Results: A total of 273 "sentinel" lymph nodes (2-3 lymph nodes per patient) were identified and removed using technetium-99mTc and a gamma probe. > Воронов Михаил Вячеславович: In 262 of the 273 removed lymph nodes, the presence of indigo carmine was detected using blue LED illumination. None of the patients experienced complications related to the use of indigo carmine or blue LED illumination.
Conclusions: Based on the preliminary data, it can be concluded that the use of indigo carmine for lymph node marking in SLNB in BC patients has potentially high efficacy and safety. Given the availability of the method - low cost of the drug and no need for additional equipment (the dye is visible to the naked eye), indigo carmine can be an alternative to ICG. Further research on a larger number of patients, as well as comparison of indigo carmine with other dyes, is required to confirm the efficacy and safety of indigo carmine.

P2-07-14: Head-to-head comparison of the dual-targeting tracer [68Ga]Ga-RM26-RGD and [18F]FDG for PET imaging of breast cancer

Qingyao Shang, Rongxi Wang, Jialin Xiang, Zhaohui Zhu, Xin Wang

Purpose/Background: Radiolabeled RM26 and RGD peptide analogs have been investigated for imaging gastrin releasing peptide receptor (GRPR) and integrin αvβ3 receptor expression in multiple types of tumors. However, the diagnostic efficacy of the RM26-RGD heterodimer for primary lesions and axillary lymph node metastases in breast cancer patients has not been systematically evaluated. This multi-center prospective study provides the first head-to-head comparison of [68Ga]Ga-RM26-RGD with conventional [18F]FDG PET/CT in breast cancer patients.
Materials and Methods: This prospective study was approved by the Peking Union Medical College Hospital ethics committee (I-22PJ246) and registered at ClinicalTrials.gov (NCT05549024). All patients provided written informed consent to receive both the [68Ga]Ga-RM26-RGD and [18F]FDG PET/CT within 1 week. Thirty-six newly diagnosed female breast cancer patients with pathologically confirmed malignant breast tumours by preoperative ultrasound-guided needle aspiration were consecutively recruited from June 2023 to June 2024. All patients underwent [68Ga]Ga-RM26-RGD PET/CT scan at 44.1 ± 10.6 min and [18F]FDG PET/CT scan at 72.8 ± 15.7 min after intravenous injection. The peripheral normal tissue was considered as background for the calculation. The tumor-to-background ratio (TBR) was calculated for further analysis. A final diagnosis was made based on the histopathological examination of the surgical excision. In addition, immunofluorescence and HE staining of breast tumors and metastatic axillary lymph node sections were also performed to further evaluate the expression of GRPR and integrin αvβ3 receptors in breast tumors.
Results: All patients tolerated the examination well and no significant adverse events related to the study were reported in any of the patients. Both the primary breast tumors and metastases showed positive [68Ga]Ga-RM26-RGD accumulation. In 36 patients, 39 lesions were surgically removed, including 36 invasive ductal carcinoma and 3 ductal carcinomas in situ. In 39 primary breast tumors, both [68Ga]Ga-RM26-RGD PET/CT (38/39) and [18F]FDG PET/CT (37/39) had a high detection rate (97.4% vs. 94.9%, $p > 0.05$). There were no significant differences in SUVmax/bkgmeanTBR (7.6 ± 5.7 vs. 5.8 ± 4.7, $p = 0.07$) and SUVmean/bkgmeanTBR (4.8 ± 3.6 vs. 3.8 ± 2.9, $p = 0.09$) of the primary tumor between [68Ga]Ga-RM26-RGD and [18F]FDG PET/CT. However, [68Ga]Ga-RM26-RGD is superior to [18F]FDG in terms of sensitivity (56.04% vs. 39.56%, $p < 0.001$), specificity (98.11% vs. 94.61%, $p < 0.001$), and accuracy (89.83% vs. 83.77%, $p < 0.001$) in detecting metastatic lymph nodes by McNemar's test. Additionally, the expression of GRPR and integrin αvβ3 receptors in both primary tumor and metastatic lymph nodes was demonstrated by immunofluorescence, verifying the tumor-specific targeting ability of [68Ga]Ga-RM26-RGD.
Conclusion: This study demonstrates that the new dual integrin αvβ3- and GRPR-targeting PET radiotracer has an equivalent performance to [18F]FDG in detecting primary breast

tumors and is superior in detecting metastatic axillary lymph nodes. [68Ga]Ga-RM26-RGD PET/CT may be of great value in the diagnosis of primary breast cancer and tumor staging.

P2-07-15: Metabolic tumor burden measured by [18F]FDG PET/CT and outcomes of patients with HER2-negative mBC treated with sacituzumab govitecan or trastuzumab deruxtecan

Romain-David Seban, Laurence Champion, Alexandre De Moura, Florence Lerebours, Delphine Loirat, Jean-Yves PiergaI, Lounes Djerroudi, Thomas Genevee, Virginie Huchet, Nina Jehanno, Irene Buvat, Francois-Clement Bidard

Aim: This study aimed to test the association between pre-treatment biomarkers using fluorine-18 fluorodesoxyglucose positron-emission tomography/computed tomography ([18F]FDG PET/CT) imaging and clinical outcomes in metastatic breast cancer (mBC) patients treated with antibody-drug conjugates (ADCs) Sacituzumab Govitecan (SG) and Trastuzumab Deruxtecan (T-DXd).
Methods: A retrospective and bicentric analysis was conducted on triple-negative mBC (mTNBC) patients treated with SG and hormone receptor positive or negative, HER2-low mBC patients treated with T-DXd, who underwent [18F]FDG PET/CT scans before therapy. Clinical, biological, pathological and PET parameters (tumor SUVmax, total metabolic tumor volume [TMTV]) were evaluated. A multivariate prediction model was developed using Cox models for progression-free survival (PFS) and overall survival (OS).
Results: The study included 128 patients: 71 mTNBC treated with SG and 57 HER2-low mBC treated with T-DXd. Median follow-up was 12.9 months in both cohorts. In the SG/T-DXd cohort, median PFS and OS were 4.8/5.8 and 8.9/9.0 months. In multivariate analyses, TMTV>median (SG: 38.5cm3; T-DXd: 91.8cm3) was associated with shorter PFS (SG: HR 2.3, 95%CI 1.2-4.4 and T-DXd: HR 2.1, 95%CI 1.3-3.9) and OS (SG: HR 2.9, 95%CI 1.3-6.7 and T-DXd: HR 2.8, 95%CI 1.2-7.1).
Conclusion: In this pretreated population, high TMTV, reflecting the metabolic tumor burden, on [18F]FDG PET/CT imaging before SG or T-DXd was associated with poor PFS and OS in mBC patients. Although SG and T-DXd rely on different targets and vectorization strategies, these two ADCs share the same baseline metabolic efficacy-associated biomarkers.

P2-07-16: Rising ESR1 Mutations in Circulating Tumor DNA (ctDNA) Mediate Endocrine Therapy (ET) Resistance to Everolimus and ET but Retain Sensitivity to Fulvestrant in HR+/HER2- Metastatic Breast Cancer (MBC)

Janice Lu, Qiang Zhang, Natalie Heater, Lisa Flaum, Huiping Liu, Patricia Robinson, Regina Stein, Claudia Tellez, Jianhua Jiao, Andrew A. Davis, Akhil Chawla, Youbin Zhang, Massimo Cristofanilli, William Gradishar

Background: Treatment with endocrine therapy and CDK4/6 inhibitors is the first-line therapy for the management of HR+/HER2- mBC. ESR1 mutations represent a type of acquired resistance in up to 40% of patients after initial ET. Recent advancements and our previous studies (ASCO-2019 #1036, 2022 #1057, and 2023 #1038) in understanding ET resistance in ESR1-mutant HR+/ HER2- mBC have highlighted the pivotal role of circulating tumor DNA (ctDNA) in monitoring treatment response and progression. Here, we report a first-of-its-kind finding of the significance of ctDNA ESR1 mutations as a factor associated with therapeutic resistance in HR+/HER2- mBC.

Methods: This study included 158 HR+/HER2- mBC patients enrolled under an IRB-approved trial (NU16B06) who received systemic treatments from 2016 to 2021 at Robert H. Lurie Cancer Center at Northwestern University. The median follow-up period was 126.3 months from the first diagnosis. 40 patients with ESR1 mutations were included for statistical analysis (Causal Inference) of the correlation between the presence of ESR1 mutations and ET resistance. Patients received various therapies including CDK 4/6 inhibitor, ET and mTOR inhibitor. None of the patients received ESR1-targeted therapy with Elacestrant. Baseline ctDNA was analyzed by Guardant 360 NGS at the time of metastatic spread and subsequent points of progression. Additional clinical, pathologic, therapy, and response data were retrospectively collected and analyzed.

Results: ESR1 mutations were identified in 10 hotspots in 40 patients. The number of patients with ESR1 mutations at each hotspot, along with the mean percentage of ESR1-mutated DNA, was as follows: 13 D538G (average 11.9%), 12 Y537S (average 5.6%), 8 E380Q (average 6.3%), 1 V392I (0.1%), 1 Y537N (1.7%), 1 L536P (3.4%), 1 L536R (11.0%), 1 L536H (23.9%), 1 K520K (0.6%), and 1 K362 (15.8%). Among the 40 ESR1-mutation positive patients, 13 received Fulvestrant and 26 received Everolimus and ET. Patients treated with Everolimus and ET had a significantly higher mean percentage of ESR1-mutated DNA compared to patients who did not receive Everolimus plus ET (17.9% vs. 6.1%, p=0.01). This indicates that a higher percentage of mutated ESR1 may be associated with resistance to Everolimus and ET. Conversely, patients treated with Fulvestrant had a significantly lower mean percentage of ESR1-mutated DNA compared to patients who did not receive Fulvestrant (6.85% vs. 18.1%, p=0.04). This suggests that an increasing percentage of ESR1-mutated ctDNA correlates with an increased treatment sensitivity to Fulvestrant. Interestingly, we identified a high rate of PIK3CA co-mutations in 24 patients (60%) among the 40 patients with ESR1 mutations, with the most common co-occurring ESR1 mutation hotspots being Y537S (8 pts), E380Q (7 pts), and D538G (5 pts). Further treatment response analysis to determine the correlation between these two gene co-mutations is underway.

Conclusions: Our findings indicate that the level changes of ctDNA ESR1 mutations have implications with regards to treatment sensitivity and resistance to various therapies in patients with HR+/HER2- mBC. These results suggest a potentially effective method for monitoring treatment response and guiding future therapy by providing new insights into targeting ESR1 pathways to overcome resistance.

P2-07-17: Palbociclib in women aged ≥70 years as first-line treatment for endocrine-sensitive Hormone Receptor-positive/Human Epidermal Growth Factor Receptor 2-negative locally advanced or metastatic breast cancer: final results of PalomAGE

Elisabeth Carola, Marina Pulido, Philippe Caillllet, Claire Falandry, Elena Paillaud, Louis Tassy, Michael Bringuier, Godelieve Rochette De Lempdes, Nicolas Jovenin, Axelle Boudrant, Jessica Grosjean, Camille Chakiba-Brugere, Anne-Claire Hardy-Bessard, Hubert Orfeuvre, Eric Legouffe, Fanny Bouteiller, Vincent Launay-Vacher, Maylis Decrop, Etienne Brain

Background: Endocrine therapy (ET) combined with a CDK4/6 inhibitor is standard of care for hormone receptor-positive (HR+) / human epidermal growth factor receptor 2-negative (HER2-) locally advanced or metastatic breast cancer (ABC). In Europe, around 40% of BC are diagnosed in women aged ≥70 years, contrasting with their underrepresentation (<5-10%) in clinical trials. PalomAGE is a French prospective, observational, real-life study, assessed the feasibility of palbociclib (PAL) combined with ET in women aged ≥70 years with HR+/HER2- ABC. PalomAGE included a geriatric assessment as recommended in this population when the G8 screening tool identified a probability of frailty. Here, we report the final results in patients with no prior systemic treatment for ABC and no relapse within 1 year after the end of adjuvant ET.
Methods: Data collected at baseline and every 3 months included sociodemographic, clinical, biological, disease and treatment response, quality of life (QoL; EORTC QLQ-C30 and ELD14), geriatric (G8 and Geriatric-COre DatasEt [G-CODE]) and safety parameters. Primary endpoint was PAL discontinuation rate (any reason) at 18 months. Secondary endpoints included time-to-treatment failure (TTF), progression-free survival (PFS), geriatric and QoL assessment, and safety.
Results: From October 2018 to December 2020, 816 patients were included, among whom 412 patients initiated PAL as first-line. Median age was 78 years (range 70-94) with 44.4% of patients ≥80 years, ECOG was ≥2 in 17.5%, visceral metastasis was present in 41.7%. For patients with geriatric questionnaires completed, baseline scores showed G8 ≤14, ADL ≤5, IADL short form ≤3 and Charlson comorbidity score ≥ 4 in 69.1%, 14.6%, 28.7% and 85.5% of patients, respectively. PAL starting dose was 125 mg, 100 mg, and 75 mg in 80.6%, 14.3%, and 5.1% of patients, respectively, combined with an aromatase inhibitor in 93.2% or fulvestrant in 6.8%. Patients initiating PAL at reduced dose were older (median age 83 years), presented more often an ECOG ≥ 2 (22.5%) and poorer geriatric scores (G8≤14, ADL ≤5, IADL short form ≤3, Charlson comorbidity score ≥4 in 82.1%, 25.4%, 35.8%, 91.9%, respectively).
Of all patients, 382 (92.7%) were evaluable for efficacy endpoints. With a median follow-up of 25.2 months (95% CI 21.7-28.4), the 18-month PAL discontinuation rate was 41.4% (95% CI 36.4-46.3) with disease progression (20.7%), toxicity (7.3%), patient's choice (6.8%), death (4.7%), or other reason (1.8%) as main causes. Median TTF and PFS were 23.0 months (95% CI 19.8–26.0) and 30.4 months (95% CI 25.7-not reached). Higher 18-month PAL discontinuation rate, shorter median TTF and PFS values were observed with

PAL initiation at a reduced dose without reaching statistical significance. The univariate analysis showed that baseline factors associated with lower TTF were higher age, poorer ECOG score, greater metastatic sites, G8≤14, IADL short form ≤3, and no person able to provide care and support. The multivariate analysis is in progress. At the end of the study, 93.7% and 38.7% of patients were still alive and under PAL treatment.
80.6% patients presented at least one adverse event (AE) related to treatment, with 63.3% neutropenia all grade (1.0% febrile neutropenia). AE led to PAL dose reduction and permanent discontinuation in 35.2% and 10.7% of patients.
Conclusion: PalomAGE confirms the feasibility of ET combined with PAL as first line for HR+/HER2- ABC in unselected women aged ≥70 years with significant prevalence of comorbidities and G8 impaired. Median PFS of 30.4 months is consistent with results obtained with PAL + ET in ET-sensitive HR+/HER2- ABC in other RCT and RW studies (PALOMA-2, PARSIFAL-LONG, PALBOSPAIN), with no new safety signal.

P2-07-18: Results from PALVEN: A Phase 1b Study of Palbociclib, Letrozole and Venetoclax in ER and BCL2-Positive Metastatic Breast Cancer

Geoffrey Lindeman, Christine Muttiah, Felicity C Martin, Michael Christie, Sarah-Jane Dawson, Jayesh Desai, Luxi Lal, Kate Moodie, Anand Murugasu, Phuong Phan, Mark R Rosenthal, Avraham Travers, Jane E Visvader, James R Whittle, Belinda Yeo

Background: CDK4/6 inhibitors induce growth arrest/senescence in breast cancer cells, which become refractory to apoptotic cell death. In preclinical models, the BCL2 inhibitor venetoclax augmented tumor response to endocrine and CDK4/6 inhibitor therapy, by triggering apoptosis. This is now being tested in PALVEN, a phase 1b dose escalation study in patients (pts) with ER+ and BCL2+ metastatic breast cancer (MBC). The maximum tolerated and recommended phase 2 dose has been defined as letrozole 2.5 mg (d1-28), palbociclib 75 mg (d1-21) and venetoclax 400 mg (d1-21). Here, we present the clinical benefit rate (CBR) and response rate (RR) at 24 wks and report treatment-related toxicity.
Methods: Participants included post-menopausal women with ER+/HER2– (ASCO/CAP) and BCL2+ MBC who had received ≤2 prior lines of systemic therapy in the metastatic setting. Patients (pts) with evaluable disease were included. Tumor assessment occurred every 8 wks. Secondary endpoints included CBR and RR defined by RECIST v1.1 within the first 24 wks of treatment. Adverse events from venetoclax, palbociclib and letrozole were reported using the CTCAE v5.0 grading system.
Results: As of 19 June 2024, sixteen pts had received venetoclax, palbociclib and letrozole treatment and fifteen were DLT-evaluable (median age 50 yrs [range 36-67]), with a median follow-up time of 29.2 months. Of the DLT-evaluable population, 8 pts had de novo MBC and 7 pts had relapsed MBC, with 9 pts having previously received endocrine therapy in either the adjuvant or metastatic setting. Three pts had received prior systemic treatment for MBC; 1st line aromatase inhibitor therapy (2 pts), chemotherapy followed by tamoxifen (1 pt). At the 24-wk tumor assessment, 60% (9/15) of patients had achieved a partial response (PR), 33% (5/15) had stable disease (SD), and one pt had progressive disease. The

CBR (rate of confirmed complete response or PR or SD ≥24 wks) was 93% (14/15 pts). Of thirteen pts with baseline measurable disease, 9 (69%) achieved a PR by 24 wks. In pts who were previously untreated in the metastatic setting, the CBR was 100% (12/12), 89% (8/9) for pts who had previously received endocrine therapy in the adjuvant or metastatic setting. For pts with strong (IHC 3+) BCL2 expression, CBR was 88% (7/8).
An interim safety analysis of all eligible pts that received at least one dose of triple therapy (n=16), determined the most common non-hematological treatment-related adverse events (TRAEs) of any grade were fatigue (75%), nausea (69%), arthralgia (50%), hot flashes (44%), constipation (44%) and diarrhea (44%). Grade ≥3 hematological TRAEs were decreased neutrophil count (63%), reduced white cell count (44%) and decreased lymphocyte count (19%). There were no AEs of special interest since dose level 1 (G3/4 AST/ALT elevations in 2 pts). No treatment-related deaths were reported. Two pts ceased triple therapy due to intolerable TRAE, including one with arthralgia attributed to letrozole alone.
Conclusion: Triple therapy with palbociclib, letrozole and venetoclax in ER+ and BCL2+ MBC is well tolerated and shows promising clinical activity in pts with endocrine sensitive and CDK4/6 inhibitor-naive disease. Our findings suggest that combining a BCL2 and CDK4/6 inhibitor in endocrine responsive breast cancer merits further investigation.
(IIS funded by NHMRC, NBCF, Cancer Australia, BCRF, BCT, VCCC, with support from AbbVie & Pfizer; NCT03900884).

P2-07-19: Health-Related Quality of Life with Sacituzumab Govitecan versus Treatment of Physician's Choice in Previously Treated Hormone Receptor-Positive/HER2-Negative Metastatic Breast Cancer: A Meta-Analysis of TROPiCS-02 and EVER-132-002 Trials

Hope S. Rugo, Binghe Xu, Anandaroop Dasgupta, Ankita Kaushik, Wendy Verret, Barinder Singh

Introduction: Two phase III randomized controlled trials (RCTs), TROPiCS-02 and EVER-132-002, compared sacituzumab govitecan (SG) versus treatment of physician's choice (TPC) in participants with HR+/HER2- [Human epidermal growth factor receptor 2, (IHC0, IHC1 positive, or IHC2 positive and ISH negative)] locally recurrent inoperable or metastatic breast cancer (MBC) who had progressed after 2-4 prior chemotherapy regimens. Prior CDK4/6 inhibitor (CDK4/6i) treatment was mandatory for inclusion in TROPiCS-02 but not EVER-132-002. In this study, we explored the health-related quality of life (HRQoL) benefits of SG vs TPC in the overall population and determined if results vary by prior CDK4/6i exposure and duration of prior CDK4/6i treatment via a meta-analysis of the two RCTs.
Methods: Meta-analysis was conducted to compare time to first clinically meaningful deterioration (TTD) of SG vs TPC using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Version 3.0 (EORTC QLQ-C30) domains (≥10 points change) and EuroQol 5 Dimensions 5 Levels Visual Analog Scale (EQ-5D-5L VAS) (≥15 points change) in the overall, prior CDK4/6i treated and fast progressor

populations (prior CDK4/6i duration of treatment: ≤12 months). A sensitivity analysis was performed, considering death to be an event. Hazard ratios and 95% confidence interval were estimated for TTD outcomes using a stratified Cox proportional hazards regression analysis.
Results: A statistically significant increase in TTD was observed with SG compared to TPC for 6 of 15 domains of EORTC QLQ C-30, including Global Health Status/QoL, physical functioning, emotional functioning, fatigue, pain, and dyspnea measures in the overall and prior CDK4/6i treated population. Amongst the remaining domains, 4 (role functioning, cognitive functioning, social functioning, insomnia) were numerically favored in SG arm, 3 (appetite loss, constipation, financial difficulty) were numerically favored in TPC arm, while 2 (nausea-vomiting and diarrhea) were significantly favored in TPC arm. Subgroup results for fast-progressors revealed significant TTD findings in similar 6 domains favoring SG, with significant benefit also observed for financial difficulties. In the sensitivity analyses, the findings remained largely consistent in the overall and prior CDK4/6i treated population. However, statistical significance in TTD favoring SG was lost in pain and gained in financial difficulties. Furthermore, SG demonstrated significantly longer TTD over TPC for EQ-5D-5L VAS, with and without considering death as an event for all three patient subgroups (HR ranging from 0.63 to 0.76, p <0.001).
Conclusions: In this meta-analysis, SG significantly improved quality of life compared to TPC for several EORTC QLQ C-30 domains and EQ-5D-5L VAS in the overall, CDK4/6i pre-treated, and fast-progressors populations. The consistency of these results across different patient populations and several time-to-event analyses enhances the generalizability of the individual trials and reinforces the HRQoL benefits associated with SG versus TPC.

P2-07-20: Sociodemographic Disparities in First-Line (1L) Treatment Patterns and Outcomes in Women With Hormone Receptor-Positive (HR+)/Human Epidermal Growth Factor Receptor 2-Negative (HER2–) Metastatic Breast Cancer (mBC) in the United States (US)

Gregory Vidal, Julie Katz, Natalia Sadetsky, Elizabeth C Dabrowski, Peter A Kaufman, Wendy Verret, Brian Stwalley, Kevin Kalinsky

Background: Recent substantial advances in targeted treatments for HR+ (estrogen/progesterone receptor-positive) and HER2– (immunohistochemistry score 0, 1+, or 2+ and fluorescence in situ hybridization test negative) mBC have led to improved outcomes. However, sociodemographic disparities in survival exist and are in part related to differences in access to health care, delays in diagnosis and treatment, income, comorbidities, and underlying disease biology. Further evaluation of treatment patterns and clinical outcomes in women with HR+/HER2– mBC is needed to identify health disparities and improve outcomes.
Methods: This retrospective observational cohort study utilized the nationwide, Flatiron Health electronic health record-derived de-identified database. Women aged ≥ 18 years with HR+/HER2– mBC , who initiated 1L treatment for metastatic disease from Jan 1, 2015

to Feb 28, 2023 were included. Sociodemographic and clinical factors, treatment patterns, time-to-next treatment or death (TTNTD), and real-world overall survival (rwOS) were evaluated by race/ethnicity, baseline socioeconomic status (SES) index (a composite of area-level measures), geographic region, and practice type. Sociodemographic and clinical factors and TTNTD were analyzed descriptively. rwOS was assessed by Kaplan-Meier methods and multivariable Cox proportional hazard regression was used to evaluate the association of rwOS with important clinical and sociodemographic factors.
Results: This study included 6974 women with HR+/HER2– mBC initiating 1L treatment. Median age was 65 years; 64% of women were non-Hispanic White (NHW), 10% were non-Hispanic Black (NHB), 8% were Hispanic/Latina (H/L) and 18% were of other or unknown race. Over one-third (37%) of women were from the Southern US and 83% were treated only in community cancer centers. Women were distributed equally by SES index (15-21% per quintile). NHW women and those treated in community centers were older (median age 66 years for both); women with higher SES index were more likely to be treated in academic centers (22% in the highest SES quintile vs 11% in the lowest quintile). More NHB women (44%) had stage IV (de novo) disease compared with NHW women (36%).
More than half of the women overall (54%) received 1L endocrine therapy + a cyclin-dependent kinase 4/6 inhibitor, with little difference between NHW and NHB women (55% vs 52%). The proportion of women receiving 1L single-agent chemotherapy (overall 15%) was higher among NHB and H/L women compared with NHW women (21% and 24% vs 14%, respectively).
Median rwOS was 41.7 months (95% CI 40.1-44.1) for NHW and 32.1 months (95% CI 28.3-35.7) for NHB. A statistically significant difference remained after adjusting for clinical and sociodemographic factors (hazard ratio [HR] 1.2, $P < 0.01$). Median rwOS was 49.7 months (95% CI 45.8-56.3) for women treated in academic centers and 37.6 months (95% CI 36.2-39.3) for those treated in community centers (HR 0.82, 95% CI 0.75-0.91). There was no statistically significant difference in adjusted rwOS by SES index and geographic region. No statistically significant difference was observed in TTNTD by race, SES index, geographic region, or treatment setting.
Conclusions: This study showed that race/ethnicity and treatment setting continue to play an important role in rwOS in HR+/HER2– mBC. Future studies could elucidate the relationship between sociodemographic factors and disparities. This can inform interventions to improve the outcomes of women with HR+/HER2– mBC.

P2-07-21: A phase II study of pembrolizumab plus fulvestrant in ER positive, HER2 negative advanced/metastatic breast cancer patients

Nancy Chan, Dirk Moore, Nadia Baka, Kari Wisinski, Jairam Krisnamurthy, Jatin Rana, Pavan Tandra, Douglas Marks, Malinda West, Deimante Tamkus, Yue Wang, Chunxia Chen, Jacqueline Wang, Lisa Arendt, Kim Hirshfield, Mridula George, Shridar Ganesan, Deborah Toppmeyer, Coral Omene

Background: The role of immune checkpoint inhibitors (ICI) has not been elucidated in ER+/Her2- metastatic breast cancer (MBC). Previous studies have demonstrated a subset of these patients may derive benefit from immunotherapy in combination with endocrine therapy. We hypothesized that pembrolizumab in combination with fulvestrant would demonstrate disease control with acceptable toxicity profile.
Methods: This was a multicenter, single arm, open label Phase II Simon's two-stage optimal design study in patients with ER+/HER2- MBC. The study was conducted through the BIG TEN Cancer Research Consortium. Patients received no more than 2 prior lines of endocrine or chemotherapy in the metastatic setting. Treatment consisted of pembrolizumab 200 mg every 3 weeks in combination with fulvestrant. The primary endpoint was to evaluate the clinical benefit rate (CBR: SD+PR+CR). The anti-tumor activity of pembrolizumab plus fulvestrant was measured by RECIST 1.1, irRECIST, and progression free survival (PFS). Scheduled staging scans occurred every 3 cycles (9 weeks). Secondary endpoints included safety and tolerability. PD-L1 status and next generation sequencing (NGS) by Tempus was performed on available samples to investigate biomarkers of response and the underlying mutational landscape. (NCT03393845)
Results: Forty-seven patients were enrolled, with median age of 61. Majority of patients (n=32, 70%) received 1 prior line of therapy in the metastatic setting (range 0-2). Forty patients (87%) had prior treatment with CDK4/6 inhibitors, with 1 patient who received it in the adjuvant setting on a clinical trial. Eleven patients (24%) received prior fulvestrant, and 1 received chemotherapy in the metastatic setting. Forty-six patients were treated with at least 1 cycle, 44 were efficacy-evaluable, and 43 remained on study at the time of first restaging imaging. One patient came off study due to clinical progression and was included in the final response analysis. Two patients without radiographic or clinical progression withdrew after adverse events unrelated to the study drugs and were not included in the final response analysis. The median PFS in evaluable patients was 3.2 months (range 0.2-23.3). The CBR at 18 weeks was 36.4% (n=16/44) by RECIST 1.1. Of the 43 patients who underwent first restaging scan, 22 (50%) patient achieved disease control, including 17 patients with stable disease and 5 patients with partial response. Amongst patients who achieved disease control, the median duration of response was 6 months (range 2.3-21.3 months). Twenty-two patients had either radiographically confirmed progression on first restaging scan or clinical progression. The most common treatment related adverse effects (TRAEs) were AST elevation (n= 15, 31.9%), ALT elevation (n= 12, 25.5%), and fatigue (n= 14, 29.8%). Majority of TRAEs (93.5%) were G1-2. TRAEs of interest included hypothyroidism (n= 8, 17.0%), hot flashes (n= 3, 6.4%), arthralgia (n= 4, 8.5%), and pneumonitis (n= 1, 2.1%, G2). There were 7 (15%) patients who experienced G3 toxicities (arthralgia, anemia, hypocalcemia, decreased lymphocyte, rash, weight loss) and of these one patient (2.1%) discontinued the study drug due to elevated AST/ALT. There were no G4+ TRAEs. In patients with available tissue for NGS utilizing the Tempus platform (648 gene panel for next generation sequencing, whole exome, and RNA sequencing), genomic alterations and tumor mutational burden were evaluated. Response will be correlated with PD-L1 status by combined positive score (CPS), prior fulvestrant exposure, BMI, and biomarkers identified on NGS as exploratory analyses.

Conclusions: The combination of pembrolizumab and fulvestrant in ER+/HER2- MBC demonstrated a manageable toxicity profile with durable response in patients who achieved disease control. The combination may be considered for further exploration to better understand biomarkers of response to ICI in this population.

P2-07-22: Cyclin-dependent kinase 7 (CDK7) inhibitor samuraciclib combined with selective estrogen receptor degrader (SERD) elacestrant in advanced HR+ breast cancer after CDK4/6i: dose escalation data from the Phase 1b/2 SUMIT-ELA study

Francois-Clement Bidard, Maxime Brunet, Amita Patnaik, Cécile Vicier, Raquel Gomez, Sacha Howell, Luisa Sanchez, Erin Roesch, Mario Campone, Agostina Stradella, Simon Lord, Carlos Garay, Paolo Mazzei, Glen Clack, Stuart McIntosh, William Gradishar

Background: Effects of CDK7 in cancer include: enhanced oncogene transcription; anti-apoptotic gene upregulation; cell cycle acceleration via CDK phosphorylation; and estrogen receptor activation, driving resistance to hormonal therapy. Thus, CDK7 inhibition represents a potential anticancer strategy. Samuraciclib (CT7001), a once-daily oral CDK7 inhibitor, combined with the SERD fulvestrant had a favorable safety profile and clinical activity in patients with HR+/HER2− advanced breast cancer (BC) previously treated with a CDK4/6i [Coombes, 2023]. Patients with no detectable TP53 mutation in baseline ctDNA appeared to have better outcomes. Oral SERDs are of interest due to their pharmacokinetic (PK) properties and convenient administration. The oral SERD elacestrant significantly improves progression-free survival (PFS) versus standard-of-care endocrine therapy in ER+/HER2− advanced or metastatic BC previously treated with a CDK4/6 inhibitor, and particularly ESR1-mutant tumors [Bardia et al. SABCS 2022]. Non-clinical data indicate that the biology underlying the samuraciclib/SERD combination translates from fulvestrant to elacestrant, in addition to overcoming other resistance mechanisms. Thus, clinical evaluation of this combination is warranted [data on file].
Methods: The phase 1b/2 SUMIT-ELA open-label dose escalation and expansion study (NCT05963997) is evaluating the safety, efficacy, and PK of samuraciclib combined with elacestrant, both dosed QD. Eligible patients (n=48) are ≥18 years, have histologically or cytologically confirmed ER+/HER2− advanced or mBC not amenable to resection or radiotherapy of curative intent, have received an AI + CDK4/6i in the adjuvant or advanced setting, are receiving a LHRH agonist if pre/perimenopausal, and have RECIST v1.1 measurable or evaluable disease. All patients undergo baseline Guardant360 ctDNA analysis to assess ESR1 and TP53 mutation status. Prior SERD, mTOR inhibitor, or chemotherapy for advanced BC are not permitted. Patients undergo RECIST v1.1 evaluation at baseline, every 8 weeks until week 48, and every 12 weeks thereafter. The primary endpoints are identification of tolerable combination doses of samuraciclib and elacestrant (phase 1b) and 6-month PFS rate (phase 2). Secondary endpoints are tolerability, clinical benefit rate at 24 weeks, ORR, DoR, best percentage change in tumor size, PK, and associations between ESR1 and TP53 mutation and efficacy/safety.

Results: The following cohorts (C) have been recruited and dosed with samuraciclib + elacestrant as follows: C1 (240+300 mg, n=6); C2 (360+300 mg, n=6); and C3 (360+400 mg, n=5). Dose escalation is complete and C4 expansion at the recommended top doses of both compounds is recruiting (360 mg samuraciclib + 400 mg elacestrant). Co-dosing of samuraciclib and elacestrant had no significant impact on the exposure of either agent. The most frequent all-grade treatment-related AEs were diarrhea, nausea, vomiting, asthenia, and abdominal pain. One subject in C1 (53-year-old female; TP53wt, ESR1wt; liver metastasis) experienced a confirmed partial response with a 37% reduction in the size of target lesions.
Conclusions: The most frequent treatment-related AEs were similar to the known safety profiles from both previous samuraciclib and elacestrant studies. With no drug-drug interactions between the treatments, further study of combination treatment in expansion C4 is supported. Preliminary signs of antitumor activity were observed.

P2-07-23: Targeting Insulin Feedback to Enhance Alpelisib (TIFA): A phase II randomized trial in PIK3CA-mutant hormone receptor-positive metastatic breast cancer

Sherry Shen, Erica Salehi, Azeez Farooki, Maria Bromberg, Yuan Chen, Dominiq Williams, Verna Solomon, Cassandra Chang, Mario Lacouture, Komal Jhaveri, Andrew Plodkowski, Lewis Cantley, Marcus Goncalves, Neil Iyengar

Background: Fulvestrant+alpelisib significantly improves progression-free survival in patients with PIK3CA-mutated metastatic breast cancer (MBC). However, PI3K inhibition induces hyperglycemia, a major cause of dose interruption and dose reduction. Novel strategies to minimize hyperglycemia and improve alpelisib drug delivery are needed.
Methods: In this phase II trial, patients receiving fulvestrant+alpelisib were randomized to 1) ketogenic diet (KD), 2) low-carbohydrate diet (LCD), or 3) canagliflozin (SGLT2i) (NCT05090358). Eligibility criteria included ≥1 activating PIK3CA mutation, measurable or non-measurable disease, hemoglobin A1c (HbA1c) <8% and fasting glucose ≤140mg/dL. The primary endpoint was the grade 3/4 hyperglycemia-free rate at 12 weeks; this was a cumulative endpoint and any grade 3/4 hyperglycemia event within the first 12 weeks was counted. The study was designed for the endpoint to be tested in each arm separately, such that ≥1 strategy could be deemed successful. Weight and serum glucose levels were measured every 2 weeks for the first 4 weeks and every 4 weeks thereafter. Patients also performed daily at-home point of care glucose and beta-hydroxybutyrate measurements to assess the level of ketosis. Continuous glucose monitoring (CGM) was done in 2-week intervals throughout the 12-week study period. Body composition was assessed on CT scans pretreatment and at 12 weeks. Diet adherence was defined as consuming ≤40g daily carbohydrates for the KD arm and ≤100g for the LCD arm on ≥70% of available complete food log days. Although expected enrollment was 106 patients, this trial closed early due to low alpelisib use.
Results: Among 15 enrolled patients, 8 were evaluable. 6/8 (75%) patients met the primary

endpoint: 2/3 in the KD arm, 2/2 in the LCD arm, and 2/3 in the SGLT2i arm; the grade 3/4 hyperglycemia rate was 25%. Mean (standard deviation, SD) glucose in mg/dL by patient within each arm was as follows: KD arm 139 (39), 100 (19), 190 (54); LCD arm 113 (16), 103 (12); SGLT2i arm 170 (59), 95 (9), 97(7). Mean CGM time in range was 85% across the cohort (25); mean (SD) by patient within each arm were as follows: KD arm 77 (17), 45 (38), missing; LCD arm 98 (6), 96 (5); SGLT2i arm 91 (17), 94 (11), 89 (15). Beta-hydroxybutyrate mean levels (SD) in mmol/L by patient within treatment arm were as follows: KD arm 0.12 (0.08), 0.15 (0.06), 0.69 (0.29); LCD arm 0.64 (0.32), 0.57 (0.28), SGLT2i arm 0.42 (0.31), 0.15 (0.08), 0.30 (0.12). Hemoglobin A1c level 12-week change ranged from 0 to +3.5%. Alpelisib mean RDI over 12 weeks ranged from 120-300mg. All 5 patients randomized to dietary arms adhered to the diet during the 12-week study period. All 8 patients had decreases in BMI at 12 weeks compared to baseline; 4/8 patients had decreases in visceral fat and 6/8 patients had decreases in subcutaneous fat on body composition measurements at 12 weeks.
Conclusions: CGM for percent time in range may be a useful way to monitor PI3K-induced hyperglycemia. Grade 3/4 hyperglycemia was lower with the study interventions than in SOLAR-1 (25% vs. 40.3% in patients with HbA1c <8%), albeit in a small number of enrolled patients; these data support further study of diet and/or SGLT2 inhibition with agents that target this pathway.

P2-07-24: Results from the Phase II Study of ROS1 Targeting with Crizotinib in Advanced E-cadherin Negative Lobular Breast Cancer (ROLo)

Alicia Okines, Elinor Sawyer, Rebecca Roylance, Anne Armstrong, Stephen Johnston, Alistair Ring, Marina Parton, Naureen Starling, Iseult Browne, Rebecca Ruiz, Kabir Mohammed, Catey Bunce, Dymphna Lee, Rachael Natarajan, Isaac Garcia-Murillas, Christopher Lord, Nicholas C Turner

Background: Lobular breast cancers are characterised by loss of function of the cell adhesion protein E-cadherin, which is commonly inactivated via CDH1 mutation. Pre-clinical studies demonstrated synthetic lethality between ROS1 inhibition and E-cadherin loss in models of lobular breast cancer and diffuse gastric cancer. We conducted a phase 2 study with the ALK/ROS1 inhibitor crizotinib to assess the potential of ROS1 inhibition in lobular advanced breast cancer (ABC).
Methods: This phase 2 multi-centre study recruited to two cohorts in parallel: Eligible patients with measurable disease, had previously treated ER+ lobular ABC confirmed E-cadherin negative by immunohistochemistry (ER+ lobular cohort), or advanced diffuse gastric cancer (DGC), lobular triple negative breast cancer (TNBC) or other CDH1-mutated solid tumours (basket cohort). The ER+ lobular cohort received crizotinib and fulvestrant, and the basket cohort crizotinib alone. The primary endpoint was confirmed response rate (RR). Secondary endpoints included clinical benefit rate (CBR) at 6 months, safety, progression-free (PFS) and overall survivals (OS). Optimal Simon 2 stage design with 80% power to exclude p0 5% and target p1 20% RR, with recruitment of 29 ER+ lobular and 29

DGC or lobular TNBC patients. At least 4 confirmed responses in 29 patients were required to consider crizotinib +/- fulvestrant worthy of future study.
Results: Twenty-seven eligible patients were recruited from five centres to the ER+ lobular cohort and 6 to the basket cohort (one DGC, 5 lobular TNBC). The median age for each cohort was 57 and 63 respectively, all patients were female. ER+ lobular patients had received a median of 2 lines of endocrine therapy (range 1-2) and 2 lines of chemotherapy (range 1-3), the basket cohort received a median of 2 lines of chemotherapy (range 1-2) for advanced disease.
One patient in the first 10 patients with ER+ lobular ABC had a partial response, but no further responses were recorded in 17 further assessable patients (4%, 1/27). None of the 6 patients with TNBC or DGC (0%) responded to crizotinib and recruitment was terminated. CBR was 11% and 0% respectively and median PFS was 1.8 months for both cohorts. Median OS was 17.5 months in the ER+ lobular cohort and 4.4 months in the basket cohort.
For the combination of fulvestrant and crizotinib, nausea (20/27, 74%) and raised liver transaminases (20/27, 74%) were the most frequent toxicities reported. Raised ALT and/or AST was grade 3 in 9/27 patients and no grade 4 or 5 events related to the treatment were reported. For crizotinib monotherapy, adverse events were consistent with the known toxicity profile.
Conclusions: Despite promising pre-clinical data, ROS1 inhibition with crizotinib was not effective combined with fulvestrant in pre-treated ER+ lobular ABC, nor as monotherapy in pre-treated lobular TNBC or DGC.
Trial Registration – Clinical Trials: NCT03620643

P2-07-25: Thymidine kinase activity as a prognostic and predictive biomarker in the Phase II PACE trial of CDK4/6 inhibition beyond progression

Nader-Marta, Yue Ren, Reshma Mahtani, Cynthia Ma, Angela DeMichele, Massimo Cristofanilli, Jane Meisel, Kathy Miller, Yara Abdou, Elizabeth Riley, Rubina Qamar, Priyanka Sharma, Sonya Reid, Naomi Ko, Harold Burstein, Michelle DeMeo, Amy Williams, Yuan Liu, Eric Gauthier, Sara Tolaney, Meredith Regan, Rinath Jeselsohn, Erica Mayer

Background: There are no validated predictive biomarkers for continuation of CDK4/6 inhibition (CDK4/6i) beyond progression in patients (pts) with estrogen receptor-positive (ER+), HER2-negative (HER2-) metastatic breast cancer (MBC). Thymidine kinase (TK) is an enzyme involved in DNA synthesis that is released into the bloodstream by proliferating cells. Lower baseline serum TK activity (TKa) levels as well as on-treatment changes (TKa decreases with CDK4/6i and increases with immunotherapy) have been associated with better outcomes. The aim of this study is to assess the prognostic value of TKa in pts previously treated with CDK4/6i, as well as its predictive value for response to CDK4/6i beyond progression with or without immunotherapy in the PACE trial.

Methods: The PACE (NCT03147287) multicenter phase II trial randomized 220 pts with ER+, HER2- MBC who had progressed on at least 6 months (mo) of prior CDK4/6i and aromatase inhibitor (AI) to receive fulvestrant alone (F), F plus palbociclib (F+P), or F+P plus the PD-1 inhibitor avelumab (F+P+A). No statistically significant differences in median progression-free survival (PFS) were observed for F+P or F+P+A compared to F. Blood samples were collected at baseline (BL, within 14 days of treatment start) and at cycle 2 day 1 (C2D1); serum TKa was quantified at a central laboratory with the ELISA-based DiviTum® TKa assay (Biovica, USA). TKa analysis was blinded to clinical data. The associations of BL and C2D1 TKa PFS were assessed using stratified Cox models, the predictive associations by testing for treatment-by-TKa interaction. In this study, prespecified TKa cutoffs were defined as 250 DuA (DiviTum unit of Activity) and the median TKa values.

