI 1.30-10.17, p=0.014) on multivariate analysis, controlled for lines of therapy. Black pts with de novo mBC also had a higher frequency of mutations within the cell cycle pathway (OR 2.59, CI 1.15-5.83, p=0.022). On multivariate analysis within the ER+/HER2- cohort, Black pts with de novo mBC were more likely to have nodal metastases (OR 2.63, CI 1.07-6.44, p=0.035), GATA3 snv (OR 3.99, CI 1.23-12.95, p=0.021), CCND1 cnv (OR 3.91, CI 1.21-12.63, p=0.023), and cell cycle pathway mutations (OR 3.19, CI 1.17-8.71, p=0.023) when compared to White pts with ER+/HER2- de novo mBC. When compared to Black pts with recurrent mBC, Black pts with de novo mBC were significantly more likely to have cell cycle pathway mutations (OR 2.71, CI 1.03-7.13, p=0.044) and less likely to have lung metastases (OR 0.33, CI 0.12-0.90, p=0.030). We observed consistent results when performing multinomial analysis comparing de novo

versus recurrent mBC across Black and White pts.
Discussion: Our findings in this large multi-institutional clinical genomic ctDNA database demonstrate that GATA3 snv, CCND1 cnv, and cell cycle pathway alterations were more common in Black versus White pts with de novo ER+/HER2- mBC, all of which have been associated with more aggressive tumor biology. Moreover, in Black patients, cell cycle pathway alterations were more common in de novo versus recurrent mBC. These differences in tumor genomics may partially explain outcome inequities between Black and White pts, and we are further exploring these findings in the context of social determinants of health.

PS9-05: Somatic Structural Variation in Breast Cancer and its Application in Longitudinal Analysis of Circulating Tumor DNA in Early Breast Cancer

Mitchell Elliott, Karen Howarth, Sasha Main, Jesús Fuentes Antrás, Philippe Echelard, Aaron Dou, Eitan Amir, Michelle B. Nadler, Elizabeth Shah, Celeste Yu, Scott Bratman, Taylor Bird, June Roh, Elza C. de Bruin, Christopher Rushton, Sofia Birkeälv, Miguel Alcaide, Lucia Oton, Sergii Gladchuk, Yilun Chen, Anthony George, Girish Putcha, Samuel Woodhouse, Philippe L. Bedard, Lillian L. Siu, Hal K. Berman, David W. Cescon

Background: Genomic structural variation (SV) is a recognized property of cancer cells, contributing to genomic instability and oncogenesis. SV breakpoints and rearrangement patterns are often tumor-specific and can reflect underlying tumor biology. The landscape and implications of SV in breast cancer has been incompletely characterized. Furthermore, the utility of using SVs for prospective circulating tumor DNA (ctDNA) detection and monitoring in early breast cancer (EBC) has not been evaluated.
Methods: SV was evaluated through whole genome sequencing (WGS) analysis in two independent breast cancer datasets: (1) The 100,000 genomes project [n=3044 patients; Genomics England, GEL], made possible through access to data and findings in the National Genomic Research Library via the Genomics England Research Environment and (2) a cohort of patients with EBC treated with neoadjuvant chemotherapy [ctDNA evaluation in early breast cancer (TRACER; n=210 patients) Princess Margaret Cancer Centre, Canada]. SV burden and type was evaluated in the GEL dataset using MANTA and in TRACER using an in-house pipeline (SV size cut-off of >50 bp). Survival correlates within the GEL dataset were evaluated using Cox proportional hazard models with cases censored after 6 years. The performance of an SV-based ctDNA assay was evaluated in BT-474 (cell line, contrived samples) and in FFPE tumors (TRACER, clinical samples) using shallow depth (~15X) WGS followed by SV detection (up to 16) via proprietary multiplex digital PCR. Longitudinal ctDNA detection was performed in the TRACER cohort.
Results:
SV was common across all breast cancer subtypes (GEL data; median SV burden: 108, range: 4-1448; median aggregate copy number of the top 16 SV: 57, range: 16-160). A higher proportion of inversions were seen in HER2-positive tumors, while deletions were common in TNBC. In a multivariate model (including clinical stage, subtype, and tumor mutational

burden), there was a significant association between higher SV count and worse overall survival (OS) in ER+/HER2- breast cancer (HR: 2.31, p=0.0207). Patients with ER+/HER2- breast cancer who experienced a clinical recurrence had higher SV copy number in the top 16 variants than those who did not (p<0.0001). In silico analyses demonstrated that personalized SV-based ctDNA panels (fingerprints) could be successfully designed for 97.1% of GEL cases. To assess the characteristics of an SV-based ctDNA assay, a limit of detection (LoD) study was performed with BT-474 using contrived cfDNA (70 ng). The LoD95 was estimated at 0.00052% tumor fraction (5 PPM) with variants detected as low as 1 in 10 million (0.00001% or 0.1 PPM in 31% of cases). A specificity of 100% was seen in 134 healthy donors using 24 different fingerprints (assessment of 1600 SVs). In an initial cohort of 55 patients (TRACER; ER+/HER2-:19, HER2+:23, TNBC:13), shallow WGS and fingerprint design were successful in all patients. The median number of SVs was 336 (range: 73-1345) with the SV type distributed in a similar fashion (more inversions in HER2+ tumors, deletions in TNBC). A trend towards higher SV copy number based on tumor-only WGS was also seen in those with ER+/HER2- disease who experienced subsequent recurrence (TRACER; SV in no recurrence vs. recurrence: 54.3 vs. 134.1, p=0.099). Shallow WGS and SV-based ctDNA assay design is underway for additional patients in the TRACER cohort.
Conclusion:
SVs are prevalent in breast cancer and associated with prognosis. Personalized SV-based panels permitted ultrasensitive ctDNA detection with high sensitivity and specificity in contrived samples, supporting assay feasibility for early breast cancer. Further analysis of the prognostic impact of SV-burden and type as well as on-treatment and adjuvant ctDNA detection in patients with EBC (TRACER) using SV tracking will be presented at the meeting.

PS9-06: Tracking structural variants in ctDNA using a high-sensitivity assay predicts relapse in the post-neoadjuvant setting: the multicenter ALIENOR trial

Hervé Bonnefoi, François-Clément Bidard, Lucas Hue, Karen Howarth, Florence Dalenc, William Jacot, Jean-Yves Pierga, Marina Pulido, Laurence Venat-Bouvet, Valérie Dumas, Marine Maréchal, Caroline Lalet, Sofia Birkeälv, Laura Salabert, Gaetan Mac Grogan

Background: Patients (pts) with breast cancer (BC) not achieving a pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) are at higher risk of relapse. The multicenter ALIENOR study (NCT03357120), conducted in patients who did not achieve pCR after NAC, is aiming to assess the prognostic value of serial ctDNA monitoring with a novel personalized, tumor-informed ctDNA assay predicated on detection of structural variants (SVs) in plasma. Here, we report the first of two pre-planned analyses from this study (3-years from last patient enrolled).
Methods: Pts with cT2cN1, cT3cN0-1 or locally advanced (cT4cN0-3 or cT1-4cN2-3) M0 BC of any immunohistochemical subtype not reaching pCR after NAC (6 to 8 cycles) were eligible. Pts were enrolled into a 5-year plasma surveillance period (first plasma sample

taken 10 to 63 days after surgery, then every 6 months for up to 5 years). A clinical assessment was performed every 6 months. Tumor blocks from surgical specimens were centrally assessed by one investigator (GMG). Tumors with >20% invasive tumor cells and at least 100 ng of DNA were evaluable. Whole genome sequencing (WGS) was performed on tumor material and personalized multiplex dPCR assays designed tracking up to 8 structural variants (SVs) for use in ctDNA analyses on all available plasma time points (SAGA Diagnostics; Lund, Sweden).
Results: 119 pts were eligible for enrollment and 87 were available for ctDNA analyses. 79 of 87 pts (91%) underwent successful SV-personalized panel design (median of 7, range 4-8 SVs per patient): 463 plasma samples underwent ctDNA testing. BC subtypes included: 41 luminal HER2-, 20 HER2+ and 18 triple-negative. At a median follow-up of 54.5 months (95% CI: 53.3-56.2) from surgery, 21 of 79 pts relapsed (distant: 19 pts, locoregional: 2 pts, distant and locoregional: 1pt). Pts with detected ctDNA, whether at any time point in surveillance (n=32) or at a landmark pre-adjuvant time point (10 to 63 days post-surgery) (n=15) had shorter recurrence-free interval (RFI): HR 20.6 (95% CI 4.8-88.8; $p<0.0001$) and 2.5 (95% CI 1.0-6.2; $p<0.05$), respectively. The median lead-time from ctDNA detection to clinical relapse was 12.2 months (range 3.4-60.6). ctDNA was detected at any time-point in 90.5% (19/21) of pts who relapsed. Of 32 pts with ctDNA detected at any time point, 19 relapsed (59.4%) and 13 are still relapse-free at last follow-up. In this later group, 6 pts positive at landmark time point only, were subsequently cleared in all time points, 3 pts positive at the last visit time point only, are pending longer follow up, and 4 pts had multiple positive ctDNA time points including several with rising levels of ctDNA. Of 47 pts with no ctDNA detected, 2 relapsed (4.3%): one with local relapse; one with brain-only metastasis. The univariate analysis showed that clinical stage, BC subtype, RCB, and age were not statistically associated with RFI.
Conclusions: Serial ctDNA assessment using a novel SV-based assay is predictive of relapse with lead-times of up to 61 months over clinical relapse. These data support further evaluation of this assay in prospective trials. Landmark-only ctDNA detection followed by clearance on therapy might represent micrometastatic disease controlled or eradicated by adjuvant treatment. Longer follow-up is required in cases with ctDNA detection without clinical relapse to fully characterize clinical accuracy and lead-times associated with SV-based ctDNA surveillance.

PS9-07: Epigenomic Characterization of ER Transcriptional Activation via Liquid Biopsy

Jonathan Beagan, Suzanne Wardell, Travis Clark, Justin Finkle, Anthony D'Ippolito, Mike Zhong, Jamey Guess, Kristian Cibulskis, Aparna Gorthi, Tyrone Tamakloe, Charlene O'Brien, Baovy Tran, Sarah Kieft, Mary McGillicuddy, Jayne M Stommel, Allison L Creason, Julian Egger, Gordon B Mills, Corrie Painter, Matthew Eaton, Donald McDonnell, J. Carl Barrett

Background:Endocrine therapies (ET) are a cornerstone treatment for estrogen receptor-positive (ER+) breast cancer (BC). ET's efficacy depends on the transcriptional addiction of

the cancer cells to estrogen receptor signaling, for which there is no current clinical test. ER IHC and ESR1 mutations are insufficient proxies for ER transcriptional dependency. A blood-based biomarker for dynamic measurement of the ER transcriptional dependency of a tumor would greatly improve our ability to identify patients who would most benefit from continued ET.

Methods:We profiled key epigenomic determinants of ER transcriptional activity in a broad array of ER+ BC cell lines, and then translated the resulting epigenomic signature into a form assayable in 1mL of plasma from BC patients. First, we profiled the epigenome of 8 breast cancer cell lines (MCF7, T47D, BT483, CAMA1, HCC1428, ZR-75-1, MDA-MB-361) in estrogen depleted media and in the presence of physiologically relevant levels of estradiol (E2, 0.1nM). Using ChIP-seq for histone modifications associated with active promoters and enhancers paired with enrichment-based DNA methylation we identified the epigenomic loci most associated with response to E2. The concurrent plating and treatment of these cell lines makes this a unique resource for the identification of enhancers, promoters, and DNA methylation marks associated with transcriptional response to estrogen signaling. We then employed the Precede multi-analyte liquid biopsy assay, which profiles these same epigenomic features from 1mL of patient plasma and used proprietary computational methods to combine information across analytes to create a patient-specific ER activity quantification algorithm robust to varying levels of circulating tumor DNA fraction (ctDNA%). We analyzed plasma from 38 patients with ER+ metastatic BC seen at the OHSU Knight Cancer Institute who had blood drawn within 1 week of tumor biopsy with ER and HER2 IHC. Additionally, we profiled 48 patient samples with the same characteristics sourced from commercial biobanks.

Results:We identified an epigenomic signature that profiles ER activity in patient plasma samples. Through a paired genome-wide analysis of all cell lines' response to E2, we identified 2320 E2-upregulated enhancers, 334 E2-upregulated promoters, and—intriguingly—0 DNA methylation loci that responded to E2 modulation. E2 responsive enhancers and promoters are linked to genes associated with estrogen response, cell cycle, and epithelial to mesenchymal transition. Many of these sites are located adjacent to known ESR1, FOXA1, and GATA3 binding sites. Computational refinement and aggregation of a subset of the E2-induced enhancers enabled the creation of an ER activity score that can be assayed in patient plasma and is robust to clinically relevant levels of ctDNA%. Patients with ER+ tumors displayed higher ER activity scores compared to patients with ER- tumors, and scores were consistently high for patients with ESR1 mutations. This plasma-based ER activity score is highly correlated with previously published RNA-based ER activity scores (Guan et al. 2019) which require biopsy tissue.