Results: BL samples were available for 198 pts (90.0%), and 176 (80.0%) had paired C2D1 samples. Median BL TKa was 408 DuA (IQR 198-822) in the overall population, 372 (202-604), 465 (203-843), and 328 (190-805) in F, F+P, and F+P+A arms, respectively. Higher BL TKa (>250 DuA) was not associated with inferior PFS (HR 1.0, 90%CI: 0.74-1.36) with all arms combined. Among those with high BL TKa, median PFS was 3.6 mo (90% CI: 1.9-7.3) for F, 5.4 mo (90% CI: 3.5-8.1) for F+P, and 8.1 mo (90% CI: 3.2-14.3) for F+P+A. Higher BL TKa (>250 DuA) was not predictive of differential PFS when comparing F with F+P (interaction p=0.16) or F with F+P+A (interaction p=0.41). Similar results were observed using the median BL TKa as a cutoff. Median TKa at C2D1 was 248 (IQR 136-546) with all arms combined, 290 (161-620), 239 (109-500), and 228.0 (149.0-492.0) for F alone, F+P, and F+P+A, respectively. High C2D1 TKa (> 250 DuA) was associated with shorter PFS (mPFS 2.4 mo vs 7.2 mo, HR 2.3, 90%CI: 1.6-3.1) with all arms combined. TKa at C2D1 was not predictive of PFS when comparing arm F with F+P (interaction P-value 0.74) or F with F+P+A (interaction P = 0.19). To evaluate TKa dynamic change, pts from all arms combined were classified in 4 groups based on TKa change between BL and C2D1 (cutoff of 250 DuA): 44 (25.0%) pts had “high to low,” 45 (25.6%) pts had “stay low,” 15 (8.5%) pts had “low to high,” and 72 (40.9%) pts had “stay high.” PFS differed based on the on-treatment TKa dynamic change: “high to low” mPFS 7.6 mo (90% CI: 7.1-16.3), “stay low” mPFS 5.6 mo (90% CI: 3.3-9.6), “low to high” mPFS 4.9 mo (90% CI: 1.7-8.2), and “stay high” mPFS 2.2 mo (90% CI: 1.4-2.6). Pts with “high to low” TKa decrease had favorable PFS compared to “stay low” (HR 0.58, 90% CI: 0.36-0.92), “low to high” (HR 0.46, 90% CI: 0.26-0.83), or “stay high” (HR 0.29, 90% CI: 0.18-0.45) groups.

Conclusion: In the PACE trial, BL TKa after progression on CDK4/6i was not associated with prognosis or benefit from different therapies. However, high C2D1 on-treatment TKa was associated with inferior outcomes. Early dynamic changes in TKa levels may allow identification of populations with distinct prognoses, possibly facilitating clinical decisions in this context.

P2-07-26: Onvansertib shows synergistic efficacy in combination with paclitaxel in HR+ breast cancer: Mechanistic insights from preclinical models

Sreeja Sreekumar, Migdalia Gonzalez, Davis Klein, Elodie Montaudon, Laura Sourd, Léa Huguet, Tod Smeal, Elisabetta Marangoni, Maya Ridinger

Background: Paclitaxel is a first-line chemotherapy for hormone receptor-positive (HR+) metastatic breast cancer patients who have progressed on CDK4/6 inhibitors and endocrine therapy (ET) and have exhausted available ET options. The response rate for paclitaxel ranges from 20-40%, with most patients eventually developing resistance, resulting in limited treatment options. Paclitaxel-resistant tumors exhibited increased expression of polo-like kinase 1 (PLK1), a serine-threonine-protein kinase that is a key mitotic regulator. Onvansertib is a highly selective PLK1 inhibitor in clinical development that showed potent anti-tumor activity in combination with paclitaxel in preclinical models of ovarian cancer and triple negative breast cancer (TNBC). A phase 1b/2 clinical trial to evaluate the safety and efficacy of onvansertib plus paclitaxel in advanced TNBC is ongoing (NCT05383196). In this study, we investigated whether onvansertib synergizes with paclitaxel and overcome paclitaxel resistance in HR+ preclinical models resistant to first-line therapies.
Methods: We assessed the efficacy of paclitaxel combined with onvansertib in HR+ breast cancer cell lines (MCF-7, T-47D, EFM-19, CAMA-1, ZR-75-1, HCC1428 and MCF7/164R-7) and patient-derived xenograft (PDX) models. The effect of this combination on cell viability, cell cycle, mitotic arrest and DNA damage was evaluated in vitro. Eight PDXs resistant to ET and CDK4/6 inhibitors abemaciclib or palbociclib were established from primary breast tumors (n=2) or metastatic biopsies (n=6). The PDX tumors were engrafted in nude mice, and the effect of onvansertib (oral, 45 mg/kg, 5 days a week) and paclitaxel (IP, 15-25 mg/kg, once a week) as monotherapies, and in combination was investigated. The impact of the combination on apoptosis and expression of selected proteins was investigated both in vitro and in vivo.
Results: The combination synergistically inhibited the viability of HR+ breast cancer cell lines. In vivo, the combination was well tolerated with minimal toxicity and exhibited enhanced anti-tumor activity compared to either agent alone across all the eight PDX models. Paclitaxel and onvansertib monotherapies showed little to no anti-tumor activity in five out of eight PDX models (HBCx-139palboR5, HBCx-124palboR25, HBCx-131, HBCx-202, and HBCx-239). Conversely, the combination induced strong anti-tumor activity in all these models. Notably, tumor regression with >50% complete response rates were observed in HBCx-139palboR5, HBCx124palboR25, and HBCx-239 PDXs. Among the eight PDX models, three were sensitive to paclitaxel (HBCx-86, HBCx-137palboR26 and HBCx-3). In these models, compared to monotherapy, the combination demonstrated greater activity, inducing tumor regression and achieving a higher rate of complete response. The antitumor activity of the combination was very durable, showing a robust delay in tumor relapse after treatment cessation. Mechanistic studies revealed pronounced mitotic arrest and DNA damage with the combination treatment in cell lines. Compared to monotherapies, the combination induced marked apoptosis, both in vitro and in vivo. A significant decrease in

c-Myc protein expression was observed in both cell lines and tumors from mice treated with the combination compared to single agents. Studies are ongoing to further understand the regulation of c-Myc with this combination therapy.
Conclusions: Our findings strongly suggest that combining paclitaxel with onvansertib extends its benefit and overcomes paclitaxel resistance. This presents a promising therapeutic strategy and merits further clinical investigation for advanced HR+ breast cancer patients who are resistant to standard-of-care therapies.

P2-07-27: Long-term administration of endocrine therapy on the gut microbiota of breast cancer patients between disease-free and recurrence

Ming-Feng Hou, Fang-Ming Chen, Chih-Po Chiang

Background: In recent years, there has been a dramatic proliferation of research concerned with the gut microbiota and breast cancer. It is well known that the best-known mechanism of the gut microbiota on breast cancer comes from "estrobolome", which refers to the gut bacterial genes whose products are capable of metabolizing estrogens. However, not only does the gut microbiota affect the metabolism of estrogen, but estrogen can also impact the composition of the gut microbiota. The isoflavone-rich diet, soy isoflavone, or long-term administration of estrogen could impact the diversity and composition of the gut microbiota. To date, little is known about the effect of oral medication with endocrine therapy (ET) on the gut microbiota, especially in long-term administration of human studies. Thus, in this study, we aimed to investigate the long-term effect of oral medication with tamoxifen and letrozole on the human gut microbiota, especially in patients between disease-free and recurrence during ET.
Methods: A total of 48 female participants were included and divided into four groups including groups I and II of Tam-T and Let-L: patients were only administered with tamoxifen or letrozole; group III of CLet-CL: patients have received chemotherapy (CTx) with anthracycline–taxane sequence plus letrozole; group IV of Recur-R: patients have received CTx plus letrozole and have a recurrence during the period of ET. Fecal samples were serially collected from patients at two different time points. At the first point, fecal samples were collected before patients received any ET, CTx, or surgery (T1, L1, CL1, and R1). At the second point, fecal samples were collected after taking tamoxifen or letrozole for about 1 year (T2, L2) and collected after taking CTx plus letrozole (total about 1 year, CL2 and R2). The fecal samples were analyzed using 16S rRNA sequencing and further analyzed with operational taxonomic units (OTUs), α/β-diversity, linear discriminant analysis (LDA) effect size (LEfSe), heat tree analysis, random forest algorithm, and Phylogenetic Investigation of Communities by Reconstruction of Unobserved States (PICRUSt) prediction.
Results: In comparisons with the same regimen of third arms at the time point of the CL1 group, we found the α-diversity was significantly reduced in patients with recurrence of ET at the time point of the R1 group ($p = 0.03$). In comparison with the group of T1, L1, and L2, the α-diversity was also reduced in the R1 group. At the OTUs level, the relative abundance of major taxons did not observe significant differences among T1 and T2, L1 and L2, CL1

and CL2 but with high abundance of Fusobacteria appeared in the R2 group. The PERMANOVA analysis showed that there was no significant difference between the first-time point and the one-year ET administration of the second-time point. However, in patients with recurrence of ET, the microbial composition was different from patients with non-recurrence. In addition, there is no significant difference in the abundance of hierarchical taxonomic among T2 vs T1, L2 vs L1, and CL2 vs CL1. In contrast, several abundances of hierarchical taxonomic have existed in Recur-R versus Let-L and CLet-CL. We found the abundance of Fusobacterium, Ruminococcus, and Parabacteroides were significantly higher in patients with recurrence of ET than in patients with non-recurrence, especially in the second-time point of R2. Interestingly, we also found that the microbiome in the R1 group was specifically enriched in the pathway of Parkinson's disease than in the R2 or non-recurrence group.
Conclusion: To our knowledge, we provide the first preliminary results of long-term administration of ET on the gut microbiota in human study. We found long-term administration with ET (one year of tamoxifen or letrozole) did not significantly impact the total microbial composition. However, we found the abundance of several critical microbial markers was significantly higher in patients with recurrence of ET than in patients with non-recurrence, especially in the second-time point of R2. In the future, accumulating case numbers and introducing multiomics approaches will be needed on this topic.

P2-07-28: Treatment de-escalation by omission of chemotherapy & the effect of adding the CDK4/6 inhibitor ribociclib in HER2-positive and hormone-receptor positive metastatic breast cancer– second interim efficacy analysis of the randomized DETECT V trial

Wolfgang Janni, Tanja Fehm, Volkmar Müller, Amelie De Gregorio, Thomas Decker, Andreas Hartkopf, Marianne Just, Jacqueline Sagasser, Marcus Schmidt, Pauline Wimberger, Tobias Engler, Maggie Banys-Paluchowski, Peter A. Fasching, Brigitte Rack, Andreas Schneeweiss, Jens-Uwe Blohmer, Jens Huober, Klaus Pantel, Thomas W. P. Friedl, Fabienne Schochter

Background: Metastatic breast cancer (MBC) is still regarded as an incurable disease with improvement of survival and maintenance of quality of life (QoL) being equally important treatment goals. In patients with HER2-positive MBC, taxane-based chemotherapy in combination with dual HER2 targeted therapy with trastuzumab (T) and pertuzumab (P) is the standard of care therapy for first line patients. However, given that adverse events associated with cytostatic treatment can seriously impact the patients' QoL, the less toxic synergistic combination of dual HER2-targeted therapy with endocrine therapy might offer a better treatment option for patients with HER2-positive and hormone-receptor (HR) positive MBC compared to cytotoxic chemotherapy-based treatment regimen.
Methods:Between 9/2015 and 11/2022, the German multicenter phase III DETECT V trial randomized 271 patients with HER2-positive and HR-positive (i.e. ER positive and/or progesterone-receptor positive) MBC in the 1st-3rd line setting 1:1 to receive T and P combined with either endocrine therapy or chemotherapy followed by maintenance

therapy with T, P and endocrine therapy. Chemotherapy and the endocrine agents could be chosen from a variety of available regimens according to physicians' choice. Based on emerging data strongly suggesting an additional benefit of CDK4/6 inhibitors, an amendment came into effect in January 2019 (after 124 patients had been randomized) with the addition of ribociclib to both treatment arms. The primary objective of DETECT V is to compare tolerability between the chemotherapy-free and chemotherapy-containing treatment arm. Secondary objectives comprise the comparison of overall survival (OS), progression-free survival (PFS) and safety between chemotherapy-free and chemotherapy-containing treatment, as well as the evaluation of the effect of adding ribociclib to both treatment arms. Here we report results of the second interim efficacy analysis with data cut off April 3rd 2024 (as based on the full ITT set of 271 patients; 54 patients still in follow up). Results:Median patient age was 60 years, 209 (77.1%) of patients were in the first line setting and 139 (51.3%) patients had a metastasis-free interval exceeding 12 months. Overall survival (OS) and progression-free survival (PFS) did not differ between patients receiving chemotherapy-free and chemotherapy-containing treatment (median OS not reached vs. 46.1 months, hazard ratio 1.07, 95% CI 0.65 – 1.77, p = 0.79; median PFS 19.1 vs. 22.4 months, hazard ratio 1.19, 95% CI 0.84 – 1.69, p = 0.34). Both OS and PFS were significantly improved by the addition of ribociclib (median OS not reached vs. 46.1 months, hazard ratio 0.42, 95% CI 0.24 – 0.74, p = 0.002; median PFS 27.2 vs. 15.6 months, hazard ratio 0.52, 95% CI 0.37 – 0.75, p < 0.001). However, exploratory analyses showed that the effect of adding ribociclib seemed to be more pronounced in the chemotherapy-containing arm (OS: hazard ratio 0.25, 95% CI 0.10 – 0.62, p = 0.003; PFS: hazard ratio 0.36, 95% CI 0.21 – 0.62, p < 0.001) as compared to the chemotherapy-free arm (OS: hazard ratio 0.65, 95% CI 0.31 – 1.36, p = 0.255; PFS: hazard ratio 0.71, 95% CI 0.44 – 1.15, p = 0.159). The 2-way interactions between randomization arm and addition of ribociclib approached significance both for OS and PFS (p = 0.087 and p = 0.088, respectively). Conclusion:Our preliminary results suggest that chemotherapy-free treatment for patients with HER2-positive and HR-positive MBC might be an effective alternative, while the addition of ribociclib may further improve survival.

P2-07-29: DNADX in advanced hormone receptor-positive and HER2-negative (HR+/HER2-) breast cancer following endocrine therapy with or without palbociclib: a correlative analysis from the GEICAM/2014-12 FLIPPER phase II randomized trial

Joan Albanell, Aleix Prat, Maria Teresa Martinez, Guillermo Villacampa, Lorena Paris, Sandra Cobo, Miriam O' Connor, Rosario Vega, Luis de la Cruz-Merino, Fara Brasó-Maristany, Ana Santaballa Bertrán, Francisco Pardo, Noelia Martínez-Jañez, Patricia Galván, Fernando Moreno, Oleguer Castillo, Isaura Fernández, Laia Paré, Jesús Alarcón, Judit Matito, Juan Antonio Virizuela, Juan de la Haba-Rodríguez, Pedro Sánchez-Rovira, Lucía González-Cortijo, Mireia Margelí, Alfonso Sánchez-Muñoz, Iria González Maeso, Antonio Antón, Juan Guerra, Ariadna Tibau, Manuel Ruíz-Borrego, Cinta Rosa Albacar, Coralia Bueno, Andrés

García-Palomo, Yolanda Fernández, Sonia González, María Rodríguez de la Borbolla, Vega Iranzo, Catherine M Kelly, Maccon M Keane, Patrick G Morris, Conleth G Murphy, Charles M Perou, Jesús Herranz, Joel S Parker, Marta Portela, Patricia Villagrasa, Rosalia Caballero, Ana Vivancos, Federico Rojo

Background: DNADX, a novel machine learning-based approach, utilizes DNA copy-number aberration (CNA) data from tumor tissue or plasma to identify clinically relevant phenotypic tumor features and classify breast cancer into 5 groups (Prat et al. Nat Comm 2023). Here, we evaluated DNADX's ability to predict prognosis and treatment benefit in advanced HR+/HER2- breast cancer following endocrine therapy and a CDK4/6 inhibitor.
Methods: FLIPPER (NCT02690480) was a multicenter phase 2 clinical trial which randomized 189 patients with HR+/HER2- advanced breast cancer to receive (1:1 ratio) first line fulvestrant with either palbociclib or placebo. DNADX was evaluated centrally in pre-treatment baseline plasma and tumor samples. Shallow whole genome sequencing (shWGS) was performed on ctDNA and tumor tissue DNA to determine the RB-LOH signature, and the 5 DNA-based groups (called Proliferative, Basal-related, Luminal-high, , CNA-flat, and TF-low [with a tumor fraction < 3%]). The primary objective was to evaluate the association of the RB-LOH signature and the DNADX subtypes determined in plasma and in tissue with progression-free survival (PFS). The secondary objective was overall survival (OS). Stratified Cox regression models were used to calculate hazard ratios (HRs) after adjusting for treatment arm and other potential prognostic factors.
Results: DNADX information was obtained from 175 pre-treatment plasma samples and 111 tumor samples. In total, 183 patients, representing 96.8% of the FLIPPER population, had either baseline plasma or tumor samples available and were included in this study. Overall, DNADX identified 57.9% pts with TF-low (n=106), 0.5% with CNA-flat (n=1), 33.3% with Luminal-high (n=61), 7.7% with Proliferative (n=14) and 0.5% with Basal-related (n=1). The median PFS in pts classified as i) TF-low, ii) CNA-flat or Luminal-high and iii) Basal-related or Proliferative was 33.8m, 24.5m and 16.5m, respectively (HRs of 2.05 and 3.42, all $p<0.001$). Results remained consistent in patients treated with palbociclib or placebo and after adjusting for clinicopathological variables. The RB-LOH signature was significantly associated with PFS (HR=1.17, 95%CI 1.02-1.34, p=0.027). In terms of OS, the median OS in pts classified as i) TF-low, ii) CNA-flat or Luminal-high and iii) Basal-related or Proliferative was 79.0m, 55.1m and 45.5m, respectively (HRs of 2.4 and 3.9, all $p<0.001$). Results remained consistent in the multivariable analysis. The RB-LOH signature in plasma was also significantly associated with OS (HR=1.31, 95%CI 1.10-1.55, p=0.002). DNADX subtypes were significantly associated with PFS and OS in plasma but not in tissue samples.
Conclusions: Liquid biopsy-based DNADX assay identifies substantial biological heterogeneity in advanced HR+/HER2- breast cancer and was a strong prognostic biomarker beyond standard clinical-pathological variables and treatment in the FLIPPER trial.

P2-07-30: Exploring Treatment Options Following Progression to CDK4/6 Inhibitor in Hormone Receptor-Positive/HER2-Negative Advanced Breast Cancer: A Systematic Review and Network Meta-analysis

Mariangela Gaudio, Michela Cinquini, Flavia Jacobs, Cristina Mazzi, Valter Torri, Antonino Carmelo Tralongo, Chiara Benvenuti, Riccardo Gerosa, Jacopo Canzian, Giuseppe Saltalamacchia, Rita de Sanctis, Armando Santoro, Alberto Zambelli

Introduction: The treatment algorithm following progression on CDK4/6 inhibitors (CDK4/6i) remains uncertain. This study aimed to conduct a comprehensive systematic review and the first network meta-analysis to evaluate the efficacy and safety of new drugs (or combined new drugs) for the treatment of Hormone Receptor-Positive/HER2-Negative (HR+/HER2-) advanced breast cancer (ABC) in patients who have progressed after first-line treatment with CDK4/6i.
Methods: PubMed, Embase, and Cochrane Central were searched from 2000 to 2024 and conference proceedings from major congresses of the last two years were retrieved. Two authors independently performed the screening, three authors extracted data, and discrepancies were resolved by consensus. The primary endpoint was progression-free survival (PFS), with overall survival (OS), objective response rate (ORR), and adverse events (AEs) as secondary endpoints. The new drugs (or combined new drugs) were compared to either standard chemotherapy (CT) or endocrine therapy alone (ET) in second-line and beyond treatment settings. Network meta-analyses were performed using random-effects models, calculating risk ratios for dichotomous outcomes and hazard ratios (HR) for time-to-event outcomes with 95% confidence intervals (CI). Heterogeneity was assessed using the I^2 statistic and chi-square test.
Results: A total of 4034 papers were identified, after removing duplicates. Out of the 67 studies screened in full-text, 26 clinical trials were selected, encompassing a total of 7083 patients and five different drug classes. Specifically, 9 studies included biological agnostic therapy (CDK4/6i, mTOR inhibitors, immunotherapy), 7 novel ET (including selective estrogen receptor degraders – oral SERD), 5 targeted therapies (PI3K, AKT and PARP inhibitors), 3 antibody-drug conjugates (ADCs: trastuzumab deruxtecan [T-DXd] and sacituzumab govitecan), and 2 CT (eribulin, VEX metronomic). Control arms consisted of either ET alone (mainly fulvestrant) or standard CT (paclitaxel, capecitabine, eribulin, gemcitabine, or vinorelbine). All network estimates coincided with pairwise estimates as no direct comparison between the new drugs existed in the literature. Among all therapies, T-DXd showed the largest PFS benefit compared to standard CT [HR 0.51 (CI: 0.45 – 0.57)], followed by ribociclib plus ET compared to ET alone [HR 0.57 (CI: 0.45 – 0.72)]. Interaction tests conducted among the five drug classes showed a significant different positive effect on PFS by targeted therapies [HR 0.61 (CI: 0.57 – 0.66)] compared to ET alone (p-value 0.009) but failed to identify significant differences in PFS among the different drug classes compared to CT (p-value 0.16), although ADCs showed a larger effect in PFS [HR 0.63 (CI: 0.50 – 0.80)]. Although ADCs showed the largest OS benefit compared to standard CT [HR 0.72 (CI: 0.58 – 0.89)], the interaction test among the drug classes was not significant (p-value 0.10), and similarly no interaction was observed for ORR. Conversely, the interaction

test for toxicity indicates a significant difference between the five drug classes compared to ET, with biological agnostic therapy showing greater toxicity [HR 4.81 (CI: 3.18 – 7.25)] compared to other treatment options.
Conclusions: This network meta-analysis showed that targeted therapies, such as PI3K, AKT, and PARP inhibitors, demonstrate significant improvement in PFS compared to ET with a positive interaction test among the different drug classes. Biological agnostic therapies offer some survival improvement but at the cost of increased toxicity as compared to other options. These findings could help tailor the most suitable treatment for each patient, determining the optimal sequence following progression to CDK4/6i for patients with HR+/HER2- ABC.

P2-08-01: Engaging breast cancer survivors in the United States in research: clinical characteristics and demographics from Susan G. Komen's ShareForCures® first cohort

Jessica Epps, Emily Marks, Carlita McIlwain, Natalia Ballón, Taylor Jennings, Natalia Iannucci, Brady Kazar, Natasha Mmeje,Victoria Wolodzko Smart, Kimberly Sabelko, Melissa Bondy, Jerome Jourquin

Background: Lack of diversity in research and reliance on small, siloed datasets limits the availability of real-world evidence, hampering the practice of precision medicine and optimization of treatments and care for all breast cancer patients.
To address these limitations, the Susan G. Komen® breast cancer foundation launched ShareForCures® (SFC). This online, IRB-approved, patient-centered breast cancer research registry engages breast cancer survivors and patients from diverse backgrounds as research partners. By facilitating the exchange of information between survivors, patients and researchers, SFC aims to drive innovative breast cancer research and improve outcomes. Guided by focus groups and pilot testing, SFC began enrolling adults living in the U.S. and diagnosed with breast cancer in July 2023.
Methods: We implemented a mixture of tactics to recruit eligible individuals to SFC. Emails, earned and paid media, digital advertising, social media posts, blogs, and in-person events were used to spread awareness and educate individuals about the registry. Potential participants could connect with the SFC team via contact forms, email, and phone for assistance.
To fully onboard, participants had to register by creating an account in the SFC online platform, accept the informed consent and medical records release forms, and complete the "About You" survey. We implemented tailored communication strategies to aid potential participants in completing the onboarding process.
Once fully onboarded, participants were assigned tasks to provide additional data: surveys (quality of life, family health history, social determinants of health), medical records, and a saliva sample for germline whole genome sequencing were collected.
Integrated data from the first cohort of SFC participants were analyzed to evaluate recruitment and engagement efforts and to provide descriptive statistics.

Results: As of June 26, 2024, 773 participants registered, with 399 fully onboarding (median age = 56 years [range: 27-82], 99% women, 81% non-Hispanic White) and 31 declining (92% participation, average of 33 enrolled/month). Most participants (92%) enrolled with no assistance, and only 3 withdrew after completing enrollment (99% retention). Participants were geographically dispersed across 86% of U.S. states. Fifty percent of participants were from communities historically under-represented in biomedical research. Most participants self-reported their first breast cancer diagnosis as invasive ductal carcinoma (61%), with 39% self-reporting ER+/HER2– disease and 77% reporting early stage (Stage 0, 1, or 2) disease. Participants also self-reported living with metastatic breast cancer (17%) and experiencing a recurrence (19%). At least one survey or data collection activity (saliva or medical records) was completed by 62% of participants (45% saliva samples, 35% medical records collected).
Conclusions: In the first year of SFC, we recruited breast cancer survivors and patients from across the U.S. using a variety of broad, direct-to-patient methods, and participants remained engaged with the registry through completion of surveys and data collection activities at or above expected rates. Continued focused recruitment of participants from communities historically under-represented in biomedical research is still needed. Participants' breast cancer diagnoses were consistent with national prevalence estimates, with an over-representation of metastatic breast cancer in SFC.

P2-08-02: Effectiveness of cyclin inhibitors in patients with Hispanic metastatic breast cancer: Real-world evidence from the Instituto Oncológico Nacional in Panama

Omar Castillo-Fernandez, Jonatan Quintero, Miguel Manzano, Kayra Sanchez, Ronald Dominguez, Juan Jimenez, Mara Lim

Introduction: The incorporation of cyclin-dependent kinase inhibitors (CDKi) has been accompanied by significant improvements in the prognosis of advanced breast cancer with positive hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) negative status. However, Hispanic patients are frequently underrepresented in clinical trials. Consequently, this study aims to assess the efficacy of CDKi in routine clinical practice within our specific population. Methods: We conducted a retrospective analysis of patients treated with a CDKi in combination with endocrine therapy at our institution from August 2018 to December 2022. We examined demographic, clinical, therapeutic, and prognostic variables. We used the chi-square test to compare variables and estimated survival using the Kaplan-Meier method, the log-rank test, and Cox proportions for multivariable analysis. Results: 299 patients were evaluated. The median age was 62 years (range 24-90). 225 (75%) were postmenopausal, and 73 (25%) were premenopausal. ECOG performance status was as follows: 24% ECOG 0, 68% ECOG 1, 6% ECOG 2, and 2% ECOG 3. 56% of patients received hormonal therapy with or without chemotherapy as adjuvant treatment. The most common sites of metastasis were the bone, lung, and liver. 62% of patients were treated in the first line, and 38% were treated in the second line. The overall response rate

was 30% in the first line and 20% in the second line. Grade 3 neutropenia was observed in 36% of patients, 5% experienced QT interval prolongation, and 32% required dose adjustment. At a median follow-up of 29.5 months, 227 patients experienced tumor progression, and 166 patients (92 in the first line and 74 in the second line) died. The median first-line progression-free survival was 22.8 months (95% CI 17.5-31.5); in the second line, it was 12.5 months (95% CI 9.3-15.6). The median overall survival in first-line patients was 49.7.4 months (95% CI 35.9-63.5), while in second-line patients, it was 31.7 months (95% CI 26.9-36.5). Independent factors associated with progression-free survival were age over 60 years (HR 0.64, 95% CI 0.48-0.85, p=0.002, use of iCDK in the second line (HR 1.72 95% CI 1.31-2.23, p= 0.001), as well as an ECOG score equal to or greater than 2 (HR 2.23, 95% CI 1.39-3.58, p=0.001) Conclusion The real-world progression-free survival and overall survival outcomes of our Latino patients using CDK4/6 inhibitors closely align with those observed in clinical trials.

P2-08-03: Real-World Treatment Challenges in HR+/HER2- mBC: Results From the RETRACT Survey of 150 US Oncologists

Hope S. Rugo, Aditya Bardia, William Gradishar, Erika Hamilton, Sara Tolaney, Komal Jhaveri, Reshma Mahtani, Sarah Hurvitz

Background: There are few published studies that evaluate the real-world barriers to the optimal management of patients with breast cancer, especially patients with metastatic disease (mBC). Clinical oncologists have a unique insight into barriers that exist both at the patient level and at the level of the health care system. The RETRACT (REal-world TReatment patterns And Considerations of Toxicity in HR+/HER2- mBC) survey was developed to explore real-world treatment patterns in patients with HR+/HER2- mBC by surveying a relatively large sample of oncologists working in academic and community centers. Topics included challenges to optimal patient treatment, providing a unique insight into this question from the provider perspective.
Methods: A survey was distributed to clinical oncologists using an internal database. The survey was accessible via an online digital platform using an invitation link and individualized credentials. Responses were collected from December 2023 through April 2024. The results were analyzed using descriptive statistics. This sub-analysis concerns the responses to the following survey question: “What are the key challenges that hinder optimal management of patients with mBC?" Respondents could choose any number of 6 pre-filled options, and an optional free text response was also available.
Results: The survey was sent to approximately 1000 oncologists working at academic or community medical centers, 187 registered on the digital platform, and 150 completed the survey, including 145 respondents who completed the item regarding key challenges to optimal patient treatment. The highest number of respondents, 118 (81%), chose treatment toxicity as a key challenge to optimal patient management. In addition, 25 (17%) respondents cited treatment efficacy and/or a lack of enough treatment options in the free-text responses. Most respondents, 84 (58%), chose financial barriers, and 12 (8%) cited

insurance barriers in the free text responses: “high copays for targeted therapies such as CDK4/6 inhibitors that require significant work on the part of pharmacy staff in order to secure financial assistance for patients, which can sometimes result in delayed start of medication.” There were also 5 (3%) respondents who cited socioeconomic barriers in the free text including “transportation” and “patients need home care for themselves, other family members, or children.” Minorities of respondents identified low health literacy among patients (32; 22%) and poor treatment adherence (30; 21%). Other free text responses included difficulty in enrolling patients onto clinical trials due to lack of availability or accessibility (5; 3%), symptoms of progression and metastasis (4; 3%), comorbid conditions (4; 3%), lack of biomarkers for treatment decisions (4; 3%), patients diagnosed at an advanced stage (2; 1%), difficulty in coordinating complex care (2; 1%), and 1 (1%) each for medical misinformation and lack of enough oncologists.
Conclusions: Oncologists who participated in the RETRACT survey identified several challenges to optimal care of patients with mBC. A large majority chose treatment toxicity, highlighting an urgent need for more tolerable treatments. In addition, education for providers can help to improve toxicity management. Financial and insurance-related challenges were frequently cited and can reduce access to existing medications due to high patient costs, increased burdens on providers’ time, and delays in treatment. These challenges are difficult to address through medical practice and are of particular concern among patient populations with fewer resources and other socioeconomic burdens such as needing childcare, lacking transportation, or lacking social support. These results show there are opportunities to improve care of patients with mBC throughout the health care pipeline.

P2-08-04: A Cohort Study of the effectiveness and tolerability of Trastuzumab Deruxtecan For The Treatment of Metastatic or Locally Advanced HER2-positive Breast Cancer.

Ameer Basta, Kyle Lien, Weihong Sun, Aixa E. Soyano, Avan Armaghani, Loretta Loftus, Junmin Whiting, Tracey O'Connor, Brian J. Czerniecki, Ricardo L. B. Costa

Background: For over 20 years, patients (pts) with human epidermal growth factor receptor-2-positive (HER2+) advanced breast cancer (BC) have been routinely treated with HER2-targeted therapies. In December 2019, the FDA approved the use of a noval antibody drug conjugate (trastuzumab deruxtecan [T-dxd]) for the treatment of pts with HER2+ progressive advanced BCs based on the impressive results of a phase 2 trial (DESTINY-B01). A subsequent phase 3 trial (DESTINY-B03) comfirmed its clinical efficacy with improvements in both progression-free and overall survivals compared to trastuzumab emtansize (T-DM1) (HR 0.33 and HR0.64; respectively). Notwithstanding, T-dxd was associated wtih increased absolute risk (AR) of clinically relevant adverse events (AEs) such as intersticial lung disease (ILD), ie all-grade AR of 15%. There is pressing need for improved knowledge on the effictiveness and tolerability of this novel agent in a real-world population.

Methods: After IRB approval, we conducted a retrospective single-institution cohort study of pts with HER2+(per ASCO/CAP guidelines) metastatic or unresectable locally advanced BC treated wtih T-dxd. We assessed the safety, tolerability, and effectiveness of T-dxd in this real-world population. Deidentified patient-, tumor- and outcome-related data including the AR of AEs of interest, and treating-physician assessments of tumor response, progressive-free and overall survivals were collected and summarized. Kaplan-Meier methods were applied to survival analyses and stratified analyses of interest were conducted. A two-sided P value < .05 was considered statistically significant.
Results: A total of 84 women and 1 man with HER2+ advanced BC treated with T-dxd between 01/2020 and 06/2024 were included. Most women were post-menopausal (75.3%), had hormone receptor + BC (58.8%) and visceral metastasis (94.1%). At the time of initiation of T-dxd, 17.6% had ECOG PS of 3-4 and 28% were smokers; median age in years was 57 (28-76). In addition, 69.4% of the pts had 1-2 prior lines of therapy for metastatic BC, 12.9% had 4 or more prior lines of therapy. Up to 44.7% of the pts had prior treatment T-DM1 and 69.4% of the pts started T-dxd at full dose regimen (5.4mg/kg every 3 wks). The estimated median progression-free survival wa 12.7 months (95% CI, 9.7-19.5) and no significant diferrences were appriciated in stratified analyses according to tumor HR expression, presence of visceral disease or prior diagnosis of CNS disease metastatic disease or prior treatment wtih T-DM1. The medial overall survival for this cohort was estimated at 28.5 months (95% CI, 17.3-NE). As many as 40% of the pts required dose reductions and fatigue was the most common reaso for dose reduction (9.4%), only 16.5% of the pts permanently discontinued T-dxd due to AEs. Common all-grade AEs were ILD (7.1%), alopecia (14.1%), diarrhea (42.4%), vomiting (49.4%) and nausea (80%), fatigue (95.3%). Grade 3 or higher AEs were observed as follows: ILD (1.2%), peripheral neuropathy (1.2%), LVEF decrease (1.2%), increased AST (2.4%), increased alkaline phosphatase (2.4%), nausea (3.5%), leukopenia (8.3%), neutropenia (10.6%), anemia (13%), and fatigue (16.5%). No grade 5 AEs were observed.
Conclusion: T-dxd showed effectiveness to treat pts with HER2+ metastatic or advanced BC in this real-world cohort of patients with pre-treated high-risk pts. Pts treated wtih T-dxd are at risk of clincally relavant but manageable AEs and require close monitoring.

P2-08-05: Pembrolizumab (P) added to Neoadjuvant Chemotherapy (NACT) for Triple Negative Breast Cancer (TNBC) in a community practice setting: Real World Evidence (RWE) for the effectiveness of the KN -522 regimen

Christopher Nabong, Monique Chang, Sujith Kalmadi, Karen Ortiz- Cruz,, Victor Chiu, Anu Batra, Leslie Klein, Emily Ho, Edgar Hernandez, Theresa Chan, Rashmi Vaidya, Joesph Di Como, Ramesh K Ramanathan, Sumeet Mendonca

Background: NACT with platinum is the standard of care approach for operable TNBC. The KN-522 trial (N Engl J Med 2022; 386:556-7), demonstrated superior outcomes with the addition of P to NACT (KN-522 regimen), the pathological complete response (pCR) was

65% and significantly superior to 51% NACT alone (NEJM 2022; 386:556-67). The event-free survival at 36 months was 85% in the P-NACT group, compared to 77% for placebo-NACT ($p<0.0001$). The KN522 regimen was approved by the FDA in July 2021, with rapid uptake in community practices. However, RWE demonstrates an efficacy-effectiveness gap between reported outcomes in phase 3 clinical trials to practice, including TNBC. In the control arm of the KN-522 study, 51% of patients had a pCR rate with NACT (without P). RWE for NACT is much lower, with pCR rate of 22% (n=255) from MD Anderson Cancer Ctr, TX (JCO. 2008; 26: 1275-81), and a pCR rate of 24.5% (n=421) from the BC Cancer registry (JCO 2024; 42: 16_suppl: e23274).
Methods: Ironwood Cancer & Research Centers , Phoenix, AZ (ironwoodcrc.com) is a large oncology practice (includes medical, radiation oncologists, and breast surgeons) in Phoenix, AZ. We reviewed medical records for all operable TNBC cases from August 2021 to May 2024. Eligible patients had pathologically documented TNBC, operable disease, received NACT+P and were scheduled for breast surgery in the time period. This project involved retrospective chart reviews and was deemed IRB review exempt.
Results: Patient characteristics: N=93, all were female. Age 29-86 yrs (median 60). 40.9% were > 65 yrs and 69.9% were post-menopausal. Performance status: ECOG 0 (54.8%), ECOG 1(12.9 %) and not determined before NACT (30.1%). Nodal status was positive in 41.9% and clinical staging was 1 (5.8%), 2 (54.8%) and 3 (39.8%). NACT+P was initiated in all 93 patients, following completion of NACT, 85 had surgery (91.4%). Lumpectomy was performed in 35.5% and mastectomy in 55.9%. The pCR rate (n=85) was 51.8%. Adjuvant therapy following surgery with P was given to 77.3% of patients. Most patients who received NACT+P met relevant selection criteria similar to the KN522 study.
Conclusions: Our analysis is notable for having older patients, lower percentage of ECOG 0 and higher percentage of stage 3 disease compared to the KN522 study. Major differences in our population compared to the KN522 study are : Age > 65 yrs (40 vs 11%), ECOG 0 (55 vs 87%) and stage 3 disease (39 vs 25%) respectively. The pCR (RWE) for NACT without P in TNBC is 22-25%. To the best of our knowledge, this analysis is the first RWE for the KN522 regimen. The pCR is doubled to 51.7% in our study with P+NACT, results support the community use of the KN522 regimen for operable TNBC patients.

P2-08-06: Comparative Analysis of Pathological Outcomes and Toxicity in Hispanic vs Non-Hispanic Patients Receiving Keynote 522 Regimen: A Retrospective Single Center Experience

Jay Parekh, Ranjit Banwait, Sarah Shaker, Aditi Sharma, Marcela Mazo-Canola

Introduction: There is limited data on the comparative outcomes between Hispanic and non-Hispanic patients in real-world settings, as this patient population was underrepresented in the original trial. This retrospective real-world study examines pathological responses and treatment-related toxicities among Hispanic and non-Hispanic patients undergoing the Keynote 522 regimen for locally advanced triple-negative breast cancer.

Methods: We conducted a retrospective analysis of patients with early stage TNBC treated on KN522 regimen and undergoing surgery at our institution from July 2021 to June 2024. Data collection included demographics, clinical stage, HER2 status, node status, and treatment pattern. Outcomes measured were pathological complete response (pCR) rate, and incidence of adverse effects (AEs). Statistical analyses to compare outcomes between Hispanic and non-Hispanic patients was performed using R v4.2.
Results: The study included 59 female patients, with 66.1% being Hispanic and a median age of 52. Pathological complete response (pCR) was achieved in 56% of patients overall, with no differences based on node status or tumor size. pCR rates were similar between Hispanic (46.1%) and non-Hispanic (50.7%) patients. Non-Hispanics had a significantly higher rate of drug dose modification (40% vs 12%), but treatment delays, drug omissions, and time from last treatment to surgery were comparable. Hispanic patients experienced higher fatigue rates (89% vs 60%). Hospitalization rates and severe (≥grade 3) toxicities, including neutropenia, anemia, and neuropathy, were similar between both groups.
Conclusion: This retrospective study supplements trial data from the real world with comparable pCR rates, with no difference based on tumor size or node status. It revealed no statistical difference in pCR rates between Hispanic and non-Hispanic patients undergoing the Keynote 522 regimen for locally advanced triple-negative breast cancer. Although non-Hispanic patients required more frequent dose modifications, overall treatment delays, drug omissions, and time from last treatment to surgery were similar across groups. Notably, Hispanic patients reported higher rates of fatigue. Hospitalization and severe toxicities, such as neutropenia, anemia, and neuropathy, were comparable between the two groups. These findings highlight the need for tailored management strategies to address specific toxicity profiles and support equitable outcomes across diverse patient populations.

P2-08-07: Benefit of neoadjuvant Pertuzumab/Trastuzumab therapy on pCR in Peruvian patients with HER2-Positive Breast Cancer

Zaida Morante, Yomali Ferreyra, Iris Otoya, Norma Huarcaya, Tatiana Vidaurre, María G. Luján-Peche, Cindy Calle, Jorge Sánchez, Guillermo Valencia, Natalia Valdiviezo, Bruno Muñante, Jorge Dunstan, Maria Laura Ramos, Gonzalo Ziegler, Silvia Neciosup, Henry Gómez

Background: Trastuzumab has significantly improved survival outcomes in HER2-positive early-stage and metastatic breast cancer. Moreover, clinical trials have shown that combining trastuzumab and pertuzumab with chemotherapy as neoadjuvant therapy further increases pCR rates in HER2-positive breast cancer (BC). In Peru, real-world evidence is currently limited because this healthcare technology was recently implemented in 2023.
Methods: A statistical analysis was conducted to evaluate the efficacy of combined Pertuzumab/Trastuzumab treatment compared to Trastuzumab alone in patients undergoing neoadjuvant therapy at the Instituto Nacional de Enfermedades Neoplásicas (INEN, Lima, Peru). Initially, we described the clinical and pathological characteristics of the patients, comparing variables between the treatment groups. Logistic regression was used

to assess the likelihood of achieving pathological complete response (pCR) across all patients. Subsequently, stratified univariate logistic regression analyses were performed within different patient subgroups to identify those who significantly benefited from the combined treatment. The statistical analysis was conducted using R programming language with the dplyr, gtsummary, and readxl libraries. A p-value less than 0.05 was considered statistically significant.
Results: A total of 109 BC HER2-positive patients were included in this analysis; 33.9% (n=37)received TCHP, while 66.1% (n=72) received TCH. Notably, pCR was significantly higher in the group that received TCHP (62.2%) than TCH (36.1%) (p=0.01). Additionally, significant differences were observed in the N stage (0.042), clinical stage (p = 0.044) and RCB (p = 0.013) between these two treatments. The overall benefit of TCHP in reaching pCR was shown in our cohort (OR=2.91, 95% CI: 1.3-6.73, p = 0.01). Significant benefits were also observed in pre-menopausal patients (OR = 4.96, 95% CI: 1.45-18.91, p = 0.01), patients with histologic grade I/II tumors (OR = 3.85, 95% CI: 1.12-14.81, p = 0.04), ER-positive (OR = 5.06, 95% CI: 1.65-16.81, p = 0.01) and PR-positive patients (OR = 6.00, 95% CI: 1.55-26.77, p = 0.01), HER2 2+ patients (OR = 2.91, 95% CI: 1.25-7.07, p = 0.01), those with node status N2/N3 (OR = 19.25, 95% CI: 2.4-425.96, p = 0.02), and clinical stage III patients (OR = 3.94, 95% CI: 1.43-11.46, p = 0.01).
Conclusions: Given the recent implementation of this healthcare technology in Peru, our findings provide early and crucial evidence supporting the adoption and widespread use of combination therapy in this patient group in the local context. Our study confirms that the combination of trastuzumab and pertuzumab with chemotherapy as neoadjuvant treatment results in a significantly higher pathological complete response rate (pCR), similar to what is observed in pivotal studies.

P2-08-08: Adjuvant Cyclin Dependent Kinase 4/6 Inhibition in Inflammatory Breast Cancer

Azadeh Nasrazadani, Rebecca Tidwell, Megumi Kai, Bora Lim, Vicente Valero, Sadia Saleem, Anthony Lucci, MDACC Inflammatory Breast Cancer Team, Wendy Woodward, Rachel M Layman

Background: Cyclin Dependent Kinase 4/6 inhibitors (CDKI) combined with endocrine therapy (ET) are used in the adjuvant setting for patients with high-risk hormone receptor positive (HR+), HER2 low/negative (HER2-) breast cancer. Our research showed that patients (pts) with the highly aggressive subset of breast cancer, inflammatory breast cancer (IBC) demonstrate a poor response to CDKIs in the metastatic setting, with a relatively short median time on treatment (ToT) of 7 months. However, the efficacy of CDKI in the adjuvant setting or after completion of induction therapy for de novo stage IV IBC who achieve no evidence of disease (NED) status has not been reported. Therefore, we analyzed outcomes in these settings for the first time.
Methods: We analyzed pts with stage III or de novo stage IV HR+HER2- IBC who received a CDKI combined with ET in the adjuvant/post-induction setting enrolled to the MD Anderson

Cancer Center (MDACC) IBC Registry. Two stage III pts received palbociclib based on the PALLAS clinical trial; the remainder received abemaciclib as part of standard care. In addition, 9 stage IV de novo pts took adjuvant CDKI after neoadjuvant systemic therapy and local therapy having achieved NED status (5 palbociclib, 2 ribociclib, 2 abemaciclib). ToT was calculated from the date of first CDKI treatment until date of last treatment. Patients last known to be continuing treatment are censored on date of last known treatment. Progression-free survival (PFS) was calculated from the date of first CDKi treatment until progression or death, whichever came first. Patients alive and free of progression were censored on their date of last follow-up. Median, 95% confidence interval (CI), and 36-month ToT and PFS are presented with Kaplan-Meier estimates from SAS 9.4.
Results: Thirty patients had stage III, and 9 had de novo stage IV disease. In the stage III cohort, median age was 49 years. Four pts were Hispanic or Latino, 1 patient was American Indian, and the remainder were White. One pt achieved a pathological complete response (pCR). At a median follow-up of 15.8 months (mos) from initiation of CDKI, median (95% CI) ToT was 25.6 (17.4, 39.5) mos. Reasons off treatment include toxicity (n=3), planned completion (n=2), one progression, one each for death unrelated to breast cancer, financial issues. Median PFS was 38.5 (20.3 - 38.5) months with 83% surviving progression-free at 3 years. One patient died without progression while one patient experienced recurrence of disease in the bone and lymph nodes. In the de novo stage IV cohort, median age was 44 years. Two patients were Hispanic or Latino and the remainder were White. No one achieved a pCR. At a median follow-up of 43.4 mos from CDKI start, median ToT was 25.0 (4.2, not reached [NR]) mos. Four pts came off treatment due to progression. Median PFS was 23.3 (4.2, NR) mos with a 3-year estimate of 44.4%.
Conclusions: Despite data demonstrating relatively short response to CDKI in patients among IBC pts in the metastatic setting, stage III and stage IV de novo pts (achieving NED after multidisciplinary management in the neoadjuvant setting) receiving CDKI and ET in the adjuvant setting appear to derive benefit with meaningful follow up time and low recurrence rates. Ongoing follow up is required to definitively determine benefit of CDKI in this population/different settings. Biomarkers to identify long responders are needed.

P2-08-09: Predictors of inadequate ovarian function suppression (OFS) in premenopausal women with hormone receptor (HR)-positive breast cancer receiving a gonadotropin-releasing hormone (GnRH) agonist in combination with endocrine therapy

Maryann Kwa, Leyla Bayat, Nancy Chan, Arturo Orlacchio, Cigdem Karayigitoglu, Doaa Ayoubi, Tsivia Hochman, Douglas Marks

Background: In premenopausal women with early-stage hormone receptor (HR)-positive breast cancer and a higher risk of recurrence, the addition of ovarian function suppression (OFS) to endocrine therapy has been shown to improve disease outcomes, as demonstrated by combined analysis of the SOFT/TEXT trials. Estradiol (E2) is the primary source of estrogen in premenopausal women and is synthesized from the ovaries through indirect

control of gonadotropin-releasing hormone (GnRH). Endocrine therapy with a GnRH agonist has become a mainstay of treatment in premenopausal women for ovarian suppression. However, studies have shown that up to 25% of patients do not achieve adequate ovarian suppression within the first year of treatment. Data remains limited regarding whether monitoring of OFS should routinely be performed and is not part of current NCCN guidelines. The aim of our study was to evaluate premenopausal women in a 'real world' setting at our institution who did not achieve adequate OFS and to assess potential contributing factors.

Methods: This was a retrospective, descriptive study of premenopausal women ≥18 years of age at our institution from 2020-2022 with stage I-III HR-positive breast cancer receiving OFS in combination with endocrine therapy with either an aromatase inhibitor or tamoxifen. OFS was achieved by use of a GnRH agonist with leuprolide or goserelin. Patients who had two or more consecutive tests showing non-suppressed estradiol levels (E2 level >20 pg/mL) were considered to have inadequate ovarian suppression. Data regarding patient age at the start of treatment, BMI, receipt of neoadjuvant and/or adjuvant chemotherapy, history of prior pregnancies, history of diabetes mellitus, and choice of initial GnRH agonist were examined. The rate of change to another GnRH agonist upon ovarian suppression failure was also determined.

Results: Twenty-six patients (age range: 27-50) were identified at our institution who received either leuprolide or goserelin. Of these patients, 25 received OFS every month (96%) and 1 received OFS every three months (4%). The rate of inadequate OFS among all patients was 30.8%. The average age at the start of treatment was 40.1 years for those with adequate OFS compared to 37.9 years for those with inadequate OFS. Average BMI was 26.7 in the adequate OFS group and 30.3 in the inadequate OFS group. In the adequate OFS vs. inadequate OFS group, 17% vs. 38% had received neoadjuvant chemotherapy, and 39% vs. 63% had received adjuvant chemotherapy, respectively. 17% of patients in the adequate OFS group had a history of diabetes mellitus, compared to 25% in the inadequate OFS group. In the adequate OFS versus inadequate OFS group, 33% versus 50% had a history of at least one term pregnancy, respectively. For those who received leuprolide initially, 67% had adequate OFS. In comparison, for those who received goserelin initially, 33% had adequate OFS. Among the patients with inadequate OFS, 50% had their treatment subsequently changed to the alternative GnRH agonist.

Discussion: This study showed that inadequate OFS was detected in 31% of the patients, half of whom underwent a subsequent change in therapy to the alternative GnRH agonist. Patients who received leuprolide initially were more likely to have adequate OFS compared to those who received goserelin. A higher BMI, history of diabetes, and history of term pregnancy were found in patients with inadequate OFS. Further research is needed to establish monitoring guidelines for estradiol and the optimal degree of ovarian suppression for premenopausal patients receiving OFS.

P2-08-10: Real World Use of Ovarian Function Suppression in Women Younger Than 35 with Early Stage ER+Her2- Breast Cancer

Poornima Saha, Kyla Lee, Debra Ziegler

Background: Premenopausal women with estrogen receptor positive (ER+) human epidermal growth factor receptor 2-negative (Her2-) breast cancer may be considered for adjuvant endocrine therapy with tamoxifen alone or ovarian function suppression (OFS) with tamoxifen (tam) or an aromatase inhibitor (AI). Results from the SOFT and TEXT trials have demonstrated an improvement in disease free survival and reduction in distant recurrence with the addition of OFS, particularly in women who are found to be at high risk and received chemotherapy or in young women age < 35. For this reason, addition of OFS should be considered for women age < 35 with ER+ breast cancer. Use of OFS, however, may be associated with an increase in toxicity and requires shared decision making between patients and clinicians. There are also no clear guidelines in place for the appropriate agent to accomplish chemical OFS with a gonadotropin releasing hormone agonist (GnRHa), dosing, or monitoring. This has led to significant variability in clinical practice. The goal of this study is to evaluate real world use of OFS in women age < 35 and describe the chosen methods for OFS in a large multidisciplinary community breast oncology center.

Methods: We analyzed the medical records of premenopausal women with Stage 1-3 HR+Her2- breast cancer from January 2012 to December 2023. We then selected women who were diagnosed at age < 35 and collected additional demographic, clinicopathologic characteristics, and treatment information. The method of OFS, either with bilateral salpingoopherectomy (BSO) or use of GnRHa, was collected including agent, dosing, and duration of therapy. Patients with non-invasive breast cancer were excluded from this study.

Results: A total of 118 women were diagnosed with early-stage breast cancer at age < 35 at our institution between 2012-2023. Of these, 48 met eligibility of having an ER+Her2- breast cancer. Ages ranged from 23-34. Node-positive disease was present in 43% of women. 35 patients were Caucasian, 6 Asian, 5 African American and 2 identified as other. 33 of 48 patients elected mastectomy. Chemotherapy was administered in 79.2% (38) of patients and the majority were treated with a 3-drug regimen (68%). Adjuvant endocrine therapy was administered in 43 of 48 patients. Of those who received endocrine therapy, 25 were treated with tam alone, 10 women received OFS + tam, and 8 women received OFS + AI. When a GnRHa was utilized for OFS, goserelin was utilized in the majority (85%) and leuprolide in 15%. GnRHa frequency was most commonly q28 days with only 6 women treated with 3 month dosing. Estradiol monitoring was inconsistent but 14 women had an estradiol level checked during their treatment with a GnRHa. A BSO was completed in 9 women during their treatment course.

Conclusion: It is well established that young women are at high risk of breast cancer

recurrence. Data from the SOFT and TEXT trials support consideration of maximal hormone suppression with OFS plus tam or an AI in women under 35. Our study shows significant variability of uptake of OFS use even in this high-risk population in the community, likely due to concern for increased toxicity. Additional research regarding optimal GnRHa dose, frequency, and monitoring is needed.

P2-08-11: Real-world safety of sacituzumab govitecan in patients with advanced triple receptor-negative breast cancer in a tertiary centre in the United Kingdom

Emma Crewe, Imun Gill, Juan Montes Gonzalez, Domingo Cano Gil, Sophie McGrath, Alistair Ring, Stephen Johnston, Alicia FC Okines, Nicolò Matteo Luca Battisti

Background: Sacituzumab Govitecan (SG) is a new treatment option in the pre-treated advanced triple negative breast cancer (aTNBC) setting. Since the regulatory approval of SG in the UK in August 2022, there remains little real-world evidence on its safety for patients with aTNBC. Its registration study documented high rates of myelosuppression in this population. In this analysis, we investigated the incidence of neutropenia in patients with aTNBC treated with SG in a large tertiary centre in the UK and its impact on patient management.
Methods: We retrospectively collected data on patients with aTNBC treated with at least one dose of SG between September 2022 and September 2023 at the Royal Marsden Hospital, London. We collected clinical data from the electronic patient records and analysed them with descriptive statistics.
Results: Thirty-nine patients were included in the analysis. Of these, 28/39 (71.7%) experienced neutropenia of any grade. This was grade 1 in 15/28 (53.5%), grade 2 in 6/28 (21.4%), grade 3 in 7/28 (25.0%) and grade 4 in 1/28 (3.6%). Four patients (14.8%) experienced febrile neutropenia requiring antibiotics and hospitalisation. In 15/28 (53.6%), neutropenia occurred prior to Day 1 of treatment and in 13/28 (46.4%) neutropenia occurred prior to Day 8. Out of the 11 patients who did not experience neutropenia, 7 (63.6%) had upfront GCSF. Out of the 28 patients experience neutropenia, 13 (46.4%) required a dose delay, 5 (17.8%) had a Day 8 dose omitted and 8 (28.6%) had a dose reduction. All patients experiencing neutropenia were prescribed secondary GCSF prophylaxis: 11 (39.3%) following the first episode of neutropenia and 3 (10.7%) after the second episode.
Conclusion: Our analysis documented a substantial rate of neutropenia in patients with aTNBC receiving SG. This is consistent with clinical trial data. Our findings support the use of primary GCSF prophylaxis to avoid preventable haematological toxicity and dose adjustments in this setting.

P2-08-12: Prediction of Chemotherapy Benefit by MammaPrintÂ® in HR+HER2- Early Stage Breast Cancer Revealed by the FLEX Registry of Real World Data

Adam Brufsky, Kent Hoskins, Henry Conter, Pond Kelemen, Mehran Habibi, Laila Samian, Robert Maganini, Rakshanda Rahman, Laura Lee, Eduardo Dias, Regina Hampton, Beth Seiling, Cynthia Osborne, Eric Brown, Jailan Elayoubi, Priyanka Sharma, Jayanthi Ramadurai, Laurie Matt-Amral, Alfredo Santillan, Sasha Strain, Philip Albaneze, Harshini Ramaswamy, Nicole Stivers, Andrea Menicucci, William Audeh, Pat Whitworth, Nathalie Johnson, Joyce O'Shaughnessy

Background: Gene expression assays play a key role in personalizing adjuvant chemotherapy (CT) treatment decisions for patients (pts) with hormone receptor (HR)-positive, HER2-negative (HR+HER2-) early stage breast cancer (EBC). The 70-gene signature, MammaPrint, determines distant recurrence risk in EBC and has demonstrated its ability to guide CT de-escalation in pts with genomically Low Risk tumors based on the MINDACT trial. In the FLEX Registry of Real World Data (RWD), we evaluated MammaPrint as a continuous variable to predict adjuvant CT benefit in HR+HER2- EBC.
Methods: This study included 1002 HR+HER2- EBC pts treated from 2017 - 2020 with endocrine therapy (ET) only or ET plus chemotherapy (ET+CT), with 5-year (yr) median follow up in the prospective, observational FLEX RWD study (NCT03053193). ET treated pts were propensity score matched to ET+CT treated pts based on menopausal status, tumor stage, and lymph node (LN) stage (n = 501 each). The MammaPrint Index (MPI) categorizes 4 risk groups: UltraLow (+1.000 to +0.356), Low (+0.355 to +0.001), High 1 (0.000 to -0.569), and High 2 (-0.570 to -1.000). The primary endpoint was Distant Recurrence Free Interval (DRFI), defined as time from diagnosis to distant recurrence or breast cancer specific death per STEEP 2.0 criteria. Kaplan Meier analysis estimated 5-yr DRFI risk as a continuous function of the MPI for each treatment group separately, with predicted 95% CIs. Cox proportional hazards model was used to test for interaction between CT treatment and clinical variables or MPI risk.
Results: Most pts were postmenopausal (73%) and LN-negative (76%), with tumor stages T1 (40.7%), T2 (46.9%), or T3 (10.8%). Tumor grades were Grade 1 (27%), Grade 2 (54.4%) or Grade 3 (19.0%). Clinical features were comparable between treatment groups, except for Grade 3, which was significantly higher in the ET+CT pts. The MammaPrint Index exhibited strong predictive accuracy for 5-yr risk of a DRFI event in both ET only ($R2 = 0.99$, $p < 0.001$) and ET+CT pts ($R2 = 0.90$, $p < 0.001$).
In ET only pts, 5-yr risk of a DRFI event significantly increased with higher MPI risk group, ranging from 0.6% to 2.2% (average [avg] 1.0%) in UltraLow, 2.2% to 4.5% (avg 3.2%) in Low, 5.6% to 14.6% (avg 10.0%) in High 1, reaching highest risk estimates of 14.8% to 24.8% (avg 19.1%) in High 2. In the ET+CT treated pts, 5-yr risk of a DRFI event ranged from 0.1% to 1.0% (avg 0.4%) in UltraLow, 1.0% to 2.1% (avg 1.5%) in Low, 2.6% to 6.4% (avg 4.4%) in High 1, and 6.5% to 10.6% (avg 8.2%) in High 2. Significant DRFI risk differences were observed between treatment groups as MPI risk increased. CT benefit ranged from 3.1% to 8.2% (avg 5.6%) in High 1, and was highest in High 2, ranging from

8.3% to 14.2% (avg 10.9%). Minimal CT benefit was observed for Low (1.7%) and UltraLow (<1.0%) Risk groups.
In a subgroup of Clinical Low Risk, MammaPrint High Risk pts (n = 209), the ET+CT group had lower risk of a DRFI event (1.8%) than the ET only group (4.5%). The multivariate Cox model demonstrated CT benefit was dependent on increasing MPI risk (HR = 0.15; 95% CI 0.02-0.97, p = 0.047). CT benefit was also significantly associated with premenopausal status, but not age, T stage or LN stage. The CT benefit was not associated with Grade 3 (HR = 0.99, 95% CI 0.10-9.76, p = 0.695).
Conclusion: In this Real World Evidence prospective, propensity score matched study, increasing CT benefit was observed with increasing MPI risk (High Risk). Patients with increasing MPI risk had significantly lower 5-yr risk of a DRFI event when treated with ET+CT than ET alone. Patients with MammaPrint indices within Low and UltraLow Risk ranges did not derive significant CT benefit, consistent with findings from MINDACT. These RWD confirm MammaPrint's comprehensive utility, as prognostic of recurrence risk and predictive of adjuvant CT benefit in HR+HER2- EBC.

P2-08-13: Effectiveness of Combined Neoadjuvant Pembrolizumab and Chemotherapy in Early Triple-Negative Breast Cancer: Real-World Evidence from Multiple Centers in Asia

Yu-Ting Lin, Liang-Chih Liu, Chin-Yao Lin, Chiann-Yi, Hsu, Chih-Chiang Hung, Ting-Yi, Liao

Background: Triple-negative breast cancer (TNBC) is associated with a poor prognosis. The KEYNOTE-522 study established the combination of pembrolizumab and neoadjuvant chemotherapy (NAC) as the recommended treatment for early TNBC. However, real-world evidence, especially in the Taiwanese population, is lacking. This multicenter retrospective study aimed to identify clinical characteristics and treatment variables associated with response to pembrolizumab plus NAC in early TNBC.
Methods: We retrospectively reviewed the multicenter medical records of patients with early TNBC who were treated with pembrolizumab plus NAC between May 2018 and October 2023. The primary endpoint was pathologic complete response (pCR). Kaplan-Meier curves were used to evaluate event-free survival (EFS) and overall survival (OS). Statistical analyses included two-sample t-test, chi-square test, and univariate analysis with a significance threshold of 0.05.
Results: Among the 72 patients in our study, the pCR rate was 51.4% (37/72). Median age at diagnosis was 50.5 years old (IQR 43.5–57.6), and mean body weight showed 58.1±9.4 kg. The rates of pCR for Stage II and Stage III patients were 56% and 41%, respectively. Kaplan-Meier curves for EFS according to pCR status after neoadjuvant treatment demonstrated a significant difference (log-rank test p = 0.003), although no significant difference was observed in overall survival (OS) with a median follow-up of 1.6 years (IQR 1.0–2.3). The probability of recurrence events was significantly associated with pCR (p = 0.001). In the pCR group, the recurrence rate was 0% (0/37), whereas in the non-pCR group, it was 25.7% (9/35). Additionally, optimizing neoadjuvant pembrolizumab dosage in

a 100 mg setting of patients showed a remarkable difference in pCR rate, achieving 68% (p = 0.01) with a per-weight dose exceeding 1.8 mg/kg. Only achieve four NAC cycles of anthracyclines along with cyclophosphamide were shown to be substantially linked with achieving pCR, with a rate of 88% (p = 0.023) in univariate analysis.
Conclusions: This real-world study provides valuable insights into the efficacy and tolerability of pembrolizumab in early TNBC. It highlights the importance of optimizing neoadjuvant pembrolizumab dosage to a per-weight dose exceeding 1.8 mg/kg in the 100 mg setting, which significantly improves the pCR rate and the completion of AC regimen cycles necessary for achieving pCR in Asian patients with early TNBC.

P2-08-14: Prognostic Value of Real-World Immunohistochemical Changes in Breast Cancer Following Neoadjuvant Chemotherapy

Marcelo Antonini, Andre Mattar, Leticia Xavier Felix, Denise Joffily Pereira da Costa Pinheiro, Eduardo de Camargo Millen, Fabrício Palermo Brenelli, Felipe Zerwes, Francisco Pimentel Cavalcante, Antônio Luiz Frasson, Odair Ferraro

Objectives: To evaluate the rate of change in immunohistochemistry (IHC) after neoadjuvant chemotherapy (NAC) in patients with breast cancer and how this can influence the disease-free survival (DFS) and overall survival (OS).
Methods: this was a retrospective, cohort study, that included female patients over 18 years of age, with a diagnosis of non-metastatic breast cancer undergoing NAC. Patients who did not achieve complete pathological responses were evaluated regarding the change in IHC before and after NAC. Quantitative and qualitative factors related to the changes in IHC were evaluated. Additionally, the prognosis of these patients were assessed by examining OS and DFS. The study was submitted and approved to the research ethics committee (CAAE 80127724.1.0000.5463).
Results: We included 369 patients and most of them (215/58.3%) did not change the IHC profile. The average age did not differ between the groups (P= 0.986) as well menopausal status (p = 0.112), histological type (p = 0.998), clinical staging (TNM) and Ki-67 index. Most of the IHC changes was seen in HR- (56.4%) when compared to HR+ (43.5%) p < 0.0001. HER2+ group showed the most change when compared to HER2- (p < 0.0001). It is interesting to notice that in HR+/HER2+ patients only 29.2% remained in the same profile, with 70.8% loosing HER2 expression and changing to HR+/HER2-. When looking at HR-/HER2+ we saw that 50% maintained with the same profile with 30.5% loosing HER expression and 19.5 gaining HR. The HR+/HER2- group had minor changes with 86.4% maintaining the same profile. The HR-/HER2- group showed interesting results with only 34.9% maintaining this profile and 14.1% acquiring HER2 and 50.9% gaining HR. It is interesting to note that among HR+/HER2+ patients, only 29.2% remained in the same profile, with 70.8% losing HER2 expression and changing to HR+/HER2-. In the HR-/HER2+ group, 50% maintained the same profile, while 30.5% lost HER expression and 19.5% gained HR. The HR+/HER2- group experienced minor changes, with 86.4% maintaining the same profile. The HR-/HER2- group showed notable results, with only 34.9% maintaining

this profile, 14.1% acquiring HER2, and 50.9% gaining HR. With a median follow up of 47.7 months (1.7-154) there was local-regional recurrences in 38 patients (10.3%), distant metastasis was observed in 109 patients (29.5%) and 94 (25.5%) patients died. Overall survival (OS) was 48.5 months, and disease-free survival (DFS) was 47.2 months. There was a worse prognosis in patients who experienced changes in their initial IHC profile (P=0.002) but there was no difference in local recurrence and distant metastasis. It is interesting to point out that patients that weren't HR-/HR- and became after NAC had worse prognosis (P< 0,001).
Conclusions: Our data suggests that changes in immunohistochemical profiles post-NAC is common and is associated with higher mortality rates, especially those who lost HR and HER2 underscoring the importance of IHC profiles as potential prognostic indicators in patients undergoing NAC for breast cancer.

P2-08-15: From Clinical Trials to Real-World Practice: Treatment Regimens, Pathological Complete Response Rates, and the Addition of Platinum Salts in Patients with Triple- Negative Breast Cancer

Maria Eleni Hatzipanagiotou, Verena Zeltner, Michael Gerken, Miriam Pigerl, Sophie Räpple, Jonas Roth, Olaf Ortmann, Monika Klinkhammer-Schalke, Stephan Seitz

Purpose: Comprehensive real-world data on current treatment methods for early triple-negative breast cancer (TNBC) are limited. To validate optimal treatments demonstrated in randomized controlled trials analyses of data obtained from routine clinical care are essential. This study aims to analyze the treatment outcomes of patients with early-stage TNBC using data from a large, population-based cancer registry.
Methods: This retrospective, non-interventional, population-based singlemulti-center study utilized data from TNBC patients diagnosed between January 1, 2010, and December 31, 2018, at the cancer registry Tumor Centre Regensburg. The data included demographics, pathology, treatment, recurrence, and survival, with follow-up extending to December 2023. 319 patients with TNBC who received neoadjuvant chemotherapy were identified. The outcomes measured were pathologic complete response (pCR), overall survival (OS), and recurrence-free survival (RFS).
Results: A total of 319 patients were included. Of these, 132 (41.4%) received neoadjuvant chemotherapy (NACT) with Epirubicin/Cyclophosphamide (EC) and Paclitaxel (EC-T), 74 (23.2%) received NACT with EC-T and Platinum (EC-P/T), and 22 (6.9%) received NACT with EC-P/nabPaclitaxel (EC-P/nabP). Other NACT protocols were administered to 91 (28.5%) patients. A pCR was achieved in 49.8% of NACT patients, with a rate of 37.1% in the subgroup without platinum. The addition of platinum significantly increased the pCR rate to 54.1% compared to EC-T (OR 3.476, 95% CI 1.655-7.300, p=0.001). EC-P/nabP led to a significant increase in the pCR rate to 77.3% (OR 8.767, 95% CI 2.421-31.744, p<.001).
Conclusion: This real-world evidence study demonstrates the increased use of platinum-based neoadjuvant therapies in alignment with current clinical guidelines, resulting in higher pCR rates. This trend is consistent with findings from randomized controlled trials.

Platinum salts should be a standard of care in the chemotherapy regiments for patients with TNBC.

P2-08-16: Comparative effects of Ribociclib, Palbociclib, and Abemaciclib on circulating and tumor infiltrating myeloid cells in metastatic breast cancer patients

Nikhila Kethireddy

Background: Cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i) are routinely used in the treatment of advanced hormone receptor positive (HR+) breast cancer (BC) patients. CDK4/6i are primarily thought to inhibit cancer cell proliferation. Recent pre-clinical evidence has demonstrated the capacity for CDK4/6i to alter immune cell activity and composition. In BC, tumor infiltrating lymphocytes (TILs) correlate with both extended survival and response to chemotherapy. In contrast, tumor associated macrophages have been associated with chemotherapy resistance possibly due to inhibition of TIL cytolytic activity. Given the important relationship between TILs, tumor associated myeloid cells, and patient outcomes, a clearer understanding of the impact of CDK4/6i on tumor immune surveillance and systemic immune composition is needed.
Methods: Patients with metastatic HR+ BC who are starting first-line ribociclib, palbociclib, or abemaciclib (ribo/palbo/abema) plus aromatase inhibitor are actively being recruited to observe changes in tumor and systemic immune composition over the course of CDK4/6i treatment. This prospective cohort will include n=20 each ribo/palbo/abema CDK4/6i-treated patients with serial blood testing collected prior to initiation and at the time of progression, with an optional on-treatment biopsy. In parallel, a retrospective cohort will be identified from archived pre- and post-treatment tumor biopsies of patients with known clinical response to treatment (N=15-20 each ribo/palbo/abema) and will be used to validate potential immune biomarkers of response identified in the prospective cohort. Collected samples are interrogated by a combination of clinical complete blood cell counts, high-parameter, flow cytometry, multiplex immunofluorescence, and single cell RNA sequencing to assess biological changes over the course of treatment and in association with patient outcomes. Enrollment began in 2023 and is currently ongoing (NCT05244434).
Results: In samples assessed thus far, we observe notable changes in circulating immune cell abundance and composition between pre-treatment and on-treatment timepoints. White blood cell counts (WBCs) and absolute neutrophil counts (ANCs) were significantly reduced in 4/4 patients. Similarly, absolute lymphocyte counts (ALCs) and absolute monocytes counts (AMCs) were reduced in 3/4 patients. Preliminary data suggests that ANCs (53% reduction) and AMCs (55% reduction) are more affected than ALCs (21% reduction) by CDK4/6i treatment. These dynamics resulted in an average decrease in a neutrophil-to-lymphocyte ratio (NLR) of 2.2 to 1.3 from pre-treatment to C2D1. Work is ongoing to comprehensively identify circulating and tumor infiltrating immune cell

phenotype changes induced by CDK4/6i, and how these changes differ between patients treated with ribociclib, palbociclib, and abemaciclib.

P2-08-18: De-Escalating Axillary Surgery in Nigeria: a phase II Single Arm Trial Protocol

Gregory Knapp, Olalekan Olasehinde, Rheann Brownstone, Omisore Oluwatosin, Adewale Aderounmu, Funmilola Wuraola, Toyosi Teniola Sotala, Omolade Betiku, Anya Romanoff, Folasade Adeyemi, Victoria Mango, Marcia Edelweiss, T. Peter Kingham, Olusegun Alatise

Introduction: Breast cancer is the most common cancer and cause of cancer related mortality in Nigeria. The majority of women present with locally advanced disease. The current standard of care for these women is neoadjuvant chemotherapy (NAC) followed by modified radical mastectomy, including complete axillary lymph node dissection (ALND). Within the last decade, the de-escalation of axillary surgery has been extended to women who present with clinically node positive (cN1) disease who are converted to clinically node negative (cN0) after NAC. In this setting, a sentinel lymph node biopsy (SLNB) is performed using a dual-tracer localization technique with methylene blue and Tc-99 sulfur colloid. This is prohibitive to axillary de-escalation in many low- and middle-income countries (LMICs) where the nuclear medicine infrastructure, to support access to Tc-99 sulfur colloid lymphoscintigraphy, is limited.
To overcome the challenge posed by the dearth of Tc-99 radiocolloid in Nigeria, this study seeks to evaluate the feasibility and efficacy of pre-operative axillary ultrasound (aUS) and a single agent (methylene blue) SLNB to stage the axilla in women converted from cN1 to cN0 disease after NAC.
Methods: This is a phase II, single arm trial being conducted at Obafemi Awolowo University Teaching Hospital (OAUTH) Ile-Ife, Nigeria. Initial inclusion criteria include: women ≥ 18-70 years of age, biopsy confirmed invasive carcinoma of the breast and clinically palpable N1 disease (cN1). Eligible patients have an aUS and if abnormal nodes are present the most suspicious undergoes core biopsy and clip placement. Patients with pathology confirmed TanyN1M0 disease will undergo NAC with curative intent as per institutional standards at the discretion of the treating surgeon.
Patients with a clinical complete response (cN0) at the completion of NAC will have a pre-op aUS. At the time of the operation, 5ml of 1% methylene blue is injected in an intra-parenchymal fashion with a 5-minute message. A sentinel lymph node will be classified as blue and/or suspicious by the operating surgeon. Surgeons performing the procedure have obtained additional training in the SLNB technique. Each sentinel lymph node will be removed and labelled separately and sequentially. A completion ALND (level 1-2) will be performed as per institutional practice and the contents labelled separately. Performance of the pre-operative clinical exam, aUS, SLNB and clipped node will be determined for each eligible patient. The study as research ethics board approval from OAUTH and was registered on clinicaltrials.gov prior to study initiation (NCT06039956).
Results: As of June 2024, 37 patients have met initial inclusion criteria and have been

consented and enrolled into the study. Nine of these have completed NAC and 6 have gone on to receive surgery as per the study protocol with a methylene blue only SLNB followed by completion axillary dissection. We expected to enrol 50 patients within the first year of the study. Target enrolment is 210 patients, which assumes a pCR of 30% and a FNR of 20% with 80% power to report on performance characteristics of the study intervention with 95% confidence intervals.
Discussion: Tc-99 sulfur colloid is not readily available in many LMICs. We have designed and commenced the implementation of a protocol to study the de-escalation of axillary surgery for women who present with locally advanced, node positive breast cancer in a low-resource environment using readily available technology.

P2-08-19: Delineating The Role of Normal Cell Types In Breast Cancer (Breast Cell Atlas)

Nelly Hernandez, Ivan Marin, Margarita Riojas-Barrett, Jessica Montalvan, Bernardo Martinez-Leal, Chandandeep Nagi, Sebastian Winocour, Nicholas Navin, Alastair M. Thompson

Background: The goal for the ATLAS study is to understand normal breast tissue. By identifying all cell types and cell states in collected disease-free breast tissue and establish an unbiased reference of normal breast cells that can be used to understand tumor growth in cancer patients. Previous studies have focused intensely on mammary epithelial cells however, there is a gap in knowledge concerning the non-epithelial cell types. Both cell types affect each other for normal breast development, lactation after pregnancy, and the more important focus on our protocol contribute to tumorigenesis. Excess tissue from healthy subjects as well as subjects who are at higher risk for developing breast cancer will be taken from women undergoing standard of care procedures such as reduction mammoplasties, prophylactic bilateral mastectomies and contralateral mastectomies from the unaffected breast. Factors such as ethnicity, age and menopause can be predictors in the breast cell type and cell state composition. Significant drawbacks that create bias could arise due to the lack of diversity in a study population. Any bias must be addressed to advance our understanding of diseased breast tissue. In this study we plan to collect clinical data from patients at the time of enrollment. Data such as participant's parity, social and economic status, lactation history, known density of the breast, estrogen, progesterone and HER2 receptor status will help to provide specific answers to the correlation between underlying cell types and the patient's association with the cancer and other genomic alteration.
Methods: This is a trial in progress. Tissue has been collected prospectively from normal breast tissue removed during prophylactic mastectomy, reduction mammoplasty or delayed asymmetry correction. This study will collect contralateral and adjacent breast tissue from 150 patients along with clinical data. Once all planned tissue collections are completed, the patients will be taken off the study.
Results: The site population has an accrual of 125 female patients. 65.6% African American,

Caucasian (Non-Hispanic) 23.2%, Caucasian (Hispanic or Latino) 5.6%, Asian 1.6%, American Indian .8%, Arabic .8% and 2.4% declined to state their race. The ages range from 18-65, with most having an unknown BRCA status. Of the 125 participants only 11.5% have BRCA 1 or 2 mutation, PALB2 mutation or CDH1 positive. Gravida ranges from 0 to 10 and Parity ranges from 0 to 7.
Conclusion: Instead of focusing on historical morphological features, the new data will perform unbiased single-cell RNA and epigenomic profiling to characterize these cell types which will serve as a reference 'Human Breast Cell Atlas' to study cell types in tumors, and how they contribute to tumor progression. While also allowing us to understand how we can improve the outcomes for women of all backgrounds.

P2-08-20: ELCIN: Elacestrant in women and men with CDK4/6 inhibitor (CDK4/6i)-naïve estrogen receptor-positive (ER+), HER2-negative (HER2-) metastatic breast cancer (mBC): An open-label multicenter phase 2 study

Virginia Kaklamani, Giorgi Dzagnidze, Nicoleta Zenovia Antone, Anu R. Thummala, Mikheil Janjalia, Patricia Santi, Carlos Barrios, Mehmet Ali Nahit Sendur, Xiaoling Zhang, Angela Gambioli, Manuel Dominguez, Kathy Puyana Theall, Tomer Wasserman, William J. Gradishar

Background: Endocrine therapy plus a CDK4/6 inhibitor (ET+CDK4/6i) is the mainstay treatment in first-line ER+/HER2- mBC; however, a subset of patients is unable to tolerate CDK4/6i, and resistance to ET arises. Intrinsic resistance mechanisms include alterations in the PI3K/AKT/mTOR or cell cycle pathways; acquired resistance mechanisms include estrogen receptor gene alpha (ESR1)-mut developing during ET in mBC. In EMERALD, single-agent elacestrant significantly prolonged progression-free survival (PFS) vs standard-of-care (SOC) ET and was associated with a manageable safety profile in patients with ER+/HER2- advanced or mBC previously treated with ET+CDK4/6i, leading to its approval as the first clinically available oral SERD. Elacestrant significantly reduced the risk of progression or death compared with SOC ET by 30% in the overall population (HR = 0.70; 95% CI, 0.55 to 0.88; P = 0.002) and by 45% in patients with ESR1-mutated tumors (HR = 0.55; 95% CI, 0.39 to 0.77; P = 0.0005) [Bidard, 2022]. To provide an option for patients unable to receive CDK4/6i and address resistance, the ELCIN trial aims to evaluate the efficacy and safety of elacestrant in patients with ER+/HER2- mBC who received prior ET but did not receive a prior CDK4/6i in the metastatic setting.
Methods: ELCIN (NCT05596409) is a single-arm phase 2 trial. Eligible patients are women or men with ER+/HER2− mBC who received 1-2 prior ET and no prior CDK4/6i or chemotherapy in the metastatic setting. Patients must have measurable disease per RECIST v1.1 or ≥1 lytic or mainly lytic bone lesion (in patients with bone disease only), ECOG PS ≤1, and no active or newly diagnosed central nervous system metastases. Patients will receive elacestrant 345 mg (400 mg elacestrant hydrochloride) once daily. The primary endpoint is investigator-assessed progression-free survival (PFS). Secondary endpoints are objective response rate (ORR), duration of response (DoR), clinical benefit rate (CBR), overall survival (OS), patient-reported outcomes (PROs), health-related quality of life (HRQoL), and

safety. Exploratory endpoints include assessing elacestrant efficacy according to ESR1-mutation status at baseline, assessing changes in biomarkers, including allele mutation frequencies in cell-free nucleic acids (cfNAs) in blood and the relationship between efficacy endpoints and allele mutation frequencies (at baseline and post-baseline). ELCIN has a planned sample size of 60 patients; recruitment is ongoing worldwide.

P2-08-21: ELEGANT: Elacestrant versus standard endocrine therapy in women & men with node-positive, estrogen receptor-positive, HER2-negative, early breast cancer with high risk of recurrence in a global, multicenter, randomized, open-label phase 3 study

Aditya Bardia, Virginia Kaklamani, Joyce O'Shaughnessy, Peter Schmid, J. Thaddeus Beck, Michelino De Laurentiis, Giuseppe Curigliano, Hope S. Rugo, Debu Tripathy, William J. Gradishar, Michail Ignatiadis, David A. Cameron, Giulia Tonini, Simona Scartoni, Jennifer Crozier, Leo Viana Nicacio, Tomer Wasserman, Sara M. Tolaney

Background: Adjuvant endocrine therapy (ET) is the standard of care (SOC) for the treatment of estrogen receptor-positive (ER+) human epidermal growth factor receptor-2 negative (HER2-) early-stage breast cancer. Despite optimized adjuvant treatments for patients with high risk of recurrence, patients continue to experience local and distant relapses, and new therapies are warranted. In the phase 3 EMERALD trial, single-agent elacestrant was evaluated vs SOC ET in ER+/HER2− metastatic breast cancer. Elacestrant significantly prolonged progression-free survival (PFS) vs SOC ET in the overall population (HR = 0.70; 95% CI, 0.55-0.88; P = 0.0018) and in patients with ESR1-mut tumors (HR = 0.55; 95% CI, 0.39-0.77; P = 0.0005) (Bidard, JCO 2022). In those pts with ≥12 months of prior ET+ CDK4/6 inhibitor (CDK4/6i) and ESR1-mut tumors, median PFS with elacestrant was 8.6 vs 1.9 months with SOC ET (Bardia, SABCS 2022). In patients with tumors without detectable ESR1-mut, a numerical difference was observed (HR = 0.86; 95% CI: 0.63-1.19). As elacestrant significantly prolonged PFS in the metastatic setting relative to endocrine monotherapy, with more pronounced activity in patients with endocrine-sensitive tumors, it is hypothesized that elacestrant should prolong invasive breast cancer-free survival (IBCFS) in the earlier adjuvant setting among patients who received prior adjuvant ET with or without a CDK4/6i. In addition, elacestrant can antagonize the estrogen receptor in tumor cells with a non-degradative antagonist function. Unlike other oral SERDs in development, elacestrant exhibits both degradative and partial agonist properties (Wardell, ERC 2015). Elacestrant could offer a new class of medication in the adjuvant setting and merits further therapeutic evaluation for patients with ER+/HER2- breast cancer with a high risk of recurrence.
Methods: ELEGANT (NCT06492616) is a global, multicenter, randomized, open-label phase 3 study designed to evaluate elacestrant compared with SOC ET (aromatase inhibitor or tamoxifen) in patients with early breast cancer and a high risk of recurrence. A total of 4,220 patients will be randomized 1:1 to continue SOC ET or switch to elacestrant therapy for a duration of 5 years. Eligible patients are women or men with ER+/HER2− node-

positive breast cancer who have completed 24 months (but not more than 60 months) of adjuvant ET and have ECOG PS ≤1. Patients who received a prior CDK4/6i or a poly ADP-ribose polymerase (PARP) inhibitor must have already completed or discontinued these treatments. Exclusion criteria include inflammatory breast cancer, any history of prior invasive breast cancer, and >6 months continuous interruption of prior SOC adjuvant ET or discontinuation of adjuvant ET >6 months prior to randomization. The primary endpoint is IBCFS. Key secondary endpoints include distant relapse-free survival (DRFS) and overall survival (OS). Additional secondary endpoints include invasive disease-free survival (IDFS), safety, and patient-reported outcomes. Exploratory endpoints include PK and biomarker analyses. Time-to-event endpoints will be reported using Kaplan-Meier estimates. Baseline demographics and other characteristics will be descriptively summarized.

P2-08-22: Effectiveness and implementation of a decision support tool to improve surgical decision-making in young women with breast cancer: The CONSYDER Study

Shoshana Rosenberg, Yushu Shi, Anna Revette, Lindsay Northrop, Laura Dominici, Jennifer K. Plichta, E. Shelley Hwang, Karen Sepucha, Maryam Lustberg, Lisa Newman, Ann H. Partridge, Rachel A. Greenup

Background: Young women with early-stage breast cancer are increasingly choosing contralateral prophylactic mastectomy (CPM) despite longstanding data demonstrating that breast conservation is equally effective as mastectomy, with comparable overall and disease-specific survival. Life-stage specific factors (e.g., breastfeeding, body image) can make surgical decisions particularly complex for young women and young women report high levels of decisional conflict regarding the surgical decision. The use of decision support tools has been shown to improve decision quality and reduce decisional regret. To optimally support young women making decisions about breast cancer surgery, we developed CONSYDER, a web-based decision aid (DA) tailored to the unique concerns of young patients. We aimed to test the effectiveness and implementation of the DA in a multi-center, pragmatic trial.
Methods: The CONSYDER Study incorporates a Type II hybrid effectiveness-implementation, stepped-wedge design. Using a mixed-methods approach, including surveys, interviews, focus groups, and audio-recordings with patients and providers, we will test the efficacy and evaluate the implementation of the CONSYDER DA across 4 sites (Weill Cornell Medicine, Yale Cancer Center, Dana-Farber Cancer Institute, Duke Cancer Institute) over a 30-36 month period. Eligibility criteria include: female and age 18-44 years with a new diagnosis of stage 0-III unilateral breast cancer. All sites have a 6-month “run-in” period (T1) where patients will not be sent the DA. Sites will then be randomized to begin delivery of the DA as part of standard clinical care during subsequent 6-month blocks (T2, T3, T4, or T5). The primary study aims are to: 1) test the effectiveness of the DA on reducing patient-reported decisional conflict (assessed by the Decisional Conflict Scale [DCS]) prior to breast cancer surgery; 2) evaluate the implementation and mechanisms of DA use.