Conclusions:ER transcriptional pathway activation correlates with changes to the epigenome that are detectable via Precede multi-analyte liquid biopsy assay, enabling a measurement of breast cancer dependence on endocrine signaling from 1mL of plasma through an ER activity score. This ER activity score is biologically interpretable and correlates with previous RNA-seq based predictors of ER activity. While ESR1 mutant patients score consistently high, a subset of ESR1 wildtype patients also demonstrate high

ER activity scores, implying a potentially expanded patient population for treatment with novel anti-endocrine agents such as SERDs.

PS9-08: Ultra-sensitive detection of circulating tumor DNA (ctDNA) in patients (pts) undergoing neoadjuvant endocrine therapy for hormone receptor-positive (HR+) early breast cancer (BC)

Albert Grinshpun, Derek Dustin, Mingyang Cai, Melissa Hughes, Molly DiLullo, McKenna Moore, Erica L Mayer, Eric P Winer, Nancy U Lin, Sara M Tolaney, Otto Metzger, Rinath Jeselsohn

Introduction: Neoadjuvant endocrine therapy (NET) is often used in HR+, HER2-negative primary BC to decrease tumor extent prior to surgery. In neoadjuvant chemotherapy treatment of HER2-positive and triple negative BC, the residual cancer burden (RCB) is prognostic and utilized for treatment decisions of adjuvant therapy. However, in HR+, HER2-negative BC, RCB is not a surrogate for sensitivity to NET and long term outcomes. Moreover, despite the approval of a CDK4/6 inhibitor for high risk early-stage HR+ BC, there are currently no biomarkers predictive of sensitivity to this class of drug in this setting.
This study aimed to investigate the potential utility of baseline ctDNA and dynamic changes during NET as a biomarker to help guide systemic treatment decisions.
Methods: The phase II PELOPS trial (NCT02764541) enrolled pts with clinical stage I-III HR+, HER2-negative BC and randomized to NET plus palbociclib or NET alone for 24 weeks prior to surgery; plasma samples were collected at baseline (BL) and prior to surgery (PS). Cell-free DNA was analyzed using Guardant Reveal powered by Infinity, a tissue-free, epigenomic assay that utilizes comprehensive methylome and DNA sequencing data for ctDNA detection. Categorical group comparison was performed using Fisher's exact test, and Mann-Whitney test were used to evaluate ctDNA dynamics.
Results: A total of 104 plasma samples from 54 pts were analyzed with successful sequencing achieved in 95.0% (95/100) of samples. At BL and PS, the detection rates were 20/50 (40%) and 6/45 (13.3%), respectively. Overall, ctDNA was detected in 27.4% (26/95) of samples. Higher tumor fraction at BL (measured as methylation score) was associated with pathological stage at surgery (median 0.049% for stage III disease vs. 0% for stage I/II, $p = 0.0006$) and higher RCB scores following NET (median 0.049% for RCBIII vs. 0% for RCBI-II, $p = 0.049$). Using binary detection methods, BL ctDNA was detected in 0% (0/3) pts with RCBI, whereas BL ctDNA was detected in 20.8% (5/24) of pts with RCBII, and 61.1% (11/18) of pts with RCBIII (RCBI-II vs. RCBIII $p = 0.005$). Comparison of ctDNA between matched BL and PS samples showed that most pts (63.4%, 26/41) with undetectable ctDNA at BL remained with undetectable ctDNA post NET (PS). Six (14.6%, 6/41) pts, all with lobular BC and RCBIII, had persistent ctDNA at both timepoints. Within this subset of pts, 67% (4/6) developed metastatic disease recurrence within 5 years of surgery. Interestingly, there were no pts (0%, 0/41) that became ctDNA positive at PS, and 22% (9/41) pts experienced ctDNA clearance from BL to PS.

Somatic variants were identified in 27% (7/26) of ctDNA detected samples. There were alterations in five oncogenes at BL (PIK3CA, MAP3K1, TERT, RHOA, AKT1), and two alterations were acquired after NET (ATM, ESR1 D538G).
Conclusions: Ultra-sensitive tissue-free ctDNA testing can detect ctDNA in a substantial proportion of pts with primary HR+ BC. The presence of ctDNA at BL in this population was associated with larger pathologic tumor size and higher RCB scores following NET. Furthermore, persistence of ctDNA after NET was associated with high rates of recurrence. This study is the first investigation into the dynamics of ctDNA during NET using the Guardant Infinity platform, and our findings suggest that ctDNA has the potential to provide valuable insights into tumor burden, sensitivity to ET, and the emergence of endocrine resistance mutations. These results are limited by the sample size but warrant further investigation of the role of ctDNA as a tool to predict sensitivity to ET and long term outcomes. Such a tool could be valuable in tailoring treatment approaches, particularly given the ongoing development of novel ETs and the addition of CDK4/6i in the adjuvant setting.

RF1-01: Effect of a weight loss intervention (WLI) on metabolic and inflammatory biomarkers in women with obesity and breast cancer: Results from the Breast Cancer Weight Loss (BWEL) Trial (Alliance)

Jennifer Ligibel, Karla V. Ballman, Linda McCall, Lingeng Lu, Melinda Irwin, Pamela J. Goodwin, Catherine M. Alfano, Vanessa Bernstein, Tracy E. Crane, Linda M. Delahanty, Elizabeth Frank, Olwen Hahn, Dawn L. Hershman, Judith O. Hopkins, Erica L. Mayer, Lori Minasian, Linda Nebeling, Marian L. Neuhouser, Electra D. Paskett, Patricia A. Spears, Vered Stearns, Cynthia A. Thomson, Anna Weiss, Julia White, Thomas A. Wadden, Clifford Hudis, Eric P. Winer, Lisa A. Carey, Ann H. Partridge

Background: Unfavorable metabolic and inflammatory parameters are associated with increased risk of recurrence, comorbidities, and cancer-specific and all-cause mortality in early-stage breast cancer. The BWEL trial (Alliance for Clinical Trials in Oncology A011401; NCT02750826) evaluates the impact of a lifestyle based WLI on invasive disease-free survival in 3180 women with stage II-III Her-2 negative breast cancer and a body mass index (BMI) of at least 27 kg/m2. Here we report the impact of the WLI on metabolic and inflammatory biomarkers.

Methods: BWEL participants were randomized to a health education (HE) alone control arm (n=1489) or to a 2-year WLI plus HE (n=1491). The WLI was delivered through telephone-based health coaching and focused on caloric restriction and increased exercise. Participants underwent collection of fasting (confirmed by self-report) blood at baseline, 6 and 24 months. Serum levels of c-reactive protein (CRP), insulin, and leptin were assessed centrally using commercial ELISA assay kits at Yale School of Public Health. Samples were run in batches with all samples from an individual patient analyzed in a single batch. The absorbance was determined at the wavelength of 450 nm with a correct reference

wavelength of 600 nm using a spectrometry (Biotek Instrument Inc, Winooski, Vermont). 10% of samples were run in duplicate, and a pooled serum sample was run in each plate for the calculation of intra-assay variation. Non-fasting samples were omitted from metabolic analyses. Summaries are reported as means (± standard deviation). Comparison of the mean changes from baseline between the treatment groups was determined with a two-sample t-test.

Results: At baseline, average BMI was 34.5 (±5.7) kg/m2, average age was 53.4 years (±10.6), and 57% of participants were postmenopausal at the time of diagnosis. Most participants were White (80.3%); 12.8% identified as Black and 7.3% as Hispanic. Fasting serum samples were available from 2725 participants at baseline, 2234 at 6 months, and 1230 at 24 months. There were no significant differences in levels of metabolic or inflammatory biomarkers between groups at baseline (Leptin: 40.2 [±23.1] ng/ml WLI vs 39.3 [±23.7] ng/ml HE; CRP: 4.2 [±2.8] mg/L WLI vs 4.5 [±2.9] mg/L HE; Insulin: 16.5 [±14.9] mIU/ml WLI vs 16.5 [±14.3] mIU/ml HE). Participants in the WLI arm experienced significant reductions in all metabolic and inflammatory biomarkers vs HE at 6 and 24 months. Leptin changed by -8.4 (±16.1) ng/ml at 6 months and -1.8 (±18.70) ng/ml at 24 months in the WLI vs +1.9 (±16.1) ng/ml and +4.6 (±20.5) ng/ml in the HE arm (both $p<0.0001$). CRP changed by -0.3 (±2.1) mg/L at 6 months and -0.4 (±2.4) mg/L at 24 months in the WLI vs +0.01 (±2.1) mg/L and +0.01 (±2.3) mg/L in the HE arm ($p=0.0004$ and 0.0014, respectively). Insulin changed by -2.4 (±17.2)mIU/ml at 6 months and -0.8 (±11.6) mIU/ml at 24 months in the WLI group vs + 0.9 (±14.7) mIU/ml and +1.9 (±14.7)mIU/ml in the HE arm ($p<0.0001$ and $p=0.0005$, respectively).

Conclusions: A telephone-based WLI led to significant improvements in metabolic and inflammatory biomarkers known to be associated with cancer recurrence, comorbidities, and survival in a cohort of participants with obesity treated for early breast cancer. Further follow-up of the BWEL trial will evaluate whether changes in biomarkers predict improvements in cancer outcomes.

RF1-02: Palbociclib plus letrozole versus weekly paclitaxel, both in combination w/ trastuzumab plus pertuzumab, as neoadjuvant treatment for patients w/ HR+/HER2+ early breast cancer: primary results from the randomized phase II TOUCH trial (IBCSG 55-17)

Luca Malorni, S. Tyekucheva, C. Zamagni, U. Hasler-Strub, A. Gombos, C. Chakiba-Brugère, M. Colleoni, A. Mueller, A.M. Minisini, D. Taylor, J.P. Salmon, E. Gallerani, A. Cariello, A. Fontana, H. Roschitzki-Voser, R. Kammler, B. Ruepp, S. Loi, G. Viale, M.M. Regan, E. Brain, L. Biganzoli

Background: HR+/HER2+ breast cancer (BC) is a biologically heterogeneous group characterized by low pathological complete response (pCR) to chemotherapy combined with anti-HER2 therapy and relative endocrine resistance in the neoadjuvant setting. CDK4/6 inhibitors (CDK4/6i) have recently shown potential for chemotherapy de-escalation when combined with endocrine and anti-HER2 therapy.
Methods: TOUCH is an international, open-label, phase II trial for post-menopausal patients (pts) with cT>1 cm, cN0 or cN1, HR+/HER2+ BC, randomized 1:1 to Paclitaxel (T) 80 mg/m2 iv on day 1,8,15 q28d for 4 cycles (arm A) or Palbociclib (Pal) standard dose/schedule for 4 cycles plus Letrozole (L) 2.5 mg/day for 16 weeks (arm B). All received 5 cycles of trastuzumab sc + pertuzumab iv (HP) standard dose q3w. Randomization was stratified by: a) age and G8 geriatric score (<65 y vs ≥65 y and G8 >14 vs ≥65 y and G8 ≤14); b) cN0 vs cN1. The primary objective was the interaction between a gene-signature of E2F pathway activity (RBsig) and pCR (ypT0/ypTis ypN0), hypothesizing higher pCR for tumors with RBsig high in T+HP, and for tumors with RBsig low in Pal+L+HP.
RNA-sequencing was performed from pre-treatment FFPE biopsies (NEBNext® UltraTM II Directional RNA Library Prep Kit with the Twist Human Core Exome + Custom IntegraGen Enrichment V2 capture System, Paired End 100b reads).
RBSig score was calculated by first standardizing each normalized gene measurement across all sequenced specimens and adding up standardized values for each gene. RbSig was dichotomized at the median. Treatment-by-RBSig interaction was estimated using logistic regression.
Results:
From October 2018 to July 2022, 145 pts were randomized (73 in arm A, 72 in arm B) in 37 centers from 4 countries. Median age was 69 years (IQR 63,73), with 99 pts (68%) being ≥65y of age (65 with G8 score >14, 34 with G8 ≤14); 132 pts (91%) had a ECOG PS 0; at diagnosis 109 pts (75%) were cN0 with a median cT of 30 mm (IQR 20-40); 76 pts (56%) had G3 tumors. More pts completed Pal vs T (94.4% vs 79.5%) and >95% completed 5 cycles of HP. Surgery was performed in 98.6% of the pts, BCS being more frequent in arm B vs A (82% vs 67%). pCR and other secondary efficacy endpoints were similar between arms. Overall, pCR was 32.9% (95%CI: 22.3-44.9) in arm A vs 33.3% (95% CI: 25.5-41.4) in arm B. RBsig was successfully determined in 115 pts who completed at least one full dose of treatment. Median RBsig was lower in arm B. There was no interaction between pCR and RBsig (p=0.18): pCR in RBsig high vs low was 31% (95%CI: 16.1-50) vs 42% (95%CI: 23.3-63.1) in Arm A, and 38% (95%CI: 20.2-59.4) vs 26% (95%CI: 11.9-44.6) in Arm B. No new safety signal was observed. Grade 3-4 adverse events were seen in 31.5% vs 54.1% of pts in arm A vs Arm B (mainly diarrhea in Arm A and asymptomatic neutropenia in Arm B).
Conclusions:
Although the primary hypothesis was not supported, TOUCH shows for the first time that, when combined with dual anti-HER2 blockade, a de-escalated chemo-free backbone of Pal+L yields pCR rates similar to weekly T. The lack of clinical impact of the increased rate of neutropenia of Pal+L suggests it might represent an attractive alternative for postmenopausal pts with HR+/HER2+ BC, especially older ones. Translational studies are ongoing to uncover potential gene-signatures with prognostic/predictive significance.

RF1-03: Three-year event-free survival (EFS) of the multicenter phase II TRAIN-3 study evaluating image-guided optimization of neoadjuvant chemotherapy duration in stage II and III HER2-positive breast cancer (BOOG 2018-01)

Fleur Louis, Anna van der Voort, Mette van Ramshorst, Antonios Daletzakis, Ingrid Mandjes, Inge Kemper, Mariette Agterof, Wim van der Steeg, Joan Heijns, Marlies van Bekkum, Ester Siemerink, Philomeen Kuijer, Astrid Scholten, Jelle Wesseling, Marie-Jeanne Vrancken Peeters, Ritse Mann, Gabe Sonke

Background Neo-adjuvant treatment with 6-9 cycles anti-HER2 based chemotherapy leads to excellent long-term survival in patients with stage II-III HER2+ breast cancer, but comes with important side effects. The TRAIN-3 study previously showed that one in three patients with hormone receptor negative (HR-) tumors and one in six with hormone receptor positive (HR+) tumors have an early pathologic complete response (pCR) after only three cycles of neo-adjuvant chemotherapy. Here, we present the results of the primary endpoint, 3-year event-free survival (EFS).
Methods TRAIN-3 is a single-arm, phase 2 study in 43 hospitals in the Netherlands. Patients with stage II–III HER2-positive breast cancer received up to nine cycles of neoadjuvant systemic therapy with paclitaxel, trastuzumab, carboplatin and pertuzumab (PTC-Ptz) and were referred for surgery once a complete radiologic response was seen on MRI. Locoregional and endocrine treatment followed national guidelines. Patients with a pCR completed one year of trastuzumab and pertuzumab as adjuvant treatment. Patients with residual invasive disease completed the 9 cycles of PTC-Ptz followed by 14 cycles of T-DM1. EFS was estimated using Kaplan-Meier statistics on an intention-to-treat basis for each HR subgroup separately. Three-year EFS rates of 88% for HR- and 90% for HR+ tumors were taken as reference. The study would be declared successful if no more than 38 events in the HR- subgroup and 34 events in the HR+ subgroup occurred after 700 patient years of follow-up.
Results 235 patients with HR- tumors received 1-3 (n=91, 38.7%), 4-6 (n=76, 32.3%) or 7-9 (n=68, 28.9%) cycles of PTC-Ptz. 232 patients with HR+ tumors received 1-3 (n=69, 29.7%), 4-6 (n=71, 30.6%) or 7-9 (n=92, 39.7%) cycles of PTC-Ptz. After a median follow-up of 39.7 months (IQR 34.8-45.4), 3-year EFS was 92.1% (95% CI 88.5-95.8) in the HR- subgroup and 92.0% (95% CI 88.5-95.6) in the HR+ subgroup. A total of 19 and 21 events were reported in patients with HR- and HR+ tumors respectively, meeting the primary endpoint. Events included 9 vs 8 distant recurrences, 7 vs 6 locoregional recurrences, 2 vs 4 non-breast second primary malignancies, 0 vs 3 second primary breast tumors, and 1 vs 0 non-breast cancer related death, in HR- and HR+ patients respectively. EFS rates in patients treated with 1-3 cycles of neoadjuvant systemic therapy were 96.0% (95% CI 91.6-100) in HR- and 97.1% (95% CI 93.3-100) in HR+ patients. Corresponding figures were 90.8% (95% CI 84.5-97.5) and 92.8% (95% CI 87.0-99.1) in patients treated with 4-6 cycles and 87.6% (95% CI 79.1-97.0) and 87.1% (80.3-94.6) in patients treated with 7-9 cycles.
Conclusions In patients with stage II-III HER2+ breast cancer, MRI-guided treatment

optimization is associated with excellent 3-year EFS. These results confirm our earlier findings on pCR rate that one in three patients with HR- disease and one in six patients with HR+ disease can be treated effectively with only three cycles of neoadjuvant chemotherapy. This approach offers a novel therapeutic option that provides a significant reduction in toxicity for this patient population.

RF1-04: Long-Term Follow-up and updated analysis from S0221, Comparing Alternative Dose-Schedules of Adjuvant Anthracycline/Taxane Therapy in High-Risk Early Breast Cancer

Azka Ali, William E Barlow, Halle CF Moore, Timothy J Hobday, Claudine Isaacs, Muhammad Salim, Jonathan K Cho, Kristine J Rinn, Kathy S Albain, Helen K Chew, Gary V Burton, Timothy D Moore, Gordan Srkalovic, Bradley A McGregor, Lawrence E Flaherty, Danika L Lew, Jieling Miao, Julie R Gralow, Gabriel N Hortobagyi, Priyanka Sharma, Lajos Pusztai, George T Budd

Background: While the landscape of metastatic breast cancer treatment has evolved over the years with incorporation of targeted agents and antibody drug conjugates, chemotherapy continues to be the mainstay of adjuvant treatment for high-risk early breast cancer. S0221 was a previously reported phase III randomized trial performed by the North American Breast Cancer Intergroup (now known as the National Clinical Trials Network [NCTN]) investigating alternative dosing schedules of chemotherapy for early breast cancer.
Methods: S0221 investigated weekly (arms 2 and 4) doxorubicin (A)/cyclophosphamide (C) + granulocyte colony stimulating factor (GCSF; filgrastim or pegfilgrastim) versus (vs.) every 2 weeks (Q2W) (arms 1 and 3) schedule AC, followed by paclitaxel (P) given Q2W or weekly for 12 weeks as post-operative adjuvant therapy in node-positive or high-risk node-negative breast cancer. Weekly AC was given as doxorubicin 24mg/m2 IV once per week and cyclophosphamide 60mg/m2 orally once per day with GCSF. Between December 2003 and November 2010, 2716 patients were randomized in a 2x2 factorial design to: 1) 15 weeks of weekly AC vs. 6 cycles of Q2W AC and 2) P weekly vs. P Q2W with GCSF support and this accounted for arms 1-4. After enrollment of 2716 patients, randomization to the two AC arms was stopped for futility and the trial was modified to study only the P schedules. Between January 2011 and January 2012, an additional 578 patients were assigned to 4 cycles of Q2W AC and randomized to P weekly vs. Q2W accounting for arms 5-6. Here, we present updated survival outcomes of four arms on the original protocol and report, for the first time, analysis of 578 patients from two additional arms on the revised protocol. Updated survival was assessed using log-rank tests and Cox regression models.
Results: At a median follow-up of 12.1 years, among the patients treated in the original protocol, there were no significant differences among the four treatment arms for disease free survival [DFS] (p=0.91) or overall survival [OS] (p=0.34). When stratified by disease subtype, the human epidermal receptor-2 (HER2) positive cohort had the highest 10-year DFS rate (77.7%) compared to HR-positive/HER2-negative (70.6%) or HR-negative/HER2-negative (70.3%) cohorts (p value = 0.0005). The HER2-positive cohort also had a superior 10-year OS rate of 82.3% compared to HR-positive/HER2-negative (78.1%) or HR-negative/HER2-negative (74.9%) cohorts (p=0.0044). Among the 578 patients assigned AC for 4 cycles and randomized to P weekly vs. Q2W P, there were no overall differences in DFS (p=0.32) or OS (p=0.42). There was no difference in 10-year DFS rate between original

(71.3%) or revised (74.4%) protocol (HR 0.80; 95% CI 0.75-1.05). Patients were also stratified in terms of sex (23 men enrolled) and race (379 Blacks enrolled). While women have superior DFS and OS compared to men, due to small number of men and wide CI, these data should be interpreted with caution. Black patients had worse DFS and OS (10-year DFS rate of 64.2% vs. 72.8%; 10-year OS rate of 70.4% vs. 79.0%) compared to non-Blacks. In terms of toxicity, cardiac toxicity profile was more favorable in arms 2 and 4 (0.5-0.7%) that used weekly AC compared to the other four arms that incorporated AC Q2W (1.1-3.3%). There was more skin toxicity with weekly AC schedule with 15.7-16.1% events compared to 2.4-4.0% events in the other four arms. There was no difference in infectious risk or changes in metabolic profile but there were more neurological AEs, and more pain with arms that used Q2W paclitaxel compared to weekly paclitaxel.
Conclusion: As there were no significant outcome differences in DFS or OS between the studied schedules with extended follow-up in the original cohort or in the additional 578 patients treated on the revised protocol, either paclitaxel schedule may be recommended, with selection based on toxicity, cost, or patient preference rather than efficacy.

[AA1]Character limit allowed 3400

RF1-05: DNA methylation patterns are similar in benign tissue from ipsilateral and contralateral breast while different from matched breast cancer, and healthy controls.

Saya Dennis, Takahiro Tsukioki, Gannon Cottone, Wanding Zhou, Yuan Luo, Patricia A. Ganz, Mary E. Sehl, Seema Khan, Susan Clare

Introduction: Epigenetic changes play a crucial role in cancer development. Among these, DNA methylation is one of the most significant due to its impact on gene expression and genome stability. Hyper-methylation generally suppresses transcription and hypo-methylation promotes it. In breast cancer research, tumor-adjacent tissue is often used as a reference for characterizing epigenetic alterations, but numerous studies suggest that the tissue adjacent to a tumor shares genomic characteristics with the tumor itself. The extent to which epigenetic profiles overlap between tumor, histologically normal tissues from the involved and uninvolved breast, and benign tissues from cancer-free individuals is unknown. Our study aims to address this gap by systematically comparing the DNA methylation profiles across these different tissue types.

Methods: A total of 72 cancer patients were selected from Northwestern University, while data from 182 cancer-free women was obtained from tissue donated to the Komen Tissue Bank. From each individual cancer patient, four regional samples were collected: tumor tissue (TU), tumor-adjacent normal tissue (AN), benign tissue from the opposite quadrant of the involved breast (OQ), and benign tissue from the contralateral uninvolved breast (CUB). From cancer-free patients, normal breast tissue was collected (CFN). From these, we created a "tumor proximity axis": CFN→CUB →OQ→AN→TU.
Methylation profiles were assayed using Illumina's Infinium Methylation EPIC v1.0 BeadChip.
Differential methylation analysis was conducted in two sets of four pairwise comparisons: (1) comparing tumor samples to the four benign tissue categories, and (2) comparing tissue categories that are adjacent along the tumor proximity axis. The differentially methylated CpGs were analyzed for enrichment of transcription factor binding sites (TFBS) and genes.

Results: Following data processing and quality control, there were 72 TU, 63 AN, 70 OQ, 72 CUB, and 182 CFN samples for analysis. Differential methylation analysis showed that TU samples had distinct methylation profiles, with more hypomethylation events compared to hypermethylation events relative to benign tissues. Case-benign tissues (AN, OQ, CUB) exhibited similar methylation profiles, distinct from CFN.
Transcription factor binding site (TFBS) enrichment analysis revealed that case-benign samples, even those distant from tumor, i.e. CUB, showed breast cancer-related methylation changes. Hypomethylated sites in CUB compared to CFN were enriched for TF binding sites TP63, GATA3, ESR1, PR, AR, NR3C1, and GREB1. TU hypermethylation events were enriched for Polycomb-repressive complex 2 (PRC2) binding, including EZH2, SUZ12, and JARID2. ER+ and ER- tumors had distinct methylation profiles. Both ER+ and ER- tumors showed hypermethylation enrichment for PRC2-related binding motifs. However, hypomethylation events differed, with ER+ tumors enriched for hormone receptor-related pathways and ER- tumors enriched for hematopoiesis/immune-related pathways. We did not find any differential methylation between benign tissues from patients with ER+ vs. ER- tumors.

Conclusions: DNA methylation changes profoundly at two points on the tumor proximity axis: CFN to CUB and AN to TU. Specifically, all case-benign tissues, including CUB, exhibited changes associated with breast cancer when compared to CFN. Although the methylation profiles of ER+ and ER- tumors differed, benign tissues showed no differences as a function of ER status of the tumor. These findings demonstrate that benign case tissue is not epigenetically "normal" and provide insights for further investigation into the process of tumorigenesis.