Secondary aims include determining the impact of the DA on decision-making preferences, breast cancer knowledge, treatment goals and preferences, anxiety, decisional regret, and self-efficacy in communication. An exploratory aim will evaluate how the DA impacts surgical choice. A sample size of 800 patients (200 per site) was selected to have approximately 80% power to detect a minimum effect size of 0.35 (clinically meaningful DCS effect sizes range 0.3 to 0.4). For the primary endopoint, we will use generalized linear models to assess if the DCS score differs between the intervention and usual care groups. An assessment for differential effects of the DA on women of different races, ethnicities, and ages (e.g., 40-44 vs. 35-39 vs. <35) will be performed by testing for a treatment by variable (e.g., race, ethnicity, age group) interaction, assuming sufficient accrual numbers for different patient subsets. As part of the implementation evaluation, we will perform semi-structured interviews with a subset of participants. Surgeon attitudes and approaches around discussing surgical options will be evaluated with a survey of surgeons prior to the implementation of the DA and at the end of the study. To complement the surgeon surveys, we will randomly sample a subset of surgeons at each site post-implementation and audio-record 4-8 consultations per surgeon to characterize how the DA may impact patient-provider communication and shared surgical decisions. We will also conduct interviews and focus groups with providers/staff involved with the delivery of the DA about perceived barriers to DA implementation at their site/practice and opportunities to improve sustainability. The CONSYDER Study opened to enrollment in March 2024. As of June 2024, 57 participants are enrolled. Clinical Trials Information: NCT06275126

P2-08-23: Evaluation of Pathological Complete Response & Immunomodulatory Effects Following Intratumoral Injection of INT230-6 Prior to Neoadjuvant Immuno-chemotherapy in Early-Stage Triple Negative Breast Cancer: A Phase II Study INVINCIBLE-4-SAKK 66/22

Ursina Zürrer-Härdi, Andreas Müller, Arianna Calcinotto, Zsuzsanna Varga, Magda Marcon, Olivier Tredan, Katrin Gysel, Katrin Eckhardt, Roch-Philippe Charles, Lewis H. Bender, Markus Joerger

Background: Triple negative breast cancer (TNBC) poses significant challenges due to its aggressiveness, high relapse rates, and increased mortality. Neoadjuvant immuno-chemotherapy (NAIC) is now a common treatment for early-stage TNBC before surgery. NAIC aims to eliminate viable cancer in the tumor, lymph nodes and possible occult distant metastases, and shrink tumors to improve surgical outcomes and prevent disease recurrence. The Keynote-522 (KN522) study revealed a 84.5% 3-year event-free survival (EFS) in early-stage TNBC patients using NAIC. The KN522 regiment also improved pathologic complete response (pCR) rates from 51.2% with neoadjuvant Chemotherapy to 64.8% with neoadjuvant immuno-chemotherapy. Larger tumors pose an increased risk for resulting in a non-pCR and breast cancer recurrence post-surgery. A new potential method to improve clinical outcome and induce immune activation pre-surgery is through novel local therapies in combination with immuno-chemotherapy that could cause increased cell

death, create personalized tumor antigens and potentially increase pCR. Arnaout et al. conducted a randomized, phase 2 neoadjuvant window-of-opportunity trial using intratumoral (IT) INT230-6, a drug product candidate comprising vinblastine (VIN), cisplatin (CIS) and a tumor dispersion and cell penetration enhancer molecule (SHAO), evaluating clinical and biological effects in patients with early-stage operable breast cancer (the INVINCIBLE trial, NCT04781725). Results in T2 to T4 tumors showed significant necrosis in74% of subjects at the time of surgery, with some patients having >95% tumor necrosis following a single IT administration of INT230-6. Gene expression analysis showed a significant difference between baseline biopsies and surgical specimens. Pathway analysis identified genes associated with TCR signaling, B-cell and T-cell activation, with increasing effects in post-treatment samples (SABCS 2023 #PS16-03).

Objectives & Endpoints: The primary objective of this study is to determine the clinical activity of IT INT230-6 in patients with early TNBC in combination with NAIC to NAIC alone. The primary endpoint is pCR in the primary tumor (ypT0/Tis) and affected lymph nodes (ypN0)

Design: This is a randomized, open-label multicenter phase 2 clinical study to determine the clinical activity, safety, and tolerability of INT230-6 in patients with early-stage, operable TNBC who undergo NAIC treatment. Key inclusion criteria include newly diagnosed, previously untreated, locally advanced non-metastatic TNBC stage cT2-4c N0-3 M0 per American Joint Committee on Cancer (AJCC) version 8. Multifocal and multicentric primary tumors are allowed, with the most advanced T stage being used for eligibility. In case of multifocal or multicentric disease, TNBC needs to be confirmed for each focus. Patients have to have measurable disease in the breast with at least one lesion with a diameter ≥2cm that is evaluable per RECIST v1.1, visible in ultrasound and injectable. Patients are either male or female with age ≥ 18 years, ECOG performance status <2, adequate bone marrow function, hepatic and renal function.
The sample size calculation for both cohorts is determined based on a single-stage phase II single-arm clinical trial design according to A'Hern. The hypothesis for the trial is as follows: Null hypothesis (H0): pCR rate ≤ 0.6, Alternative hypothesis (H1): pCR rate ≥ 0.8. The specified parameters for the sample size calculation are: Type I error: 10% (one-sided), Power: 80%. The accrual duration is expected to be 12 months, and the trial therapy per patient will be eight months. The duration of follow-up is 36 months.

P2-08-24: Exploring the correlation between Superparamagnetic Iron Oxide counts at the axilla and Ductal Carcinoma In Situ size after Primary Breast Surgery: Preliminary Study Results

Bernardo Martinez-Leal, Ivan Marin, Jessica Montalvan, Margarita Riojas-Barrett, Nelly A. Hernandez, Logan Healy, Elizabeth Bonefas, Stacey A. Carter, Alastair M. Thompson

Background/Objectives: Approximately 25% of Breast Cancer in the United States is categorized as Ductal Carcinoma In Situ (DCIS). Traditionally patients undergoing mastectomy for DCIS undergo Sentinel Lymph Node Dissection (SLND) which puts the patient at risk of lymphedema. Superparamagnetic Iron Oxide (SPIO) nanoparticles have proven similar detection rate compared to Radioisotope (Technetium 99) and blue dye in detecting SLN, and avoiding unnecessary SLND. An ongoing study involving SPIO for the detection of SLN revealed that 79% of the enrolled participants to the Sentinot2 Study have avoided unnecessary SLND. This interim analysis attempts to demonstrate a positive correlation between the Magtrace (SPIO) counts obtained at the axilla after primary breast surgery, and DCIS size in the subjects that received delayed SLND. The rates of Lymphedema in the SLND group will be a secondary outcome.
Methods: Subjects with a preoperative diagnosis of DCIS, enrolled in the Sentinot2 study at Baylor College of Medicine from November 2021 to July 2024 who underwent a delayed SLND as part of their treatment. Pearson's correlation coefficient will be used to verify the correlation strength between the Magtrace counts and DCIS size.
Results: For the interim analysis, 4 subjects received delayed SLND. The average age was 57.5; average BMI was 32.15kg/m2; The average size of the largest measurement of their DCIS on mammogram prior to primary breast surgery was 24mm. The Magtrace counts obtained at the axilla after the primary breast surgery ranged from 0 to 1920, with a mean of 696. The average size of the largest measurement of their DCIS after their primary breast surgery was 23mm. The correlation between the Magtrace counts at the axilla and the DCIS size after the primary breast surgery revealed a Pearson's r of 0.958 with a p-value of 0.042. The Lymphedema rate was 0% in this group of subjects that underwent delayed SLND.
Conclusions: The present study showed a strong positive correlation between Magtrace counts at the axilla and the size of the DCIS after the primary breast surgery. We plan further data collection to determine if this result is consistent.

P2-08-25: FITWISE: Feasibility study of tirzepatide for weight loss intervention in early stage hormone receptor positive/HER2 negative breast cancer

Coral Omene, Mridula George, Maria Kowzun, Shicha Kumar, Firas Eladoumikdachi, Lindsay Potdevin, Jonathan Smith, Kathleen Toomey, George Raptis, Lori Schleischer, Trishala Meghal, Gerardo Capo, Dirk Moore, Eileen White, Joshua Rabinowitz, Lydia Lynch, Yibin Kang, Kellen Olszewski, Adana Llanos, Elisa Bandera, Anita Kinney, Deborah Toppmeyer, Shridar Ganesan

Background: In obesity, significant hormonal and inflammatory changes create a mitogenic microenvironment and promote tumorigenesis. Obesity at time of breast cancer (BC) diagnosis and following treatment is associated with poorer BC survival, particularly for hormone receptor positive (HR+)/human epidermal growth factor receptor 2 negative (HER2-) BC. Furthermore, weight gain is a common side-effect of the adjuvant endocrine therapy necessary to decrease the risk of recurrence. Obesity disproportionately affects

Black women 57.2% vs. 38.2% Non-Hispanic White women, with central obesity and higher adiposity being associated with higher all-cause and breast cancer-specific mortality among Black BC survivors. Previous reports have indicated that a 5% weight loss is sufficient to reverse the metabolic disarray induced by obesity. Tirzepatide, an analogue of gastric inhibitory polypeptide (GIP), and a dual GIP and GLP-1 Receptor Agonist, a first -in-class new drug, demonstrated substantial and sustained reductions in body weight (up to 21%) and reversal of cardiometabolic disarray in a 72-week weight loss clinical trial. We hypothesize that tirzepatide will result in ≥5% in body weight reduction in obese patients during the adjuvant treatment of HR+/Her2- BC.
Trial Design: This is a single arm, phase II, non-randomized trial for the weekly administration of tirzepatide for two years of weight loss intervention during the adjuvant treatment of early-stage HR+/HER2- BC. Patients fitting the obesity body mass index (BMI) criteria, BMI ≥30 kg/m2 or ≥27 kg/m2 with at least one weight related comorbidity will be eligible. This study will enroll 20 Black and 20 Non-Black BC patients at the Rutgers Cancer Institute/RWJ Barnabas Health System. This will enrich the cohort of trial participants with the Black population that has an established disparity in HR+/Her2- breast cancer and obesity related outcomes.
Specific Aims: The primary endpoint is to determine how many patients achieve a 5% or more body weight reduction at the end of study treatment with tirzepatide. Secondary endpoints include safety and tolerability and to determine the feasibility of using tirzepatide for weight loss intervention during the adjuvant treatment for HR+/Her2- BC, based on discontinuation rates. Changes in different obesity measurements such as BMI, body fat distribution via Waist/Hip Ratio (WHR) and waist circumference will be assessed. 3-year invasive disease-free survival, 3-year distant relapse-free survival will be determined and changes in obesity related metabolic markers and ctDNA will be assessed. Exploratory objectives investigating adipokines and their receptors, metabolomic pathways and immune cell metabolism will be conducted.
Statistical Methods: Our outcome of interest will be the percentage of patients with a weight loss of more than 5 percent. We plan to carry out a 5 percent level one-sided test of proportions in a single-arm study. With 40 patients, we have 80 percent power to detect an increase from 0.42 (the derived estimated proportion with weight loss exceeding 5 percent with standard therapy) to 0.617 in patients treated with tirzepatide.
Results: This is a clinical trial in progress with IRB approval (approval number: Pro2024000646) and can be found on clinicaltrials.gov. Results will be presented at a future date.
Conclusion: Successful outcomes from this trial would demonstrate that tirzepatide administration can lead to substantial weight loss and significant improvement in cardiometabolic health in obese BC patients, and may help reduce the risk of BC recurrence during the adjuvant treatment for HR+/HER2- breast cancer. The exploratory objectives may provide biological insights and potential targets for treatment.

P2-08-26: FLEX: A Real-World Evidence, Full Transcriptome Study in 30,000 Patients with Early-Stage Breast Cancer

Robert Maganini, Ellis Levine, Kent Hoskins, Sarah Thayer, Alfredo Santillan, Sung Ho-Lee, Eduardo Dias, Regina Hampton, Eric Brown, Maxwell Brown, Joyce O' Shaughnessy, Nicole Stivers, Harshini Ramaswamy, Katie Quinn, Isha Kapoor, William Audeh

Background: The advent of subtype-specific treatments, particularly hormone therapies and HER2-targeted therapies, has significantly improved survival rates and quality of life for breast cancer (BC) patients. Over the last decade genomic signatures have enabled improved classification of BC into distinct molecular subtypes, providing prognostic and/or predictive information about the metastatic potential of the tumor beyond those of clinicopathologic features. Despite marked progress, BC remains the most frequent cause of cancer death among women globally, accounting for almost 15.5% of all new female BC cases in the US. These poor clinical outcomes warrant further understanding of tumor heterogeneity and identifying genomic signatures, particularly variation within the subset of ER positive early-stage breast cancer (EBC). Pairing the full genome expression data with comprehensive clinical information enables further tumor stratification and a deeper understanding of tumor biology driving EBC. The ongoing, multi-center FLEX study (NCT03053193) seeks to enroll 30,000 patients to create a large-scale, diverse, population-based registry of full genome expression data matched with clinical data to investigate new gene expression signatures of prognostic and/or predictive value in a real-world setting. Efforts are focused on increasing clinical trial enrollment of racial/ethnic minorities and other historically underrepresented groups in clinical trials in the US to promote efficacy in outcomes and health equity. Additional objectives include supporting investigator-initiated sub-studies to address yet unresolved clinically relevant questions in EBC over 5-10 years of follow-up. Methods: FLEX is a large, multi-center, prospective, observational trial that enrolls patients (male or female) who are ≥ 18 years old with histologically proven stage I-III breast cancer. All patients with up to 3 positive lymph nodes who receive standard of care MammaPrint (70-gene signature risk of recurrence), with or without BluePrint (80-gene signature molecular subtype) on a primary breast tumor and consent to clinically annotated full transcriptome data collection are eligible for enrollment. FLEX fosters collaboration across 95 sites in the US, 2 sites in Canada, 1 site in Greece, and Israel. This initiative encourages investigator-initiated sub-studies, promoting diverse research perspectives and potentially enhancing the scope and robustness of the overall study. Within 7 years of trial initiation, FLEX total enrollment amounts to 16,980 EBC patients. To address racial/ ethnic disparities in clinical trials, a concerted effort has led to the inclusion of 1,377 Black, 530 Latin American (LA)/Hispanic, 353 AAPI, out of 14,330 EBC patients with self-reported race and ethnicity, making FLEX the most diverse study on EBC patients to date. Such diversity in FLEX sets a valuable precedent for future research aiming to improve healthcare outcomes for all groups. Currently FLEX supports 12 in-progress investigator initiated sub-studies in 2024, with over 45 abstracts accepted at congresses internationally (2018-2024), including 11 presentations and 2 poster spot-light sessions that address the underlying differences in tumor biology and clinical outcomes in Black, LA,

and AAPI populations. Overall, as FLEX continues to grow, the study strives to leverage full transcriptome data to enhance precision medicine in EBC. By identifying molecular subtypes and predictive biomarkers, the trial intends to equip clinicians with enhanced tools for tailoring treatment strategies more effectively in EBC. The FLEX trial represents a pioneering effort in integrating genomic data and clinical information on a large scale to improve outcomes and reduce disparities in EBC. Its emphasis on diversity, comprehensive data collection, and collaborative research pursuits places it at the forefront of precision medicine in EBC.

P2-08-27: ICARUS-BREAST02: Safety, Tolerability, & Anti-tumor Activity of patritumab deruxtecan (HER3-DXd) monotherapy & combinations in patients (pts) with inoperable advanced breast cancer (ABC) following progression on trastuzumab deruxtecan (T-DXd)

Barbara Pistilli, Stefan Michiels, Rasha Cheikh-Hussin, Magali Lacroix-Triki, Pierre Guyader, Lambros Tselikas, Souad Cosse, Tiffany Malleck, Jacqueline Deneuve, Ghada Nachabeh, Françoise Farace, Marianne Oulhen, Patricia Kannouche, Andrea Sporchia, Esther Pang, David Sternberg, Dalila Sellami, Noemie Corcos, Fabrice André, Fernanda Mosele, Guillaume Montagnac

Background: The human epidermal growth factor receptor 3 (HER3) is a key member of the ErbB family overexpressed in 50-70% of breast cancers. HER3 plays a critical role in promoting cancer progression, metastasis development across all breast cancer subtypes, being as such associated with poor patient outcomes. Furthermore, HER3 has a key role in driving therapeutic resistance to anti-EGFR1/2 inhibitors, endocrine therapy and PI3K-pathway targeted therapies. HER3-DXd is an investigational antibody drug conjugate containing a human anti-HER3 immunoglobulin G1 monoclonal antibody conjugated via a cleavable peptide linker to an exatecan derivative payload (topoisomerase-I inhibitor), with a drug to antibody ratio of 8:1. HER3-DXd as single agent has shown promising activity in patients with heavily pretreated ABC, across different subtypes and regardless of HER3 expression levels [Krop I et al, Journal of Clin Oncol 2023]. Given that T-DXd has become a standard therapy in pts with HER2-positive (HER2-pos) and HER2-low (IHC 1+ or IHC 2+ ISH neg) ABC and since HER3 plays a key role in resistance to anti-HER2 targeted therapies, our study aims at evaluating the efficacy and safety of HER3-DXd in pts with HER2-pos or HER2-low ABC who had disease progression on prior treatment with T-DXd. HER3-DXd will be given either as single agent or in combination with therapies that have shown to improve HER3-DXd activity in preclinical data.

Patients and Methods: ICARUS-BREAST02 is an ongoing platform study, currently composed of 2 modules: module 0 explores HER3-DXd as single agent in pts with HER2-low ABC (HER2-low cohort) in the safety run-in and dose-expansion part; module 1 evaluates the combination of HER3-DXd and olaparib in pts with HER2-pos ABC (HER2-pos cohort) in the dose-finding part and in both cohorts in the dose-expansion part. HER3-DXd

monotherapy (IV 5.6 mg/kg Q3W) or combined with olaparib (starting dose 100 mg b.i.d PO days 8-14 every 21 days) will be administered until disease progression and/or unacceptable toxicity. The study started on March 21May15thst, 2024 with part 1a (HER3-DXd monotherapy in HER2-low cohort). If none out of 3 pts or <2 out of 6 pts experience dose-limiting toxicity during the first cycle, the study will move to part 1b in which dose-escalation and de-escalation of olaparib combined with HER3-DXd will be assessed using the Bayesian optimal interval (BOIN) design.. In the dose-expansion part (part 2), we will monitor the efficacy endpoint using the Bayesian optimal phase 2 (BOP2) design, with predefined optimized stopping boundaries for interim analysis.
Eligible pts are women or men with ABC whose ECOG PS is ≤1, with ≥1 non-irradiated measurable lesion, who progressed while on T-DXd or within 2 months from its discontinuation for any reason. Prior trastuzumab and CDK4/6 inhibitors are required in HER2-pos and HER2-low cohort, respectively. Pts are excluded if they have, but not limited to, a history of interstitial lung disease/pneumonitis, clinically significant corneal disease, evidence of leptomeningeal disease or unstable/active brain metastases. The primary endpoint of part 1 is safety as measured by DLTs, frequency and severity of any adverse event (AE) graded by NCI-CTCAE v5.0; proportion of treatment discontinuations, interruptions, and dose reductions due to any AEs; frequency and severity of laboratory abnormalities defined by NCI-CTCAE v5.0; while the primary endpoint of part 2 is investigator-assessed objective response rate (ORR) as per RECIST v1.1. Mandatory collection of tumor and blood samples (including circulating tumor cells (CTC) and ctDNA) is performed pre-treatment, on treatment and at resistance for exploratory translational analyses. New combination treatment modules could be added during the study, via protocol amendment.

P2-08-28: Implementing geriatric assessment for dose Optimization of CDK 4/6-inhibitors in older Breast Cancer patients (IMPORTANT trial) – a pragmatic randomized-controlled trial

Emanuela Risi, Laura Biganzoli, Athina Christopoulou, Fjermeros, Elena Fountzilas, Jürgen Geisler, Raquel Gomez-Bravo, Peeter Karihtala, Paris Kosmidis, Angelos Koutras, Helena Linardou, Henrik Lindman, Iván Martínez-Ballestero, Anna Belén Rodríguez, Icro Meattini, Montserrat Munoz-Mateu, Mukhrizah Othman, Amanda Psyrri, Aglaia Schiza, Nikolaos Spathas, Meri Utriainen, Luca Visani, Thanos Kosmidis, Antonis Valachis

Background: Current evidence from both randomized trials and real-world evidence studies suggests that older patients with advanced hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) breast cancer derive clinical benefit from the addition of cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors to endocrine therapy. However, a higher risk for adverse events due to CDK4/6 inhibitors among older patients is evident, leading to a trend of initiating CDK4/6 inhibitors at a lower dose in clinical practice, though without evidence. The aim of the present randomized trial is to investigate whether lower initial dose of CDK4/6 inhibitors combined with endocrine therapy is comparable to

full dose in older patients with advanced HR+/HER2-breast cancer that are assessed as vulnerable/frail based on comprehensive geriatric assessment (CGA).
Trial Design: We designed a multi-national, open-label, pragmatic randomized controlled trial with non-inferiority approach. Patients ≥70 years old with advanced HR+/HER2-breast cancer with no curative intention, no prior treatment in an advanced setting, and suitable to receive a combination of CDK4/6 inhibitors plus endocrine therapy according to treating physician, are eligible for study inclusion. After informed consent, included patients fill out a self-administered CGA tool and categorized accordingly to fit, vulnerable, or frail, depending on the number of impaired CGA domains. Fit patients receive full dose of CDK4/6 inhibitors and endocrine therapy whereas vulnerable/frail patients are randomized to either -1 level lower CDK4/6 inhibitor dose or full dose and endocrine therapy. The randomization is stratified by type of CDK 4/6 inhibitor, type of endocrine therapy, and level of vulnerability. The treating physician decides on the choice of CDK4/6 inhibitor (abemaciclib, ribociclib, palbociclib) and endocrine therapy (aromatase inhibitors, fulvestrant). The primary endpoint is time to treatment failure whereas secondary endpoints include overall treatment utility, progression-free survival, overall survival, time to chemotherapy initiation, toxicity, quality-of-life, time to quality-of-life deterioration and cost-effectiveness. The evaluation of disease progression, toxicity assessment, and the follow-up strategy resembles clinical practice to enhance the pragmatic design approach of IMPORTANT trial. The trial also enables a hybrid decentralized approach where the initial patient visit is in-person whereas the visits for efficacy and toxicity evaluation can be performed digitally according to local practices. In total, 495 patients are planned to be included to allow 346 vulnerable/frail patients to be randomized.
Enrolment: The trial is open for recruitment since February 2024 with a recruitment period of 30 months.
Clinical Trial Registration: NCT06044623 (ClinicalTrials.gov)

P2-08-29: Lenvatinib and Pembrolizumab in Endocrine Resistant Breast Cancer with Letrozole in the Advanced setting – a Phase II Study (LaPemERLA)

Yoon-Sim Yap, Tira Jing Ying Tan, Hui Zhen Gay, Elizabeth Ann Lee, Sze Huey Tan, Timothy Kwang Yong Tay, Babar Nazir, Choon Hua Thng, Mabel Wong, Ryan Shea Ying Cong Tan, Zewen Zhang, Han Yi Lee, Joshua Zhi Chien Tan, Bernard Ji Guang Chua, Sophia Yien Ning Wong, Jack Junjie Chan, Jun Ma, Chung-Lie Oey, Veronique Kiak Mien Tan, Kah Suan Lim, Jason Yongsheng Chan

Background and Rationale: There is an unmet need to develop more effective immune-based therapies in the hormone receptor (HR)+HER2- breast cancer (BC) subtype, especially in the metastatic setting. We hypothesise that lenvatinib, a multi-kinase inhibitor with activity against vascular endothelial growth factor receptors 1-3, fibroblast growth factor receptors 1-4 and ret protooncogene, will enhance the immunogenicity in HR+ BC through normalisation of the tumor vasculature, suppression of myeloid-derived

suppressor cells and regulatory T cells, increased T-cell infiltration of the tumor, and possibly increased apoptosis. Since the estrogen receptor (ER) pathway has been implicated in the immune escape of HR+ BCs, letrozole will be required to suppress the HR pathway concurrently.

Study DesignPhase II open-label, non-randomized study will recruit up to 40 subjects with advanced ER and/or progesterone receptor positive HER2- BC which has progressed on standard endocrine therapy. The treatment will be defined in 6-weekly cycles. Lenvatinib and letrozole will be given orally daily from Day -14, while pembrolizumab will be administered intravenously during week 1 of each cycle from Cycle 1 Day 1 (C1D1), with daily lenvatinib and letrozole. Ovarian suppression will be required for premenopausal, perimenopausal and male patients. The study treatment will be continued for up to a maximum of 18 6-weekly cycles (approximately 2 years) per patient. Treatment may be discontinued upon disease progression, intolerable toxicities, or patient's withdrawal request. Subjects will undergo at least 1 mandatory biopsy – pretreatment before Day -14 lenvatinib and letrozole run-in phase. Posttreatment biopsy at the following timepoints will be optional: 1) at or up to 3 days before C1D1, 2) within 3 weeks of receiving pembrolizumab in C1, 3) post-progression.

Eligibility: Key inclusion criteria: age ≥21 years; histologically confirmed HR+/HER2- metastatic BC; disease progression after at least 1 line of palliative endocrine therapy (prior adjuvant/palliative letrozole is allowed); any number of lines or prior targeted therapy (except lenvatinib) is allowed; ≤1 line of palliative chemotherapy; measurable disease based on RECIST 1.1; availability of tumor sample and be a candidate for tumor biopsy. Key Exclusion Criteria: unstable intracranial disease; contraindications to lenvatinib or pembrolizumab.

Objectives: Primary objective: to determine the efficacy of pembrolizumab, lenvatinib and letrozole in patients with advanced HR+HER2- BC in terms of the objective response rate (ORR).

Secondary Objectives: To assess the anti-tumor activity of this combination treatment in advanced HR+HER2- BC (progression-free survival, duration of response, clinical benefit rate and overall survival) as well as safety.

Exploratory Objectives: To identify biomarkers in peripheral blood/plasma, tumor and faecal specimens that are predictive of efficacy and toxicity to this triplet combination therapy; To investigate differences in tumour characteristics in biopsies taken post treatment with lenvatinib + letrozole, and post treatment with pembrolizumab in addition to lenvatinib + letrozole versus baseline.

Statistical Method: A Simon's 2-stage design will be used to allow early stopping if there is no strong evidence suggesting that the treatment regimen is active; testing for an ORR of 30% versus 10% with one-sided alpha of 5% and power of 90%. A total of 22 evaluable patients will be analyzed in the first stage and the trial will stop early if there are fewer than 3 responders. If 3 or more patients experience objective response, trial accrual will continue to the second stage. An additional 18 patients will be accrued for a total of 40 patients.

This study is registered with clinicaltrials.gov (NCT05286437)

P2-08-30: Longitudinal measurement of serum Progranulin (PGRN/GP88) in metastatic breast cancer patients enrolled in a prospective study.

Ginette Serrero, Binbin Yue, Paula Rosenblatt, Jennifer Latteri, Amy Avergas, Kevin Hu, Ghazal Kango, Srindi Radhakrishnan, Daikripa Radhakrishnan, Katherine Tkaczuk

The ability to monitor response to therapy and disease progression in metastatic breast cancer (MBC) patients is a major step in patient management. Imaging remains the method of choice for the assessment of disease status and the monitoring of disease progression. However, this approach remains expensive, exposes patients to radiation and thus is performed every 2-3 months. During this time interval, the disease may progress on ineffective treatment with an increased risk of treatment related toxicities due to the inability to detect progression at earlier times. Circulating levels of tumor associated biomarkers such as CA15-3 and CEA are used to track the disease status of MBC as a complement to imaging. However, even though they can provide information about disease progression, the monitoring of disease status through the measurement of drivers of disease can provide a complementary approach to existing strategies used in the standard of care in order to fine-tune monitor the disease status and improve the management of MBC patients undergoing treatment.
Progranulin, also called Glycoprotein 88kDa (PGRN/GP88) is an autocrine growth factor overexpressed in breast cancer. PGRN plays a significant role in breast tumorigenesis. PGRN/GP88 overexpression in invasive ductal carcinoma (IDC) is associated with malignant phenotype, estrogen independence, increased proliferation, survival, angiogenesis, and drug resistance. High PGRN/GP88 tumor expression measured by immunohistochemistry in estrogen receptor positive IDC is an independent prognostic marker associated with increased risk of recurrence and mortality. Clinical studies have demonstrated that serum PGRN levels determined by sandwich enzyme immunoassay are elevated in breast cancer patients, compared to healthy individuals. In MBC patients, low serum PGRN levels correlate with increased overall survival. Based on these observations, the measurement of serum PGRN/GP88 levels in MBC patients can provide additional information to monitor MBC disease status. A prospective study was established to identify whether there is a statistically significant change in serum PGRN/GP88 levels associated with time to progression of breast cancer as measured by RECIST 1.1 criteria in MBC patients. Under IRB approved protocols at the University of Maryland Greenebaum Comprehensive Cancer Center and at two Baltimore Medstar Health Facilities, a total of 103 female breast cancer patients with measurable or evaluable metastatic disease will be consented and enrolled. For inclusion, patients have been re-staged within 4 weeks and will continue or begin new therapy. Currently, we have enrolled sixty-five subjects at the three facilities with blood samples collected every 2-3 months or whenever there is an event such as clinical progression. Standard laboratory assessment and radiographic imaging/staging every 2-3 months on study will complement blood collection. The samples are stored at -70C until evaluation of PGRN/GP88 using an enzyme linked immunoassay developed by A&G Pharmaceutical. The poster will provide a status on the prospective trial and provide preliminary analysis of PGRN level in correlation with disease status determined as

responder, stable or progressing based on the RECIST criteria.
This study is supported by grant R44CA210817 from the National Cancer Institute to Ginette Serrero

P2-09-01: Preliminary Findings from the Breast Cancer Combined Visualization And Characterization Tools (bCOMBAT): Low-Dose PEM and Liquid Biopsy Study

Vivianne Freitas, Oleksandr Bubon, Samira Taeb, Frederick Au, Supriya Kulkarni, Sandeep Ghai, Shayna Parker, Michael Waterston, Alla Reznik

Purpose: This study evaluates the effectiveness of low-dose Positron Emission Mammography (PEM) and liquid biopsy in detecting and characterizing breast abnormalities in high-risk patients.
Materials and Methods: Approved by the research ethics board, this prospective study involves high-risk women from the Ontario Breast Screening Program (OBSP) at the University Health Network (UHN). Participants scheduled for MRI-guided biopsy of suspicious lesions detected by standard MRI are subjected to low-dose PEM using 74 MBq of fluorine 18-labeled fluorodeoxyglucose (18F-FDG) and liquid biopsy for plasma analysis.
Preliminary Findings: Among the first high-risk 24 patients analyzed (median age 41; range 33–66) from a planned cohort of 100, four had biopsy-confirmed cancer, including two cases of ductal carcinoma in-situ (DCIS) and two of invasive cancer. Of these, low-dose PEM imaging identified three malignancies and missed one DCIS, with no false positives reported. Liquid biopsy, measuring tumor content and performing fragmentomic analysis on cell-free DNA, did not detect any cancers. Further analysis using cell-free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIP) is pending.
Conclusion: Early results indicate that low-dose PEM is more sensitive than liquid biopsy for detecting breast cancer in high-risk populations and maintains high specificity relative to MRI.

P2-09-02: Two Years Post-COVID-19: Evaluating the Impact on Brazil's Mammographic Screening Program

André Mattar, Marcelo Antonini, Denise Joffily Pereira da Costa Pinheiro, Marina Diógenes Teixeira, Andressa Gonçalves Amorim, Odair Ferraro, Francisco Pimentel Cavalcante, Felipe Zerwes, Marcelo Madeira, Eduardo de Camargo Millen, Antônio Luiz Frasson, Fabrício Palermo Brenelli, Luiz Henrique Gebrim, Ruffo Freitas-Junior

Objectives: The objective of this study was to assess the impact of the COVID-19 pandemic, after two years, on mammographic screening in Brazil evaluating BIRADS® results, breast cancer diagnosis rates, and breast cancer stage.
Study Design: This was an ecological observational study was based on retrospective data from Brazil's mammographic screening program from 2015 to 2023.

Methods: Data were obtained from the national screening database DATASUS – SISCAN (Cancer System Information) and retrieved in March 2024. Inclusion criteria comprised completeness of mammogram data (incomplete records were excluded), female participants aged 50 to 69 years, and mammograms exclusively performed for screening purposes. The study analyzed the number of mammograms conducted during the specified period, focusing on BIRADS® test results.
Results: Out of 23,851,371 mammograms performed between 2015 and 2023, 15,000,628 were included for analysis. A significant reduction of 39.6% in mammograms was observed in 2020 compared to 2019, followed by a 12.6% decrease in 2021. Notably, a substantial rise in BIRADS categories 4 and 5 examinations was seen post-pandemic. Breast cancer staging analysis revealed a shift towards more advanced stages (III and IV) diagnosed post-pandemic, suggesting potential delays in detection and diagnosis.
Conclusions: In conclusion, the study highlighted significant discrepancies in mammographic screenings and breast cancer diagnosis rates over nine years, with the pandemic reflects the significant influence on the timing and stage at diagnosis, suggesting potential delays in detection and diagnosis that resulted in later identification of more advanced disease stages.

P2-09-03: USING OF SULPHUR HEXAFLUORIDE (SF6) FOR DETECTION OF SENTINEL LYMPH NODE IN OUTPATIENT PRACTICE: PRELIMINARY RESULTS FROM AN EFFICACY AND SAFETY STUDY

Maria Sharavina

Introduction: Sulfur hexafluoride (SF6) is a contrast medium widely used in sonography to visualize lymph nodes. The use of SF6 in outpatient practice can reduce the time and improve the quality of diagnostics, which contributes to more effective treatment of patients.One of the main advantages of this contrast agent is its safety and good tolerability, which makes it preferable in clinical practice.
The purpose of this study was to evaluate the efficacy of fine-needle aspiration biopsy (TAB) of sentinel lymph nodes with sulfur hexafluoride on an outpatient basis in patients diagnosed with breast cancer but with no data on metastasized lymph nodes and to evaluate the safety and tolerability of SF6 for this procedure.
The objective of this study was to identify SF6-labeled sentinel lymph nodes at the outpatient stage and verify them with fine-needle aspiration biopsy.
Materials and method: 30 patients diagnosed with breast cancer but with no evidence of metastasis-affected lymph nodes, who were scheduled for surgical treatment as the first stage, underwent the procedure of staining axillary lymph nodes with SF6 contrast agent in the tissue around the tumor. Sonography was performed using a 7.5 MHz linear transducer to visualize the contrast stained lymph nodes. Next, TAB of the lymph nodes was performed and visualized on an ultrasound scanner. The material was sent for cytologic examination (CI). The frequency of detection of "signal" lymph nodes was further analyzed and the presence of complications was investigated.

Results: Two out of 30 patients with sulfur hexafluoride (SF6) identified metastasis-affected lymph nodes by cytologic examination, which allowed a change of treatment plan to neoadjuvant first-stage chemotherapy. None of the patients had complications related to the use of sulfur hexafluoride.
Conclusions: The use of SF6 allows for improved visualization of sentinel lymph nodes at the outpatient stage and improved diagnostic accuracy, thus allowing for minimally invasive diagnosis without hospitalization of the patient and planning more effective treatment for patients.

P2-09-04: A Randomized Study Assessing Interventions to Improve Comfort During Screening Mammography

Nikki Verma, Mazo Canola, Kenneth Kist, Joel Michalek, Lillian Franco, Pamela Otto, Virginia G. Kaklamani

Introduction: Multiple publications have demonstrated that screening mammography reduces breast cancer mortality through early detection. However, the discomfort and anxiety reported by patients constitutes a significant barrier to screening. Despite this, there is little research on strategies to reduce discomfort and anxiety associated with mammography screening and improving patient compliance with national screening recommendations. Furthermore, literature suggests lower rates of mammography in particular racial and ethnic groups. Studies considering barriers to screening mammography in racial minority groups are limited and in need of further investigation.
Objective: To determine in a double blinded randomized clinical trial with a 2x2 factorial design if the use of local analgesia and calming music can improve patient satisfaction during routine mammographic screening.
Methods: A total of 251 women who presented for mammographic screening were randomized to receive breast lidocaine gel 4% at a dose of 1200 mg on one breast and placebo gel on the other and experience calming music or no music. Patients with history of mastectomy, breast cancer or recent analgesic use were excluded. Pain was measured with a 5-point face pain scale.
Results: Of the 251 patients who were randomized between June 2017 and October 2019, 195 self-identified as Hispanic (77%). Patients were randomized to a partially balanced blinded 2×2 factorial of Music (M) [Yes, No] by Lidocaine (L) [Lidocaine, Placebo] with sample sizes: Music and Lidocaine N=79, Music and Placebo N=47, No Music and Lidocaine (N=51) and No Music and Placebo (N=74).A total of 126 patients were randomized to music [M] vs 125 to no music. Significance was not observed for all 9 outcomes (Age, Hispanic ethnicity, and 7 measures of pain). In particular, the ML interaction remained non-significant throughout, suggesting that the effect of Music did not vary with Lidocaine, and the effect of Lidocaine did not vary with Music. Pain expectation across all groups was similar. Despite this, the majority of patients in both groups expressed no reluctance for future mammograms.
Conclusion: The addition of calming music and breast lidocaine gel did not show a

statistically significant difference in the level of pain perceived by patients getting screening mammography. There seems to be a trend for less severe pain (pain score 4 and 5) when these strategies are combined. Further prospective trials with larger patient populations are needed to explore these interventions. Despite the perceived pain most patients were still willing to return for a mammogram the following year. This study was conducted in a primarily Hispanic population and lends itself to further trials and guideline development in this demographic.

P2-09-05: Evaluating the Impact of Mammographic Screening on 5-Year Breast Cancer Survival: A Propensity Score-Adjusted Retrospective Cohort Study in a Tertiary Hospital in São Paulo, Brazil

Fernando Wladimir Silva Rivas, José Maria Soares Jr., Bruna Salani Mota, Isabel Cristina Esposito Sorpreso, Tatiana Natasha Toporcov, Jose Roberto Filassi, Laura Testa, Edia di Tulio Lopes, Laura Raíssa Schio, Yann-Luc Patrick Comtesse, Edmund Chada Baracat, Rodrigo Goncalves

Background: In Brazil, breast cancer (BC) is the most prevalent and deadly form of malignant neoplasia among women. Despite therapeutic advances, late detection remains a significant barrier to achieving a reduction in mortality rates comparable to those observed in developed countries. Organized mammographic screening is advocated as the most effective preventive measure for early detection of cancer in asymptomatic women. The Brazilian government recommends biennial mammography for women aged 50 to 69; however, population coverage is low, and screening is often conducted opportunistically. This situation underscores social inequalities in healthcare access among different groups of women affected by this disease, frequently resulting in poorer prognoses. This study, conducted at the Instituto do Câncer do Estado de São Paulo (ICESP), aims to estimate the 5-year overall survival based on the detection method, while controlling for potential confounding factors among asymptomatic women diagnosed with BC through mammography and those diagnosed after the onset of symptoms.
Methods: This retrospective cohort study included patients selected from ICESP's hospital-based cancer registry, admitted between Jan 1, 2016, and Dec 31, 2017, and followed until Feb 28, 2024. Patients were divided into two groups: asymptomatic women diagnosed with breast cancer through mammography (group 1 – G1) and those diagnosed after the onset of symptoms (group 2 – G2). We described the demographic, diagnostic, and therapeutic characteristics of patients in the two study groups according to the method of breast cancer detection. Five-year survival rates were reported as percentages and compared using the log-rank test and multivariate Cox regression analysis. A propensity score was employed to adjust for the effect of mammographic screening on breast cancer while adjusting for covariates previously associated with the detection method. A 95% confidence level was used in all analyses.
Results: A total of 1,812 medical records were analyzed, and 1,507 patients were included in the statistical analyses. Among these, 313 (20.8%) asymptomatic patients were

diagnosed due to abnormal mammography findings (G1), and 1,194 (79.2%) presented symptoms before screening exams (G2). Significant differences between the study groups were identified in age, race/color, religion, marital status, nulliparity, and molecular subtype. Additionally, the groups differed in histologic grade, pathologic tumor, lymph node stage, and therapies received, such as conservative surgery, adjuvant chemotherapy, and radiotherapy. Median overall survival (OS) was not reached in either group. Overall survival at the fifth year was 69.5%, with a median follow-up of 72 months. The cumulative mortality at the fifth year, according to the detection method, was 10.93% (95% CI, 7.9%-14.9%) in G1 and 34.7% (95% CI, 32%-37.4%) in G2 ($p<0.001$). The detection method was associated with a substantial 5-year mortality reduction in univariate analysis (RR=0.42, 95% CI: 0.28-0.63). However, when adjusted for sociodemographic confounders associated with the detection method (age, marital status, religion, race, and previous pregnancy) using a propensity score, the reduction in mortality attributable to mammographic screening was 13.7% (95% CI: 8.9-18.5%, $p<0.001$), and 8.1% (95% CI: 1.4%-14.8%) when further adjusted for molecular subtype, tumor size, node status, and treatment modalities. Conclusion: The method of detection significantly impacts breast cancer survival despite demographic, clinical staging, molecular subtype, and therapeutic differences between screen-detected and symptomatic cases. The observed mortality reduction was lower than that reported in experimental studies and in countries with organized screening programs. Improving access to screening and screening coverage is crucial to achieving greater reductions in breast cancer mortality.

P2-09-06: Bi-annual mammography does not detect more local recurrences than annual mammography in Asian female patients with breast cancer

Byeongju Kang, Jeeyeon Lee, Soo Jung Lee, Hye Jung Kim, Won Hwa Kim, Yee Soo Chae, In-Hee Lee, Ho Yong Park

Background: According to NCCN recommendations, patients who have undergone breast-conserving surgery and radiation therapy are advised to have annual mammography 6 to 12 months after completing radiation therapy. However, mammography sensitivity is only 40-60% in Asian females[JL1] , who have a higher rate of dense breast tissue. The authors evaluated whether bi-annual mammography can detect more locoregional cancer recurrence than annual mammography in the early period after breast conserving surgery (BCS) in Asian women with breast cancer.
Methods: The data of 736 female patients who had received BCS with radiotherapy between 2011 and 2015 at Kyungpook National University Chilgok Hospital was reviewed. All patients were followed up after completing adjuvant treatments biannually for the first 3 years and annually for a further 7 years. Locoregional recurrence or distant metastasis was evaluated with blood tests, tumor markers, mammography, breast ultrasonography or MR, chest and abdominal CT scans, bone scans and PET/CT. In addition, locoregional recurrences was analyzed by examining which imaging modalities detected them.