RF1-06: Association of polygenic-based breast cancer risk prediction with patient management

Katie Johansen Taber, Sarah Ratzel, Elisha Hughes, Alexander Gutin, Jeff Jasper, D. Claire Miller, Devika Chawla, Brady DeHart, Laura Becker, Pamela Morin, Julia Certa, Allison Kurian

Background:A breast cancer (BC) risk predictor that combines the Tyrer-Cuzick (TC) risk model with a polygenic risk score ("combined risk score" or CRS) has been shown to significantly improve risk prediction over TC alone. Guidelines recommend that individuals predicted to have ≥20% remaining lifetime risk of BC undergo enhanced management, including annual screening mammography (SM) as early as age 30, annual breast MRI, and genetic counseling (GC). However, little is known about whether and how clinicians manage patients based on risk predicted by CRS. Here, we describe the uptake of mammography, breast MRI, and GC following receipt of CRS results.
Methods:De-identified administrative claims data from the Optum Labs Data Warehouse were linked with de-identified TC and CRS results originally provided to ordering clinicians between August 1, 2017 and November 30, 2021. Patients were included in the cohort if they had continuous medical and pharmacy enrollment for ≥360 days prior to and ≥360 days after the CRS result and were ≥18 years of age. Patients were excluded if they had a history of breast malignancy, BC, or any metastatic cancer during baseline; evidence of BC prevention measures (tamoxifen, raloxifene, aromatase inhibitors, pre-menopausal ovarian function suppression, or mastectomy) prior to receiving CRS results; or evidence of any cancer diagnosis in the ≥360 days after receiving CRS results. Patients were divided into

four subgroups based on their lifetime risk predicted by CRS and by TC alone (high risk (+): ≥20%, average risk (-): <20%): CRS+ TC+, CRS+ TC-, CRS- TC+, and CRS- TC-. Patient management claims were assessed in the ≥360 days after the CRS test date.
Results:The study cohort consisted of 8,662 patients: 2,443 (28.0%) CRS+ TC+, 696 (8.0%) CRS+ TC-, 856 (9.9%) CRS- TC+, and 4,687 (54.1%) CRS- TC-. Mean lifetime risk of breast cancer predicted by the CRS in each group was 29.9% (SD 7.9%), 24.5% (SD 4.3%), 16.4% (SD 2.6%), and 11.2% (SD 4.4%), respectively. Among the 3,309 patients with ≥20% lifetime risk predicted by TC (TC+), 856 (25.9%) had a lifetime risk <20% predicted by the CRS (CRS-). Conversely, among the 5,383 patients with lifetime risk <20% predicted by TC (TC-), 696 (12.9%) had a lifetime risk ≥20% predicted by the CRS (CRS+). Following receipt of CRS results, compared to the CRS- TC-group, the rate of SM in patients under age 40 years was 2.4, 2.2, and 1.9 times higher in the CRS+ TC+, CRS+ TC-, and CRS- TC+ groups, respectively; the rate of breast MRI was 13.8, 8.3, and 7.9 times higher in the CRS+ TC+, CRS+ TC-, and CRS- TC+ groups, respectively; and the rate of GC was 3.2, 2.9, and 2.4 times higher in the CRS+ TC+, CRS+ TC-, and CRS- TC+ groups, respectively.
Conclusions:For a substantial proportion of patients, the CRS predicted a different risk level compared to TC, suggesting that these patients should be managed differently based on their CRS result. Patients with a ≥20% lifetime risk for BC were more likely to undergo enhanced management compared to those with a lifetime risk <20%, regardless of whether their risk was based on the CRS or on TC. These results suggest that clinicians recommended management aligned with guidelines for those with ≥20% lifetime risk, even when such risk was predicted by the CRS.

RF1-07: Multifactor analysis for pathologic complete response (pCR) in a chemotherapy-free regimen of durvalumab, trastuzumab, and pertuzumab (DTP Trial) in HER2-enriched early breast cancer

Polly Niravath, Mailin Li, Jian Guan, Wei Qian, Fotis Nikolo, Jenying Deng, Xen Ping Hoi, Tiffany Sheu, Susan L Haley, Mary Schwartz, Sunil Mathur, Kai Sun, Hahn Mai, Keith S. Chan, Steven T. C. Wong, Aleix Prat, Jenny C Chang

Background: The treatment landscape for HER2-positive breast cancers has significantly changed in recent years with the expansion of anti-HER2 therapies, aiming to de-escalate or potentially eliminate use of standard cytotoxic agents. Previously, we demonstrated a 67.6% pathologic response rate (Residual Cancer Burden, RCB 0/1) using a chemotherapy-free regimen of durvalumab, trastuzumab, and pertuzumab in a biologically selected subset of HER2-enriched tumors. Here, we present preliminary analysis of multiple clinical and immune factors that contribute to achieving pCR. Methods: Between 07/2020 and 02/2024, 39 patients with previously untreated stage I-III, ER/PR-negative, HER2-enriched breast cancer (BluePrint®, Agendia) received durvalumab [1120 mg intravenously (IV), every 3 weeks (Q3W)], trastuzumab (8 mg/kg IV loading dose, 6 mg/kg IV Q3W), and pertuzumab (840 mg IV loading dose, 420 mg IV Q3W) for 6 cycles. Multifactor correlation analysis with pCR was performed using clinical characteristics (age, T, N, stage, nuclear grade, BMI), biomarker datasets including patients' baseline HER2DX signatures (Prat et al, Lancet Oncology 2020) (immune, luminal, proliferation, and HER2 amplicon), and immunohistochemical assays [% tumor infiltrating lymphocytes (TILs), %Ki67, and PD-L1 Combined Positive Score (CPS)]. Statistical analyses, including Point Biserial correlations, Chi-Square association tests, and logistic regression, were performed using SAS 9.4 software with significance set at $p<0.05$. Results: Of 39 patients, 2 patients were not

evaluable – one due to an unrelated myocardial infarction and the other due to loss to follow-up. Six patients showed residual disease after DTP therapy and subsequently received standard salvage TCHP chemotherapy. Primary end-point as pathological response rate was 67.6% (N=25/37) with 18/37 patients achieving RCB0 and 7/37 patients achieving RCB1 status. Most adverse events were mild (grade 1-2), with only 5 patients experiencing grade 3 adverse reactions. Our analyses showed pCR was negatively associated with tumor size (p=0.007), nodal status (p=0.036), and advanced clinical stage (p=0.018) but positively associated with % TILs (p=0.02) and PD-L1 CPS score (p=0.038). We also found the HER2DX luminal signature to be associated with pCR (p=0.032). Additional analyses on tumor microenvironment and immune cell crosstalk are currently ongoing with paired baseline and end-of-treatment single cell RNA-sequencing as well as Xenium spatial transcriptomics. Conclusion: While immune markers such as TILs and PD-L1 scores are not typically measured in HER2-positive breast cancers, this data opens up the possibility of rationally leveraging targeted therapies in this subset of immune and HER2-sensitive breast cancers, thus potentially avoiding chemotherapy in the future for this biologically selected group. This regimen holds promise as an effective, relatively non-toxic, and biologically-driven alternative to standard chemotherapy for patients with HER2-enriched subset of early breast cancer. Clinical trial information: NCT03820141. Research Sponsor: Houston Methodist Hospital and Astrazeneca

RF2-01: Factors Influencing Additional Nodal Disease and Pathologic Nodal Upstaging with Axillary Dissection in Patients with Residual Node-Positive Breast Cancer After Neoadjuvant Chemotherapy Enrolled on Alliance A011202 Clinical Trial

Judy Boughey, Vera Suman, Kelly J. Hunt, Bruce G. Haffty, Thomas Buchholz, W. Fraser Symmans, Tracy L. Rieken, Travis J. Dockter, Jordan D. Campbell, Anna Weiss, Julie A. Bradley, Joshua M. V. Mammen, Ann H. Partridge, Lisa A. Carey

Background: The Alliance for Clinical Trials in Oncology A011202 randomized phase III trial enrolled patients (pts) with clinical T1-3 N1 breast cancer (BC) with residual node-positive disease on sentinel lymph node (SLN) surgery after treatment with neoadjuvant chemotherapy (NAC) to assess whether the recurrence-free interval with radiation to the undissected axilla and regional LNs (AxRT group) is non-inferior to axillary lymph node dissection (ALND) with RT (ALND group). Herein we report on the nodal burden in both groups of pts prior to randomization, and the percentage of pts who had additional positive nodes in the ALND group.
Methods: The pathologic findings from surgery after completion of NAC of all eligible pts were summarized using descriptive statistics. A positive SLN was defined as metastasis ≥0.2 mm present in a node harvested at SLN surgery. Fisher's exact test was used to assess whether the post-chemotherapy pathologic (ypN) category increased with the number of positive LNs found on ALND.
Results: Of 1627 eligible pts registered on A011202, 785 (48.2%) were randomized to ALND and 842 (51.8%) to AxRT. Median age at study entry was 51 years (range: 19-87). Clinical T category prior to NAC was: cT1 in 18.7%, cT2 in 58.9% and cT3 in 22.4% of ALND; cT1 in 20.2%, cT2 in 56.5% and cT3 in 23.3% of AxRT group. Tumor subtype distribution was: 12.1% ER-/PR-/HER2-, 18.6% HER2+, 69.3% ER+ and/or PR+ HER2-. Disease was grade III in 41.5% of ALND group and 38.6% of AxRT group.
The median number of LNs examined from SLN surgery was 4 (range: 1-8) for both ALND

and AxRT arms. There were 99 pts (6.1%) who had 1 LN examined, 240 (14.8%) had 2 LNs examined, and 1288 (79.2%) had 3-8 LNs examined. Among the pts with 2-8 LNs examined from SLN surgery, 815 (53.3%; ALND: 53.7%; AxRT: 53.0%) had 1 positive SLN; 409 (26.8%; ALND: 26.6%; AxRT: 26.9%) had 2 positive SLNs; and 304 (19.9%; ALND: 19.7%; AxRT: 19.8%) had ≥3 positive SLNs. Nodal disease from SLN surgery was macroscopic in 83.6% (ALND: 84.9%; AxRT: 82.3%).
In the ALND arm, 361 pts (46.0%) had additional positive nodes on ALND. This was significantly higher in pts with macrometastatic disease in the SLNs (47.5%) compared with those with micrometastatic disease in SLNs (37.1%) (p=0.043), but no significant differences were found between tumor subtypes (p=0.075). The percentage of pts with additional positive nodes on ALND increased as the number of positive nodes from SLN surgery increased: 33.3% with 1 positive SLN, 52.6% with 2 positive SLNs and 75.9% with ≥3 positive SLNs.
The number of additional positive nodes on ALND was 1 for 130 (36.0%) pts, 2 for 70 (19.4%) pts, and ≥3 in 161 (44.6%) pts. ALND resulted in an increase in ypN category in 24.7% (194/785) of pts; 148 (18.8%) went from ypN1 to ypN2, 29 (3.7%) from ypN1 to ypN3, and 17 (2.2%) from ypN2 to ypN3.
The increase in ypN category for the HER2+ BC [17.1% (25/146)] was significantly lower than that seen in the ER+ and/or PR+ HER2- BC [27.3% (150/549)] (p=0.013) and trended toward being lower than in ER- PR- HER2- BC (26.8% (19/71) (p=0.108).
Conclusion
In patients with residual nodal positive disease after NAC, the rate of additional node-positive disease on completion ALND is high (46%) and increases with presence of SLN macrometastases and as the number of positive SLNs increases. ALND findings resulted in ypN category increase in 24.7% overall; this increase was less frequent in HER2+ disease. Additional data will be critical to understanding the value of ALND in the setting of positive SLNs after NAC in terms of impact on adjuvant treatment recommendations and outcomes.

RF2-02: Axillary surgery after neoadjuvant systemic therapy (NST) for early-stage breast cancer – Treatment algorithms and prognostic impact of residual micrometastases in five neoadjuvant studies

Johannes Holtschmidt, Fabienne Warnecke, Andreas Schneeweiss, Peter A. Fasching, Theresa Link, Sabine Schmatloch, Mattea Reinisch, Peter Klare, Carsten Denkert, Marianne Just, Vesna Bjelic-Radisic, Claus Hanusch, Jens-Uwe Blohmer, Michael Untch, Christoph Salat, Kristina Lübbe, Jens Huober, Kerstin Rhiem, Valentina Nekljudova, Sibylle Loibl, Christine Solbach

Background: For patients (pts) undergoing NST, the axillary status before– and after NST is of major importance for systemic and locoregional treatment. The relevance of nodal micrometastases (ypN1mi) for postneoadjuvant treatment decisions needs to be addressed. A prior analysis in this data set suggested that ypN1mi after NST may have an impact on survival, but the results were limited because of the uncertainty in which clinical situation they had been detected.
Methods: Data from 3199 pts with early BC, who were enrolled in five neoadjuvant AGO-B /

GBG trials (GeparSepto, GeparOcto, GeparNuevo, GeparX, GeparOla) conducted between 2012 and 2019 were included. Initial clinical nodal stage (cN), occurrence of ypN1mi, and axillary intervention were retrospectively analyzed and correlated to outcome.
Results: 3126/3199 (97.7%) pts underwent breast surgery and information was available on initial cN status and axillary intervention. TNBC, HER2+ and HR+/HER2- BC was reported in 38.9%, 29.1% and 32.0%, respectively.
In 1803 cN0 pts we had evaluable information: at baseline pts received sentinel lymph node biopsy (SLNB-BL) only (1155; of which 846 had pN0, 306 pN+ and 3 pNx) or no axillary intervention (NIL) (641) or upfront axillary lymph node dissection (ALND) (7). Of the 641 pts who had no axillary intervention at baseline: after NST pts received SLNB (SLNB-post) only (507) or ALND (79) or targeted axillary dissection (TAD) only (9) or completion ALND as a consequence of SLNB-post/TAD (ALND-c) 17 or NIL (28). For all pts without axillary intervention at baseline, incidence of ypN0 was: 76.6%, 96.8%, 95.8% for HRpos/HER2-, HER2+, TNBC respectively. In case of ypT0, the incidence of ypN0 was: 89.7%, 98.7%, 98.5% for HRpos/HER2-, HER2+, TNBC respectively.
In 1321 cN+ pts we had evaluable information: at baseline pts received no axillary intervention (1105) or SLNB-BL (202; of which 50 had pN0; 151 pN+; 1 pNx) or upfront ALND (14). Of the 1105 pts without axillary intervention at baseline: 876 pts received ALND after NST or limited surgery only (119; of which SLNB-post 96; clipped node resection 5; TAD 18) or c-ALND following limited surgery (100) or NIL (10). For all pts without axillary intervention at baseline, incidence of ypN0 after NST were: 35.8%, 84.4%, 64.4% for HRpos/HER2-, HER2+, TNBC respectively. In case of ypT0, incidence of ypN0 was: 83.1%, 98.8%, 88.0% for HRpos/HER2-, HER2+, TNBC respectively.
Current major guidelines recommend surgical axillary staging to be performed preferably after NST irrespective of cN status. Excluding all pts with LN intervention at baseline, pts with cN0 at baseline but with ypN1mi after NST had a significantly worse iDFS with a hazard ratio (HR) of 4.01 (1.47, 11.0) p=0.007, DDFS HR 5.34 (1.94, 14.7) p=0.001, and OS 5.74 (1.36, 24.2) p=0.017 compared to ypN0 after NST . 5 year LRR rates were 4.1%; 7.0%; 10.0% for ypN0, ypN1, ypN2-3 respectively with no LRR in ypN0i+ or ypN1mi. The results in the cN0 overall cohort did not differ.
In pts with cN+ before NST, the prognostic relevance of ypN1mi seemed less pronounced. Also excluding all pts with LN surgery at baseline, pts with cN+ at baseline but with ypN1mi after NST had a significantly worse iDFS HR 1.87 (1.10, 3.18) p= 0.021 and a trend for worse DDFS HR 1.67 (0.926, 3.03) p= 0.088 and OS HR 1.91 (0.919, 3.96) p=0.083 compared to ypN0 after NST. 5-year LRR rates were 4.8%; 8.6%; 8.6%; 13.0% for ypN0, ypN1mi, ypN1, ypN2-3 respectively with no LRR in ypN0i+. The result in the cN+ overall cohort did not differ.
Conclusion: Results from 3199 pts included in our analysis demonstrate a prognostic impact of ypN1mi in pts with initially cN0 and axillary intervention performed exclusively after NST. In pts with initially cN+, a remaining smaller amount of tumor residuals seems less impactful. Outcome results from prospective trials with less axillary intervention in certain subgroups after NST are needed.

RF2-03: Diagnostic performance of axillary ultrasound after neoadjuvant chemotherapy in initially node-positive breast cancer patients – results from the prospective AXSANA registry trial (NCT04373655)

Steffi Hartmann, Di Micco R, Banys-Paluchowski M, Schmidt E, Gentilini OD, Ditsch N, Stickeler E, de Boniface J, Schroth J, Karadeniz Cakmak G, Hahn M, Thill M, Reimer T,

Fröhlich S, Wihlfahrt K, Berger T, Lux MP, Kolberg HC, Rubio IT, Gasparri ML, Kontos M, Bonci EA, Niinikoski L, Murawa D, Pinto D, Peintinger F, Ruf F, Basali T, Rief A, Schlichting E, Nina H, Valiyeva Qanimat H, Vanhoeij M, Rebaza L, Aktas Sezen B, Kadayaprath G, Dostalek L, Kothari A, Perhavec A, Ivanov T, Zippel D, Thongvitokomarn S, Kühn T and the AXSANA Study Group

Background: Axillary ultrasound (AUS) is the most widely used imaging procedure to assess the lymph node status in breast cancer patients before surgery. While AUS provides excellent results for predicting axillary involvement in patients undergoing primary surgery, its performance after neoadjuvant chemotherapy (NACT) so far has not been analyzed in large prospective multicentric studies, especially in patients who convert from node-positive to node-negative disease.
Methods: The AXSANA study is a prospective, non-interventional, international registry study investigating different surgical axillary staging procedures with regard to disease-free survival, axillary recurrence rate, and quality of life in patients presenting initially with node-positive breast cancer who convert to a clinically node-negative status after NACT. In the current analysis, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of AUS after NACT are analyzed for all patients included in the AXSANA study between June 1, 2020, and May 31, 2024, whose surgical treatment after NACT was completed. All datasets were systematically monitored.
Results: Among 3,841 eligible patients, 3,429 women (89.3%) underwent AUS after NACT before surgery. The result of the AUS was unclear in 168 of these patients (4.9%), suspicious in 1,061 (30.9%), and unsuspicious in 2,200 (64.2%). Axillary pathological complete response was achieved in 1,794 of 3,261 patients (55.0%) with either suspicious or unsuspicious AUS results after NACT. Sensitivity was 46.4% (95% CI 43.8%-49.0%), specificity 78.8% (95% CI 76.9%-80.7%), PPV 64.2% (95% CI 61.2%-67.1%), and NPV 64.3% (95% CI 62.2%-66.3%).
Conclusions: To our knowledge, this analysis provides the largest dataset from a prospective cohort study to investigate the diagnostic performance of AUS after NACT in initially node-positive breast cancer patients. Our data clearly show that the pathological nodal status after NACT cannot reliably be determined with AUS alone. Consequently, surgical axillary staging remains indispensable to assess the axillary lymph node status after chemotherapy in node-positive breast cancer patients that convert to ycN0. Axillary lymph node dissection based on suspicious AUS results after NACT may lead to surgical overtreatment in many patients.

RF2-04: Ultrahypofractionated versus conventional fractionated sequential boost after whole-breast radiation therapy in breast cancer patients. One-year cosmetic outcomes of a randomized, controlled, phase 3 trial (ULTIMO).

Melanie Machiels, Redouane Oulkadi, Daan Stas, Reinhilde Weytjens, Sarah De Vos, Pieter Smolders, Klaartje Steensels, Philip Poortmans

Objective: There is a growing body of evidence for using ultrahypofractionated (UHF) radiation therapy (RT) for whole-breast RT (WBRT), demonstrating excellent oncological and cosmetic outcome (CO) [1,2]. The question arises, whether the boost given to the lumpectomy cavity could also be given in an UHF way. The ULTIMO trial compares side effects, quality of life and CO at 3 years in breast cancer patients referred for postoperative

WBRT with an indication for a boost to the lumpectomy cavity. Patients were randomized to receive either an UHF single boost dose of 6 Gy or a conventionally fractionated (CF) boost of 10 Gy in 5 fractions. Assuming an alpha/beta value of 3, these schemes are equivalent for tumor control, but with regard to late side effects an additional 2 Gy is given with the 6 Gy UHF boost. Therefore, a possible difference in late side effects including CO should be investigated. Hereby, we report the COs at 1 year.

Methods: From April 2022 to November 2022, 132 patients were randomized. CO was assessed at baseline (pre-RT) and at 1 year after RT using different modalities; 1/digitalized photographs in 2 positions (i.e., arms up and alongside the body, respectively) for a computer-based (i.e., BCCT.core arms down/up [3]) evaluation and a panel-based evaluation; 2/patient-reported outcome measures (PROMs) (i.e., EORTC QoL questionnaire C30 and BR23 [4]). Computer- and panel-based CO was scored using a 4-point Likert scale (0 = Excellent, 1 = Good, 2 = Fair, 3 = Poor). PROMS analyzed for the current analysis included: the patient's opinion on the breast appearance (0 = no difference, 3 = large difference), and patients' overall satisfaction with the treated breast (0 = very satisfied, 1 = reasonably satisfied, 2 = not dissatisfied, 3 = dissatisfied, 4 = very dissatisfied). Side effects were scored using the CTCAE 5.0.
Change in scores was calculated by subtracting the baseline score from the 1-year score. Mann-Whitney U tests compared delta changes between groups, and Wilcoxon signed-rank tests assessed within-group changes.

Results: Follow-up data at 1 year was available for 107 of the 132 patients, 54 received an UHF boost and 53 patients a CF boost. No significant differences were found in baseline COs between groups (BCCT.core down, $p = 0.168$; BCCT.core up, $p = 0.394$; panel-scored CO, $p = 0.422$; PROM satisfaction, $p = 0.459$). However, significant more patients in the UHF group rated their post-surgery CO (i.e., PROM appearance of the breast) worse at baseline ($p = 0.021$).
Overall, an Excellent-Good cosmetic result was scored more often than a Fair-Poor result for both treatment groups at 1 year post-RT: 79% BCCT.core down, 82% BCCT.core up, 88% panel-scored CO for the CF boost vs. 65% BCCT.core down, 63% BCCT.core up, 88% panel-scored for the UHF boost.
Seventy-five percent of patients in the CF group vs. 67% in the UHF group reported to be very to reasonably satisfied with the treated breast after 1 year. Within-group comparisons showed no significant changes in COs from baseline to 1 year post-RT for both CF boost (BCCT.core down, $p = 0.325$; BCCT.core up, $p = 0.716$; panel-scored CO, $p = 0.540$; PROM appearance, $p = 0.408$; PROM satisfaction, $p = 0.962$) and UHF boost (BCCT.core down, $p = 0.203$; BCCT.core up, $p = 0.211$; panel-scored CO, $p = 0.253$; PROM appearance, $p = 0.584$; PROM satisfaction, $p = 0.659$).
The delta changes in COs did not significantly differ between the two groups (BCCT.core down, $p = 0.952$; BCCT.core up, $p = 0.264$; panel-scored CO, $p = 0.506$; PROM appearance, $p = 0.641$; PROM satisfaction, $p = 0.892$).
No high-grade late adverse events (CTCAE ≥ grade III) were reported.

Conclusion: An UHF single sequential boost dose of 6 Gy resulted in similar cosmetic outcomes at 1 year post-RT as compared to a CF sequential boost dose of 10 Gy in 5 fractions. No significant differences were observed in the change of cosmetic scores between the two boost fractionation schemes, however the 3-year results have to be awaited.