Results: The mean age of the patients was 51.3 (SD, ±10.1) years and the average BMI was 23.6 (SD, ±0.5) kg/m2. During 10 years of follow-up, there were 47 cases (6.4%) of lococoregional recurrence, 31 cases (4.2%) of distant metastasis, and 44 cases (6.0%) of death. The organs where local recurrence occurred as single or multiple, were the ipsilateral breast (n=10, 21.3%), contralateral breast (n=20, 42.6%), and regional lymph nodes (n=18, 38.3%). There was a total of 29 cases of recurrence in the breast, with 8 cases confirmed within the first 3 years. In image surveillance performed at 6-month intervals, 5 cases (62.5%) of cumulative result were detected via mammography, and 7 cases (87.5%) via ultrasound. The incidence of recurrence showed in biannual mammography was as follows: no cumulative results at 6 and 12 months in the first year, 2 cumulative results at 18 and 24 months in the second year, and 5 cumulative results at 30 and 36 months in the third year. The results of the biannual analysis of breast cancer recurrence through mammography over the first 3 years were the same as those of the annual analysis.
Conclusion: In detecting early in-breast recurrence in Asian women with breast cancer, it was confirmed that biannual mammography did not detect more recurrences than annual mammography.

P2-09-07: Diagnostic performance of TILs-US Score and LPBC in biopsy specimens for predicting pathological complete response in patients with breast cancer

Hideo Shigematsu, Kayo Fukui, Akiko Kanou, Erika Yokoyama, Makiko Tanaka, Mutsumi Fujimoto, Kanako Suzuki, Haruka Ikejiri, Ai Amioka, Emiko Hiraoka, Shinsuke Sasada, Akiko Emi, Koji Arihiro, Morihito Okada

Background: TILs-US score is a non-invasive method for predicting lymphocyte-predominant breast cancer (LPBC) in surgical specimens. The diagnostic performance of TILs-US score for predicting pathological complete response (pCR) was compared with LPBC in biopsy specimens.
Methods: TILs ≥ 50% in biopsy specimens was defined as biopsy-LPBC, and a TILs-US score ≥ 4 was categorized as TILs-US score high. Basic nomogram for pCR was developed using stepwise logistic regression based on the smallest Akaike Information Criterion, and LPBC and TILs-US score nomograms were developed by integrating biopsy-LPBC or TILs-US scores into basic nomogram. The diagnostic performance of the nomograms was compared using area under the curve (AUC), categorical net reclassification improvement (NRI), and integrated discrimination improvement (IDI).
Results: This retrospective study evaluated 118 breast cancer patients, including 33 cases (28.0%) with biopsy-LPBC, 52 cases (44.1%) with TILs-US score high, and 34 cases (28.8%) achieving pCR. The sensitivity, specificity, positive likelihood ratio, negative likelihood ratio, and AUC for predicting pCR were 0.53, 0.82, 2.96, 0.57, and 0.68, respectively, for biopsy-LPBC, and 0.76, 0.69, 2.47, 0.34, and 0.73, respectively, for TILs-US score. The LPBC nomogram showed significant improvements in categorical NRI ($p = 0.023$) and IDI ($p = 0.007$) compared to the basic nomogram, but not in AUC ($p = 0.25$). Meanwhile, the TILs-US

nomogram exhibited significant improvements in AUC ($p = 0.039$), categorical NRI ($p = 0.010$), and IDI ($p < 0.001$).
Conclusions: The TILs-US score demonstrated diagnostic performance comparable to biopsy-LPBC to predict pCR in breast cancer treated with neoadjuvant chemotherapy.

P2-09-08: Correlating Breast Density with FDG-avidity on PET Imaging

YiLi Zhao, Mary Salvatore

Purpose: It is well documented that breast density is an independent risk factor for the development of breast cancer[1]. Unlike traditional mammograms, PET-CT is uniquely positioned to analyze both the anatomy and metabolism of the breast parenchyma. FDG-avidity seen on PET-CT has been shown to correspond to the proliferation and number of tumor cells, though uptake in different types of breast cancer is variable, [2,3]. High FDG activity is not specific to malignancy, however, and can reflect increased metabolic activity in physiologic tissue like brown adipose tissue [4]. Increased metabolic activity in breast fibroglandular tissue could help explain the increased risk of malignancy in dense breasts. This study evaluates the correlation between FDG-avidity and tissue density of the breast in patients without breast malignancy.
Patients and Methods: Radiology reports for PET-CTs from Jan. 1 - Sept. 1, 2023 were extracted from a single hospital site. Ten reports were selected in each age category (groups 30-39, 40-49, 50-59) in reverse chronological order. Inclusion criteria included female gender and complete visibility of bilateral breast tissue on PET-CT. Exclusion criteria included patients with primary breast cancer or with known metastases to the breast tissue (n=7), and prior breast procedures including implants (n=1).
Each breast was scored on a scale of 1-4 on CT based on BI-RADS guidelines for breast density [5]. On attenuation-corrected PET imaging, each breast was scored on a scale of 1-4 based on the percentage of tissue with FDG-avidity.
Results and Conclusion: There was a positive correlation between breast density and FDG-avid breast tissue with correlation coefficient (cc) of 0.53 ($p<0.01$, n=30). The positive correlation was maintained within each age category, cc= 0.45 in ages 30-39 ($p=0.04$, n=10), cc= 0.75 in ages 40-49($p<0.01$, n=10), and cc= 0.67 in ages 50-59 ($p<0.01$, n=10). For most patients, the FDG-avidity of the breast correlated directly with the amount of fibroglandular tissue, though exceptions included a patient with extremely dense breast tissue (4) and minimal FDG-avidity (1) and one with scattered fibroglandular tissue (2) but high FDG-avidity (4). Given this positive correlation, increased metabolic activity in breast fibroglandular tissue may explain the association between breast density and development of breast cancer.

P2-09-09: Image-based breast cancer risk assessment based on dense mammographic tissue subtypes

Andre Khalil, Joshua Hamilton, Anthony Attaya-Harris, Christine Lary, Kendra Batchelder

Introduction: Cancer prediction models that incorporate mammographic breast density measurements with other clinical factors report area under the ROC curve (AUC) ranges from 0.56 to 0.62 [1]. A major challenge in exploring the links between cancer risk and breast density lies in tumor microenvironment changes that promote a breast tumorigenic environment [2, 3]. The organization of stromal and glandular breast tissue subtypes plays a crucial role in influencing tumor invasion [4]. However, there has been limited research on subtypes of mammographic dense tissue and their potential links to risk. To address this, we developed a method that can segregate mammographic dense tissue into two textural subtypes: active, which is structurally reorganizing, versus passive [5, 6]. We found that tissue restructuring associates with early tumor onset and may be detectable before radiological diagnosis [7]. On an exploratory set of longitudinal screening mammograms, we demonstrated that the composition and temporal dynamics of dense tissue subtypes may influence cancer risk [7]. Now, using 13,323 mammography screenings from the OPTIMAM mammography image database [8, 9], we present a retrospective case-control analysis demonstrating the potential of using density subtypes as predictive metrics for breast cancer at three time points prior to diagnosis.
Methods: Standard bilateral mammographic screening views acquired on Hologic's Selenia units were categorized into three timeline groups: "Time 0": screening visits no more than 1.5 years prior to diagnosis (for n=798 cases) or their last assessment episode (for n=3747 controls); "Time 3": those within 1.5 and 4.5 years (n=341 cases; n=4908 controls); and "Time 6": those within 4.5 and 7.5 years (n=97 cases; n=3429 controls). Mammograms were analyzed following the method in [5, 6] to obtain the amount of each mammographic tissue subtype: fatty tissue, passive dense tissue, or active dense tissue. A generalized linear model was developed to predict cancer vs. control status with the predictive variables consisting of the amounts of fatty, passive dense, and active dense tissue from the four mammographic views. The model is strictly image-based and does not consider any other information. Our main objective was to assess the predictive accuracy of this model for the Time 3 group through calculation of the AUC. We also assessed the model for the Time 6 and Time 0 groups. A Kolmogorov-Smirnoff (KS) test was used to test the age populations.
Results: The Time 3 patient ages between the cases and controls were from the same distribution (KS test p-value = 0.14). The predictive model yielded AUC of 0.603 for the

Time 3 group. The AUC was 0.595 and 0.614 for the Time 6 and the Time 0 groups, respectively.
Conclusion: Our model is at least comparable or outperforms models from the literature (AUC 0.56 to 0.62), but without additional factors beyond the mammographic views, which shows potential for an eventual integration into clinical models [1]. The images and data used in this publication are derived from the OPTIMAM imaging database [8]. We would like to acknowledge the OPTIMAM project team and staff at the Royal Surrey NHS Foundation Trust who developed the OPTIMAM database, and Cancer Research UK who funded the creation and maintenance of the database.

P2-09-10: Accuracy of stereotactic vacuum-assisted breast biopsy for investigating suspicious calcifications in 2,274 patients a Public Hospital in Brazil

André Mattar, Marcelo Antonini, Andressa Gonçalves Amorim, Marina Diógenes Teixeira, Danielle Arbache, Ana Luisa de Souza Lopes, Paulo Leonardo Miranda Sposito, Marina Fleury de Figueiredo, Isadora Santelo Leonardo, Gabriella Amorim Baia, Fabrício Palermo Brenelli, Felipe Zerwes, Antonio Luiz Frasson, Eduardo de Camargo Millen, Luiz Henrique Gebrim

Backgroud: The cost and morbidity associated with surgical biopsy for breast cancer diagnosis have led many physicians to explore less invasive alternative procedures. Recently, image-guided percutaneous core-needle biopsy has become a commonly used method for diagnosing both palpable and non-palpable breast lesions. While core-needle biopsy has high sensitivity rates for nodules it has several disadvantaged in microcalcifications because of the potential for histological underestimation. Vacuum-assisted stereotactic biopsy (VAB) was developed to address some of these limitations, particularly in cases with uncertain malignant potential in pathological finding.
Objectives: To evaluate the accuracy of vacuum-assisted stereotactic biopsy (VAB) in the investigation of non-palpable suspicious calcifications.
Methods: In a retrospective study from July 2012 to November 2023 we included 2,274 women with suspicious calcifications detected on mammography (BI-RADS 4 and 5) that had VAB performed at Hospital da Mulher, São Paulo, Brazil. Fragments were obtained and sent to anatomopathological study; a metal clip was placed on the biopsy site. Four groups were analyzed, based on the biopsy results: benign, uncertain malignant potential (UMP), Ductal Carcinoma In Situ (DCIS) and invasive carcinoma (IC).

Results: Patients median age was 56y. Pathology results on VAB were classified respectively as benign n=1,525 (67.06%), UMP lesions n=87 (3.83%), DCIS n=488 (21.46%) and IC n=174 (7.65%). Benign and UMP lesions results were clustered to form a new group (lower risk lesions) and so DCIS and malignant lesions (higher risk lesions). The sensitivity of the method was 91.7 %, specificity was 97.1%, false negative rate was 3%, positive predictive value (PPV) was 92.4%, negative predictive value (NPV) was 96.9%. Interestingly 129 patients (5,67%) with benign results were submitted to surgery and 35.66% of them the results showed IC (n=23), DCIS (n-23) or UMP (n=25).
Conclusion: VAB has a good accuracy to distinguish lower and higher risk lesions groups. It has high predictive value in both benign and malignant lesions, guiding therapeutic planning. Correlation between the anatomopathological result and the imaging is crucial since patients with negative results who were submitted to surgical investigation presented a important percentage of malignant findings or findings of uncertain potential.

P2-09-11: Improved Prediction of Axillary Lymph Node Metastasis in Early-Stage Breast Cancer Using Deep Learning on Routine Mammography

Daqu Zhang, Looket Dihge, Ida Arvidsson, Pär-Ola Bendahl, Magnus Dustler, Julia Ellbrant, Kim Gulis, Malin Hjärtström, Mattias Ohlsson, Cornelia Rejmer, David Schmidt, Sophia Zachrisson, Patrik Edén, Lisa Rydén

Background: Sentinel lymph node biopsy is the standard axillary nodal staging procedure and is routinely performed. With a trend towards de-escalation of axillary surgery, recent studies indicate that prediction models incorporating imaging modalities can reassess the necessity of surgical axillary nodal staging. However, the clinical utility of MRI is constrained by accessibility, and ultrasound is highly operator-dependent. Mammography, the primary imaging modality for all breast cancer patients, has drawn little attention in nodal staging. This study aims to employ advancements in deep learning (DL) to comprehensively evaluate the potential of routine mammography for predicting nodal metastasis in preoperative clinical settings.
Methods: The study included 1,281 breast cancer patients (age: 62.7 ± 11.5 years, tumor size: 15.3 ± 8.0 mm) diagnosed between 2009 and 2017 at two hospitals in Region Skåne, Sweden. Among these patients, 378 were node-positive and 903 were node-negative. Patients diagnosed in 2017 (n=126) were assigned to the test set, while those from 2009-2016 (n=1,155) were used for model development and cross-validation by period and region (2009-2012 at site 1, 2015-2016 at site 2). Input characteristics included routine preoperative clinical data and features from core needle biopsies: age, BMI, menstrual status, mode of detection, histological grade, histopathological type, and molecular subtype. DL models were constructed in two steps. First, a vision transformer was developed to learn task-specific mammographic features through supervised learning, predicting tumor size, multifocality, lymphovascular invasion, and lymph node metastasis, using two resolutions: the region of interest (ROI) emphasizing the tumor and the full mammographic image. Next, prediction models were trained using both clinical and mammographic features.

Results: Double cross-validation on the development set showed that models using only preoperative clinical variables achieved an area under the receiver operating characteristic (ROC) curve (AUC) of 0.629 ± 0.020. Incorporating ROI-based mammographic features increased the AUC to 0.670 ± 0.018, while utilizing full images resulted in a comparable AUC of 0.669 ± 0.019. Predictive accuracy was improved by 3.4% for patients from 2009 to 2012 at site 1 and by 11.9% for patients from 2015 to 2016 at site 2. Notably, on the independent test set from 2017 at site 2, the combined model of preoperative clinical variables and full mammograms achieved an AUC of 0.784 ± 0.044, outperforming the clinical model that used postoperative tumor size and multifocality (AUC of 0.731 ± 0.051). Thus, DL applied to routine mammography enhanced the prediction of nodal metastasis by 10.6% compared to preoperative clinical models.
Conclusion: Our findings underscore that routine mammograms, particularly full images, can enhance nodal status prediction in clinical models. They have the potential to compensate for key postoperative predictors such as tumor size and multifocality, aiding in patient stratification prior to surgery. Interestingly, the added value of mammography for nodal staging varied largely across different periods and regions due to advancements in screening equipment and procedures.

P2-09-12: A Public Health Initiative To Enhance Screening Mammography (MMG) In Northeast Argentina Utilizing A Novel Thermal Screening Device & Breast Cancer Risk Assessment

Karina Maidana, Nickolas Stabellini, Jorge Salazar, Jaime Pira, Alberto J. Montero

Background: Breast cancer (BC) is the leading cause of cancer mortality in Argentina, with approximately 30% of cases diagnosed at an advanced stage. MMG is the cornerstone of BC screening; however, many obstacles remain. Many women either opt out or have poor access to screening MMG. Given these challenges, changes are needed. We hypothesized that empowering primary care providers to stratify patients (pts) based on BC risk & imaging urgency would enhance MMG rates.
Methods: A public health initiative was implemented in Corrientes, Argentina—the province with the 3rd highest BC incidence in the country. The initiative incorporated the use of Celbrea® (CEL) a single-use class I breast medical device designed to detect asymmetric temperature changes, FDA and ANMAT-cleared as an additional clinical support tool for breast disease detection (86% sensitivity, 87% specificity). The program adopted a prioritization system using BC risk assessment and CEL results. Pts at high risk for breast cancer and with a significant CEL result had the highest priority and underwent MMG within ≤2 weeks. Those at high risk with a non-significant CEL result, or average risk and significant CEL result, had intermediate screening priority, with a screening MMG performed within <2 months. Pts with average breast cancer risk and non-significant CEL had the lowest screening priority, with MMG performed within ≤12 months.
Results: 10,343 pts underwent CEL use, with 712 positive tests. The median age for the entire cohort was 43 [interquartile range (IQR) 34-52]. Other baseline demographic factors

(IQR): median BMI: 28.2 (24.6-32.4); current smoker: 13%; daily alcohol intake: 16%; median age of menarche: 13 (12-14); prior childbirth: 83%; median age first childbirth: 21 (18-25); % menopause: 32%; median age of menopause: 48 (43-50); family history of breast or ovarian cancer: 38%; dense breasts: 17%. The prior MMG rate was 41.8% (67.6% in pts with MMG officially recommended [n=3,532]), while 9.2% and 20.9% had MMG in the last 12 and 24 months (14.9% and 35.3% in pts with MMG officially recommended), respectively. In June-Dec 2022, 2,437 MMGs were performed. In Jun-Dec 2023, following implementation, the number increased to 4,127 (69% increase; p=0.008).
Conclusions: Baseline BC risk assessment and Celbrea® utilization for prioritizing MMG screening, led to a significant increase in screening MMG rates. This initiative encouraged many women at higher BC risk, who had never undergone a screening MMG, to have their first screening. Further prospective follow-up is warranted.

P2-09-14:Diagnostic Accuracy assessing residual disease in breast cancer patients receiving neoadjuvant systemic therapies (NST) is comparable between contrast enhanced mammography(CEM)& breast magnetic resonance imaging(MRI)across various cancer subtypes

Whitney Harris, Bhavika Patel, Heidi Kosiorek, Richard Sharpe, Karen Anderson, Donald Northfelt, Lida Mina, Felipe Batalini, Brenda Ernst, Carlos Vargas, Imon Banerjee, Patricia Cronin, Julie Billar, Richard Bold, Barbara Pockaj

Purpose: To compare the diagnostic accuracy of post-treatment contrast-enhanced mammography (CEM) to MRI in the detection of residual tumor following neoadjuvant systemic therapies (NST). Methods: This retrospective study included women with newly diagnosed breast cancer who underwent post NST imaging with either MR and/or CEM imaging from September 2014 to December 2023. Imaging findings on post-NST was compared with surgical pathology. For this study, pathological complete response (pCR) was defined as the absence of invasive cancer and/or DCIS within the breast at surgery. Radiological complete response (rCR) was defined as no residual tumor seen on post-contrast post-treatment imaging. Accuracy was further stratified by various breast cancer tumor subtypes. Sensitivity, specificity, PPV and NPV values were calculated. Results: We identified 397 unique patients with pathologically confirmed invasive breast cancer who underwent either post-treatment contrast-enhanced imaging, 338 (85%) with CEM, 313 (79%) with MR imaging, and 254 (64%) patients who had both CEM and MR. Mean age was 54 (range 25–83) years. 57% of patients were post-menopausal, 82% were white, 69% of patients had dense breasts. NST consisted of chemotherapy in 76% and endocrine therapy in 24% of patients. Tumor subtype analyses included 29% Triple Negative disease ER-/HER2-, 38% Estrogen driven (ER+/HER2-), and 33% HER2 positive disease (HER2+/ER+ 24% and HER2+/ER- 9%), 90% of tumors were clinical T1 or T2, 66% had no axillary disease. 57% of patients ultimately underwent mastectomy and 43% underwent BCT. rCR was identified in 47% (159/338) of cases by CEM and 39% (121/313) by MR. Overall, 35% (160/452) achieved pCR. Comparing CEM versus MRI for assessment of residual disease,

the sensitivity was 74% versus 81%, specificity 83% versus 71%, PPV 88% versus 82%, and NPV 65% versus 69% respectively. Specificity was higher for CEM as compared to MRI (p=0.02). NPV was lowest for ER+/HER2- subgroups for both CEM (39%) and MRI (44%). Conclusions: Diagnostic accuracy of post-treatment response on CEM imaging is comparable to that of MRI in assessing residual malignancy amongst various breast cancer tumor subtypes. Specificity (defined as the ability to correctly identify patients achieving pCR after preoperative therapy) was increased with CEM compared to MR imaging. Sensitivity (defined as ability to correctly identify residual disease (non-pCR) after preoperative therapy) is slightly better with MR than CEM.

P2-09-16: A Phase 1b/2 study of palazestrant (OP-1250) in combination with ribociclib, in patients with estrogen receptor-positive, human epidermal growth factor receptor 2-negative (ER+/HER2-), advanced or metastatic breast cancer

Virginia Borges, Jason A. Mouabbi, Jo Chien, Sara Nunnery, Cynthia X. Ma, Shakeela Bahadur, David A. Potter, Dhanusha Sabanathan, Antoinette R. Tan, Lixian Sun, Morena Shaw, Daniela Vecchio, Nancy U. Lin

Background: Aromatase inhibitors (AIs) in combination with the cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) ribociclib improve outcomes in patients (pts) with ER+/HER2- advanced or metastatic breast cancer (mBC) and is a current standard of care for first-line treatment. However, resistance eventually develops, most commonly (~50%) due to mutations in ESR1.
Palazestrant (OP-1250) is a small molecule oral complete estrogen receptor (ER) antagonist (CERAN) and selective ER degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity of both wild-type (ESR1-wt) and mutant (ESR1-mut) ER. In a phase 1/2 monotherapy study (NCT04505826) in pts with previously treated ER+/HER2- mBC, palazestrant was well tolerated with favorable pharmacokinetics (PK) supporting once a day (qd) dosing, and antitumor activity observed in both ESR1-wt and ESR1-mut disease at the recommended phase 2 dose (RP2D) of 120 mg. In preclinical studies, palazestrant in combination with ribociclib demonstrated activity in both ESR1-wt and ESR1-mut breast cancer models.
This study evaluates the safety, PK, and antitumor activity of palazestrant in combination with ribociclib in pts with ER-positive, HER2– mBC (NCT05508906).
Methods: Pts with evaluable ER+, HER2– mBC with ≤2 prior ETs (prior CDK4/6i allowed) and ≤1 prior line of chemotherapy were included. Pts received oral palazestrant at escalating doses of 30, 60, and 120 mg qd in combination with the approved dose of oral ribociclib (600 mg qd on a 3-weeks-on, 1-week-off schedule every 4 weeks). The RP2D dose of 120 mg of palazestrant was administered in dose expansion.
Results: As of May 14, 2024, 63 pts received 30 mg (n=3), 60 mg (n= 3) or 120 mg (n=57) of palazestrant in combination with ribociclib. Forty-two pts (67%) had measurable disease and 35 (56%) had visceral disease at baseline. Forty-six pts (73%) received prior CDK4/6i.

Among them, 34 (74%) pts received one prior treatment and 12 (26%) received two prior treatments with CDK4/6i ; 34 (74%) pts received prior palbociclib, 11 (24%) prior abemaciclib and 8 (17%) prior ribociclib. Fifteen pts (24%) did not receive any prior treatment in the metastatic setting[LNU1] [MB2] [MS3] . Mutations in ESR1 were present at baseline in 17 pts (29%).
At data cutoff, [MS4] [SK5] [MS6] [MS7] 39 pts (62%) remain on treatment. No dose-limiting toxicities were observed. The most common treatment-related AEs (TRAEs) across all dose levels were neutropenia (78%), nausea (65%), fatigue (46%), decreased WBC (40%), diarrhea (35%), and anemia (32%). The most common grade 3 and 4 TRAE was neutropenia (36% and 10%, respectively). Anti-tumor activity including partial responses and prolonged disease stabilization were observed with the longest treatment duration of 12 months and ongoing. Clinical benefit rates (CBR) were 79% among all CBR-eligible pts (n=29) and 78% among the CBR-eligible patients with prior CDK4/6i treatment (n=23). No meaningful effect of palazestrant on ribociclib PK or ribociclib on palazestrant PK were observed, consistent with previously reported data.
Conclusions: Palazestrant in combination with ribociclib was well tolerated and safety was consistent with the known profiles of each drug and similar to combinations of ribociclib with ET. Encouraging preliminary efficacy from the combined agents, including in pts with prior CDK4/6i treatment was observed. Updated data will be presented. Findings from this study support further clinical development of palazestrant in combination with ribociclib for the first line treatment of ER+/HER2–mBC.

P2-09-17: Precision medicine based on similarity network fusion (SNF) subtypes of multi-omics in CDK4/6 inhibitor failed HR+/ HER2- advanced breast cancer: the Linux trial

Wenjuan Zhang, Xi Jin, Huiping Li, Xiaohua Zeng, Peng Ji, Xiyu Liu, Li Chen, Xinyi Sui, Linxiaoxi Ma, Yue Gong, Chao Chen, Yuee Teng, Jing Shi, Aodi Li, Lei Zhao, Jin Yang, Nan Wang, Yaxin Liu, Hanfang Jiang, Ran Ran, Ruyan Zhang, Bin Shao, Xinyu Gui, Linhui Zhang, Wenyan Chen, Yun Wang, Qiang Peng, Tao Sun, Yujun Jiang, Yangyang Duan, Yufeng Jia, Fangyuan Dong, Dan Lv, Ningning Zhang, Xinrui Liang, Zhigang Zhuang, Shusen Wang, Deyuan Fu, Sujie Ni, Zhixian He, Jiong Wu, Keda Yu, Guangyu Liu, Xin Hu, Yizhou Jiang, Zhonghua Wang, Lei Fan

Background: Endocrine therapy combined with CDK4/6 inhibitor represents the first-line standard treatment for HR+/HER2- metastatic breast cancer. However, there is no well-defined standard of care following resistance to CDK4/6 inhibitors. In previous study, we innovatively classified HR+/HER2- breast cancers into four subtypes using large-scale multi-omics data and similarity network fusion (SNF) (Nat Genet. 2023) : SNF1 for canonical luminal, SNF2 for immunogenic, SNF3 for proliferative and SNF4 for receptor tyrosine kinase (RTK)-driven. This platform trial aimed to evaluate the efficacy and safety of precision therapy based on SNF subtyping in patients with HR+/HER2- metastatic breast cancer who have failed CDK4/6 inhibitors treatment .

Methods: The Linux trial was an ongoing, multi-center, open-label, randomized controlled phase II platform trial utilizing a Bayesian Optimal Interval design. Eligible participants had histologically confirmed HR+/HER2- breast cancer that had progressed with a CDK4/6 inhibitors treatment for metastatic disease. Participants were categorized into four SNF subtypes and randomly assigned (2:1) to receive either subtyping-based precision therapy or physician's choice of chemotherapy (TPC) . The subtyping-based precision therapies included: everolimus (10 mg orally daily) + fulvestrant for SNF1, camrelizumab (200 mg intravenously on days 1 and 15) and famitinib (10 mg orally daily) + TPC for SNF2, fuzuloparib (100 mg orally bid) + TPC for SNF3, and apatinib (250mg orally daily) + TPC for SNF4. The primary endpoint was the objective response rate (ORR) for precision treatment group versus the control group in the intention-to-treat (ITT) population. Safety was analyzed in all patients who received at least one dose of the study drugs and had safety records.
Results: Between Jan 16, 2023 and May 23, 2024, 110 female participants were enrolled and randomly assigned to the subtyping-based group (n=70) or control group (n=40), with a median of two previous lines of therapy (range, 1-6). At the data cutoff, the median follow-up was 9.1 months. The ORR was 48.6% (34/70, 95% CI: 36.6%–60.6%) in the subtyping-based group compared to 17.5% (7/40, 95% CI: 5.2%–29.8%) in the control group in ITT patients. The subgroup ORRs of subtyping-based groups vs. control groups were 10.0% vs. 10.0% for SNF1, 70.0% vs. 30.0% for SNF2, 30.0% vs. 20.0% for SNF3, 65.0% vs. 10.0% for SNF4. Treatment-related adverse events were well managed. Grade 3-4 treatment-related adverse events occurred in 24 participants (34.3%) in the subtyping-based group, compared to 11 participants (27.5%) in the control group. No treatment-related deaths were reported in either group.
Conclusions: Our findings highlight the potential clinical benefits of SNF subtyping guided precision medicine in patients with HR+/HER2- breast cancer, suggesting a direction for further clinical investigation. Phase III randomized clinical trials for SNF2 and SNF4 assessing the efficacy of SNF subtyping-based strategies are now underway. (Linux, ClinicalTrials.gov, NCT05594095)

P2-09-18: Comparison of Suboptimal vs. Adequate Ovarian Suppression during Adjuvant Endocrine Therapy for Premenopausal Women with Breast Cancer: An Exploratory Analysis of the PREFER and GIM 23 Studies

Simone Nardin, Edoardo Chiappe, Chiara Lanzavecchia, Tommaso Ruelle, Irene Giannubilo, Maria Grazia Razeti, Roberto Borea, Lucrezia Barcellini, Diletta Favero, Marta Perachino, Luca Arecco, Chiara Molinelli, Davide Soldato, Maria Maddalena Latocca, Alessia Levaggi, Giulia Buzzatti, Claudia Bighin, Valentina Barbero, Michela Lia, Barbara Cardinali, Marco Bruzzone, Eva Blondeaux, Lucia Del Mastro, Matteo Lambertini, Francesca Poggio

Background: The combination of LHRH analog (LHRHa) and aromatase inhibitors (AI) represents the standard adjuvant endocrine therapy (ET) for premenopausal women at intermediate and high risk of relapse. However, complete ovarian suppression may not be

achieved through LHRHa, and international guidelines provide different indications on how to monitor these patients and how often to evaluate hormonal status.

Methods: PREFER (NCT02895165) and GIM 23-POSTER (NCT05730647) are two Italian prospective, observational studies enrolling premenopausal women eligible to receive (neo)adjuvant chemotherapy and/or adjuvant ET. We conducted an exploratory analysis to investigate which factors were associated with suboptimal ovarian suppression during LHRHa treatment. We divided the enrolled patients into two groups: patients with suboptimal ovarian suppression (non-suppressed group) and patients with adequate ovarian suppression (suppressed group), based on estradiol levels (higher than 25.1 ng/L for non-suppressed) or resumption of menstruation at least 3 months after the start of ET plus LHRHa. Clinical features, treatment type and outcomes were compared between the two groups. Kaplan Meier method was used to estimate the percentage of patients with suboptimal suppression and Cox models were used to explore possible related factors.

Results: As of June 2024, out of 1863 patients registered (827 in the PREFER and 1036 in the GIM 23), all subjects enrolled in the coordinating center (n=545) were included in the present analysis. Median follow-up was 44.4 months (interquartile range [IQR] 20.6-84). Among the patients undergoing adjuvant ET (n=343), 202 received LHRHa plus AI, and 141 LHRHa plus tamoxifen: 315 have been included in the suppressed group, while 28 in the non-suppressed group. Median age at diagnosis was 38 years (IQR 33-44) in the non-suppressed group compared to 39 years (IQR 36-43) in the suppressed group. Clinical characteristics, including age, BMI, baseline FSH, and estradiol levels, did not correlate with suboptimal ovarian suppression. Regarding treatment, no significant differences in developing suboptimal ovarian suppression were found between those who received LHRHa during chemotherapy, those who did not receive LHRHa during chemotherapy, and those who were not administered chemotherapy. On the contrary, the use of AI was associated with an increased risk of suboptimal ovarian suppression: HR 12.83 (95% CI 3.01-54.65; p=0.001). The proportion of patients not-suppressed was 5.1% (95% CI 3.2-8.2) in the first year of LHRHa treatment and 10.5% (95% CI 7.1-15.4) after five years.

Conclusions: Among premenopausal women receiving LHRHa as part of adjuvant ET, approximately 10% did not achieve complete ovarian suppression. Since no baseline clinical or treatment features seem to be associated with suboptimal ovarian suppression, except for the combination with AI, all patients receiving this treatment should perform serial monitoring of hormonal profile throughout the years of adjuvant ET to identify those who are not adequately suppressed.

P2-09-19: Efficacy of cyclin-dependent kinase 4/6 inhibitor + endocrine therapy in patients w/ hormone receptor-positive, HER2-negative advanced or metastatic breast cancer w/ liver or lung only metastases: a US Food & Drug Administration pooled analysis

Raissa Kentsa, Hee-Koung Joeng, Melanie Royce, Suparna Wedam, Mirat Shah, Preeti Narayan, Xin Gao, Joyce Cheng, Mallorie Fiero, Shenghui Tang, Christy Osgood, Richard Pazdur, Paul Kluetz, Jennifer Gao, Laleh Amiri-Kordestani

Background: The standard of care treatment for patients (pts) with hormone receptor-positive (HR+), HER2-negative metastatic breast cancer is a CDK 4/6 inhibitor (CDKI, abemaciclib, palbociclib, ribociclib) added to endocrine therapy (ET). Patients with liver or lung metastases may have a worse prognosis and derive different amounts of benefit from the addition of a CDKI. This pooled analysis examines whether patients with only lung (LuOM) or liver (LiOM) metastases may respond differently to CDKI-based treatment.
Methodology: We pooled individual patient data from 7 randomized trials of CDKI+ET for patients with HR+, HER2-negative MBC submitted to the FDA before January 1, 2024, in support of marketing applications. The primary endpoint was investigator-assessed progression-free survival (PFS), and overall survival (OS) was a key secondary endpoint in all 7 trials. The analyses included all pts who received at least 1 dose of CDKI/placebo (PBO) with ET (aromatase inhibitor [AI] anastrozole or letrozole, or fulvestrant [F]). Using descriptive statistics, we performed a prespecified exploratory subgroup analyses in patients with LiOM or LuOM. Pts with bone-only disease, pleural lesions/effusion, ascites, other visceral metastasis, only nodal disease, and both lung and liver metastases were excluded. Analyses were performed in subgroups of pts treated with CDKI+AI only and pts with CDKI+F only. OS analyses were only performed on pts treated with CDKI+F based on data available at the time of this analysis. Median (med) PFS and OS were estimated using Kaplan-Meier (K-M) methods. Hazard ratios (HR) with 95% confidence intervals (CIs) for PFS and OS were estimated using Cox regression models. for PFS and OS were estimated using Cox regression models.
Findings: Seven trials were used for PFS analyses (n=4200) and 1582 pts met inclusion criteria for the LiOM (n=651) and LuOM (n=931). Key baseline demographic and prognostic factors appeared similar between the subgroups. Accuracy of site of metastases and treatment allocation were limited to information captured in trials and datasets.
LuOM PFS: 389 pts received CDKI+AI, 248 pts received PBO+AI, 197 pts received CDKI+F, and 97 pts received PBO+F. Med PFS was 25.3 mo (21.6-28.1) for CDKI+ET vs 15.2 mo (13.5-19.2) for PBO+ET (HR 0.64, 95% CI 0.53-0.78). Med PFS for CDKI+AI was 27.8 mo (23.1-31.1) vs 16.7 mo (13.8-24.2) for PBO+AI (HR 0.60, 95% CI 0.47-0.76). Med PFS for CDKI+F was 19.6 mo (13.8-not estimable [NE]) vs 14 mo (11.1-8.7) for PBO+F (HR 0.72, 95% CI 0.51-1.00).
LiOM PFS: 142 pts received CDKI+AI, 141 pts received PBO+AI, 234 pts received CDKI+F, and 134 pts received PBO+F. Med PFS was 11.2 mo (9.4-13.1) for CDKI+ET vs 5.6 mo (3.6-7.0) for PBO+ET (HR 0.59, 95% CI 0.49-0.72). Med PFS for CDKI+AI was 13.1 mo (10.4-14.9)

vs 9.4 mo (5.6-11.2) for PBO+AI (HR 0.63, 95% CI 0.47-0.84). Med PFS for CDKI+F was 9.4 mo (7.6 -12.9) vs 3.4 mo (2.0-5.4) for PBO+F (HR 0.51, 95% CI 0.40-0.65).
Three trials were used for OS analyses (n=1948). CDKI+F OS (n=662): 431 pts received CDKI+F (197 LuOM and 234 LiOM) and 231 pts received PBO+F (97 LuOM and 134 LiOM). In LiOM, med OS was 31.8 mo (28.0-36.5) for CDKI+F vs 25.3 mo (21.9-31.8) for PBO+F (HR 0.77, 95% CI 0.59-1.01). In LuOM, med OS was 48.2 mo (41.5- NE) for CDKI+F vs 51.6 mo (36.3-NE) for PBO+F (HR 0.90, 95% CI 0.61-1.31), although these results should be interpreted with caution due to the high level of censoring after 3 years and limited follow up. KM curve of LuOM suggested non-proportional hazards; a restricted mean survival time analysis showed a difference at 54.4 mo of 0.98 mo (SE 2.2).
Conclusion: Prior results show that pts with liver/lung metastases benefit from the addition of CDKI to ET. This pooled analysis suggests there may be differences in amount of benefit with adding CDKI to ET based on the site of the metastasis and the choice of ET. Further research is needed to understand which subgroup of pts with lung metastases may benefit more or less from adding CDKI to ET.

P2-09-20: Impact of body mass index (BMI) on the safety and efficacy of ribociclib (RIB) in patients (pts) with HR+/HER2- advanced breast cancer (ABC): pooled analysis of the MONALEESA (ML)-2, -3, and -7 trials

Yoon-Sim Yap, Alexis LeVee, Mario Campone, Sherko Kummel, Yeon Hee Park, Yen-Shen Lu, Vered Stearns, Fatima Cardoso, Eric Winer, Melissa Gao, Gary Sopher, Yogesh Chattar, Joanne Mortimer

Background: Studies evaluating the relationship between BMI and outcomes in breast cancer have had conflicting results. While some studies have found obesity to be associated with lower efficacy in early breast cancer, the same relationship has not been consistently found in ABC. To date, few studies have examined the effect of BMI on outcomes in pts receiving CDK4/6 inhibitors (CDK4/6i) + endocrine therapy (ET), which is the recommended standard of care in first-line HR+/HER2− ABC. The individual ML trials have shown consistent benefit with RIB + ET in pts with HR+/HER2− ABC. This pooled analysis examined the effect of BMI on the efficacy and safety of first-line RIB + ET in pts with HR+/HER2− ABC in the ML trials.
Methods: ML-2, -3 and -7 are randomized, phase 3, placebo (PBO)-controlled studies that investigated RIB (600 mg) + ET (letrozole, fulvestrant, or anastrozole) in pts with HR+/HER2− ABC. Pts who received tamoxifen in ML-7 or had early relapse (≤12 months after [neo]adjuvant ET) were excluded from this analysis. Given the similar efficacy across BMI subgroups (<25, 25 to <30, and ≥30) and the small number of pts who were underweight, pts were categorized into 2 BMI groups for this analysis: <25 (underweight + normal weight) and ≥25 (overweight + obese). Progression-free survival (PFS) and overall survival (OS) between treatment arms stratified by study and liver/lung metastases were evaluated by Kaplan-Meier methods. Safety and tolerability outcomes included the frequency of adverse events (AEs), dose reductions, and dose interruptions.

Results: Of the 1190 pts (RIB, n = 655; PBO, n = 535), 484 (41%) had a BMI <25 (underweight 6%; normal weight 94%), and 706 (59%) had a BMI ≥25 (overweight 55%; obese 45%). Median PFS was longer with RIB vs PBO in both BMI groups (BMI <25: 30.1 vs 15.0 mo; HR 0.56; 95% CI 0.44-0.70 and BMI ≥25: 35.7 vs 19.4 mo; HR 0.56; 95% CI 0.47-0.68). Longer median OS was observed with RIB vs PBO in both BMI groups (BMI <25: 63.4 vs 51.4 mo; HR 0.77; 95% CI 0.60-0.98 and BMI ≥25: 73.9 vs 57.6 mo; HR 0.70; 95% CI 0.57-0.87). In the RIB arm, fewer pts received subsequent chemotherapy in the BMI ≥25 group vs BMI <25 (26% vs 33%), while more pts received subsequent targeted therapy (including CDK4/6i) in the BMI ≥25 group vs BMI <25 (30% vs 25%). In the RIB arm, lower rates of all-grade (G) and G3/4 neutropenia were observed in pts with BMI ≥25 vs <25 (all grade 71% vs 85%; G3/4 58% vs 76%); however, the rates of hepatobiliary toxicity (all grade 30% vs 29%; G3/4 15% vs 12%) and QT interval prolongation (all grade 10% vs 11%; G3/4 4% vs 4%) were similar between BMI groups. In the RIB arm, dose reductions (41% vs 55%) and dose interruptions (71% vs 80%) due to AEs were less frequent in the BMI ≥25 group vs BMI <25, and a longer median time to first dose reduction (24 vs 9.5 mo) and time to drug discontinuation (25.9 vs 19.9 mo) were observed in pts in the BMI ≥25 group vs BMI <25.
Conclusion: This pooled analysis demonstrated that RIB + ET vs PBO + ET improved PFS and OS in pts with HR+/HER2– ABC, regardless of BMI. Pts with BMI ≥25 experienced a lower incidence and severity of neutropenia, less frequent dose reductions and interruptions, and longer time to first dose reduction and drug discontinuation vs pts with BMI <25. This study provides additional evidence for the benefit of RIB + ET in pts with HR+/HER2– ABC across BMI categories.

P2-09-21: Low-level Aurora kinase A (AURKA) amplification as a novel personalized biomarker of CDK4/6 inhibitor (CDK4/6i) resistance in patients with hormone-receptor positive (HR+) metastatic breast cancer

Seth Wander, Ezgi Karaesmen Rizvi, Roosheel Patel, Erik Knudsen, Georg F. Bischof, Lisa D. Eli, Karthik Giridhar

Background: CDK4/6i have established roles in treating patients (pts) with high-risk early-stage and metastatic HR+/HER2- breast cancer (HR+ MBC). Understanding the genomic and molecular factors that dictate CDK4/6i response is a critical area of research. Low-level copy number gains in the mitotic spindle regulator AURKA have been implicated in promoting CDK4/6i resistance via whole-exome sequencing of tumor samples, and constitutive overexpression provokes resistance in vitro [Wander et al. Cancer Discov 2020]. Developing a clinical biomarker of AURKA copy number gain poses unique challenges given the generally low-level AURKA gain observed in resistant samples. Validation of a reliable assay to detect AURKA-dependent CDK4/6i resistance in the clinic may enable personalized use of emerging AURKA inhibitors such as alisertib, which is currently being evaluated for this indication (ClinicalTrials.gov identifier NCT06369285).
Methods: De-identified clinical and genomic records of pts with HR+ MBC in the Tempus

database whose tumors were sequenced using xT (DNA) and xR (RNA) were investigated. Tempus xT is a targeted, tumor–normal matched DNA panel that detects single-nucleotide variants, insertions and/or deletions, and copy number variants in 648 genes. Tempus xR is a whole-exome capture, next-generation sequencing assay that identifies transcriptional evidence of chromosomal rearrangements resulting in expression of fusion RNA species. Copy number analyses were performed with a proprietary algorithm assessing tumor purity, ploidy, and B-allele frequencies to estimate copy numbers and minor allele counts. RNA-based analyses classified low and high expressors based on median gene expression values. Real-world progression-free survival (rwPFS) was the time from start of CDK46/i to first recorded disease progression (determined by the primary treating oncologist), death from any cause, or initiation of a subsequent treatment line. Survival analyses were right-censored at 5 years.
Results: 848 pts with HR+ MBC with DNA sequencing prior to CDK4/6i were identified. Common pathogenic genomic alterations included PIK3CA (SNV: 43.7%; CNV: 2.4%) and ESR1 (SNV: 12.2%; CNV: 6%; fusion: 1.8%). 4.1% of biopsy samples harbored RB1 alterations. AURKA copy number gains were identified in 15.0% of pts, with most demonstrating low-level amplification (copy number 4–7: 13.8%; copy number >7: 1.2%). Of note, these low-level amplifications would not routinely be reported by available sequencing platforms in clinical settings. Linear regression modeling showed that AURKA copy number correlated with RNA expression (p-value <0.001). Overall, 713 pts with DNA sequencing prior to CDK4/6i exposure also had rwPFS information. Those whose tumors harbored high- or low-level AURKA amplifications (n=116) had inferior rwPFS on CDK4/6i (9.9 vs 17 months for no AURKA amplification (n=597; p=0.00032).
Conclusions: In this large, real-world translational research cohort of pts with HR+ MBC, low-level AURKA copy number gain was common. These data report the first evidence suggesting that low-level amplifications in AURKA, which conventional sequencing platforms miss, can provoke meaningful changes in gene expression as assessed via RNA transcriptome analysis. Further, low-level AURKA amplifications predict inferior outcomes on CDK4/6i for pts with HR+ MBC. Real-world clinical data for pts whose tumors harbored RB1 mutations, which have been associated with alisertib sensitivity in both the preclinical and clinical settings, trended with shorter rwPFS on CDK4/6i in this dataset and will be presented at the meeting. Efforts to refine these and other potential biomarkers that may guide clinical deployment of alisertib are ongoing.

P2-09-22:First-line inavolisib/placebo + palbociclib + fulvestrant in PIK3CA-mutated, hormone receptor+, HER2- locally advanced/metastatic breast cancer w/ relapse during/within 12 months of adjuvant endocrine therapy completion: INAVO120 long-term safety

Cristina Saura, Nicholas Turner, Komal L. Jhaveri, Seock-Ah Im, Sibylle Loibl, Peter Schmid, Sherene Loi, Dejan Juric, Dimitrios Tryfonopoulos, Philippe L. Bedard, Yoon Sim Yap, Rafael Villanueva Vazquez, Erhan Gokmen, Igor Bondarenko, Xiaojia Wang, Konstantinos Papazisis,

Eirini Thanopoulou, Noopur Shankar, Samuel Lim, Yanling Jin, Thomas J. Stout, Kevin Kalinsky

Background: INAVO120 (NCT03006172) previously demonstrated a statistically significant and clinically meaningful improvement in investigator-assessed progression-free survival (stratified hazard ratio 0.43; 95% CI, 0.32 to 0.59; P<0.0001) with inavolisib (inavo) + palbociclib (palbo) + fulvestrant (fulv) vs placebo + palbo + fulv, with manageable safety and good tolerability. Here we report long-term safety data from the inavo arm.
Methods: Safety and exposure analyses were conducted in all patients (pts) who received ≥1 dose of any study treatment (tx) (Safety Analysis Set; SAS). The current analysis includes all pts in the inavo arm on study tx for ≥1 year (yr) and those pts on study tx for ≥2yr. Demographic data are reported in the Full Analysis Set (FAS); defined as all pts who were randomized to receive study tx. NCI-CTCAE v5.0 was used to report safety data.
Results: The SAS and FAS populations included 162 and 161 pts in the inavo arm, respectively; in both the SAS and FAS populations, 69 pts were on study tx for ≥1yr and 27 were on study tx for ≥2yr (cut-off date: Feb 2, 2024).
The median ages were 53.0yr (range: 27–77) and 52.0yr (range: 27–69) for the 1yr and 2yr populations, respectively. The median tx durations for inavo were 21.6 months (range: 12.3–42.9) and 29.9 months (range: 25.5–42.9); the median relative dose intensities for inavo were 96.7% (range: 39.7–100.0) and 96.8% (range: 48.8–100.0).
All pts experienced an adverse event (AE). In the respective 1yr and 2yr populations, 88.4% and 88.9% of pts had a grade 3–4 AE. The most common grade 3–4 AEs were neutropenia, neutrophil count decreased, leukopenia, and white blood cell count decreased (55.1%, 31.9%, 8.7%, and 8.7%, respectively) in the 1yr population; and neutropenia, neutrophil count decreased, anemia, leukopenia, white blood cell count decreased, and anal fistula (51.9%, 29.6%, 7.4%, 7.4%, 7.4%, 7.4%, respectively) in the 2yr population. Grade 5 AEs were reported in 2.9% and 0% of pts; while serious AEs were reported in 27.5% and 44.4% of pts, respectively. All pts experienced an AE related to any study tx; 91.3% and 88.9%, respectively, experienced an AE related to inavo.
The incidence of key selected AEs (hyperglycemia, diarrhea, stomatitis/mucosal inflammation, and rash; grouped terms) were 63.8%, 56.5%, 55.1%, and 36.2% in the 1yr population; and 59.3%, 66.7%, 40.7%, and 44.4% in the 2yr population. Key selected AEs mainly occurred during earlier tx cycles.
Discontinuation from any study tx due to an AE was reported in 1.4% and 3.7% of pts, respectively; no pts discontinued inavo due to an AE in either long-term population. Inavo dose interruptions due to an AE were reported in 79.7% and 85.2% of pts; the most common AE leading to inavo dose interruption was hyperglycemia (30.4% and 25.9%) in both long-term populations. Inavo dose reductions due to an AE were reported in 18.8% and 14.8% of pts. The most common AEs leading to inavo dose reductions were hyperglycemia (2.9%) and stomatitis (2.9%) in the 1yr population, while in the 2yr population the AEs leading to inavo dose reductions were diarrhea, stomatitis, papulopustular rosacea, platelet count decreased, hyperglycemia, and myalgia (one pt each [3.7%]).
Conclusions: The long-term safety profile of inavo + palbo + fulv in the populations on study

tx for ≥1yr and ≥2yr was consistent with the INAVO120 SAS population reported previously, and similar to the long-term safety data of the phase 1 GO39374 study (NCT03006172). No new or unexpected AEs were reported.

P2-09-23: Differential outcomes of patients with HR-positive/HER2-negative metastatic breast cancer and a pathogenic BRCA1/2 or PALB2 variant under first line CDK4/6 inhibition

Timothé Guinel, Amélie Lusque, Audrey Mailliez, Vincent Massard, Isabelle Desmoulins, Monica Arnedos, Anthony Gonçalves, Thomas Bachelot, Suzette Delaloge, Jean-Sebastien

Background: Patients (pts) with HR-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (MBC) and pathogenic BRCA1/2 or PALB2 variants may derive less absolute benefit from CDK4/6 inhibitors (CDK4/6i) and endocrine therapy (ET).

Methods: The ESME MBC platform (NCT03275311) is a French real-world database including data from each newly diagnosed MBC patient having initiated at least one treatment from 2008 onwards in 18 comprehensive cancer centers. All women who initiated a first line treatment with CDK4/6i + ET between 2013 and 2023 were selected. Multivariable models including a Cox proportional hazard with a time-varying approach and landmark analyses at different timepoints (at the initiation of the first-line therapy and at 6 months after the initiation of the first line) assessed the association between BRCA and PALB2 status (categorized as BRCA/PALB2m (mutated), BRCA/PALB2wt (wild type), and untested), with progression-free (PFS) and overall survival (OS).

Results: Among 21696 pts with HR+/HER2- MBC, 4820 received 1st line ET + CDK4/6i and were eligible for this analysis (n=90 BRCA/PALB2m, n=523 BRCA/PALB2wt, n=4207 untested at the initiation of the first line). CDK4/6i included palbociclib (74%), ribociclib (17%), abemaciclib (13%) while ET partner included aromatase inhibitor (78,3%), fulvestrant (15,5%), or other (6,3%). BRCA/PALB2m carriers were younger and has less de novo MBC compared to untested patients. At the cut-off date of 2024/05/16, the median follow-up was 44.0m [43.1-45.1]. Median first line PFS was significantly shorter in BRCA/PALB2m pts compared with BRCA/PALB2wt and untested ones: 11.2m [8.9-16.1], 15.7m [14.2-17.3] and 18.9m [18.0-20.0] in BRCA/PALB2m, BRCA/PALB2wt and untested patients, respectively. In the multivariable analysis (including age, number of metastatic sites, presence of visceral metastases, de novo status, tumor grade and type of relapse (endocrine sensitive/resistant status), BRCA/PALB2m patients had a lower PFS compared to BRCA/PALB2wt patients (adjusted HR [95% CI] 1.48 [1.15; 1.90], p=0.003). Time-varying approach and landmark analysis at 6-month showed consistent results. This lower PFS did not translate into a lower adjusted OS with a median OS of 49.7m [42.2-not reached] and 50.1m [45.1; 57.2] in BRCA/PALB2m and BRCA/PALB2wt patients respectively (adjusted HR [95% CI] 0.93 [0.64; 1.36]).

Conclusion: In this large cohort of HR+/HER2− MBC patients treated with first line CDK4/6i+ ET, pathogenic variants identified in BRCA or PALB2 genes are associated with a significantly lower PFS. The role of PARPi as first line therapy for these patients is currently investigated (NCT06380751) and further research is needed to determine if similar differences are observed in early breast cancer.

P2-09-24: Correlation of TROP2 expression with outcomes of sacituzumab govitecan with or without pembrolizumab in patients with metastatic hormone receptor-positive/HER2-negative breast cancer: an exploratory analysis from the phase II SACI-IO HR+ trial

Ana Garrido-Castro, Se Eun Kim, Mengni He, Jennifer Desrosiers, Rita Nanda, Yara Abdou, Amy S. Clark, Ruth L. Sacks, Thomas O'Connor, Natalie Sinclair, Steve Lo, Amy Thomas, Eileen Wrabel, Molly DiLullo, Tasnim Rahman, Katherine Junkins, Hajer Rahee, Ashka Patel, Paulina B. Lange, Tess O'Meara, Tanya E. Keenan, Deborah A. Dillon, Nancy U. Lin, Harold J. Burstein, Elizabeth A. Mittendorf, Nabihah Tayob, David L. Rimm, Sara M. Tolaney

Background: Sacituzumab govitecan (SG) is a TROP2-directed antibody drug conjugate (ADC) approved for previously treated triple negative and hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (MBC) based on improvements in progression-free (PFS) and overall survival (OS) compared to chemotherapy (CT). Benefit with SG was observed regardless of TROP2 expression by immunohistochemistry (IHC), although the increase in response and survival rates with SG was greater in patients (pts) with higher TROP2 levels. SACI-IO HR+ is a randomized, open-label phase II study that compared SG with or without pembrolizumab in HR+/HER2- MBC (NCT04448886). Here we report the correlation of TROP2 expression by quantitative immunofluorescence (QIF) with clinical outcomes.

Methods: Pts with unresectable locally advanced or metastatic HR+ (ER≥1% and/or PR≥1%), HER2- breast cancer treated with ≥1 prior endocrine therapy and 0-1 chemotherapy for MBC were randomized 1:1 to Arm A (SG plus Pembrolizumab) or Arm B (SG). TROP2 expression was measured centrally by QIF. FFPE tissue (baseline research biopsy or most recent archival sample prior to study therapy) was stained using a Leica BOND Autostainer and imaged on a RareCyte CyteFinder II HT instrument. TROP2 protein was quantified in amol/mm2 with Qymia extension (v0.0.6) in Qupath (0.4.3) using a cell line standard curve calibrated by mass spectrometry. Association of TROP2 (as a continuous variable, median, and by quartiles) with PFS, OS, and G3 or higher treatment-emergent adverse events (TEAE) was evaluated using the Cox proportional hazards model, and the p-value from the log rank test was reported.

Results: Tumor samples from 82 pts (38 Arm A; 44 Arm B) who started study therapy were analyzed, of which 34 (41.5%) had PD-L1+ (defined as CPS ≥1) tumors. 72 (87.8%) pts had received prior CDK4/6 inhibitor therapy; 43 (52.4%) had no prior CT for MBC. Median

follow-up was 11.2 months (mo). Median TROP2 protein concentration was 4312.5 amol/mm2.
Among all pts, TROP2 was not significantly associated with PFS as a continuous variable (hazard ratio [HR] per 1-unit increase in log amol/mm2: 0.96, p=0.55) or by quartiles (≤25% [ref], median PFS 8.7 mo; >25%-50%, 4.5 mo, HR 1.86, p=0.09; >50%-75%, 6.7 mo, HR 1.14, p=0.74; >75%, 6.2 mo, HR 0.91, p=0.81). Median PFS was not significantly higher in pts with TROP2 levels ≥ vs < median (6.7 vs 5.9 mo; HR 0.77, p=0.31). TROP2 was not associated with PFS in either treatment arm (Arm A: HR 0.90, p=0.34; Arm B: HR 1.01, p=0.91) or by PD-L1 status (PD-L1+: HR 0.92, p=0.44; PD-L1-: HR 0.97, p=0.79).
Similarly, no significant associations between TROP2 and OS were observed among all pts (HR per 1-unit increment: 1.05, p=0.66), by treatment arm (Arm A: HR 1.05, p=0.79; Arm B: HR 1.03, p=0.85) or PD-L1 status (PD-L1+: HR 1.08, p=0.70; PD-L1-: HR 1.00, p=0.99).
Median OS did not significantly differ by TROP2 levels ≥ vs < median (17.3 vs 18.0 mo; HR 0.93, p=0.86). TROP2 by QIF was not associated with G3 or higher TEAE in all pts (HR per 1-unit increment: 1.00, p=0.99) or by treatment arm (Arm A: HR 0.81, p=0.42; Arm B: HR 1.16, p=0.41).

Conclusion: In this prespecified exploratory analysis of the SACI-IO HR+ trial, TROP2 expression by QIF was not associated with survival outcomes across all pts, by treatment arm or by PD-L1 status. Exploratory outcome analyses by TROP2 IHC expression and association with QIF will be reported.

P2-09-25: Subgroup Analyses From the Phase 3 EVER-132-002 Study of Asian Patients With HR+/HER2- Metastatic Breast Cancer

Joohyuk Sohn, Shusen Wang, Min Yan, Seock-Ah Im, Wei Li, Xiaojia Wang, Ying Wang, Dongdong Jiang, Theresa Valdez, Yiran Zhang, Yilin Yan, Kimberly M. Komatsubara, Wei-Pang Chung, Fei Ma, Ming-Shen Dai, Binghe Xu

Background: The EVER-132-002 randomized phase 3 study compared sacituzumab govitecan (SG) with chemotherapy treatment of physician's choice in Asian patients with hormone receptor–positive/human epidermal growth factor receptor 2–negative (HR+/HER2–) metastatic breast cancer (mBC). The primary end point of progression-free survival (PFS) per blinded independent central review (BICR) was met (HR, 0.67; 95% CI, 0.52-0.87; P = .0028). Overall survival (OS) was also improved with SG vs chemotherapy (HR, 0.64; 95% CI, 0.47-0.88; P = .0061), and the observed safety profile was manageable and consistent with other trials of SG. We present efficacy and safety by prior treatment with CDK4/6i and HER2 status from EVER-132-002.
Methods: Patients were enrolled from China, Korea, and Taiwan and were required to have HR+/HER2– mBC with 2-4 prior lines of systemic chemotherapy. Prior CDK4/6i treatment was not required for enrollment. Patients were randomized 1:1 to receive SG (10 mg/kg IV days 1 and 8 of 21-day cycle) or chemotherapy. The primary end point was PFS per BICR, and secondary end points included OS and safety. For the subgroup analysis, patients were

grouped by prior CDK4/6i treatment in the metastatic setting (yes/no) and by HER2 status (HER2 immunohistochemistry [IHC]0/HER2-low). HER2-low was defined as HER2 IHC1+ or HER2 IHC2+ and fluorescence in situ hybridization–negative.
Results: Of 331 patients (SG, n = 166; chemotherapy, n = 165), 161 (49%) received prior CDK4/6i (SG, n = 81; chemotherapy, n = 80) and 170 (51%) did not (SG, n = 85; chemotherapy, n = 85); 99 (30%) patients were HER2 IHC0 (SG, n = 53; chemotherapy, n = 46) and 232 (70%) were HER2-low (SG, n = 113; chemotherapy, n = 119). Age, baseline body mass index, and ECOG performance status were well balanced across subgroups and treatment groups. Patients in all subgroups and treatment groups had received a median of 2 prior systemic chemotherapy regimens in the metastatic setting.
PFS per BICR was improved with SG vs chemotherapy in patients with (HR, 0.56; 95% CI, 0.39-0.81) and without (HR, 0.79; 95% CI, 0.55-1.13) prior CDK4/6i treatment. OS was also improved with SG vs chemotherapy for patients with (HR, 0.50; 95% CI, 0.31-0.80) and without (HR, 0.77; 95% CI, 0.50-1.20) prior CDK4/6i treatment. PFS per BICR was improved with SG for patients who had HER2 IHC0 (HR, 0.59; 95% CI, 0.36-0.94) and HER2-low status (HR, 0.74; 95% CI, 0.55-1.00) compared to chemotherapy. OS was also improved with SG vs chemotherapy for patients who were HER2 IHC0 (HR, 0.65; 95% CI, 0.36-1.18) and HER2-low (HR, 0.61; 95% CI, 0.42-0.89).
Grade ≥ 3 treatment-emergent adverse events (TEAEs) were more common for SG than chemotherapy in patients with (80% vs 67%) and without (83% vs 72%) CDK4/6i, and for patients who were HER2 IHC0 (77% vs 71%) and HER2-low (84% vs 69%). The most common grade ≥ 3 TEAEs with SG were neutropenia (65%-71% across subgroups), leukopenia (37%-45% across subgroups), and anemia (16%-23% across subgroups) in all subgroups.
Conclusions: SG improved efficacy vs chemotherapy in Asian patients with HR+/HER2– mBC regardless of whether patients had received prior CDK4/6i in the metastatic setting and regardless of whether they had HER2 IHC0 or HER2-low status. The safety profile of SG was similar across the subgroups analyzed, and efficacy and safety in these subgroups were consistent with those observed in the ITT population. These results further support SG as an effective treatment option for patients with HR+/HER2– mBC irrespective of prior CDK4/6i treatment or HER2 status.

P2-09-26: Real world progression free survival in elderly vs. younger HR+/HER2- advanced breast cancer patients treated with first-line endocrine therapy plus CDK4/6i: a sub-analysis of the multicenter, PALMARES-2 study

Francesca Ligorio, Leonardo Provenzano, Giuseppe Fotia, Mario Giuliano, Gianpiero Rizzo, Angela Toss, Marta Piras, Marianna Sirico, Barbara Tagliaferri, Monica Giordano, Daniela Miliziano, Daniele Generali, Donata Sartori, Alberto Zambelli, Giacomo Mazzoli, Alessandra Gennari, Nicla La Verde, Rebecca Pedersini, Matteo Lambertini, Andrea Botticelli, Giancarlo Pruneri, Giuseppe Curigliano, Maria Vittoria Dieci, Claudio Vernieri

Background: Elderly (>75 years old) patients (pts) with Hormone Receptor-positive, Human Epidermal growth factor Receptor 2-negative advanced Breast Cancer (HR+/HER2- aBC) are a special clinical population characterized by more comorbidities, a higher number of concomitant therapies and globally higher frailty when compared to younger pts. The Cyclin-Dependent Kinase 4/6 inhibitors (CDK4/6i) palbociclib, ribociclib and abemaciclib in combination with endocrine therapy (ET) are the standard-of-care, first-line treatment for HR+/HER2- aBC pts regardless of their age. In the whole patient cohort of the PALMARES-2 study, the largest real-world study comparing the effectiveness of the three CDK4/6i, we recently showed that abemaciclib and ribociclib are more effective than palbociclib However, the real-world effectiveness of CDK4/6i in elderly vs. younger pts remains poorly investigated.
Methods: PALMARES-2 is a population-based, multicenter, real-world study that is evaluating the effectiveness of first-line line ET+CDK4/6i in consecutive HR+/HER2- aBC pts treated in 18 Italian cancer centers between 1st January 2016 and 1st September 2023. The primary study endpoint is real-world Progression-free Survival (rwPFS), defined as the time between CDK4/6i initiation and tumor progression, as assessed according to radiological, clinical and/or biochemical parameters. Here, we compared rwPFS in elderly (defined as >75 years old) vs. younger (≤75 years) pts. Multivariable Cox regression modelling was used to adjust the association between individual CDK4/6i and rwPFS for clinically relevant variables.
Results: Elderly pts accounted for 15.2% (n=302) of the whole PALMARES-2 study cohort (n=1982 pts). When compared to younger pts, elderly pts were less likely to have an ECOG PS of 0 (56% vs. 79%, p<0.001) or bone-only disease (17% vs. 25%, p=0.002), and more likely to have lobular tumor histology (25% vs. 17%, p=0.002), lung metastases (36% vs. 25%, p<0.001), and to have received palbociclib (57% vs. 37%, p<0.001). After adjusting for clinically-relevant covariates, elderly pts had independently better rwPFS when compared to younger pts in the whole study cohort (adjusted Hazard Ratio [aHR]: 0.77; 95% CI: 0.67-0.90, p<0.001), as well as in endocrine-sensitive (aHR: 0.76; 95% CI: 0.61-0.94, p=0.013) and endocrine-resistant (aHR: 0.80; 95% CI: 0.79-0.81, p<0.001) settings. We found a strong interaction between patient age and the type of CDK4/6i in affecting rwPFS (p inter<0.001), with ribociclib and abemaciclib being significantly more effective than palbociclib in younger pts (aHR: 0.77, 95% CI: 0.67-0.89, p<0.001) but not in elderly pts (aHR: 0.99; 95% CI: 0.92-1.06, p=0.73). Among 789 pts receiving ET plus palbociclib (n=616 younger; n=173 elderly), elderly pts had significantly better rwPFS at both univariate (median rwPFS in elderly vs. younger: 38.9 vs. 26.6 months; HR: 0.69, p val=0.006) and multivariable (aHR: 0.69; 95% CI: 0.57-0.84; p<0.001) analysis. We did not observe significant rwPFS differences in elderly vs. younger pts treated with ribociclib (aHR: 0.93; 95% CI: 0.76-1.13, p=0.45) or abemaciclib (aHR: 0.85; 95% CI: 0.59-1.22, p=0.37).
Conclusion: Elderly women are a numerically and clinically relevant subset of all HR+/HER2- aBC pts receiving first-line line ET plus CDK4/6i in a real-world setting. When compared to younger pts, elderly pts treated with palbociclib have significantly better rwPFS. Our findings, together with different safety profiles, manageability and drug-drug interactions of the three CDK4/6i, point to palbociclib as the preferred CDK4/6i in the

majority of elderly pts. Longer follow-up is required to compare overall survival in elderly vs. younger pts.

P2-09-27: Alpelisib (BYL719) with continued endocrine therapy following progression on endocrine therapy in hormone receptor–positive, HER2-negative, PIK3CA-mutant metastatic breast cancer: A Big Ten Cancer Research Consortium Study (BTCRC-BRE19-409)

Darian Louthan, Marina N Sharifi, Oana C. Danciu, Jairam Krishnamurthy, Monali K. Vasekar, Kent Hoskins, Michael Lasarev, Jens Eikhoff, Ruth M. O'Regan, Kari B. Wisinski, Cristina I. Truica

Background: Activating mutations in the PIK3CA gene are found in ~40% of patients with hormone receptor-positive (HR+) breast cancer (BC). The p110α-specific PI3K inhibitor alpelisib (ALP) is FDA-approved in combination with fulvestrant (FUL) for treatment of patients with HR+ HER2 negative (HER2-) PIK3CA mutated, advanced BC (ABC). The benefit of adding alpelisib to fulvestrant following progression on non-fulvestrant endocrine therapy (ET) was demonstrated in the SOLAR-1 study, but the majority of these patients were CDK4/6 inhibitor (CDKi) naïve. The BYLieve study established that alpelisib plus switch ET was effective after progression on prior CDKi/ET combination. We hypothesized that clinical benefit of both settings is driven by the addition of alpelisib, and therefore switch from CDKi to alpelisib without change in ET at time of progression on CDKi/ET combination could lead to similar benefit while preserving additional ET options for later lines of therapy. Methods: In this single arm, non-randomized phase II study, patients with PIK3CA-mutated HR+ HER2- ABC with progression on AI or FUL were continued on prior ET with addition of ALP at 300mg daily for 28-day cycles. Antihistamine rash prophylaxis was encouraged, and after enrollment of the first 13 patients, metformin hyperglycemia prophylaxis was encouraged. In contrast to the SOLAR-1 study, all patients received prior CDKi; no more than two prior lines of ET and no chemotherapy in the metastatic setting was allowed. Primary endpoint is progression free survival (PFS). Secondary objectives are overall response rate (ORR), clinical benefit rate (CBR), duration of response (DOR), overall survival (OS) and safety/tolerability. Results: 21 patients were enrolled, 4 (19%) with continued AI and 17 (81%) with continued FUL. Median age was 63 and all patients were female. 81% of patients identified as non-Hispanic white, 4.7% as African American, and 9.5% as Hispanic/Latino. 33% of patients had de novo metastatic disease and 85.7% had visceral involvement at time of study entry. 42.8% of patients had 2 prior lines of ET. 90.5% of patients had prior palbociclib, and 9.5% had prior ribociclib. 52.3% had PIK3CA exon 9 hotspot mutations and 23.8% had PIK3CA exon 20 hotspot mutations. At time of data cutoff, median follow up was 10.8 months, with 2 patients still on treatment. Patients received a median of 5 cycles of treatment (range 1-12), and 42.8% required ALP dose reductions, including 9.5% to 250mg daily and 33% to 200mg daily. No new safety signals were noted. Most common toxicities included hyperglycemia in 71% of patients (29% grade 3), fatigue in 62% (0% grade 3), nausea in 57% (5% grade 3), diarrhea in 52% (10% grade 3), and

rash in 38% (10% grade 3), comparable to reported rates in the SOLAR-1 and BYLieve cohorts. 67% of patients experienced grade 3 toxicities, similar to rates seen in SOLAR-1 and BYLieve trials, however in contrast to those studies, no grade 4 toxicities were seen here. Additionally, only 14.2% patients discontinued due to toxicities, lower than the rates reported in SOLAR-1 and BYLieve, possibly due to the encouraged use of prophylaxis with anti-histamine and metformin. 5 patients experienced SAEs at least possibly related to alpelisib, including hyperglycemia (1), diarrhea (2) and hypoxia (2). At 6 months, 6/21 (29%) of patients remained on combination therapy, 2 with AI and 4 with FUL. Progression free survival, clinical benefit rate, and duration of response will be presented. Conclusions: In HR+HER2- PIK3CA-mutant metastatic breast cancer progressing on ET/CDKi combination therapy, continued ET with switch from CDK4/6 inhibitor to alpelisib at time of disease progression is feasible and safe and clinical responses are seen. Planned correlative studies will assess circulating biomarkers of PI3K signaling that may identify which patients would benefit from this approach.

P2-09-28: Dalpiciclib plus endocrine therapy for visceral crisis in advanced breast cancer: a multicenter, prospective, external controlled phase 2 study

Hongnan Mo, Yuee Teng, Li Cai, Huihui Li, Xinhong Wu, Jing Yao, Yu Wang, Fei Ma

Background: Patients with visceral crisis due to advanced breast cancer (ABC) have a poor prognosis, even with first-line chemotherapy. Visceral crisis has been a common exclusion criterion in clinical trials for patients with ABC. Thus, data on their efficacy in ABC patients with visceral crisis is limited. This study aims to explore the efficacy and safety of dalpiciclib plus ET in hormone receptor-positive, human epidermal growth factor receptor 2-negative (HR+/HER2−) ABC patients with visceral crisis.
Methods: This multi-center, prospective phase 2 study used a Simon two-stage design to evaluate HR+/HER2− ABC patients with visceral crisis, defined as pleural effusion; ascites; abdominal pain from liver or peritoneal metastasis; dyspnea from pleural effusion or lymphangitic spread in the lungs; elevated liver enzymes (> 2 × ULN); rapid bilirubin increase (> 1.5 × ULN) without Gilbert syndrome or biliary obstruction; pathologically confirmed bone marrow metastasis; and hemoglobin < 100 g/dL. Patients were treated with dalpiciclib (150 mg/day for 21 days, followed by 7 days off) plus the investigator's choice of ET (experimental group). If 9 or more subjects had survived at 6 months in the first stage, then 35 additional subjects would be enrolled. The null hypothesis would be rejected if 28 or more subjects out of a total of 53 had survived beyond 6 months. Results were compared to real-world data from an external control group receiving chemotherapy, which followed the same inclusion and exclusion criteria. Inverse probability of treatment weighting (IPTW) approach was used to estimate the average treatment effect on the treated (ATT). Variables in propensity-score-adjustment including age, ECOG, disease recurrence, number of metastatic sites, lines of prior treatment, and classification of visceral crisis. Primary endpoint was the 6-month survival rate. Secondary endpoints included but

not limited to OS, PFS, 3-month treatment failure rate (TFR), time to treatment failure (TTF), duration of disease control (DDC), and safety.
Results: Between February 2023 and May 2024, 17 of 18 patients in the experimental group survived 6 months of treatment in the first stage and proceeded to the next stage. Subsequently, an additional 35 patients were enrolled in the second stage. Of the 53 patients in total, 12 were not followed up for 6 months, while 37 survived 6 months, successfully rejecting the null hypothesis that the 6-month survival rate was ≤ 44%. In the external control group, 157 patients were included. After IPTW adjustment, the effective sample size was approximately 50 patients. Compared to the chemotherapy, dalpiciclib plus ET was associated with substantially longer PFS (median 9.03 months [95% CI 7.20-12.65] vs 4.63 months [95% CI 2.92, 5.65]; HR = 0.334 [95% CI 0.200-0.557], P < 0.001) and longer TTF (median 9.46 months [95% CI 6.41-12.48] vs 4.14 months [95% CI 2.53-5.13]; HR = 0.34 [95% CI 0.207-0.570], P < 0.001). The 3-month TFR in the experimental group (22.6% [95% CI 12.28-36.21]) was considerably lower than in the external control group (40.0% [95% CI 26.41-54.82], P = 0.0876). Median DDC was 8.67 months (95% CI 7.13-NE) in the experimental group, and 4.76 months (95% CI 3.65-6.05) in the external control group, respectively. Treatment-related adverse events occurred in 100% of patients in the experimental group and in 93.6% of patients in the external control group. Lower rates of abnormal liver function were observed in the dalpiciclib plus ET versus chemotherapy group (increased alanine aminotransferase: 17% vs. 28.7%; increased aspartate aminotransferase: 22.6% vs. 40.1%).
Conclusions: Compared with chemotherapy, dalpiciclib plus ET promotes better PFS for patients with HR+/HER2− advanced breast cancer experiencing a visceral crisis, with a manageable safety profile.
Clinical trial identification: NCT05431504

P2-09-29: Landscape analysis of breast cancer ovarian metastases reveals biology and potential therapeutic targets

Steffi Oesterreich, Laura Savariau, Ye Qin, Osama Shah, Ahmed M Basudan, Olivia McGinn, Zheqi Li, Tiantong Liu, Nilgun Tasdemir, Pooja Tallapaneni, Lan Coffman, Esther Elishaev, Saumya D. Sisoudiya, Smruthy Sivakumar, Ethan S. Sokol, Jennifer M. Atkinson, Peter C. Lucas, Adrian V. Lee

Background: Treatment resistance and metastases occur in 10-20% of patients with invasive lobular carcinoma (ILC), the most common special histological subtype of breast cancer. ILC often metastasize to the ovary, a site that is less common for the majority of no special type tumors (NST) also referred to as invasive ductal carcinoma (IDC). The hallmark of ILC is loss of E-cadherin (CDH1), which maps to chromosome 16q. There are limited studies on genomics and transcriptomics of ovarian metastases in patients with breast cancer.
Methods: Mutations and copy number changes were analyzed from 15,613 local breast cancer tissues (of which 1,350 were from patients with ILC), 22,010 non-ovarian

metastases, and 246 ovarian metastases, all of whom underwent tumor-only sequencing using the FoundationOne®CDx or FoundationOne® assays. A scar-based measure of HRD (HRDsig), incorporating copy number and indel features, was called using a machine learning-based algorithm. In addition, we analyzed a cohort of 27 breast cancer ovarian metastases from patients seen at UPMC, consisting of 13 ILCs, 8 NST, and 6 mixed Ductal Lobular Carcinoma (mDLC) using RNA seq and targeted DNA sequencing using the MammaSeq panel. Finally, functional studies including proliferation, migration, transwell chemotaxis and haptotaxis, and invasion assays as well as a series of stainings were utilized to study role of calcium sensing receptor (CaSR) in ovarian metastases.
Results: From a total of 246 ovarian metastases, 115 had CDH1 mutations. There were fewer CDH1 mutations in the ovarian metastases (47%) compared to the primary breast ILCs (81.3%). Consistent with this, there was a reduced frequency of 16q losses, the arm with CDH1, in ovarian metastases relative to local ILC (64% vs 84%, P=3.4X10^-9). These results highlight that while CDH1-mutations are enriched in ovarian metastases, they can also develop in non-ILC tumors. Comparing ovarian and non-ovarian metastases, we detected an enrichment of CDH1, PIK3CA and TBX3 mutations, and an attenuation of mutations in TP53, ESR1, MYC, and CDKN2B. There were no differences in TMB or MSI status, but HRDsig-positive cases were fewer in the ovarian metastases. Median age of patients with ovarian metastases was 52 years, non-ovarian metastases 60 years, local breast cancer (any subtype) 57 years, and local ILC 62 years. The younger age in patients with ovarian metastases was confirmed in the UPMC cohort, where median age at diagnosis of the primary tumor for patients with ovarian metastases was 43 years. In the UPMC cohort, the median disease-free survival of patients with ovarian metastases was 49.5 months, which is 14 months longer compared to that for all patients with breast cancer metastases. As expected, the majority of patients had received endocrine therapy (75%) and/or chemotherapy (56%). Like in the FMI cohort, the most frequent mutations were found in CDH1 and PI3K. Additional mutations were identified in KMT2C, FOXA1 and RUNX1, ERBB2, ERBB3, ATM, and JAK3. Transcriptomic analysis identified up-regulation of activated G protein coupled receptor (GPCR) pathways in ovarian metastasis compared to the primary tumor and normal ovarian tissue, including metabotropic glutamate receptor signaling. In functional studies, calcium sensing receptor (CaSR), a GPCR that was highly overexpressed in ovarian metastases, enhanced migration upon activation with calcium or calcimimetic, which could be blocked with the calcilytic NPS2143. Activated CaSR triggered the MEK/ERK pathway-dependent reorganization of F-actin fibers which was reversed upon treatment with MEK inhibitors. CaSR-induced migration was enhanced with estrogen stimulation and reduced with anti-estrogen receptor (ER) inhibitors.
Conclusions: Our study provides the largest comprehensive characterization of ovarian metastases in patients with breast cancer. It not only deepens our understanding of ILC ovarian
metastasis but provides the foundation for future studies aimed at improved prevention and treatment of breast cancer metastasis to the ovary.

P2-09-30: Real-world comparative efficacy of CDK4/6 inhibitors in first-line treatment of HR+/HER2- metastatic breast cancer

Adam Brufsky, Richard S. Finn, Otto Metzger, Rodrigo Goncalves, Cynthia Huang-Bartlett, Sameet Sreenivasan, Ula Nur, Jessica Davies, Alex Grigorenko

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) combined with endocrine therapy (ET) is the most common first-line (1L) treatment for hormone receptor-positive (HR+) and human epidermal growth factor receptor 2-negative (HER2−) metastatic breast cancer (mBC). Registrational studies for palbociclib (P), ribociclib (R), and abemaciclib (A) have shown consistent PFS benefit; nevertheless, overall survival (OS) results have been inconsistent. No head-to-head studies directly comparing CDK4/6i have been conducted, and although cross-trial comparisons can provide insights, they are limited by differences in trial design and patient population. We have used real-world evidence (RWE) data to directly compare real-world OS (rwOS) with different CDK4/6i when used as 1L treatment for patients with mBC treated in the USA.
Methods: This retrospective open-cohort study used data from two US de-identified electronic health record-derived data sets: primary analyses were conducted using data from the Flatiron Health database, which were then verified using data derived from the Tempus database. Eligible patients had HR+/HER2− mBC and received 1L metastatic treatment with CDK4/6i + ET between January 1, 2016, and April 30, 2023 (Flatiron Health), or December 31, 2022 (Tempus). Patients were followed from the first date of 1L treatment until death or last known activity. Median rwOS for each CDK4/6i was estimated using the Kaplan–Meier methodology. Treatment effects were analyzed using adjusted Cox proportional hazards models, including covariate and propensity score adjustments. Subgroup analyses were also conducted on patients treated with CDK4/6i + aromatase inhibitors (AI) as well as in patients who had a treatment-free interval (TFI) >12 months between last adjuvant ET and metastatic diagnosis date and were then treated with CDK4/6i + AI.
Results : 4,567 patients were selected from the Flatiron Health database (3,504, 575, and 488 treated with P, A, and R, respectively) and 612 from the Tempus database (494, 65, and 53, respectively). In the Flatiron Health database, median (95% CI) rwOS was 43.8 (41.7–46.6) months for P, 43.2 (34.5–48.8) months for A and 44.2 (37.3–51.1) months for R. Adjusted hazard ratios: 1.09 (95% CI: 0.89–1.33) for P versus A and 1.07 (95% CI: 0.90–1.28) for P versus R. Subgroup analyses also showed a similar risk of death between CDK4/6i for patients who received CDK4/6i + AI (2,334, 341, and 355 treated with P, A, and R, respectively. Adjusted hazard ratios 0.90 [95% CI: 0.66–1.23] for P versus A and 1.08 [95% CI: 0.88–1.33] for P versus R) and those with a TFI>12 months (2,226, 349 and 232 treated with P, A and R, respectively. Adjusted hazard ratios 0.91 [95% CI: 0.66–1.25] for P versus A and 1.11 [95% CI: 0.90–1.37] for P versus R). Findings were confirmed with Tempus data; adjusted hazard ratios indicated a similar risk of death between CDK4/6i: 0.92 (95% CI: 0.51–1.68) for P versus A and 1.14 (95% CI: 0.64– 2.05) for P versus R.
Conclusions: Our findings, using mature follow-up data, showed similar rwOS outcomes when different CDK4/6i are combined with ET as 1L treatment for patients with

HR+/HER2− mBC. Results were consistent across RWE databases. As 1L treatment evolves, these findings contribute to the ongoing development of combination strategies, such as novel oral selective estrogen receptor degraders, to improve clinical outcomes in patients with HR+/HER2− mBC and guide clinical decision-making.

P2-10-01: Real-world Experience with CDK4/6 Inhibitors in Hormone Receptor-Positive Metastatic and Recurrent Breast Cancer in Asian Population

Bo-Fang Chen, Chi-Cheng Huang, Ling-Ming Tseng, Yi-Fang Tsai, Ta-Chung Chao, Pei-Ju Lien, Yen-Shu Lin, Chin-Jung Feng, Yen-Jen Chen, Han-Fang Cheng, Chun-Yu Liu, Jiun-I Lai

Purpose: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) combined with endocrine therapy have demonstrated significant clinical benefits in progression-free and overall survival. This study investigates the outcomes associated with two kinds of CDK4/6i, palbociclib and ribociclib, in patients with hormone receptor (HR) positive metastatic and relapsed breast cancer to inform real-world evidence of treatment strategies.
Methods: This retrospective study included 340 Taiwanese patients with HR-positive advanced breast cancer from the Taipei Veterans General Hospital, between 2018 and 2023. We analyzed patient characteristics, treatment strategies and outcomes associated with two CDK4/6i. The efficacy of patients who experienced economic burden and interrupted CDK4/6i treatment after 2 years of national health insurance(NHI) reimbursement was also investigated.
Results: Patients receiving ribociclib and palbociclib showed no significant differences in age, histology, body mass index(BMI), or pathologic status. The distributions of disease status and endocrine therapy partners were comparable between the two groups. The dose reduction rate was similar, while patients with palbociclib tended to discontinue CDK4/6i usage, and those with ribociclib tended to switch to the other CDK4/6i or endocrine partners. Patients with palbociclib had a higher prevalence of prior chemotherapy for advanced diseases. There was no significant difference in progression-free survival (PFS) between the two CDK4/6i in the first-line setting. Adverse prognostic factors were increasing HER2 IHC score, higher Ki-67 levels, visceral and liver metastasis, prior chemotherapy, and endocrine therapy resistance while higher BMI, bone-only metastasis, and letrozole treatment were associated with a lower risk of progression. This limited follow-up time in our study was insufficient to assess the outcomes of patients treated with interrupted CDK4/6i for up to two years under the NHI reimbursement policy.
Conclusion: Treatment outcomes between the two types of CDK4/6i did not differ significantly, indicating the safety and efficacy of CDK4/6i for the Asian population. Ribociclib and palbociclib showed similar efficacy in PFS in the real-world setting.

P2-10-02: SACISUR, results of a real-world evidence observational study of the use of Sacituzumab-Govitecan (SG) in triple negative metastatic breast cancer (mTNBC) clinical practice in the south of Spain.