RF2-05: Validation of the association between TILs, ER status and benefit of radiotherapy in node positive, breast cancer patients: a DBCG study

Demet Özcan, Anders W.M. Nielsen, Jan Alsner, Else Maae, Mette H. Nielsen, Lars Stenbygaard, Lise B.J. Thorsen, Jens Overgaard, Birgitte V. Offersen, Trine Tramm

Background: Studies of the Danish Breast Cancer Group (DBCG)82bc cohort of high-risk breast cancer (BC) patients randomized to +/- postmastectomy radiotherapy (RT) showed that high levels of tumor-infiltrating lymphocytes (TILs) in treatment-naïve tumor predicts improved overall survival (OS), especially for patients with estrogen receptor-negative tumors (ER-) (doi: 10.1080/0284186X.2021.1989629). The association was mediated through distant tumor control rather than local control. We aimed to validate these findings in modernly treated, irradiated BC patients and to investigate the predictive value of TILs in terms of benefit from RT.
Methods and Materials: Patients originated from the DBCG-IMN2 cohort (N=980), including node-positive (N+) BC patients with T1-T3 disease, treated between 2007-2014 with breast-conserving surgery or mastectomy, axillary dissection, and loco-regional RT. Irradiation of the internal mammary nodes (IMN-RT) was administered in 460 right-sided patients (47%), and 520 left-sided patients (53%) did not receive IMN-RT (IMN-RT allocated per laterality).
All patients had systemic adjuvant therapy including taxanes, trastuzumab and letrozole. Formalin-fixed, paraffin-embedded treatment-naïve tumor tissue was collected from 980 patients. Stromal TILs were estimated on whole slide Hematoxylin & eosin-stained sections following international guidelines. Tumors were categorized into "low" and "high" TILs groups using a 30% cutoff.
Endpoints included loco-regional recurrence (LRR), distant metastasis (DM), and OS. Kaplan-Meier and Aalen-Johansen estimators along with univariate Cox regression analysis were used for statistical evaluation.
Results: Of the 980 patients, 798 (81%) had estrogen receptor-positive (ER+) tumors, whereas 182 (19%) had ER- tumors. TILs were successfully scored in 911 tumors, and among these, 737 (81%) had low TILs and 174 (19%) high TILs.
Patients with ER-/low TILs tumors (N=88) had significantly worse OS compared to ER-/high TILs (N=76) with an adjusted Hazard Ratio (adj. HR) of 0.3 (95% CI: 0.2-0.6), and absolute reduction in OS at 10-years of 30% (47% vs. 77%). No significant difference in OS was observed among patients with ER+ tumors (adj. HR 0.9 (0.6-1.5)), and the interaction test between ER status and TILs was significant (p=0.006). A similar association was found for DM (adj. HR 0.3 (0.2-0.6)), where patients with ER-/low TILs tumors had a 24% absolute higher 10-year risk (42% vs. 18%) compared to ER-/high TILs. No significant difference in DM was observed among ER+ tumors (adj. HR 0.6 (0.4-1.1)). TILs did not impact LRR in patients with either ER- tumors (adj. HR 1.3 (0.3-5.5)) or ER+ tumors (adj. HR 3.2 (0.9-11.0)).
The association between RT, TILs and OS as previously described in the DBCG82bc study was further validated since a predictive value of TILs in terms of IMN-RT was seen. Patients with low TILs and right-sided tumors, receiving IMN-RT, had an absolute improvement in OS at 10-years of 9% (79% vs. 70%) compared to patients who did not receive IMN-RT (adj. HR 0.7 (0.5-0.9)). For patients with high TILs, an absolute OS improvement at 10-years of 3% was non-significant (79% vs. 76%). Subdividing by ER status did not affect these results.
Conclusions: This study validates previous findings in the DBCG82bc cohort, indicating a robust association between TILs and ER status in irradiated, N+ BC patients. It further supports that poorer OS in irradiated patients with low TILs is mediated through

compromised distant tumor control rather than through local failure. The data suggests a predictive value of TILs in terms of IMN-RT, where the addition of IMN-RT was associated with improved OS in patients with low TILs. The results emphasize the potential of TILs as a biomarker in tailoring more personalized RT strategies for BC patients.

RF2-06: A Nationwide Double-Blind Phase III RCT Comparing Olanzapine and Prochlorperazine for Refractory Chemotherapy-Induced Nausea in NCORP Community Practices

Luke Peppone, Chunkit Fung, Joseph Guido, Gary Morrow, Michelle Janelsins, Charles Kamen, Joseph Roscoe, Thomas Saphner, Samer Kasbari, Eva Culakova

Background: Despite following ASCO guidelines for antiemetic use during chemotherapy, nausea remains a clinically significant issue and persists as a major concern for patients, surpassing vomiting in significance. Current ASCO guidelines recommend olanzapine or a dopamine antagonist like prochlorperazine for refractory chemotherapy-induced nausea and vomiting (CINV). However, there is a lack of direct empirical comparisons to establish their relative efficacy.

Methods: URCC 16070 enrolled chemotherapy-naïve breast cancer patients starting a high/moderate emetogenic chemotherapy regimen. They were prescribed antiemetics per ASCO guidelines. Screening and assessments occurred during Cycle 1 (N=1,363), followed by randomization for Cycle 2. Patients experiencing ≥ moderate nausea (≥3 on a 1-7 scale) in Cycle 1 and willing to continue (n=310) were randomized in a 1:1:1 ratio to three arms: 1) ASCO regimen plus olanzapine (OLZ), 2) ASCO regimen plus prochlorperazine (PC), or 3) ASCO regimen plus placebo (PBO). Nausea (on a 0-10 scale) and vomiting were assessed via the MASCC Antiemesis Tool (MAT); change in average and maximum nausea are the primary outcomes. A clinically meaningful difference was defined as a ≥2.0 point difference in MAT max nausea between the groups. Quality of life (QOL) was measured using FACT-G. Intent-to-treat analyses (ANOVA and Cohen's Δ effect size calculation for continuous data, chi-square for categorical data) evaluated whether olanzapine or prochlorperazine improved nausea compared to placebo, testing between-arm differences in nausea change from Cycle 1 to 2 at p=0.025.

Results: Among the 310 randomized patients, the median age was 50.7 years, and 80.7% were White, 12.3% Black, 5.8% Asian, and 4.2% Hispanic/Latino, with no significant between-arm differences. The change in MAT maximum nausea was statistically significant for the OLZ (max change = −2.95: Cohen's Δ = 0.58) and PC arms (max change = −2.46: Cohen's Δ = 0.37) compared to the placebo (max change = −1.58; p <0.001 vs OLZ, p = 0.036 vs PC). Similar changes were noted for MAT average nausea in the OLZ (avg change = −2.59: Cohen's Δ = 0.57) and PC arms (avg change = −1.94: Cohen's Δ = 0.28) against the placebo (avg change = −1.29; p <0.001 vs OLZ, p = 0.043 vs PC). As expected, overall QOL decreased in all groups from pre-chemo to post-chemo (FACT-G mean: pre-chemo = 86.9, Cycle 1 = 78.5, Cycle 2 = 77.6). The decrease in QOL in the OLZ arm was significantly less compared to placebo (FACT-G mean between-group difference = +4.91; p = 0.006), while the change in the PC arm was not significantly different from placebo (FACT-G mean between-group difference = −0.87; p = 0.61). Clinically meaningful between-group differences in the FACT-G Physical (mean difference = +2.28; p = 0.008) and Functional (mean difference = +1.81; p = 0.009) subscales were also observed for the OLZ group compared to placebo. Vomiting

rates decreased in the OLZ group (Cycle 1: 17.4% vs Cycle 2: 2.0%) and the PC group (Cycle 1: 16.4% vs Cycle 2: 3.7%) versus the placebo (Cycle 1: 13.2% vs Cycle 2: 8.1%; p=0.12) but lacked significance due to low numbers. In terms of direct comparison, OLZ exhibited superiority over PC in terms of QOL (FACT-G mean difference = +5.80; p = 0.006), but not for nausea control (MAT max nausea: mean difference = +0.67; p = 0.142; MAT avg nausea: mean difference = +0.53; p = 0.054).

Conclusions: This URCC NCORP phase 3 RCT establishes OLZ as a highly effective option for managing refractory nausea during moderate to highly emetogenic chemotherapy. Both statistically and clinically significant reductions in nausea, as well as clinically meaningful improvements in QOL, particularly in physical and functional domains, highlight OLZ's substantial impact. For patients who may not tolerate OLZ, PC remains a viable alternative. These results support OLZ's incorporation into antiemetic protocols and underscore its role in enhancing patient outcomes. Funding: R01CA200579, UG1CA189974

RF3-01: TBCRC 056: A Phase II Study of Neoadjuvant Niraparib with Dostarlimab for Patients with BRCA- or PALB2-mutated Breast Cancer: Results From the ER+/HER2- Cohort

Erica Mayer, Noah Graham, Roberto A. Leon-Ferre, Mariya Rozenblit, Cesar Santa-Maria, Steven Isakoff, Jennifer Specht; Nadine Tung, Vandana Abramson, Jennifer Desrosiers, Beyza Koca, Sara M. Tolaney, Eric P. Winer, Ian E. Krop, Antonio C. Wolff, Geoffrey I. Shapiro, Nabihah Tayob, Jennifer L. Guerriero

Background: PARP inhibitors (PARPi) have an approved role in treating patients (pts) with germline BRCA1/2 mutated (gBRCAm) breast cancer in the advanced and early settings, with activity also seen in pts with gPALB2m. Preclinical data suggest PARPi exposure leads to intratumoral activation of the proinflammatory cGAS/STING pathway, recruiting CD8+ T cells, and sensitizing gBRCAm cancers to immune-targeted therapy. Preoperative treatment with PARPi monotherapy has demonstrated notable pathologic complete response (pCR) rates. TBCRC 056, an open-label randomized phase II study, evaluates the PARPi niraparib (N) with the anti-PD-1 antibody dostarlimab (D) in the neoadjuvant treatment of gBRCAm or gPALB2mHER2-negative breast cancer, with cohorts for both triple negative breast cancer (TNBC, Arms A and B) and hormone receptor positive (HR+) disease (Arm C). Results from Arm C are being presented.
Methods: Eligible pts in Arm C had a gBRCAm or gPALB2m and a tumor size of >1.0 cm, ER and/or PR+ (>10%). All pts in Arm C received 18 weeks of combination N 200 mg orally once daily and D 500 mg IV every 3 weeks (1 cycle = 3 weeks), with mandatory baseline (BL) and week 3 core tumor biopsies. After 18 weeks, pts either underwent surgery or received additional preoperative systemic therapy (per physician's choice) if residual disease was present on imaging. The primary study objectives are to evaluate pCR at surgery as well as change in stromal tumor infiltrating lymphocytes (sTILs) from BL to 3 weeks in Arms A and B. Evaluation of pCR and change in sTILs in Arm C are secondary study objectives, with pCR to be reported with a two-sided exact 90% confidence interval without hypothesis testing. Change in sTILs between BL and 3 weeks was evaluated using a Wilcoxon signed-rank test, and the association between sTILs and pCR was assessed using a Wilcoxon rank sum test.
Results: Accrual to Arm C was completed after 18 pts with HR+/HER2- breast cancer were enrolled and treated between April 2021 and May 2024 (5 gBRCA1m (27.8%), 13 gBRCA2m

(72.2%), 0 gPALB2m). Median age was 41.8 years (range 28.8-61.9), 14 were self-reported White (77.8%), 4 (22.2%) Black, and none Hispanic. Stage distribution was 38.9% stage I, 44.5% stage II, and 16.7% stage III. All 18 pts had ER+ >10% disease. Sixteen of 18 pts have completed protocol therapy through surgery, with results pending for 2 pts. Among evaluable pts, 10 (62.5%) completed 6 cycles of D with mean number of cycles received 4.7. Six pts discontinued D early (1 progressive disease, 1 withdrawal of consent, 4 unacceptable adverse events (AE)). Thirteen pts (81.2%) completed 6 cycles of N with mean number of cycles received 5.4. Three pts discontinued N early (1 progressive disease, 1 withdrawal of consent, 1 unacceptable AE). The most common AE (> grade 2) with D+N were rash (25.0%), elevated liver function tests (18.8%), diarrhea (12.5%), and hypertension (12.5%). Of the 16 pts evaluable for response at this time, 3 had pCR at surgery (18.8%, (90% CI 5.3% - 41.7%)), 11 (68.8%) had residual disease (3 RCB-I, 4 RCB-II, 4 RCB-III), and 2 (12.5%) received additional chemotherapy before surgery. Among 12 pts with evaluable sTILs at BL and 3 weeks, mean sTILs at BL was 11.9% (range 1.0% – 35.0%), mean sTILs at week 3 was 23.8% (range 5.0% - 90.0%), with a mean absolute increase of 11.9%; Wilcoxon signed rank p=0.09). Higher sTILs (as a continuous variable) at BL was associated with pCR (odds ratio 1.09, 95% CI 1.00 – 1.19, Wilcoxon rank sum p = 0.03).
Conclusions
In pts with gBRCAm HR+/HER2- breast cancer, 18 weeks of PARPi and anti-PD1 resulted in a pCR rate of 18.8%, and a mean absolute increase of sTILs of 11.9% at 3 weeks. Further data from the TNBC cohort of this study are awaited. Given the reported activity of PD-1 inhibitors in the preoperative management of HR+ breast cancer, additional exploration of targeted non-chemotherapy approaches is of great interest in this pt population.

RF3-02: Efficacy of adjuvant avelumab by PD-L1, tumor infiltrating lymphocytes and residual cancer burden in high-risk triple negative breast cancer: secondary and exploratory endpoints of the phase III A-BRAVE trial.