Alejandro Falcón-González, Llabrés-Valenti Elisenda, Henao-Carrasco Fernando, Urbano-Cubero Rocío, Godoy-Ortiz Ana, Nieto-Ramírez Julio César, Vargas-Prado Ana Milena, González-Haba Alba, Martín-Calero Braulio, Morales-Estévez Cristina, Valero-Arbizu María, Chavarría-Piudo Natalia, González-Flores Encarna, Casaut-Lora Estefanía, Díaz-Redondo Tamara, Estalella-Mendoza Sara, Zarcos-Pedrinaci Irene, Morales-Pancorbo David, Acosta-Sánchez Ariadna, Vicente-Rubio Elena, De Toro-Salas Rubén, Cano-Jiménez Alicia, Pascual-López Javier, Sánchez-Guisado Antonia, Cruz-Jurado Josefina, De la Fuente- Domínguez Icíar, Rodríguez-García Jose Andrés, Torres-Zurita Alberto, Salvador-Bofill Javier, Ruiz-Borrego Manuel

Background: SG is a new antibody-drug conjugate against Trop-2 that has been approved for the treatment of mTNBC after progression on at least one previous line of chemotherapy (CTX) for advance disease. In the ASCENT trial, progression-free survival (PFS) and overall survival (OS) were longer with SG compared with CTX (5.6 vs 1.7 months PFS and 12.1 vs 6.7 months respectively).
Methods: This was an observational multicentre retrospective study.
We included patients with mTNBC treated at least with 1 cycle of SG between 1 January 2022 and 31 December 2023. This study has been supported by SAOM (Andalusian Society of medical oncologist). The aims of the study were analysing efficacy and safety of SG in our population. Special populations of patients with central nervous system (CNS) metastasis will be presented in a different poster.
Statistical analysis was made by IBM SPSS statistics, including descriptive results of the population and survival analysis by Kaplan-Meier.
Results: We report the data of 159 female patients treated in 18 different hospitals of Andalucía, Canarias and Extremadura (Spain). The median age was 53 years (46.5 % premenopausal, 35.2% Her2low). 75.5% of the patient had visceral disease, only 13.9% had CNS disease. 17.6% were de novo, stage I-III patients were treated with CTX in the early setting in 59.7% in neoadjuvant and 28.9% in the adjuvant setting. Pathological complete response was 17.5% in the case of neoadjuvant treated patients.
Previous line of therapy was 3 (1-8) with a medium of 7 cycles of SG. SG was received in second line in 41.8% patients, 3.8 % in first line and 54.4% patients third line or beyond. 17% received immunotherapy in first line.
With a median follow-up of 11.8 months, PFS was 5.2 months (95% CI, 4.05-6.27) and OS was 10.5 months (95% CI, 7.6-13.5) (fig 2). The percentage of patients with an objective response was 31.2% (68.9% with clinical benefit rate).
The incidence of diverse adverse events were neutropenia 59.4% (G3-4 30.4%), diarrhea 49% (G3-4 8.2%), nauseas 45.3% (G3-4 0.6%) and ALT/AST elevation 24.5% (G3-4 1.9%). The use of GCSF were 29.6 % as primary prophylaxis and 17.6 % as secondary prophylaxis. 5.7% of the patients finished SG due to adverse events and 43.4% had at least one dose reduction.

Conclusions: SG is a safe and promising option in mTNBC real-world patients. Our results were similar to that obtained in ASCENT trial and even better if we exclude patients with CNS metastasis.

P2-10-03: Real world outcomes of adjuvant chemotherapy in invasive lobular carcinoma of the breast: a retrospective cohort from a reference center in Brazil

Raelson Miranda, Thamires Haick Martins da Silveira, Douglas Tozzo, Leticia de Mello Graziano, Laura Testa

Background: Invasive lobular carcinoma is the second most common breast cancer histology and has lower response rate to chemotherapy (CT) compared to ductal/no special type (NST) tumors. In the adjuvant setting, many guidelines recommend CT based on the criteria used for NST. However, the benefit of CT is not necessarily the same. Here, we present survival outcomes of patients with invasive lobular carcinoma from a retrospective cohort.
Methods: This study has included patients seen at Instituto do Cancer do Estado de São Paulo, Brazil, between 2015 and 2020. Only patients with invasive lobular carcinoma in stages I-III have been enrolled.
Results: After screening, 153 records from patients were included to review, divided in stages I (22%), II (47%) , and III (31%). Mean of age at diagnosis was 62y (range: 28 - 91 years). Received chemotherapy as adjuvant, neoadjuvant and omitted in 76 (50%), 16 (10%), and 61 (40%) respectively. The median of disease-free survival in adjuvant, neoadjuvant and omitted were respectively 11y, 1.4y and 9.4y (p=0.0001); and median of overall survival (mOS) were 13.3y, 5.5y and 7.5y (p = 0.0395). Analyzed by staging, for stage I mOS was not raged among groups (p=0.011), stage II 13y, 5.5y and 7.2y (p=0.006), and stage III: 6.2y, 5.9y, and 4.6y (p=0.56). In a multivariable Cox proportional regression, the hazard ratio (HR) for age, staging and HER2 3+ were 1.07 (p=0.001), 4.2 (p= 0.0001), and 8.9 (p=0.001) respectively.
Conclusion: In our study, disease-free survival and overall survival were longer for adjuvant chemotherapy than neoadjuvant, specially for stage I and II. Although age, staging and HER2 3+ were independent risk factors for shorter overall survival.

P2-10-04: Effectiveness and toxicity profile of pertuzumab in combination with trastuzumab and taxane in patients with HER2 positive metastatic breast cancer treated in the Costa Rican Health Care System

Priyanka Khanna, Denis U. Landaverde

Background: The first line of treatment for HER2-positive metastatic breast cancer is the combination of pertuzumab, trastuzumab and taxanes. In Costa Rica, since 2014, this

combination began to be used in the national health care system, however its impact was not yet known since no local studies had been reported showing its e"ectiveness. The present study aimed to assess the performance of this treatment in our public health care system
Methods: From August 2015 to August 2021, a total of 148 patients were included in this study, with a histological diagnosis confirmed of HER2-positive metastatic breast cancer, who received pertuzumab, trastuzumab, and taxane (paclitaxel or docetaxel) as first-line treatment. Descriptive statistics were used for the demographic, clinical, and pathological characteristics. Statistical analysis of survival was performed using the log-rank test, and the Cox proportional hazards model. All the data were analyzed with the SPSS 20.0 program for Mac (Chicago, IL). Toxicities reported were recorded as established in the CTCAE
Results: The median age was 58 years, 81% of patients had performance status 0, 54% were hormone receptor positive, 90% received adjuvant or neoadjuvant chemotherapy, 42% had metastatic visceral disease including CNS. Paclitaxel was the most frequently taxane used with an average of 16 weekly cycles. The median duration of pertuzumab and trastuzumab together was 22.7 months. The most frequent reason for suspension was progression (56.1%) and only 3.4% due to toxicity; 3.4% of the patients abandoned treatment. The most frequent adverse events were peripheral neuropathy (34%), diarrhea (21%), febrile neutropenia (1)%, and grade 3 cardiotoxicity was seen in 2 patients. The most frequent site of progression during treatment was the brain (38.5%). With a median follow-up of 27.5 months, progression-free survival was 19 months (95% CI 15-25). Median overall survival of 73 months (95% CI 38-74). Conclusions This is the first study conducted in a Central American population confirming that the results obtained in the pivotal clinical trial were replicable in our population increasing the real-world data in our region.

P2-10-05: Survival in Older Women Receiving Adjuvant Radiation Monotherapy vs. Endocrine Monotherapy Following Lumpectomy

Tori Chanenchuk, Kerri-Anne Crowell, Ton Wang, Laura H. Rosenberger, Gayle A. DiLalla, Susan G. R. McDuff, Gretchen Kimmick, E. Shelley Hwang, Jennifer K. Plichta

Background: Breast cancer is increasingly prevalent in women over 65, and most are diagnosed with hormone receptor positive disease. While younger patients with early-stage breast cancer are treated with both adjuvant radiation therapy (RT) and endocrine therapy (ET), many clinical trials have shown that omitting radiation among older patients who take adjuvant ET does not decrease survival. However, ET is difficult for many older patients to tolerate, and some may prefer a short course of RT monotherapy instead of ET. While ET can reduce both local and distant recurrence risk, older women with favorable breast cancers may have a sufficiently low distant recurrence risk that omission of ET may be reasonable, if RT is given to reduce local recurrence. Therefore, the aim of this study was to determine whether treatment with adjuvant RT monotherapy results in comparable overall survival (OS) to treatment with adjuvant ET monotherapy in women age ≥65 diagnosed with favorable early-stage breast cancer.

Methods: Patients aged ≥65, diagnosed in 2010-2020 with ER+/HER2-, prognostic clinical stage I breast cancer (cT1-2, N0), who underwent lumpectomy, were selected from the National Cancer Database. Patients who received any chemotherapy and/or any neoadjuvant therapy were excluded. Differences across groups were tested. The Kaplan-Meier method was used to estimate OS, and log-rank tests were used to test for differences in OS between groups. Stratified analyses were conducted based on age group (65-69, 70-74, 75-79, 80+). A Cox Proportional Hazards model was used to estimate the association of the treatment group with overall survival after adjustment for available covariates.
Results: The final cohort included 91,505 patients, with 13.5% receiving no adjuvant therapy, 11.8% receiving RT alone, 29.5% receiving ET only, and 45.2% receiving both RT and ET. The median follow-up for the entire cohort was 67.6 months. Patients in the RT-only and ET-only groups were of similar age [median (IQR): RT 73yo (69-79) vs ET 75yo (71-80); p<0.001], although patients in the ET-only group were less likely to have a comorbidity score of 0 (ET 75.4% vs RT 80.8%; p<0.001). Patients in the ET-only group had minimally larger tumors [median tumor size (IQR): ET 1 (0.7-1.5) vs RT 0.9 (0.6-1.3); p<0.001], were less likely to have grade 3 tumors (ET 7.01% vs RT 8.38%; p<0.001), and were slightly more likely to have PR+ disease (ET 91.4% vs RT 89.6%; p<0.001).
In the unadjusted Kaplan-Meier analysis, patients receiving ET-only had a slightly lower 5-year OS compared to the RT-only group [ET 85.8% (85.3-86.3%) vs RT 88.9% (88.2-89.6%); log rank p<0.001]. A similar trend was observed when stratified based on age group, although notably less pronounced (all log rank p<0.05). In the adjusted multivariable analysis, RT alone remained associated with a slightly better OS than ET alone [ET ref, RT hazards ratio 0.91 (95% CI 0.85-0.97)].
Conclusions: For older patients with early-stage, ER+/HER2- breast cancer, survival outcomes were largely similar for those who received adjuvant RT monotherapy vs adjuvant ET monotherapy. While prior studies have evaluated de-escalation of radiotherapy, de-escalation of endocrine therapy has not been as extensively explored. Direct comparisons of RT alone vs ET alone may be warranted in this unique population with variable life expectancy and potentially different treatment preferences.

P2-10-06: Safety and efficacy of trastuzumab deruxtecan and concomitant radiation therapy in patients with metastatic breast cancer: a multicentre international retrospective cohort study

Luca Visani, Ivica Ratosa, Barbro Linderholm, Rupert Bartsch, Domen Ribnikar, Jacopo Scialino, Niccolò Bertini, Ilaria Bonaparte, Dimitar Stefanovski, Nika Dobnikar, Magdalena Sojar, Angelika Starzer, Isacco Desideri, Chiara Mattioli, Cecilia Petruccioli, Jacopo Nori, Lorenzo Orzalesi, Simonetta Bianchi, Marianna Valzano, Viola Salvestrini, Carlotta Becherini, Lorenzo Livi, Icro Meattini

Background. Trastuzumab deruxtecan (T-DXd) has emerged as the standard treatment for patients with metastatic HER2-positive (HER2+) breast cancer (BC) following disease progression on first-line therapy containing taxanes and trastuzumab, as demonstrated by

the findings of the DESTINY-Breast03 trial. Subsequently, results from the DESTINY-Breast04 have extended the approval of T-DXd to include HER2-low patients. Radiation therapy (RT) is often necessary in the metastatic setting, either for palliative purposes or with ablative intent in cases of oligometastatic or oligoprogressive disease. Our retrospective study aims to assess the safety of concurrent use of T-DXd and RT in a consecutive multicentre international cohort of BC patients.
Methods. We conducted a retrospective analysis of patients diagnosed with metastatic HER2+ or HER2-low BC, who were treated at four leading European institutions. Patients started treatment with T-DXd between May 2021 and March 2024, with some receiving concomitant RT with palliative or ablative intent and others not. We defined ablative RT based on biological dose with threshold of minimum 50Gy EQD2(10) delivered in a maximum of 12 fractions, according to the EORTC and European Society for Radiotherapy (ESTRO) OligoCare (EORTC-1822-RP) study. The primary objective of the study was to assess the association between RT administration and adverse events (AEs) exceeding grade (G) 2. In all cases RT was administered within one month before Cycle 1 of therapy with T-DXd or during systemic treatment without any drug interruption.
Results. Data of 118 consecutive patients treated with T-DXd with or without RT were retrospectively evaluated. Thirty-three patients received RT immediately before (within a month) or during T-DXd, for a total of 34 concomitant RT treatments, while 85 patients did not. Median age was 55 years old (range 30-88). At a median follow up of 18 months (range 1-33), 8 patients (24.2%) had died in the RT group and 17 patients (20.0%) in the no-RT group. Sixty-two patients (52.5%) received T-DXd as fourth or further line of systemic therapy, while 38 (32.2%) in third line and 15 (12.7%) in second line. Three patients (2.6%) with early metastatic disease relapse (<6 months after adjuvant anti-HER2 therapy completion) received T-DXd as first line treatment. Median total RT dose prescription was 34Gy (range 8-48) with a median number of fractions of 4 (range 1-15). Median EQD2 dose was 64Gy (range 12-104) and median BED 76Gy (14-125). The most frequently treated site was central nervous system (51.5%; n=17/33), followed by bone (33.3%; n=11/33). Fifteen patients received RT with ablative intent (45.5%), 18 patients RT with palliative intent (54.5%). A chi-square test of independence was performed to examine the relation between RT administration and the development of >G2 toxicity. The relation between these variables was not significant ($p=0.79$; significance level $p<0.05$). Regarding toxicities of special interest for T-DXd, 3 cases of G3 fatigue have been reported in no-RT group (3.5%) with 1 case in the RT group (3.0%). Overall, only 1 case of G3 nausea was observed (in the no-RT group). Grade 2 interstitial lung disease (IDL) or G2-3 pneumonitis were observed in 4 cases in RT group (12.1%) and in 8 cases in no-RT group (9.4%). No radionecrosis events were reported among the 17 patients treated with intracranial RT.
Conclusions. Our preliminary data are encouraging regarding the potential safety of this combination, showing that concurrent RT did not increase severe acute toxicity. Data from larger series are needed to confirm these results.

P2-10-07: Practice patterns and survival analysis of early-stage HER-negative breast cancers with low and intermediate levels of hormone receptor expression: a 2018-2020 US National Cancer Database analysis

Dionisia Quiroga, Julie A Stephens, Gilbert Bader, Mathew A Cherian, Ashley P Davenport, Margaret E Gatti-Mays, Kai CC Johnson, Daniel Stover, Robert Wesolowski, Nicole Williams, Nerea Lopetegui-Lia, Arya M Roy, Samilia Obeng-Gyasi, Bridget A Oppong, Sachin R Jhawar, Sagar Sardesai

Background: Breast cancer (BC) with low hormone receptor (HR) expression (1-10%) is classified as HR-Low BC. We previously demonstrated that pathologic complete response (pCR) rates and biologic features of HR-Intermediate HER2-negative BC (11-30%), much like HR-Low BC, are similar to triple negative breast cancer (TNBC). Here, we report treatment patterns and overall survival (OS) for HER2-negative BC by level of HR expression from the US National Cancer Database (NCDB).

Methods: Patients (pts) with stage I-III HER2-negative BC diagnosed in 2018-2020 were categorized into four groups by estrogen receptor (ER) and progesterone receptor (PR) expression: ER<1% and PR<1% (HR-Neg), ER 1-10% and/or PR 1-10% (HR-Low), ER >11-30% and/or PR>11-30% (HR-Int), ER >30% and/or PR >30% (HR-High). Pts with undocumented HR status or without curative intent surgery were excluded. The primary outcome was OS by HR expression. Key secondary outcomes were treatment patterns and OS by neoadjuvant chemotherapy (NAC) response and endocrine therapy (ET) use. Categorical variables were compared between the groups using a Chi-square test. OS survival was explored using Kaplan Meier estimates, log-rank tests and univariate/multivariable cox proportional hazard models.

Results: 395,757 incident cases of early-stage HER2-negative breast cancer were identified, including 8857 (2.2%) HR-Low and 4375 (1.1%) HR-Int BC. HR-Low and HR-Int cohorts reported more advanced stage at diagnosis and were more likely to be node-positive with higher Ki-67 scores than HR-High BC (p<0.001 for all). HR-Low and HR-Int groups consisted of proportionally more Black patients than HR-High (20%, 19% vs 9%; p< 0.001). Oncotype DX results were more likely to be obtained with increasing levels of HR expression (HR-Neg 1%, HR-Low 11%, HR-Int 25%, HR-High 43%; p< 0.001). ET use was more frequent in HR-High than HR-Low or HR-Int BC (87%, 46% & 71%; p <0.001). The use of immunotherapy increased with lower expression of HR (HR-Neg 5%, HR-Low 4%, HR-Int 3%, HR-High 1%; p< 0.001). Additionally, NAC use was more frequent in HR-Low and HR-Int than HR-High (31%, 24% & 5%, p< 0.001). pCR rates were correlated with significantly higher OS at the 3 year (y) timepoint for all levels of HR expression (p< 0.001). NAC response had a significantly greater impact on 3y OS in the HR-Low (pCR 96.5%, no pCR [NR] 62.2%) and HR-Int (pCR 94.5%, NR 56.8%) groups compared to HR-High (pCR 96.7%, NR 91.5%).

Multivariable analyses showed significantly worse OS in HR-Neg (hazard ratio [HazR]: 2.73), HR-Low (HazR: 2.70), and HR-Int (HazR: 2.64) compared to HR-High tumors after

adjusting for age, tumor size, nodal status and grade (p< 0.001 for each). 5y OS in HR-Low, HR-Int, and HR-High groups were 78.5%, 81.4%, and 89.0% respectively. Among HR-positive BC, ET use was associated with longer OS in multivariable analyses (HazR: 0.85) with 5y OS for HR-Low (ET 82.3%, no ET 74.7%), HR-Int (ET 84.4%, no ET 73.1%), and HR-High (ET 90.0%, no ET 80.7%) groups (p< 0.001 for each).

Conclusions: HR-Low and HR-Int HER2-negative BC are rare subtypes with distinct biologic features compared to HR-High BC. This real-world analysis reveals significant differences in the survival outcomes, management, and treatment responses of HR-Low and HR-Int BCs. ET use is less common with lower HR expression yet associated with improved 5y OS. The use of immunotherapy is more frequent with lower HR expression; however, requires further investigation in HR-Low and HR-Int BC. The binary categorization of HR does not adequately address disease heterogeneity. This may contribute to outcome disparities in patients with HR-Low and HR-Int, HER2-negative BC.

P2-10-08: The Impact of Time-to-Surgery (TTS) for Breast Cancer Prognosis After Neoadjuvant Chemotherapy

Xin Wang, Xiyu Kang, Xiaona Lin, Yining Song, Li Zhang, Huixia Huo, Chenxuan Yang, Zijun Zhao, Jiaxiang Liu, Qingyao Shang, Jiaxian Yue

Background: Neoadjuvant chemotherapy (NAC) is a crucial component of comprehensive treatment for breast cancer, but the optimal timing for surgery post-neoadjuvant treatment remains contentious. Performing surgery too early may not allow sufficient recovery from bone marrow suppression, whereas delaying surgery might reduce the efficacy of the NAC. This study focuses on the effect of time to surgery (TTS) on survival outcomes and other clinical benefits, in an attempt to decipher an appropriate interval for breast cancer patients.
Methods: In this multi-institutional, retrospective study, patients receiving surgical resection post NAC between March 2010 and April 2022 from four medical centers in China were enrolled. Eligible patients were females aged 18 or older, diagnosed with stage II or III, or locally advanced breast cancer, who had initially been treated with neoadjuvant chemotherapy. The main exclusion criteria were bilateral breast cancer, stage IV disease, not having a full course of NAC, receiving neoadjuvant immune-related therapy or neoadjuvant endocrine therapy. Demographics, clinical characteristics, and treatment history were collected. Kaplan-Meier analysis was used to estimate overall survival (OS), disease-free survival (DFS), disease-specific survival (DSS) and local recurrence-free survival (LRFS). Univariate and multivariate Cox analyses were also conducted to discern the prognostic significance of TTS, alongside other factors including pCR status, Ki-67 index, etc.
Results: A final sample of 404 met criteria (39.9% hormone receptor-positive and 38.1% HER2-positive, 22.0% triple-negative breast cancer). Median age of diagnosis was 47, with median 45 months of follow-up. Patients were stratified into 2 groups based on the median

time interval between NAC and surgery: short-TTS group (TTS<25 days , n=194, 48.0%) and long-TTS group (TTS≥25 days, n=210, 52.0%). Patients in short-TTS group demonstrated improved OS (p=0.036) and DFS (p=0.011) compared to those with delayed surgeries beyond 25 days. However, the TTS did not significantly affect DSS (p=0.056) or LRFS (p=0.274). In univariate COX analysis, OS and DFS were significantly worse for long-TTS group, with a hazard ratio of 1.90 (95% CI, 1.04-3.48; p=0.036) and 1.72 (95% CI, 1.13-2.60; p=0.011) respectively. Multivariate analysis also verified that TTS stood as an independent prognostic factor for DFS (HR, 1.66; 95% CI, 1.08-2.55; p=0.022) rather than OS (HR, 1.87; 95% CI, 1.00-3.50; p=0.051). In subgroup analysis, we observed improved DFS in short-TTS group who did not achieve a pathologic complete response (pCR) (p=0.012) or expressed a Ki-67 index lower than 20% (p=0.040).
Conclusion: Our study indicated a better OS and DFS in all patients when surgery was performed within 25 days post neoadjuvant chemotherapy. Based on these findings, we suggest that patients might benefit from an interval of less than 25 days from the completion of NAC to surgery, especially for those with a Ki-67 index lower than 20% or those likely to have residual tumor based on imaging. For the first time, our study revealed that both pCR status and Ki-67 indices were important factors when determining the proper TTS for NAC patients. Future studies to confirm these results are warranted.
Keywords Breast cancer; Neoadjuvant chemotherapy; Time to surgery; pathologic complete response.

P2-10-09: Can an AI-based Clinical Decision Support System (CDSS) in the treatment decision-making process for breast cancer contribute to healthcare cost reduction ?

Barbara Bussels, Isabelle Kindts, Sandra Steyaert, Philip Poortmans, Adelheid Roelstraete, Caroline de Beukelaer, Mona Bové, Sander Goossens, Peter De Jaeger

Background: Reducing breast cancer treatment costs is vital for global patient care, especially in low-income countries, and alleviates the financial burden on healthcare systems, fostering better resource allocation for new therapies.
Material and methods :
The BreaCS consortium developed an AI-based CDSS for early breast cancer patients, targeting three questions at diagnosis : definitive tumor size (pT), nodal involvement and response to primary systemic therapy (PST). A multimodal fusion of the EUSOMA clinical data, biopsy pathology data and the preoperative MRI trained the AI based-model.
The economic impact was assessed using the real-world EUSOMA database from the consortium, comprising 5,000 early breast cancer patients. The impact on healthcare costs was calculated based on the treatment of 1,200 new early breast cancer patients annually by the consortium. Only the costs of the unnecessary surgical procedures were calculated according to the Belgian reimbursement system excluding non-surgical costs, hospital admission and other related expenses.

Results: Accurate prediction of the tumor size will refine decisions about breast-conserving surgery (BCS) versus mastectomy (ME), reducing the need for reconstructive surgeries. In our database, 42,5 % of patients had a superior pathological T stage compared to clinical staging. This led to 5% of patients requiring second breast surgery, with half undergoing a re-excision and the other half a ME. The annual cost for a second surgery for the consortium is estimated at 9000 euro.
Conversely, 40,5 % of patients had a smaller pathological T stage compared to the clinical estimation. 25 % of these patients had a pT1 while presenting with a cT2-3. Considering that the cT3 patients (approximately 3%) received unnecessary ME's, the cost for unnecessary reconstructions is estimated on a yearly basis to be 53,536 euro for the entire consortium.
Prediction of lymph node involvement will eliminate the need for any axillary surgery in pN0 patients. Of the entire population 71,7% underwent a sentinel lymph node biopsy (SLNB), of which 40,4 % had pN0. Approximately 350 SLNB could have been avoided, related to a cost of 70,000 euros on a yearly basis.
18% of patients receiving PST had a pCR. In these cases, predicting response might allow omitting all surgical procedures. For patients with a pCR, 66.4% received SLNB, 42,7 % axillary LN dissection, 38,6 % a ME and 56,8 % a BCS. All these surgeries have a combined total cost of 13,800 euro.
Conclusions: An AI-based CDSS that can predict tumor size, lymph node involvement and response to PST could reduce the surgical costs for early breast cancer treatment with approximately 150,000 euro on a yearly basis for 1200 patients. This excludes non-surgical costs, treatment of sequelae and impact on quality of life of the patients.

P2-10-10: Integration of Novel Antibody–Drug Conjugates in Advanced HER2-low, Hormone Receptor-positive and Triple-negative Breast Cancer

Kemi Obajimi, Kristen Rosenthal, Sara M. Tolaney, Melinda L. Telli, Komal Jhaveri, Timothy Quill

Introduction: The emergence of sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd) into the armamentarium has changed the treatment landscape for patients with HER2-low, hormone receptor (HR)-positive and triple-negative advanced breast cancer (TNBC). SG is approved for specific patients with previously treated, advanced TNBC or HR-positive/HER2-negative breast cancer. T-DXd is approved for specific patients with previously treated advanced HER2-positive or HER2-low breast cancer, as determined by an FDA-approved test. Here, we report on an online educational program to understand current clinical knowledge about and use of SG and T-DXd by healthcare professionals (HCPs) using a small-group educational workshop experience to address challenges faced by HCPs who provide care for patients with breast cancer.
Methods: Between November 2023 and January 2024, we developed an educational program for oncology HCPs on newer antibody–drug conjugates (ADCs) in advanced breast cancer. A preactivity, case-based online survey was deployed to HCPs to assess current

clinical challenges and inform the development of specific topics for the educational workshop. A subset of HCPs was randomly selected and invited to participate in small-group workshops led by an expert in breast cancer management to discuss specific clinical challenges and provide personalized feedback on evidence-based implementation of SG and T-DXd in the treatment of patients with advanced HR-positive/HER2-negative breast cancer or TNBC. After the workshop, the learners were asked to retake the survey, and their responses were used to assess the efficacy of the educational intervention.
Results: Of 69 breast cancer oncologists who participated in the online preactivity survey, 30 were selected to participate in the workshop. Across key patient-case scenarios identified as topics of educational need with the preactivity survey, approximately 30% to 50% of workshop participants changed their treatment approach after the workshop. For example, when asked to select treatment for a woman with HR-positive metastatic breast cancer and a fluctuating HER2 immunohistochemistry (IHC) status over the course of her disease, 10% of participants selected T-DXd initially, but after the workshop, 63% opted to treat the patient with T-DXd. In another scenario, 57% opted to hold treatment and closely monitor a patient receiving T-DXd with scattered ground glass opacities in both lungs on a CT scan who is asymptomatic and has normal vital signs, including an oxygen saturation level of 98%. After the workshop, approximately 90% would hold rather than to permanently discontinue treatment. Finally, for a patient with HR-positive/HER2 IHC 0 metastatic breast cancer and progression in the liver, when asked to select a testing approach to determine the optimal next-line therapy, only 57% initially chose to repeat a tissue biopsy of the liver to assess HR/HER2 status, which increased to 90% after participation in the workshop.
Conclusions: These data highlight specific challenges that HCPs are encountering with the integration of SG and T-DXd into clinical practice. The simulation of real-life clinical situations and participation in workshops with breast cancer experts helped to inform treatment decision-making and improved HCPs application of evidence-based medicine. These results show the impact of comprehensive educational models—developed from insights from learner surveys and expert perspectives on key data—to equip HCPs with the knowledge to ensure their practice aligns with current recommendations and increase confidence in making evidence-based treatment decisions for patients.

P2-10-11: Utilization and impact of endocrine therapy in male patients with early breast cancer – results from a large German real-world claims data analysis

Dominik Dannehl, Tobias Engler, Tjeerd Dijkstra, Alexandra von Au, Lea Volmer, Markus Hahn, Sabine Hawighorst-Knapstein, Ariane Chaudhuri, Markus Wallwiener, Florin-Andrei Taran, Armin Bauer, Sara Brucker, Stephanie Wallwiener, Andreas Hartkopf

Male breast cancer (BC) is a rare entity and presents a significant clinical challenge due to its late diagnosis and the resulting poorer prognosis compared to female BC. As shown by prior studies, approximately 99% of male BC patients are hormone receptor-positive (HR+).

Given the lack of large prospective trials on optimal therapy of male BC, treatment is analogous to that of female BC. The objective of this study was to analyze the use of endocrine treatment (ET) in male patients with early BC using claims data from a large German health insurance provider (AOK Baden-Wuerttemberg) and to assess the impact of ET on overall survival (OS).

Male patients who underwent surgery for early breast cancer between July 1st 2010 and December 31st 2019 were included into the analysis. As the data-set did not include information on the HR status, we assumed all patients to be HR+. Utilization of endocrine therapy was assessed based on filled prescriptions. Overall survival (OS) was defined as the period between first diagnosis of EBC until death.

In total, 144 male BC patients were included, as well as 432 age-matched controls. 21/144 patients (15%) did never use any ET. Most of the patients who received ET (93/107) were treated with tamoxifen (87%). Patients, treated with ET showed the same nodal status (N0: 72/107, 67%; N+: 35/107, 33%) as compared to patients without ET use (N0: 18/21, 86%; 3/21, 14%, p=0.091). However, patients treated with ET as compared to patients without ET were more likely to receive radiation therapy (with ET: 61/107, 57%; without ET: 2/21, 10%; $p < 0.001$) and to receive chemotherapy (with ET:54/107, 50%; without ET:1/21 (5%), $p < 0.001$). 5-year OS of patients who never started with ET was significantly reduced compared to patients with ET (without ET 37 % (95 % CI: 20 – 69 %) vs. with ET 74 % (95 % CI: 64 – 84 %), $p < 0.001$). Multivariate cox regression including age, nodal involvement, use of radiation therapy, and chemotherapy use revealed that age and intake of ET were independent prognostic factors for OS.

Although nearly all male breast cancer patients are HR+ a clinically relevant proportion never starts with ET. These patients have a significantly reduced OS as compared to patients who start with ET. Future research should focus on adherence to ET and factors that influence the utilization of ET.

P2-10-12: Pembrolizumab in Early Triple-negative breast cancer: Real world data in Hispano-American women (PETRHA) - Initial results

Daniela Vazquez-Juarez, Alejandro Aranda-Gutierrez, Yanin Chavarri-Guerra, Fernando E. Petracci, Omar Peña-Curiel, Ernesto Korbenfeld, Felix Urtasun, Francisco Acevedo, Enrique Jose Zamudio Lozoya, Luisa Fernanda Gonzalez Gonzalez, William Armando Mantilla, Sandra Franco, Claudia Haydee Arce Salinas, Karla Alicia Centelles López, Eva Willars, Monserrat Alvarado Hernandez, Bertha Alejandra Martinez-Cannon, Henry Gomez, Maricela Garcia Garces, Angel Lopez-Galindo, Mauricio Lema, Camila Lema, Cynthia Villarreal-Garza

Currently, the standard of care for women with stage II-III triple-negative breast cancer (TNBC) includes neoadjuvant chemotherapy combined with pembrolizumab, followed by adjuvant pembrolizumab. Notably, approximately 10% of the participants in the KEYNOTE-

522 trial were Hispanic or Latino, highlighting a gap in evidence regarding the benefit of pembrolizumab in this population. This study aims to evaluate the efficacy and safety of pembrolizumab in patients diagnosed with early TNBC treated in the region.
Hispano-American women diagnosed with early TNBC, including estrogen and progesterone receptors <10%, who received pembrolizumab as part of their systemic therapy were included in this multicenter retrospective cohort. Descriptive statistics were used to analyze sociodemographic and clinicopathological characteristics. Independent samples T-test, X2, and Fisher's exact tests were used to evaluate associations between variables, employing logistic regressions to calculate odds ratios (OR) when appropriate.
A total of 214 patients were included. 116 (54.2%) lived in Mexico, 53 (24.8%) in Argentina, 19 in Chile (8.9%), 18 in Colombia (8.4%), and 8 (3.7%) in Peru. Most women (58.2%) received cancer care in the private setting and the remaining in public/governmental settings. The median age at diagnosis was 44.0 years (IQR: 36.0 - 53.0 years), 57.7% were premenopausal, and 63.6% had node-positive disease.
Neoadjuvant pembrolizumab was administered 200 mg q3w in 83.7% and 400 mg q6w in 16.3% of patients. Seventy-three (34.1%) patients did not complete the planned number of neoadjuvant pembrolizumab cycles (8 cycles for q3w and 4 cycles for q6w). The reasons for not completing neoadjuvant pembrolizumab were immune-related adverse events (irAEs) (29/73; 39.7%), lack of access (26/73; 35.6%), disease progression (6/73; 8.2%), patient decision (1/73; 1.4%), and other (24/73; 32.9%). Patients treated in the private sector were more likely to complete neoadjuvant pembrolizumab than those in public or government-funded settings (66.7% vs 33.3%, $p = 0.002$).
The rate of pathological complete response (pCR) was 59.9% in the overall population, with a higher pCR rate among patients who completed the planned number of pembrolizumab cycles compared to those who received an incomplete number of cycles (69.8% vs. 42.5%, $p<0.01$, respectively). When considering patients who did not complete the standard number of neoadjuvant chemotherapy cycles, only an incomplete number of pembrolizumab cycles emerged as a predictive factor for non-PCR, with an OR of 0.32. irAEs occurred in 32.5% and 44.4% of those who completed and did not complete the planned number of pembrolizumab cycles, respectively. Overall, the most frequent any-grade irAEs were hypothyroidism (14.1%), rash (9.6%), and hepatitis (9.1%). No grade 5 irAEs were reported.
The efficacy and safety of neoadjuvant pembrolizumab in our population is consistent with data from the pivotal trial. However, our study highlights several key aspects regarding the treatment of early TNBC in Hispano-American women using neoadjuvant pembrolizumab. Disparities in access to pembrolizumab therapy were reflected as women with private insurance were more likely to complete pembrolizumab compared to those in public or governmental settings. Additionally, our study found a significantly lower pCR rate among women who did not complete the planned number of pembrolizumab cycles, underscoring the importance of treatment adherence. These findings emphasize the need for strategies to improve access to pembrolizumab, manage irAEs in a timely and appropriate manner, and support patients in completing their treatment regimens in our region.

This work was conducted on behalf of the Latin American Breast Cancer Association (LABCA).

P2-10-13: The Real World Practice of Prospectively Breast Cancer Screening Program for High Polygenic Risk Score Population in Taiwan

Yu-Wen Weng, I-Chen Tsai, Jie-Ru Yang, Tzu-Hung Hsiao, Chih-Chiang Hung, Chia-Hua Liu

Purpose: Breast cancer is the most common cancer among females in Taiwan, accounting for 28.5% of all newly diagnosed cancers in women. The risk of breast cancer can vary from person to person and is influenced by a combination of genetic, environmental, and lifestyle factors. Currently, mammography was the main modality of breast cancer screening in Taiwan.
A polygenic risk score (PRS) is a numerical score that is calculated based on an individual's genetic information, specifically their DNA sequence variants, in order to estimate their risk for developing a particular disease or condition. To calculate a PRS, genetic variants that have been identified as being associated with the disease or trait of interest are combined and weighted according to their effect sizes. These effect sizes represent the strength of the association between the genetic variant and the disease or trait. The weighted genetic variants are then summed to create an overall score that represents an individual's genetic risk for the disease or trait.
We designed a prospectively study to recall the patients with high PRS for receiving breast examination to determinate the correlation of PRS and breast cancer in Taiwan and demonstrate the real world practice.

Materials and Methods: The PRS of the study were estimated using genotyping data from the Taiwan Precision Medicine Initiative (registered number SF19153A). We supposed top 10% population (totally 1001 patients) for the definition of high PRS, and targeted the patient between 35 to 60 years old. We tried to call back these patients to receive breast examination since 1st April, 2023, and collected their baseline characteristics by structured questionnaire. Breast sonography is the main modality for examination, if the patient is older than 45 years old or 40 years old with family history of breast cancer, mammography is also performed.

Results: Total 599 patients between 35 to 60 years old were selected as high PRS. We contacted all of them, but only 140 patients (23.5%) came back to our hospital and received breast examination. The other patients refused to receive examination (n=69, 11.5%), visited other hospital (n=60, 10%), or had incomplete contact information (n=330, 55%). The median age of these 140 patients was 46.7 years old, and the youngest patient was 39 years old.
Eventually, 5 cases (3.6%) were diagnosed as breast cancer. Family history of cancer, menopause status, exposure to contraceptive agents, less times of pregnancy and delivery, lack of exercise, and alcohol consumption seemed like risk factors for breast cancer in this

screening program, but had no statistically significant difference.

Conclusion: In real world practice, it was still a predicament that the called-back rate of PRS breast cancer screen program was still low (23.5%). Nevertheless, the breast cancer detection rate for high PRS in our study was 3.6%, which is higher than the mammography-based screening program in Taiwan (0.5%). There is a long way to go to promote this program and make it a useful and effective tool for breast cancer screening.

P2-10-14: HER2 evolution in breast cancer: Evidence from an AI-assisted real-world data analysis of 3 million women in a diverse urban population

Maylis Larroque, Shunmugam Mohan, Jean-Patrick Tsang, Tielman Van Vleck, Hadrian Green, Tessa Williams, Rob Hale, Otis Jackson, Scott Briercheck, Chris Tackaberry, Erin Gardner, Stefan Santos, Francisco Esteva

Introduction: HER2 positive status gives breast cancer patients a wide range of treatment options. Previous HER2-targeted therapies did not show benefit in patients with low HER2 expression who were treated in the same way as HER2 negative cancers. Regulatory approval of trastuzumab deruxtecan for patients with low HER2 expression addresses a significant unmet medical need and impacts HER2 status reporting. As part of a qualitative exploratory analysis we utilized a novel AI-based approach to analyze a large unstructured real-world dataset, providing insights into biomarker testing and real-world prescribing practices. We found a number of patients with multiple HER2 statuses reported at different points in their patient journey.
Methods: A retrospective analysis of Real-World Data (RWD) was performed on 3 million females aged over 18, using data from a health information exchange (HIE) that includes six urban health systems in the US, varying significantly in size and activity profile. A total of 25 million clinical documents - principally visit and discharge summaries - were analyzed using Natural Language Processing (NLP) specifically optimized for medical language. This analysis generated a curated cohort of 17,125 female breast cancer patients diagnosed and actively treated between August 2021 and August 2023 at three of the six health systems, which contributed most of the cohort. Patients were included in the curated cohort if their data showed evidence of at least two relevant biomarker tests, such as ER/PR, HER2, BRCA1/2, PIK3CA, AKT1, or PTEN. Patient records demonstrating discordant results where the treating physician had recorded HER2 low, HER2 positive and HER2 negative findings either at the same time or at different times were manually examined. Patients who had been described as: “HER2 low”; “HER2: 1+”; “HER2: 2+ with no amplification by FISH”; “HER2: 2+, negative by FISH” or variations of these statements with the same meaning were considered HER2 low. Patients with “HER2: 0” or “HER2 negative” were considered HER2 negative. Patients with “HER2: 2+” but no qualifying reference to the result of a FISH test were considered HER2 positive.
Results: Distribution by age group and stage in the curated cohort of 17,125 patients closely matched national statistics. Evidence of biomarker testing was strongest for ER/PR, then

HER2, then BRCA1/2, and finally PIK3CA, AKT1, or PTEN in descending order of frequency, consistent with the evolution of breast cancer care. A total of 55 patients with discordant results showing all three possible values of HER2 status were found. Transitions from HER2 positive to either HER2 low then HER2 negative or to HER2 negative then HER2 low occurred at a similar rate to transitions to HER2 positive from either of the other statuses. Conclusions: AI-supported analyses of very large RWD datasets can be conducted rapidly, revealing patterns of evolving disease and practice across entire populations and within subgroups with complex inclusion/exclusion criteria. Our study shows that reporting of HER2 positive, HER2 low and HER2 negative status in tumor samples from the same patient is more common and dynamic than previously thought. Further research is needed to understand the evolution of HER2 status, including its relationship to disease progression and treatment with potentially significant implications for clinical practice.

P2-10-15: Reproducibility of the interactions of race on outcomes and toxicities associated with treatment of HER2+ Breast Cancer across databases

Britney Fitzgerald, Justin Petucci, Vasant Honavar, Monali Vasekar

Objective: Investigate the reproducibility of the interaction of race on outcomes and toxicities associated with HER2+BrCa treatment across multiple data sources.

Background: HER2+ breast cancer (BrCa) is an aggressive subtype, accounting for 20-30% of all BrCa cases. Trastuzumab, a monoclonal anti-HER2 antibody, remains the cornerstone of treatment. Previously, we identified race as a factor associated with increased toxicities and poorer outcomes in HER2+BrCa treatment using the TrinetX Database. Further investigation into the outcomes and toxicities in minority groups is necessary, emphasizing the importance of utilizing databases for such research.

Design/Methods: In this propensity score-matched cohort study we used the TriNetX Research Network to compare mortality of HER2+BrCa in non-Hispanic African American (NHAA) women to a corresponding non-Hispanic White cohort (NHW). Qualification into the two race based HER2+BrCa cohorts required the presence of a C50 ICD-10-CM diagnosis code and at least one proxy for HER2 positivity such as Trastuzumab (index event). Cohorts were matched for age, BMI, comorbidities, and lab values using 1:1 matching with a greedy nearest neighbor search. Toxicity outcomes were also compared between the cohorts. The associations of observed outcome frequencies in the two cohorts were tested for significance using the chi-square test. The odds ratios with 95% confidence intervals, are reported as an effect size and significance estimation. As a test of robustness of the results based on the TriNetX data, we compared the outcome of all time mortality after diagnosis across unmatched NHAA and NHW cohorts using the well-established SEER and NCDB patient-level databases.
Results: Using SEER, 68,697 patients met the inclusion criteria for HER2+BrCa (57,554

NHW, 11,143 NHAA). The median age at the index event was 60-64 years for NHW and 55-59 years for NHAA. In the unmatched HER2+BrCa cohorts, the odds of death for NHAA were 1.32 times higher than for NHW, with a P-value of < 0.00001. Using NCDB, 352,553 patients met the inclusion criteria (305,219 NHW, 47,334 NHAA). In these cohorts, the odds of death for NHAA were 1.61 times higher than for NHW, also with a P-value of < 0.00001. Using TriNetX, the odds of death at 5 years after diagnosis for NHAA were 1.1379 times higher than for NHW in the unmatched HER2+BrCa cohorts, with a 95% confidence interval. TriNetX data also showed that NHAA women had significantly increased odds of neuropathy and cardiomyopathy at 1, 3, and 5-year intervals after the HER2+BrCa index date, compared to NHW women. Additionally, the odds of an emergency room visit (for any reason) were up to 79% higher in NHAA women compared to their NHW counterparts. There was a lack of detailed toxicity data points, such as neuropathy and cardiomyopathy, in the NCDB and SEER databases, preventing cross-comparison.
Conclusion: We found increased odds of mortality for NHAA patients compared to NHW patients with HER2+BrCa undergoing Trastuzumab therapy across all three databases. Although toxicity data could not be directly compared across sources due to lack of granularity, the consistency of mortality findings highlights the reliability of our previous results from the TriNetX Database. In TriNetX, NHAA women with HER2+BrCa demonstrated higher odds of experiencing neuropathy, cardiomyopathy, and emergency room visits compared to their NHW counterparts. These results emphasize the importance of considering racial impact on HER2+BrCa outcomes and highlight the utility of real-world data sources like TriNetX for exploring BrCa outcomes and treatment toxicities. Our findings suggest the need for further research and targeted interventions to address disparities and improve treatment outcomes in diverse populations.