Maria Vittoria Dieci, Giancarlo Bisagni, Lorenzo Nicolé, Peter Schmid, Vittoria Fotia, Federico Piacentini, Adolfo Favaretto, Giulia Bianchi, Saverio Cinieri, Lucia Del Mastro, Domenico Corsi, Michelino de Laurentiis, Grazia Arpino, Marta Mion, Antonino Musolino, Antonella Ferro, Donata Sartori, Fable Zustovich, Simon Spazzapan, Alessandra Gennari, Claudio Zamagni, Stefano Tamberi, Tommaso Giarratano, Elisa Gasparini, Giovanna Magni, Gian Luca De Salvo, Pierfranco Conte, Valentina Guarneri

Background: The A-BRAVE trial showed an improvement in long-term outcome with the anti-PD-L1 avelumab administered as adjuvant therapy for high-risk early TNBC patients. Here, we report the efficacy of avelumab according to PD-L1, tumor infiltrating lymphocytes (TILs), and residual cancer burden (RCB).
Methods: The phase III A-BRAVE trial randomized 466 patients with high risk early TNBC to 1-year avelumab vs observation after completion of standard surgery and neoadjuvant/adjuvant chemotherapy. High risk was defined as high disease burden in case of primary surgery (n=83 Stratum A) or invasive residual disease (breast and/or nodes) after neoadjuvant chemotherapy (n=383 Stratum B). Avelumab vs observation improved outcomes (Conte P ASCO 2024): +5.1% in 3-yr DFS in ITT and Stratum B (non-significant, co-primary endpoints); +8.5% in 3-yr OS in ITT (p=0.035) and Stratum B (p=0.070); +7.5% in 3-yr DDFS in ITT (p=0.028).
Here, we report DFS (secondary endpoint), DDFS and OS by PD-L1 status in ITT, as well as

DFS, DDFS and OS by post-neoadjuvant chemotherapy TILs and RCB in Stratum B. PD-L1 was evaluated on surgical tumor samples (Stratum A) and diagnostic core-biopsies (Stratum B) with the IHC 73-10 RUO assay (Agilent Technologies); the % of positive stromal cells/total stromal cells was calculated with digital pathology. PD-L1 high was defined according to a previously published >21% cut-off (Dieci MV, Eur J Cancer 2020). In Stratum B, surgical samples were evaluated for TILs (centrally) and RCB (locally) according to guidelines. Only p values <0.05 are shown.

Results: PD-L1 expression was prognostic: every 1% increment was associated with improved DFS (HR 0.99, 95%CI 0.97-1.00, p=0.014), DDFS (HR 0.98, 95%CI 0.97-0.99, p=0.005) and OS (HR 0.99, 95%CI 0.97-1.00, p=0.049). PD-L1 high vs PD-L1 low patients showed better outcome: 3-yr DFS 80.6% vs 64.3%, p=0.004; 3-yr DDFS 85.1% vs 69.8%, p=0.002; 3-yr OS 89.6% vs 79.5%, p=0.032. No significant interaction between PD-L1 and treatment arm was observed for any efficacy endpoint. However, the benefit of avelumab vs control was more evident for PD-L1 low: 3-yr DFS 67.3% vs 61.1%, 3-yr DDFS 73.6% vs 65.9%, 3-yr OS 84.6% vs 74.1% in PD-L1 low; 3-yr DFS 77.1% vs 84.4%, 3-yr DDFS 85.7% vs 84.4%, 3-yr OS 91.4% vs 87.5% in PD-L1 high.
In Stratum B, RCB was prognostic. Outcomes by RCB I, II and III were: 3-yr DFS 76.7%, 67.5%, 32.4%; 3-yr DDFS 76.5%, 73.6%, 39.7%; 3-yr OS 83.1%, 81.7%, 46.6%, p<0.001 for all endpoints. No significant interaction for any efficacy endpoint was observed between RCB and treatment arm. The benefit of avelumab vs control by RCB category was: RCB I (n=30, 3-yr DFS 84.6% vs 70.6%; 3-yr DDFS 84.6% vs 70.6%; 3-yr OS 84.6% vs 82.4%), RCB II (n=224, 3-yr DFS 67.3% vs 67.6%; 3-yr DDFS 75.8% vs 71.3%; 3-yr OS 87.4% vs 75.7%), RCB III (n=55, 3-yr DFS 44.6% vs 19.2%, p=0.028; 3-yr DDFS 55.0% vs 23.1%, p=0.003; 3-yr OS 57.5% vs 33.6%, p=0.026).
TILs on residual disease were significantly prognostic in Stratum B: every 1% increase was associated with: HR 0.98 95%CI 0.97-0.99, p=0.002 for DFS; HR 0.98 95%CI 0.97-0.99, p=0.004 for DDFS; HR 0.98, 95%CI 0.96-1.00, p=0.010 for OS. Results were similar after correction for RCB.
There was no significant interaction for any efficacy endpoint between TILs and treatment arm. The benefit of avelumab vs control was more evident in TILs<10% (3-yr DFS 57.7% vs 50.0%; 3-yr DDFS 64.7% vs 53.6%; 3-yr OS 74.6% vs 61.8%) than TILs>10% (3-yr DFS 72.5% vs 75.4%; 3-yr DDFS 81.5% vs 79.2%; 3-yr OS 89.6% vs 85.6%).
Conclusions: Efficacy of avelumab for high-risk TNBC did not significantly differ by PD-L1 in the ITT, or by TILs and RCB in Stratum B. However, these biomarkers help identifying subgroups of patients at poorer prognosis deriving the greatest magnitude of benefit from this treatment.

RF3-03: Nivolumab + Ipilimumab (NIVO+IPI) compared to capecitabine for triple-negative breast cancer patients with residual disease after neoadjuvant chemotherapy – Final results of BreastImmune-03, a multicenter randomized open-label phase II trial.

Olivier Trédan, Delphine Loirat, Sylvie Chabaud, Thierry Petit, Frédéric Viret, Christelle Levy, Philippe Toussaint, Aurélien Robert, Julien Grenier, Laura Mansi, Jean-Philippe Spano, Anne Patsouris, Olfa Derbel, Christelle Jouannaud, Jean Marc Ferrero, Jean Sébastien Frenel, Yann Molin, Louis Doublet, Pierre-Etienne Heudel, Mathilde Bernardin, Delphine Tatu, Gwenaële Garin, David Pérol, Jean-Yves Pierga, Thomas Bachelot

Background - Early triple negative breast cancer (TNBC) with moderate to extensive residual disease after neoadjuvant chemotherapy and surgery is associated with high risk of recurrence. Before the era of (neo)adjuvant anti-PD-1 antibody treatment, capecitabine was a treatment option in the adjuvant setting. BreastImmune-03 trial was designed to evaluate the efficacy of post-operative nivolumab + ipilimumab (NIVO+IPI) compared to capecitabine for patients (pts) with class II or III Residual Cancer Burden (RCB) after standard neoadjuvant chemotherapy.
Methods - BreastImmune-03 was a multicenter, randomised, open-label phase II trial comparing a dual immunotherapy regimen (NIVO+IPI: nivolumab (360 mg intravenously [IV], every 3 weeks for 8 doses) and ipilimumab (1 mg/kg IV, every 6 weeks for 4 doses)) versus capecitabine (1000 mg/m^2 BID, 14 days on / 7 days off for 8 cycles) as adjuvant treatment in TNBC with RCB II-III after neoadjuvant chemotherapy and surgery. Randomization (1:1) was stratified by center, ECOG performance status (PS), and RCB class. A total of 114 pts (46 events) were needed to detect an improvement from 60 to 80% of the 2-year disease free survival (DFS) rate (Hazard ratio [HR]: 0.44; 80% power, alpha 5%). Secondary endpoints include overall survival (OS), local-regional recurrence rate (LRR), distant metastasis-free survival (DMFS), safety according to CTCAE 5.0, and quality of life scales.
Results - From July 2019 to October 2021, 95 pts were randomized: 50 in the capecitabine arm and 45 in the NIVO+IPI arm (median age: 47 years [29-82], ECOG PS 0: 80%, RCB III: 40%) across 17 French centers. Due to an unexpectedly high rate of biological myocarditis in the NIVO+IPI arm (11% versus 2% in capecitabin arm), enrollment was prematurely closed based on independent data monitoring committee recommendation. With a median follow-up of 34.3 months (interquartile range: 33-36), 39 events (relapse or death) were reported: 17 (38%) in the NIVO+IPI arm versus 22 (44%) in the capecitabine arm (HR: 0.84; 95% CI: 0.45-1.59; log-rank test p-value: 0.59). There was no difference in terms of OS (HR: 0.98; 95% CI: 0.44-2.20; log-rank test p-value: 0.97), nor in LRR and DMFS. Notably, 38% of pts discontinued treatment prematurely due to treatment-related adverse events (AE) in the NIVO+IPI arm, compared to 14% in the capecitabine arm. The most common AE (>10%) in the NIVO+IPI arm were myocarditis (grade 3 only), hyperthyroidism (28.9%), hypothyroidism (22.2%), diarrhea (11.1%) and fatigue (31.1%).
Conclusion – Although BreastImmune-03 trial was prematurely ended, a 6-month postoperative NIVO+IPI combination does not seem to improve clinical outcomes in TNBC pts with RCB II-III compared to capecitabine. In addition, immune-mediated AE limit the use of the NIVO+IPI combination in this setting. A centralized collection of tumor and blood tissue has been performed and translational correlative studies are ongoing.
Clinical trial information: NCT03818685

RF3-04: NRG-BR004: A Randomized, Double-blind, Phase III Trial of Taxane/Trastuzumab/Pertuzumab with Atezolizumab or Placebo in First-line HER2-positive Metastatic Breast Cancer

Vicente Valero, Gong Tang, Charles E. Geyer, Jr, Priya Rastogi, Shannon L. Puhalla, Jiahe Li, Stephen K.L. Chia, Erin F. Cobain, Elias Obeid, David B. Page, Andrew S. Poklepovic, William J. Irvin, Jr, Adam M. Brufsky, Irene L. Wapnir, J. Marie Suga, Eleftherios P. Mamounas, Norman Wolmark

Background: The CLEOPATRA trial established trastuzumab, pertuzumab, and docetaxel (THP) as a standard of care for first-line metastatic, HER2-positive breast cancer with

median progression-free survival (PFS) of 18.7 months and median overall survival (OS) of 57 months. NRG-BR004 was a phase III, placebo-controlled trial designed to determine whether the addition of the PD-L1 inhibitor atezolizumab to THP would improve PFS, relative to THP/placebo in patients with newly documented HER2-positive measurable metastatic breast cancer.

Methods: In this double-blinded phase III trial, patients with newly documented HER2-positive measurable metastatic breast cancer were randomly assigned (in a 1:1 ratio) to receive atezolizumab (1200 mg IV) or placebo on days 1 and 22 every six weeks until progression or for two years, combined with 1) a taxane regimen selected by investigator (weekly paclitaxel 80 mg/m2 IV on days 1, 8, 15, 22, 29, and 36, or docetaxel 75 mg/m2 IV on days 1 and 22 every six weeks) administered until progression or toxicity required discontinuation and 2) trastuzumab with pertuzumab on days 1 and 22 every six weeks until progression or toxicity required discontinuation. The primary endpoint, PFS, was assessed by investigators using RECIST 1.1 criteria.

Results: One hundred ninety out of the planned 600 patients were randomized over 37 months from May 1, 2019, to May 20, 2022. An imbalance in Grade 5 AEs coupled with continued poor accrual and the changing landscape in HER2+ metastatic breast cancer resulted in the permanent closure to further enrollment in May of 2022. A decision was made to discontinue atezolizumab/placebo in patients receiving the investigational component of the trial therapy and to unblind investigators and patients. Treatment with the standard components of therapy continued at investigator discretion. The study continued to collect information on PFS events, deaths, and late immune adverse events through April of 2024.

The primary analyses were performed in September 2024. Median follow-up for PFS was 31.1 months and 35.6 months for OS. Characteristics for the randomly assigned patient population included median age of 52 years, 66% had estrogen-receptor positive disease, 79% had visceral metastases, 4% had brain metastases, 82% had presented with de novo metastatic disease, and only 14% were PD-L1 positive. Characteristics were balanced between the two arms. The mean and median number of cycles of trastuzumab, pertuzumab, and taxanes were similar in the atezolizumab and placebo arms.

Total grade 2, 3, and 4 adverse events were similar across both arms. Grade 5 events totaled 6 in the atezolizumab arm and 0 in the placebo arm at the time of closure of the study and discontinuation of atezolizumab/placebo.

Two-year PFS was 54.0% and 45.6% in the atezolizumab-THP arm and placebo-THP arm (hazard ratio 0.73 [0.49, 1.09]), respectively. Three-year OS was 86.4% and 81.7% in the atezolizumab-THP arm and placebo-THP arm (hazard ratio 0.8 [0.39, 1.63]), respectively. Stratified log-rank test was used to compare the distribution of PFS and OS between the two treatment arms with estrogen receptor status and prior neoadjuvant or adjuvant trastuzumab as the stratification factors.

Conclusions

Accrual to BR004 was closed to further enrollment in May 2022 and atezolizumab/placebo was discontinued due to poor accrual and the imbalance in Grade 5 events between the two arms, 6 deaths in the atezolizumab-THP arm versus 0 in the placebo-THP arm. The results suggest checkpoint inhibitors may have activity in metastatic HER2+ breast cancer, but further studies would be necessary to establish efficacy and improve safety.

RF3-05: A Phase 2 Study of Neoadjuvant HER2-targeted Therapy +/- Immunotherapy with Pembrolizumab (neoHIP)

Heather McArthur, Isaac Chan, Jorge Leal, Stephanie Rice, Laura Spring, Katherine Sanchez, Jin Sun Bitar, Nisha Unni, Samira Syed, Reva Basho, Alison Conlin, Sasha Stanton, Kelly Perlewitz, Glenda Delgado, Namrata Peswani, Yuan Yuan, David Chan, Ina Patel, Swati Sikaria, Navid Sadeghi, Mai Badran, Lynette Currie, Jessica Curtin, Natalie Boy, Joey Di Padova, Christina DiLauro Abaya, Michelle Phillips, Nasir Qureshi, Meredith Carter, Stephen Shiao, Farnaz Dadmanesh, Rochelle Horadam, Ravi Thadhani, Sujata Patil, Adam Brufsky, David Page

Background: Immune checkpoint inhibition (ICI) is synergistic with HER2-directed therapy in pre-clinical models. Clinically, pembrolizumab (K)-mediated ICI in addition to HER2-directed therapy with trastuzumab (H) was safe and demonstrated modest activity in H-resistant HER2-positive (HER2+) metastatic breast cancer. Because ICI may confer more robust activity when administered earlier in the course of disease, H and K administered in the curative-intent, treatment-naive setting may allow for de-escalation of chemotherapy; confer life-long, tumor-specific immunity; and ultimately improve cure rates. Moreover, the synergy of H and K with paclitaxel (T) may overcome the need for dual HER2-blockade with H plus pertuzumab (P). In this randomized, multicenter, phase 2, open-label trial, the efficacy and safety of neoadjuvant THP vs THP-K vs TH-K were explored.
Methods: In this multicenter, prospective, randomized phase 2 study, treatment-naive patients aged ≥18 years with stage II-III HER2+ breast cancer were randomized and stratified by clinical nodal status (positive vs. negative) and hormone receptor status (positive vs negative). Arm A received weekly T at 80 mg/m2 for 12 weeks, H at 8mg/Kg (loading dose) followed by 6mg/Kg every 3 weeks x 3 doses, P at 840mg (loading dose) followed by 420mg/Kg every 3 weeks x 3 doses (THP); Arm B received THP plus K at 200mg every 3 weeks x 4 doses (THP-K); and Arm C received TH-K every 3 weeks x 4 doses. Definitive surgery occurred 3-6 weeks after the last dose, followed by postoperative treatment at the treating physician's discretion per local standards. The primary endpoint is pathologic complete response (pCR; ypT0/Tis ypN0). Secondary endpoints include pCR rates defined by ypT0ypN0 and ypT0/Tis, residual cancer burden (RCB), event-free survival (EFS), and safety.
Results: 138 patients with untreated, stage II-III HER2+ breast cancer were enrolled between January 4, 2019, and March 25, 2024: 58 to Arm A, 58 to Arm B, and 22 to Arm C (enrollment to Arm C was terminated after a prespecified interim efficacy analysis). In Arm A, 4 patients were discontinued before surgery. The primary endpoint, pCR (ypT0/Tis ypN0) was achieved in 28 of 54 (51.9%) and 39 of 58 (67.2%) evaluable patients in Arms A and B, respectively. After a prespecified interim analysis, enrollment to Arm C was discontinued due to a pCR rate <40%. Secondary endpoints for alternative definitions of pCR rates included 46.3% vs 51.7% for ypT0ypN0 and 53.7% vs 68.9% for ypT0/Tis in Arms A and B, respectively. Among the 54 patients in Arm A evaluable for RCB: 28 (51.9%) of 54 were classified as RCB-0, 9 (16.7%) as RCB-1, 13 (24.1%) as RCB-2, and 4 (7.4%) as RCB-3. Among the 58 patients in Arm B evaluable for RCB: 39 (67.2%) of 58 were classified as RCB-0, 4 (8.6%) as RCB-1, 12 (20.7%) as RCB-2, and 2 (3.5%) as RCB-3. At this interim analysis (data cut off, September 30, 2024), the median follow-up is 24 months. In the THP arm, 25.9% of patients experienced grade 3 adverse events (AEs), compared to 22.4% in the THP+K arm. None of the grade 3 AEs in Arm A were immune-related events (irAEs). Of the 116 patients enrolled to Arms A and B, 57.8% were White/non-Hispanic, 22% Hispanic, 11.5% Asian, 5.2% Black/African American, 0.9% American Indian, and 2.5% other. On Arm

A, 15 of the 30 (50%) White/non-Hispanic subjects achieved pCR; similarly, 7 of the 14 (50%) Hispanic subjects achieved pCR. However, on Arm B, 27 of the 35 (77.14%) White/non-Hispanic subjects achieved pCR while only 6 of the 12 (50%) Hispanic subjects achieved a pCR.
Conclusion: This is the first study to demonstrate the synergy between ICI and dual HER2-directed therapy in curative intent setting. Thus, early administration of the combination may allow for de-escalation of cytotoxic chemotherapy and improve long-term outcomes in high risk, HER2+ disease. Additionally, the impact of response to specific therapies by racial groups warrants further investigation.

RF3-06: Mepitel Film for the Reduction of Radiation Dermatitis in Post-mastectomy Radiation Therapy: Results from Alliance A221803: A Multicenter Phase III Randomized Clinical Trial

Kimberly Corbin, Minji Lee, Kristofer Roberts, Oudom Kour, Jon Strasser, Robert Mutter, Sarah E. James, Karen M. Winkfield, Arshin Sheybani, Whitney Beeler, Kim Creach, Jennifer Vogel, Melissa Vyfhuis, Selina Chow, Maryam Lustburg, Kathryn J. Ruddy, Charles Loprinzi

Background: Radiation dermatitis (RD) is a frequent side effect and source of morbidity in patients receiving radiation treatment (RT) for breast cancer (BC), particularly for those undergoing post-mastectomy radiation (PMRT). The Alliance A221803 phase III randomized trial investigated the potential of Mepitel Film (MF) to mitigate RD in this at-risk patient population. We hypothesized that MF would reduce the severity of RD compared to institutional standard of care (SoC).
Methods: Patients undergoing conventionally fractionated PMRT for non-inflammatory BC were randomized in a 2:1 fashion to receive either MF or institutional SoC. Stratification factors included patient body mass index (BMI) (< 25; 25-29.99; and ≥ 30), planned RT bolus (yes; no), planned RT boost (yes; no), and the presence or absence of reconstruction. The primary endpoint was the difference in area under the curves (AUCs) estimated from the repeated measures (means) mixed model using the patient-completed symptom scale component of the modified Radiation-Induced Skin Reaction Assessment Scale (mRISRAS) weekly during RT, 1-2 weeks after the end of RT (EoT), and at 3 months post-RT between the two arms controlling for stratification factors. The primary analysis included the first 192 assessable patients. Secondary endpoints included non-blinded provider component of the mRISRAS score, the combined (patient symptom scale and provider component) mRISRAS score, and acute adverse events (AEs) by CTCAE V5.0. This trial is registered on ClinicalTrials.gov (NCT04989504).
Results: Between July 26, 2022 and January 4, 2024, 216 patients enrolled, with 143 assigned to MF and 73 to SoC. Stratification factors were balanced. Forty-five (21%) out of 216 enrolled patients were planned to have boost, 140 (65%) reconstruction, 75 (35%) planned bolus, and BMI was < 25 (26%), 25-29.99 (31%), and ≥30 (43%). Eight patients in the SoC arm withdrew consent prior to RT, leaving 65 patients in the SoC and 143 patients in the MF arm in the modified intention-to-treat analysis. Median age was 53 years. Eight or 9 survey timepoints were collected depending on receipt of boost, with a median of 8 mRISRAS surveys completed per patient. The estimated AUC was 45.10 in the SoC arm and 33.88 in the MF arm, with a difference in AUC (MF-SoC) of -11.22 (95% CI: -19.90, -2.54; p=0.012), meeting the primary endpoint of a significant reduction in patient-reported RD with MF compared with SoC. The improvement was observed across all stratification factors. In a pre-specified analysis, a statistically significant arm × timepoint interaction

effect was seen, showing that patient-reported mRISRAS scores were lower with MF during RT at week 4, 5, and 6 of RT as well as at 7-14 days after the EoT (p = 0.0267). The combined patient and provider mRISRAS scores also identified less RD with MF, with a difference in AUC of -16.10 (p =0.011). The reduction in AUC with MF for unblinded provider mRISRAS scores was not statistically significant (AUC difference [MF-SoC -3.65 [95% CI: -9.35, 2.05, p=0.21]). Grade 2 at least possibly related or grade 3+ regardless of attribution RD was reduced with MF (44.6% in SoC, 25.2% in MF, p=0.005), whereas there was no significant difference in acute acneiform rash (1.54% in SoC vs. 1.4% in MF, p=0.94), pruritus (6.2% in SoC, 9.1% in MF, p=0.47), or skin infection (0% in SoC, 4.2% in MF, p=0.09). No grade 4 or 5 adverse events (AEs) were reported. Long-term follow-up is ongoing for evaluation of chronic AEs and reconstruction outcomes.
Conclusions: Mepitel Film significantly reduces RD compared to SoC in patients undergoing RT for breast cancer. These findings support the use of MF as a new SoC option for RD prevention in patients undergoing PMRT.

RF3-07: ROSCO: Response to Optimal Selection of neoadjuvant Chemotherapy in Operable breast cancer: Randomised phase III, stratified biomarker trial of neoadjuvant 5-Fluorouracil,Epirubicin & Cyclophosphamide vs Docetaxel & Cyclophosphamide chemotherapy

Daniel Rea, S. Pirrie, L. Hayward, S. Chan, M. Varughese, S. Spensley, U. Barthakur, M. MacKenzie, S. J. Bowden, C. Gaunt, E. Southgate, N. Nicholson, P. Wetherell, M. Soden, L. Billingham, C. Brookes, D. Cameron, J. Starczynski, J. Dowds. H. Earl, R. Stein, A. Graham, A. Shaaban, S. McIntosh, F. Raja, J. Abraham, K. Taylor, T. Piper, Z. Billyeald, D. Wheatley, J. Bartlett

Biomarkers for specific cytotoxic chemotherapy sensitivity could better inform drug selection. Both CEP17 duplication and abnormal Topoisomerase 2 copy number appear associated with anthracycline sensitivity in the adjuvant setting (Bartlett et al 2015). This data is however not currently applied clinically. Taxanes are a routine component of adjuvant and neoadjuvant chemotherapy either in combination or sequenced with anthracyclines, or increasingly used in the absence of anthracyclines. ROSCO: ISRCTN15094808 was designed to prospectively evaluate the clinical utility of these two biomarkers for initial neoadjuvant chemotherapy selection.

Between November 2015 and May 2023, 990 consenting patients with early breast cancer considered suitable for neoadjuvant chemotherapy were randomised to four cycles of either Epirubicin and Cyclophosphamide with optional 5 Fluorouracil ((F)EC), or Docetaxel and Cyclophosphamide (TC). Patients with Grade 1 or 2 ER Rich, PR Rich, HER-2 negative tumours and all T1 N0 tumours were excluded. All HER-2 positive cancers were treated with concurrent anti HER-2 antibodies. Participants were stratified by centrally assessed biomarker status as biomarker normal (BM normal) with both CEP17 and TOP2A normal, or biomarker abnormal (BM abnormal) with CEP17 duplication and/or TOP2A abnormal. Surgery was performed after 4 cycles of chemotherapy; where pathological complete response (pCR) was not achieved, crossover to the alternative treatment arm for a further 4 cycles was given in an adjuvant setting. Crossover before surgery was permitted where interim biopsy after 4 cycles confirmed viable residual disease. The primary endpoint of the

study is pCR ypT0/Tis ypN0 after initial neoadjuvant chemotherapy.

Of the 990 patients consented, 496 were randomised to TC and 494 to (F)EC. 24 patients with no cancer seen in interim biopsy received further neoadjuvant chemotherapy and also had pCR at final surgery, these are considered in the primary analysis as non pCR.

Data from 950 patients are evaluable for the primary endpoint. Overall pCR was 245 (26%): the TC arm was 131 (27%) and (F)EC arm was 114(24%). Overall BM was normal in 233 (24%) with BM abnormal in 756 (76%).

With TC the pCR percentages for BM normal and abnormal were very similar: 30% and 27% respectively. For (F)EC BM normal, pCR is 17% and for FEC BM abnormal, it is 26%. Final data cleaning is ongoing, testing for treatment by biomarker interaction will be presented.

Higher response to (F)EC in the biomarker abnormal group was observed across all pathological subtypes tested.

Sensitivity analysis excluding 35 TC and 22 (F)EC patients where crossover chemotherapy was given off protocol neoadjuvantly despite a negative core biopsy or where patients withdrew prior to the primary endpoint was conducted. The pCR proportions observed in the treatment by biomarker groups were not impacted.

Preliminary analysis of this large prospective evaluation of CEP17 and TOP2A as potential predictors of anthracycline sensitivity conducted in a neoadjuvant context shows that evaluation of these biomarkers shows no predictive value for sensitivity to TC but demonstrates differential pCR to (F)EC. Suggesting women with BM abnormal cancers are likely to benefit more from inclusion of anthracyclines. Anthracycline-free chemotherapy may be considered as an option for women with BM normal cancers.