P2-10-16: A randomized phase III clinical trial of yoga for chemotherapy-induced peripheral neuropathy treatment (YCT)

Ting Bao, Mingxiao Yang, Marissa Mumford, Katherine Han, Anna M. Tanasijevic, Lauren Piulson, Mehul Shrivastava, Iris Zhi, Jun J. Mao

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and debilitating side effect among cancer survivors receiving neurotoxic chemotherapy that can cause functional disabilities and significantly increase the risk of falls. Currently, there are limited approaches to managing CIPN symptoms and related functional limitations. We conducted a pilot study that demonstrated yoga therapy's feasibility and preliminary efficacy in improving CIPN pain and functional outcomes. We then developed the YCT trial to assess the effect of yoga therapy on improving pain and balance symptoms among cancer survivors with CIPN pain.

Methods: YCT is a prospective phase III multicenter, parallel three-arm randomized clinical trial at Dana-Farber Cancer Institute (DFCI) and Memorial Sloan Kettering Cancer Center (MSK) (ClinicalTrials.gov Identifier: NCT05121558). YCT aims to determine the efficacy of

an eight-week yoga treatment vs. education control (EC) vs. usual care (UC) in improving CIPN pain and balance in cancer survivors. We plan to enroll and randomize 268 participants (2:1:1) to yoga, EC, and UC groups to detect an effect size of at least 0.48 for the primary pain outcome at eight weeks post-randomization between yoga vs. EC, with 80% power and a 2.5% Type I error rate, assuming 12% attrition by week 8 and 20% attrition by week 24. Major eligibility criteria include adults who 1) have no evidence of disease or stable diseases, 2) have completed neurotoxic chemotherapy such as platinum agents, taxanes, vinca alkaloids, and bortezomib at least three months before enrollment, 3) have a clinical diagnosis of CIPN with moderate to severe pain, defined as a score of at least four on the Brief Pain Inventory (BPI) average pain item, and 4) have experienced self-identified CIPN balance difficulty. Eligible subjects in the yoga arm will receive hourly gentle therapeutic yoga classes taught by protocol-trained oncology yoga instructors, twice weekly for eight weeks, and practice home-based yoga. Subjects in the EC arm will receive hourly education classes taught by protocol-trained healthcare instructors twice weekly for eight weeks. Subjects in the UC arm will continue usual care for eight weeks. We offer free yoga sessions for participants in control groups after study completion. Aside from patient-reported outcome measures (i.e., BPI, FACT/GOG-Ntx, QLQ-CIPN 20), we measured functional improvements by functional reach, timed up-and-go, and chair-to-stand tests. We also conducted quantitative sensory testing to assess changes in sensory function. Progress: 1) We are transitioning this trial to a multicenter trial, with DFCI as the coordinating center and MSK as a subsite; 2) As of July 9, 2024, 126 of the planned 268 participants have been enrolled. We anticipate initiating participant enrollment at DFCI in August 2024. The anticipated accrual completion is December 2025.

P2-10-17: A randomized phase III study of first-line saruparib (AZD5305) + camizestrant vs CDK4/6i plus physician's choice endocrine therapy or + camizestrant in patients w/ BRCA1/BRCA2/PALB2 mutations & HR+/HER2- advanced breast cancer (EvoPAR-Breast01)

Pedram Razavi, Judith Balmaña, Stephen J. Luen, Mario Campone, Laura Cortesi, Norikazu Masuda, Kyong Hwa Park, Qingyuan Zhang, Emily Nizialek, Cathy Qi, Karen Cui, Sibylle Loibl, Mark Robson, Filipa Lynce

Background:Emerging evidence indicates that homologous recombination deficiency (HRD) contributes to resistance to cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) plus endocrine therapy (ET). Patients with germline or somatic (g/s) mutations in BRCA1, BRCA2, and/or PALB2 genes (BRCA1m/BRCA2m/PALB2m) and hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer have poorer outcomes with first-line standard-of-care CDK4/6i plus ET than patients without these mutations. Clinical benefit with poly(ADP-ribose) polymerase inhibitors (PARPi) has been demonstrated in patients with HRD breast cancer, and PARPi are approved for the treatment of patients with gBRCA1/BRCA2m and HR-positive/HER2-negative early or advanced breast cancer. Clinical trials have shown that PARPi use in early

lines of therapy can result in a greater magnitude of benefit. PARPi use may also induce reversion mutations that restore homologous recombination proficiency, potentially sensitizing tumors to CDK4/6i. Saruparib (AZD5305) is a first-in-class highly selective PARP1 inhibitor that has increased potency and improved pharmacokinetic and pharmacodynamic properties compared with other approved PARPi. The phase III EvoPAR-Breast01 study (NCT06380751) is evaluating the efficacy and safety of saruparib plus camizestrant, a next-generation oral selective estrogen receptor degrader (SERD) and pure estrogen receptor antagonist, vs physician's choice of CDK4/6i plus ET or CDK4/6i plus camizestrant in participants with g/s BRCA1m/BRCA2m/PALB2m HR-positive/HER2-negative advanced breast cancer.
Trial design:EvoPAR-Breast01 is a randomized, open-label, 3-arm, multicenter, global study. This study will enroll pre-, peri-, and postmenopausal women, and men ≥18 years of age with histologically confirmed estrogen receptor-positive (expression in >1% of cells, irrespective of progesterone receptor status) and HER2-negative (immunohistochemistry score of 0, 1+, 2+/in situ hybridization non-amplified) advanced breast cancer. Patients must have an ECOG PS 0–1 and known BRCA1m/BRCA2m/PALB2m identified by local germline or central tumor testing. ET is permitted up to 28 days prior to randomization. Patients with disease progression ≤84 days from the last dose of (neo)adjuvant chemotherapy for early breast cancer or ≤365 days from the last dose of adjuvant CDK4/6i, PARPi, and/or platinum chemotherapy, or oral SERD for early breast cancer are excluded, as are patients who have received prior systemic treatment for locoregionally recurrent or metastatic breast cancer. Patients with uncontrolled cardiovascular disease and history of, or suspected, myelodysplastic syndrome/acute myeloid leukemia are not eligible for inclusion. Participants will be randomized 2:2:1 to receive saruparib plus camizestrant, physician's choice CDK4/6i (abemaciclib, ribociclib, or palbociclib) plus physician's choice ET (fulvestrant, letrozole, anastrozole, or exemestane), or physician's choice CDK4/6i plus camizestrant, respectively. Treatment will continue until disease progression per RECIST v1.1, unacceptable toxicity, or participant-initiated withdrawal. The primary endpoint is progression-free survival (PFS) by blinded independent review committee in the saruparib plus camizestrant vs CDK4/6i plus ET arms. Overall survival (OS) is a secondary endpoint. Planned statistical analyses of PFS and OS will be conducted using a stratified log-rank test. Participant enrollment is ongoing. Approximately 500 participants will be randomized across the three arms.

P2-10-18: A study to evaluate the safety and efficacy of vosilasarm (EP0062), an oral SARM, as monotherapy and in combination with standard of care regimens in patients with relapsed locally advanced or metastatic AR+/HER2-/ER+ breast cancer

Joyce O'Shaughnessy, Erika Hamilton, Noelia Martinez, Elisa Fontana, Rodrigo Sanchez-Bayona, Patricia LoRusso, Carlo Palmieri, Anne Armstrong, Valentina Boni, Meritxell Bellet

Ezquerra, Aidan Doherty, Mags McDonagh, Sital Patel, Geoff Fisher, Sue Brook, Hendrik-Tobias Arkenau, Hyo Han

Abstract: AR activation exerts potent antitumor activity across a number of ER+ /AR+ breast tumors, including those resistant to standard-of-care endocrine therapy and CDK4/6 inhibitors (Hickey et al, Nature Medicine 2021 27: 310-320). Agonist activation of AR alters the genomic distribution of ER and essential co-activators resulting in repression of ER-regulated cell cycle genes and upregulation of AR target genes, including known tumor suppressors. The clinical activity of SARMs has now been confirmed in several studies (LoRusso et al. Clinical Breast Cancer 2022 22;1 67-77, Palmieri et al Lancet Oncol 2024 25: 317-325).
Vosilasarm (EP0062) is an oral, non-steroidal, Selective Androgen Receptor Modulator (SARM) in development for the treatment of AR+/HER2-/ER+ locally advanced or metastatic breast cancer. This ongoing study (NCT05573126) is evaluating the safety and initial efficacy of vosilasarm in patients with AR+/HER2–/ER+ locally advanced or metastatic breast cancer as monotherapy and in combination.
Module A, which is ongoing, is comprised of dose optimisation cohorts in a 3+3 design, to investigate safety, tolerability, PK and PD and to define the optimum dose for planned combination expansions. 20 patients have been included to-date across 4 dose cohorts.
In Module B, vosilasarm is being evaluated in combination with standard-of-care therapies in patients with relapsed AR+/HER2-/ER+ locally advanced or metastatic breast cancer to confirm safety and explore efficacy. Approximately 20 patients will be included initially across 2 cohorts:

Cohort 1. Vosilasarm + elacestrant in patients with AR+/HER2-/ER+/ESR1mut + advanced/metastatic breast cancer that has progressed on one or two prior lines of endocrine therapy, including prior CDK4/6 inhibitor
Cohort 2. Vosilasarm + everolimus + exemestane in patients with AR+/HER2-/ER+ advanced/metastatic breast cancer that has progressed on a prior endocrine therapy + CDK4/6 inhibitor

Key inclusion criteria are as follows:

Post-menopausal women, ≥18 years
ECOG performance status of 0 to 1
Locally advanced or metastatic breast cancer
ER+, HER2- as per ASCO CAP guidelines
AR+, as defined as ≥ 10% AR nuclei staining by IHC
Endocrine-therapy-sensitive breast cancer defined as:

a) greater than 2 years of adjuvant endocrine therapy prior to development of advanced or metastatic disease,
OR
b) previous response (without disease progression for at least 6 months) to one of the

following treatments in the advanced/metastatic setting: SERD +/- CDK 4/6 inhibitor, AI +/- CDK 4/6 inhibitor

Measurable disease defined by RECIST version 1.1, or bone-only disease

The vosilasarm dose will be selected from the findings of the dose finding/optimisation cohorts in Module A. Combination agents will be initiated at approved doses. An initial 3-6 patients will be enrolled in order to assess safety and tolerability of vosilasarm + the combination agent and to establish the appropriate combination dose for vosilasarm, with subsequent expansion to 10 patients per cohort. Cohorts may be expanded to 25 patients dependent on safety and efficacy findings.
Endpoints include incidence and severity of AEs and SAEs, plasma PK parameters, Clinical Benefit Rate (CBR, complete response, partial response, or stable disease) at 24 weeks, ORR, duration of response, PFS, OS and quality of life.
Planned blood and tissue biomarkers in this study include prostate-specific antigen (PSA), cancer antigen (CA) 15-3, and circulating tumour DNA (ctDNA).
Recruitment of combination cohorts will be initiated in Q4 2024.

P2-10-19: A011801 (CompassHER2 RD): Postneoadjuvant T-DM1 + tucatinib/placebo in patients with residual HER2-positive invasive breast cancer

Ciara O'Sullivan, Karla V. Ballman, Linda M. McCall, Tyler J. Zemla, Anna C. Weiss, Melissa P. Mitchell, Victoria S. Blinder, Nadine M. Tung, William J. Irvin, Sailaja Kamaraju, Matthew P. Goetz, William F. Symmans, Virginia F. Borges, Ian E. Krop, Ann H. Partridge, Lisa A. Carey

Background: Patients with HER2+ early breast cancer (EBC) and invasive residual disease (RD) after neoadjuvant therapy (NAT) have a higher risk of relapse than patients who have a pathologic complete response (pCR). Escalation of therapy in patients with RD using post-neoadjuvant T-DM1 has become the new standard of care, leading to improved invasive disease-free survival (iDFS), but patients with estrogen receptor (ER)-negative or nodal RD have suboptimal outcomes, and central nervous system recurrences are a challenge. More effective treatment strategies are urgently needed. A011801 (CompassHER2 RD) is an escalation trial for patients with high-risk HER2+ RD after neoadjuvant systemic therapy, evaluating the addition of the HER2 selective tyrosine kinase inhibitor (TKI) tucatinib to post-neoadjuvant T-DM1. Methods: Eligibility and Intervention: Patients with high-risk HER2+ RD (i.e. ER-, node-positive, or both) after a predefined course of neoadjuvant HER2-directed treatment are randomized 1:1 to adjuvant T-DM1 + placebo, vs. T-DM1 and tucatinib with adjuvant RT +/- ET. Eligibility criteria include completion of ≥ 6 cycles of NAT, including ≥ 9 weeks of paclitaxel and trastuzumab +/- pertuzumab. All chemotherapy (CT) must be completed preoperatively unless participating in EA1181 (~15-30% will be participants in the CompassHER2 pCR de-escalation companion trial); these patients must receive postoperative CT to complete ≥ 6 cycles prior to enrollment on A011801. Pts who

received prior HER2-targeted TKIs or antibody-drug conjugates are ineligible. Objectives: The primary objective is to determine if iDFS is improved with addition of tucatinib to T-DM1 in patients with HER2+ EBC with RD after neoadjuvant systemic therapy; secondary endpoints include overall survival, breast cancer free survival, distant recurrence-free survival, brain metastases-free survival and disease-free survival. Correlative objectives include the association of i) tumor infiltrating lymphocyte (TILs) levels in the primary tumor and RD with iDFS, ii) TILs with tucatinib benefit, iii) iDFS and circulating tumor cells (CTC) at serial timepoints and iv) the magnitude of benefit of tucatinib (iDFS) in patients with/without detectable pretreatment CTCs. Quality of life and pharmacokinetic endpoints are also being evaluated. Statistics: A011801 is a prospective, double-blind, randomized, phase III superiority trial; stratified by i) receipt of postoperative CT (Y/N), ii) hormone receptor-status (+/-), and iii) pathologic lymph node status (+/-). The study targets an absolute difference of 5% in iDFS (control vs. experimental arm 82% & 87%, HR = 0.7), with a two-sided alpha of 0.05 and power of 80%. The sample size is 981; target accrual = 1031 pts; activation and estimated completion dates are 01/6/21 and ~ 01/2028. Accrual as of 7/1/2024: 741 patients. Support: U10CA180821, U10CA180882; Pfizer Inc; ClinicalTrials.gov Identifier: NCT04457596

P2-10-20: ACE-BREAST-03: A phase 2 trial evaluating ARX788, an anti-HER2 antibody drug conjugate (ADC), for the treatment of HER2+ metastatic breast cancer (mBC) in patients who have been previously treated with trastuzumab deruxtecan (T-DXd)

Joyce O'Shaughnessy, Kashif Ali, Sami M. Ali, Kevin Kalinsky, Margaret Block, Priya Jayachandran, Debu Tripathy, Laila Agrawal, Sibel Blau, Michael A. Danso, Denise Yardley, Jay Andersen, Adrienne Gropper Waks, Igor Makhlin, Petros Nikolinakos, Richard Zuniga1, Janice M. Lu, William John Gradishar, Kamel Abou Hussein, Hope S. Rugo

Background: HER2-targeted ADCs revolutionized treatment for patients with HER2+ mBC. The HER2-targeted ADC, T-DXd, improved PFS and OS vs T-DM1 as second- line treatment for HER2+ mBC and is now the preferred treatment option in this setting. However, improved treatment options are needed for patients with disease progression on T-DXd. Novel technological advances in design of the antibody, linker, and payload of ADCs may further improve the safety/tolerability and efficacy, widening the therapeutic window to address resistance to other anti-HER2 therapies.
ARX788 is a next-generation anti-HER2 ADC stably conjugated to AS269 (a potent tubulin inhibitor). Proprietary site-specific oxime conjugation chemistry, enabled by incorporation of synthetic amino acids into the antibody construct, maximizes the delivery of the cytotoxic payload to tumor cells and minimizes systemic exposure to free payload. A phase 2/3 study in China demonstrated that ARX788 had significantly improved PFS compared with the combination of lapatinib and capecitabine (HR 0.64 [0.49, 0.82], p = 0.0006) in patients treated with prior trastuzumab and taxane (ASCO 2024 Abstract 1020). In addition, ARX788 has shown antitumor activity in heavily pretreated patients with HER2+ and HER2-low

mBC, including those with prior T-DXd exposure.
Methods: ACE-Breast-03 (NCT04829604) is a phase 2 trial evaluating ARX788 in patients previously treated with T-DXd. The primary efficacy endpoint is response rate by RECIST v1.1. Approximately 40 patients will be enrolled. Eligible patients have HER2+ mBC and up to 5 prior treatment regimens for mBC, including T-DXd. Patients with stable brain metastases who are off steroids are eligible. Treatment includes 1.5 mg/kg Q3W ARX788 until unacceptable toxicity or disease progression. Tumor status is assessed every 9 weeks through 27 weeks and every 12 weeks thereafter. The study is currently enrolling in the US.

P2-10-21: ADELA: A randomized, phase 3, double-blind, placebo-controlled trial of elacestrant plus everolimus versus elacestrant in ER+/HER2-advanced breast cancer (aBC) patients with ESR1-mutated tumors progressing on endocrine therapy (ET) plus CDK4/6i

Antonio Llombart-Cussac, José Manuel Pérez-García, Elena Lopez-Miranda, Rui Rui Zhang, Miguel Sampayo-Cordero, Juliana Carvalho-Santos, Pablo Gili Pozo, Marta Beltran, Carlos H. Barrios, Giuseppe Curigliano, Rupert Bartsch, Anne Clair Hardy Bessard, Anna Compagnoni, Kathy Puyana Theall, Thomas Buechele, Tomer Wasserman, Javier Cortés

Background: ET+CDK4/6i is the standard-of-care (SOC) in 1L ER+/HER2- aBC; however, tumors eventually develop resistance. Constitutive activation of the PI3K/AKT/mTOR pathway can contribute to endocrine resistance in breast cancer. A common type of acquired resistance mechanism consists of alterations in the estrogen receptor 1 (ESR1) gene. ESR1 mutations occur in 40-50% of patients with breast cancer and predominantly emerge in the metastatic setting after prolonged exposure to AI regimens. There is an unmet need for novel therapeutic approaches to overcome different resistance mechanisms and improve clinical outcomes in patients with ER+/HER2- aBC with ESR1-mutated tumors who progress following ET+CDK4/6i. Elacestrant is a next-generation oral SERD that binds to the estrogen receptor alpha and induces its degradation. In the EMERALD study, single-agent elacestrant demonstrated a statistically significant and clinically meaningful improvement in PFS versus SOC ET in patients with ESR1-mutated tumors (HR = 0.55; 95% CI, 0.39-0.77; P = 0.0005) [Bidard 2022]. Differences were particularly notable among patients who received prior ET+CDK4/6i ≥12 months; median PFS with elacestrant was 8.6 months vs 1.9 months with SOC ET (HR = 0.41; 95% CI, 0.26-0.63) [Bardia, SABCS 2022]. The crosstalk between the ER and PI3K/AKT/mTOR pathways provides a rationale for evaluating the combination of elacestrant with specific PI3K/AKT/mTOR inhibitors. Everolimus, an mTORC1 inhibitor, is indicated for the treatment of postmenopausal women with HR+/HER2- aBC in combination with exemestane after progression on non-steroidal AIs. The ADELA study aims to compare elacestrant + everolimus vs elacestrant + placebo in ER+/HER2- aBC patients with ESR1-mutated tumors progressing on ET+CDK4/6i.
Methods: ADELA (NCT06382948) is an international, multicenter, phase 3, randomized, double-blind, placebo-controlled trial. Eligible patients are adult women or men with ER+ (≥10% positive stained cells), HER2- aBC with ESR1-mutated tumors, previously treated

with at least one and no more than two lines of ET for aBC, and evidence of disease progression on prior treatment with a CDK4/6i in combination with ET for aBC after ≥ 6 months. Patients receiving CDK4/6i-based therapy in the adjuvant setting are also eligible, provided that disease progression is confirmed after ≥ 12 months of treatment but <12 months following CDK4/6i treatment completion in this scenario. Other criteria include measurable (RECIST v.1.1) or evaluable disease, adequate bone marrow and organ function, and ECOG PS 0-1. Exclusion criteria include prior chemotherapy for aBC, active uncontrolled or symptomatic brain metastasis, and/or leptomeningeal disease. Patients will be randomized 1:1 to 28-day cycles of oral elacestrant 345 mg + everolimus 7.5 mg QD or elacestrant 345 mg + placebo QD until disease progression or unacceptable toxicity, based on the dose determined in the ongoing ELEVATE trial (NCT05563220). Patients will receive dexamethasone mouthwashes four times daily during the first 8 weeks. Stratification factors are presence of visceral metastases (yes vs no) and duration of prior CDK4/6i-based therapy (≥12 vs <12 months). The primary endpoint is blinded independent review committee (BIRC)-assessed PFS. Secondary endpoints include investigator-assessed PFS and OS, BIRC- and investigator-assessed ORR, CBR, DoR, TTR, and best percentage change in target lesions, as well as safety and quality of life. PFS will be estimated using the Kaplan-Meier method. Stratified log-rank tests will be used to assess treatment-group differences. The planned enrollment is 240 patients.

P2-10-22: APOBEC3 as a Biomarker of Response to Neoadjuvant Chemotherapy in Breast Cancer: A Pilot Study

Enrico Moiso, Aaron Cheng, April Risinger, Shraddha Dalwadi, Robert Marciniak, Reuben Harris, Kate Lathrop

Introduction: It is widely accepted that invasive breast cancer is comprised of multiple molecular subtypes that can be predictive of benefit to specific therapeutic interventions and prognostic as to risk of recurrence and development of metastatic disease. However, the molecular profiling of invasive breast cancer is fluid and an area of rapid discovery. The APOBEC3 family of proteins, particularly APOBEC3A (A3A) and APOBEC3B (A3B), are DNA deaminases that have been linked to mutational signatures in breast cancer. Retrospective studies have shown A3B mRNA expression is associated with decreased overall survival and resistance to tamoxifen and worse outcomes in patients on hormonal therapy and a CDK4/6 inhibitor. However, prospective trials evaluating the association between A3A and A3B expression with response to current neoadjuvant therapies are lacking.
Methods: We are conducting a non-randomized, single institution window trial to examine the association between A3A and A3B expression and pathologic response to standard of care neoadjuvant chemotherapy regimens. The eligible study population includes: all subtypes of breast cancer, stage II or III, available diagnostic tissue for APOBEC3 expression testing, anticipated neoadjuvant therapy followed by surgery. APOBEC3A/A3B expression, both at mRNA and protein levels, will be defined on the initial diagnostic tissue and the post neoadjuvant therapy tissue in patients with residual disease and compared to pathological

complete response rate. APOBEC3A/3B expression will also be correlated to the different major histology groups: hormone receptor positive, HER2 positive, and triple negative. This trial opened July 2023 and has accrued at the time of submission 35 patients. Target accrual is 100 patients. All patients are recruited in the breast medical oncology clinic at the Mays Cancer Center.
Anticipated Results and Conclusions: At the time of presentation, we anticipate having 50% of our targeted patient accrual on trial with 30% of patients with pre and post neoadjuvant clinical data with correlation to pathological response. Based on preclinical data, we expect altered sensitivity to neoadjuvant treatment in APOBEC3 expressing tumors. Understanding the role of APOBEC3 enzymes in early phase of breast cancer treatment response will identify patients at risk for treatment resistance and thus present an opportunity to target this patient population with novel therapeutic approaches.

P2-10-23: ASSESSING CLINICAL FEATURES AND OUTCOME OF BREAST CANCER IN PALB2 MUTATION CARRIERS: AN EUROPEAN MULTICENTRIC RETROSPECTIVE HOSPITAL-BASED COHORT CONTROL STUDY (PALBREAST)

Laura Cortesi, Benedetta Pellegrino, Federica Caggia, Martina Manni, Marta Venturelli, Isabella Marchi, Elena Barbieri, Angela Toss, Ugo de Giorgi, Elisa Gasparini, Claudia Degli Esposti, Chiara Casarini, Geertruida H de Bock, Elen Vettus, Evandro de Azambuja, Mateja Krajc, Lazar Popovic, Hayane Akopyan, Aleksander Myszka, Alonso Atanasio Pandiella, Katarzyna Pogoda, Svetlana Bajalica Lagercrantz, Massimo Dominici

Background: PALB2 is a breast cancer susceptibility gene that encodes the BRCA2-interacting protein. Mono-allelic mutations of PALB2 are associated with an increased risk for breast and ovarian cancer in women, prostate cancer in men, and pancreatic cancer in both genders. Women with no family history of breast cancer have a cumulative risk of 33%, compared to 58% in women with two or more family members with breast cancer. Several studies aimed to describe breast cancer phenotypic characteristics in PALB2 mutation carriers. Some of these studies suggested an association with triple-negative phenotype, older age at diagnosis (>60 years), tumor size > 2 cm, negative HER2 status, lymph nodes positive and bilaterality. Nevertheless, results among different studies are contradictory and no data on prognosis of these patients are reported. Furthermore, the clinical potential of PARP inhibition beyond currently approved indications to additional patients whose tumors have (epi)genetic changes affecting homologous recombination repair (HRR) raises new interest in PALB2 mutations as molecular target. So far, the study is aimed to collect, in an European dataset, a large number of PALB2 related BC characteristics starting from 2010 until now and to evaluate the outcome of those patients. This database will be useful for establishing the clincal needs for PALB2 patients, particularly in order to design new interventional studies with target therapies
Trial design: PALBREAST is a multicenter hospital-based retrospective cohort control study conducted across several Institutions with known expertise in managing hereditary breast cancer. It is planned to enroll at least 300 PALB2-related BC diagnosed at the different Units

and 300 BC as control group tested for multigene panel and resulted negative for mutations. It is expected to complete the accrual in one year; furthermore, a minimum follow-up of one more year is required for the final analysis of primary and secondary endpoints. Each participant with PALB2 mutations and BC will be registered in the database where age and modality at diagnosis, type of surgery (quadrantectomy vs. mastectomy vs bilateral mastectomy), tumor characteristics (grading, histology, carcinoma in situ vs invasive, multifocal vs multicentric, proliferation rate, hormonal receptors, nodal status) stage, age at relapse, treatment (neoadjuvant vs adjuvant, chemotherapy vs hormonal treatment), follow-up status will be inserted. A CT/PET for the last follow-up will be performed at the end of the study. All participants will be followed by telephone for overall survival until the end of the study.
The primary end-points are incidence and mortality rates of gPALB2-BC. Secondary end-points are to evaluate the modalities of diagnosis and the imaging characteristics, the type of surgery (bilateral vs. monolateral), the somatic PALB2 mutations rates evaluated by centralized RAD51 assay in the control group, the Disease Free Survival (DFS), and Overall Survival (OS) in comparison with patients with somatic mutations and wild-type PALB2 breast cancer, adjusted for age, stage and period of diagnosis, matched for age, stage, subtype and diagnosis period. Also, the type of therapy (chemotherapy, hormonal treatments and target therapies) and the rate of second BC and other tumors in the patients and in the family will be evaluated. Planned statistical analyses of DFS and OS will be conducted using a stratified log-rank test. Participant enrolment is ongoing. Ninety-seven patients have been already registered in three different centers in Italy.
Clinical trial identification: NCT06403904
Funding: This study was supported by AstraZeneca.

P2-10-24: ASTRO-VAC CNS : Bria-IMT in the Management of Tumor Agnostic Metastatic CNS Lesions

Sailaja Kamaraju, Jonathan Thompson, Deepak Kilari, Ben George, Blaise Bayer, Tamar Aghajanian, William Williams, Charles Wiseman, Giuseppe Del Priore

Background: The Bria-IMT regimen has demonstrated the ability to induce a robust immune response and achieve disease control in heavily pre-treated advanced breast cancer (BC) patients. Bria-IMT is an irradiated allogeneic BC cell line that has been engineered to secrete GM-CSF and may function as antigen-presenting cells. Bria-IMT antigens are taken up by dendritic cells and presented to T cells, generating a tumor-directed immune response. Prior presentations report that Bria-IMT is able to induce regression of intracranial metastases. In the ongoing randomized phase 2 and (NCT03328026) and previously completed trials, a reduction in the size and/or number of intracranial lesions was observed in 5 out of 6 evaluable patients with a median maximal decrease of 60% (range -42% to -100% decrease) in the sum of the diameters in multiple BC subtypes. Bria-IMT is well tolerated with no concerning adverse events (AEs). Disease control after prior antibody-drug conjugates (ADCs) has been observed in 40% of patients, and clinical benefit has been

seen in 5/7 patients with untreated intracranial metastases. CD8+ Immuno PET shows an increase in CD8+ tumor infiltrating lymphocytes suggesting systemic activation and infiltration into lymphoid organs and metastatic sites. Sequencing of CPI with BC and the latest phase 3 formulation are associated with improved clinical outcomes, including OS (median 13.4 months), PFS, and CBR, which are reflected in the design of this ongoing pivotal registration enabling Phase 3 study.
[https://clinicaltrials.gov/study/NCT06072612]. Methods: This is a single site, open label, single-arm, phase 1, multi disease basket trial to evaluate the feasibility and efficacy of the Bria-IMT regimen in combination with pembrolizumab (CPI) in patients with CNS metastases who progress on SOC therapy. Eligibility encompasses all solid tumors with Life expectancy of ≥ 12 weeks and ECOG ≤ 2. Prior surgical resection and/or radiation therapy to CNS lesions are permitted following recovery from these procedures prior to enrollment. Prior immune therapy is allowed if administered more than 6 weeks before the first cycle of Bria-IMT. The Bria-IMT regimen includes: Day -2/-3 Cyclophosphamide 300mg/m2, Day 0; 20 million irradiated SV-BR-1-GM cells intradermally in 4 sites, and 0.6 mcg peg α interferon subcutaneously in the inoculation sites. CPI will be administered every cycle q3wks on day -2/-3. The primary endpoint is to evaluate the safety and feasibility of Bria-IMT in combination with pembrolizumab in patients with solid tumor CNS metastasis. Safety of the treatment will be measured by the frequency and severity of adverse events (AEs). Incidence of dose-limiting toxicities (DLTs), including immune-related toxicities and treatment-related toxicities. Key secondary endpoints will be intracranial disease control rate (measured as ORR, SD, PR, CR, PFS), extracranial disease control (measured as ORR, SD, PR, CR, PFS), and radiographic progression-free survival. Follow-up will be continued for 3 months after treatment termination. Each subject is anticipated to participate in the trial for approximately 6 months unless withdrawn from study or is lost to follow-up before the end of the study. Clinical trial identification Short Title: ASTRO-VAC., Sponsor: Bria Cell

P2-10-25: AXSANA: Status of the international prospective multicenter cohort study evaluating different surgical methods of axillary staging in clinically node-positive breast cancer patients treated with neoadjuvant chemotherapy (NCT04373655)

Maggie Banys-Paluchowski, Nina Ditsch, Elmar Stickeler, Jana de Boniface, Oreste D. Gentilini, Michael Hauptmann, Guldeniz Karadeniz Cakmak, Isabel T. Rubio, Maria L. Gasparri, Michalis Kontos, Eduard-Alexandru Bonci, Laura Niinikoski, Dawid Murawa, Geeta Kadayaprath, David Pinto, Florentia Peintinger, Ellen Schlichting, Lukas Dostalek, Helidon Nina, Hagigat Valiyeva Qanimat, Ashutosh Kothari, Marian Vanhoeij, Andraž Perhavec, Tsvetomir Ivanov, Douglas Zippel, Lía P. Rebaza, Sarun Thongvitokomarn, Bilge Aktas Sezen, Sarah Fröhlich, Tomasz Berger, Franziska Ruf, Angelika Rief, Esther Schmidt, Kristina Wihlfahrt, Timo Basali, Marc Thill, Michael P. Lux, Sibylle Loibl, Hans-Christian Kolberg, Toralf Reimer, Jens-Uwe Blohmer, Markus Hahn, Steffi Hartmann

Background: The optimal surgical staging procedure of the axilla in patients who convert from a clinically positive (cN+) to a clinically negative node status (ycN0) after neoadjuvant chemotherapy (NACT) is still controversial. Diverse techniques such as Axillary Lymph Node Dissection (ALND), Targeted Axillary Dissection (TAD), Target Lymph Node Biopsy (TLNB), and Sentinel Lymph Node Biopsy (SLNB) alone are given preference in different international guidelines. So far, no prospective comparative data on the oncological outcome or the morbidity by procedure are available. Further research is needed to de-escalate axillary surgery in this patient group safely.

Trial design

AXSANA is an international prospective cohort study including initially cN+-patients converting to ycN0-status after NACT and treated with different axillary staging techniques according to the standard at their treating institution. AXSANA was initiated by the EUBREAST (European Breast Cancer Research Association of Surgical Trialists) network and includes patients with cT1-4c tumors, who present initially with axillary lymph node metastasis scheduled for neoadjuvant chemotherapy. According to an amendment in 2020, the inclusion of patients with highly suspicious nodes without confirmation using a minimally invasive biopsy is allowed. All patients converting to ycN0 status undergo follow-up for 5 years regardless of the ypN status.

Primary endpoints: Invasive disease-free survival, axillary recurrence rate, and health-related quality of life (HRQoL). HRQoL is evaluated using four standardized questionnaires (EORTC QLQ-C 30, EORTC QLQ BR 23, Lymph ICF, and SOC-13) at baseline and 1, 3, and 5 years after surgery.

Secondary endpoints: Feasibility and performance of different axillary staging techniques (detection rate, number of removed lymph nodes and association with complications, operating time, and use of clinical and economic resources); impact of learning curve, and the detailed mapping of surgical and oncological treatment standards in different countries. The effect on different regional treatment strategies (radiotherapy, ALND) in patients with ypN0(i+), ypN1(mi), and ypN1 is assessed.

Current status of the study: 5,499 patients from 290 study sites and 27 countries were enrolled in the study between June 2020 and June 2024. Among 3,382 ycN0-patients with a defined surgical concept 909 (26.8%) women were scheduled for ALND, 1,817 (53.6%) for TAD, 547 (16.2%) for SLNB, 19 for TLNB (0.7%) and 90 (2.7%) for other procedures. A target lymph node was marked in 3,099 patients, most frequently using clips/coils (2,418, 78.0%), followed by magnetic seeds (n=320, 10.3%), carbon ink (n=228, 7.4%), and radar markers (n=138, 4.5%).

Funding: AGO-B, Claudia-von Schilling Foundation, Ehmann Foundation, Eugen und Irmgard Hahn Foundation, AWOgyn, Merit Medical, Endomagnetics, Mammotome

Target accrual: unlimited

P2-10-26: Adjuvant pembrolizumab and chemotherapy or surveillance in Early Triple Negative breAst cancer with high stromal tumor-infiltrating lymphocytes (sTILs) score (ETNA)

Elie Rassy, Stefan Michiels, Magali Lacroix-Triki, Roberto Salgado, Paolo Nuciforo, Fatima Zohra Toumi, Jérôme Lemonnier, Juan Manuel Ferrero-Cafiero, Vittoria Barberi, Susana Muñoz, Isabel Pimentel, Esther Zamora, Maria Borrell, Oliver Tredan, Sophie Pellegrino, Fabrice André, Mafalda Oliveira, Barbara Pistilli

Background: Several studies have shown that patients with stage I TNBC derive limited, if any, benefit from chemotherapy. sTILs, a surrogate marker for an active adaptive antitumor immune response, are strongly prognostic and predictive in patients with TNBC across all treatment settings. A recent individual patient-data meta-analysis has shown optimal survival outcomes in patients with stage I TNBC and sTIL ≥ 50% who did not undergo (neo)adjuvant systemic therapy, with a linear association between sTILs and prognosis [Leon Ferré et al, JAMA 2024].
Trial Design: ETNA trial (NCT06078384) is a phase II, open-label, international, multicenter, biomarker-driven study designed to evaluate chemotherapy de-escalation in patients with T1b/c N0M0 TNBC (ER/PgR < 10% by IHC) and sTILs ≥ 30% in resected primary tumors. Eligible patients who have undergone adequate breast cancer surgery will be included in one of two cohorts based on their sTILs levels, as determined by a central review of the surgical specimen. Cohort 1 will include patients aged > 40 years with 30% ≤ sTILs < 50% and those aged ≤ 40 years with 30% ≤ sTILs < 75%. Patients will receive 9 cycles of adjuvant pembrolizumab 200 mg every three weeks and Paclitaxel 80 mg/m^2 weekly for 12 doses. Cohort 2 will include patients aged > 40 years with sTILs ≥ 50% and those aged ≤ 40 years with sTILs ≥ 75%, who will undergo standard surveillance without adjuvant systemic treatment. A total of 1728 pT1b/cN0M0 TNBC patients will be screened for inclusion. Based on the TNBC pooled analysis [Leon Ferré et al, JAMA 2024] and the prevalence of young patients < 40 years in the stage I TNBC population of CANTO (10%), we expect 12.5% of screened patients to be eligible for cohort 1 and 8% for cohort 2. The study will enroll 216 patients in cohort 1 and 138 patients in cohort 2. The primary endpoint is 5-year distant disease-free survival in the 2 cohorts. Secondary endpoints include 5-year invasive disease-free survival, distant recurrence-free survival and overall survival, safety analysis, and quality of life evaluations. Cohorts 1 and 2 will be analyzed independently. Ancillary studies will be performed on the surgical and blood samples to explore prognostic biomarkers and obtain a comprehensive description of TILs in patients with early-stage TNBC. Site activation is currently ongoing.

P2-10-27: An Open Label Study of BTX-A51 in Patients with ER+/HER2- GATA3 Mutant and Wild Type Metastatic Breast Cancer

Zung Thai, Alexander Philipovskiy, Judy Wang, Denise Yardley, David Cook, Senthil Damodaran

Background: GATA3, a transcription factor, plays a critical role in the development of breast tissue. Mutations in GATA3 are observed in approximately 15% of hormone receptor positive (HR+) breast cancers (BC) and are associated with shorter progression free (PFS) and overall survival (OS). In BC these mutations tend to be exclusive of TP53 mutations. Preclinical studies have demonstrated that targeting MDM2 can be synthetic lethal in HR-positive BC GATA3 somatic mutations. BTX-A51 is a multi-specific kinase inhibitor of casein kinase 1 alpha (CK1α) and cyclin-dependent kinases 7 and 9 (CDK7 and CDK9), that synergistically targets master regulators of cancer to activate apoptosis. In preclinical models, BTX- A51 treatment increased p53 levels while decreasing expression of MDM2 and myeloid cell leukemia-1 (MCL-1), resulting in programmed cell death. In Phase 1 studies in patients with advanced acute myeloid leukemia and solid tumors, BTX-A51 showed encouraging clinical activity including objective clinical responses at dose levels that are safe and well-tolerated. Consequently, the current study will test the hypothesis that MDM2 inhibition with BTX-A51 will improve clinical outcomes in patients with GATA3 mutant HR+/HER2-negative metastatic BC.

Methods: This is phase 2, open-label, multi-institutional study evaluating the efficacy, safety, and pharmacokinetics (PK) of BTX-A51 in patients with ER+/HER2- GATA3 mutant and wild type metastatic BC. Key inclusion criteria include pre- and postmenopausal women and men aged ≥18 years; have histologically confirmed HR+/HER2-negative advanced / metastatic BC not amenable to resection or radiotherapy of curative intent; have received at least 2 lines of endocrine therapy and no more than 3 lines of chemotherapy in the adjuvant or advanced setting; and have RECIST v1.1 evaluable disease. Patients will receive BTX-A51 orally at 21 mg 3 times a week on a 28-day cycle and will undergo RECIST v1.1 evaluation at baseline and every 8 weeks. Treatment will continue until progression, death, unacceptable toxicity, or withdrawal from the study. The primary endpoint is objective response rate (ORR) per Investigator assessment. Secondary endpoints include tolerability, disease control rate at 24 weeks, duration of response, progression free survival, overall survival, and PK of BTX-A51. Blood samples for circulating tumor DNA will be collected at baseline, prior to C2, and prior to C3. The study employs a Simon- 2 stage design with a total of 40 patients and 22 patients enrolled to Stage 1. If ≥2 patients respond in the first stage, the study will proceed to stage 2. If ≥ 5 responses are observed among the total of 40 patients, the treatment will be regarded as promising. This two-stage design yields 90% power under the alternative hypothesis of ORR 20% (null ORR 5%) while controlling the one-sided type I error at 5%. Of the first 22 patients enrolled, ≥ 13 should have a pathogenic GATA3 mutations with ≥ 24 patients with GATA3 mutations enrolled in total. The study is currently recruiting patients with ER+/HER2- negative metastatic breast cancer (NCT04872166).

P2-10-28: COMPASS-TNBC - A phase Ib/II, open-label, modular, dose-finding and dose-expansion study to explore safety and anti-tumor activity of novel therapeutics in patients with early relapsed mTNBC. Module 1: Dato-DXd & Module 2: Dato-DXd + durvalumab.

Thomas Grinda, Rasha Cheikh-Hussin, Magali Lacroix-Triki, Kamar Serhal, Chayma Bousrih, Elie Rassy, Francoise Farace, Marianne Oulhen, Jean-Luc Perfettini, Awatef Allouch, Guillaume Montagnac, Fernanda Mosele, Ines Vaz-Luis, Joana M Ribeiro, Alessandro Viansone, Benjamin Verret, Suzette Delaloge, Jacqueline Deneuve, Claude Coutier, Juliette Gouenard, Fabrice André, Stefan Michiels, Barbara Pistilli

Background: Approximately half of all patients (pts) who develop metastatic triple negative breast cancer (mTNBC) after standard neo/adjuvant systemic treatment (NAST) experience a relapse occurring during or within 12 months following the completion of curative treatments, defined as early relapse. Early relapsed mTNBC is a distinct aggressive entity, often resistant to standard therapies and with a poor prognosis (median overall survival, [OS] < 10 months). Given the limited effectiveness of currently available options, new treatment strategies are hardly awaited in this situation. COMPASS-TNBC has been co-designed with a patients' association and wishes to broaden inclusion criteria to meet the important medical need in this situation. It assesses the efficacy of new treatment strategies and conducts translational analyses across different modules, in patients with early relapse mTNBC. The first 2 phase II modules are: Module 1 - Datopotamab deruxtecan (Dato-DXd, an anti-TROP2 antibody-drug conjugate (ADC) with a cleavable linker, and a topoisomerase I inhibitory payload) as monotherapy; Module 2 - Dato-DXd + durvalumab, an anti–PD-L1 monoclonal antibody (mAb).
Methods: Eligible pts are aged ≥18 years, have untreated unresectable or metastatic TNBC (ER and PR < 10%, HER2 non 3+ and non-amplified), have received NAST at the localized stage and have radiological (RECIST) and histological evidence of early relapse (≤12 months from the end of curative treatments). Pts must have an ECOG PS of 0-2, adequate organ function, and ≥1 nonirradiated measurable lesion. Stable CNS metastases (including leptomeningeal disease) are allowed. Pts are excluded if they have clinically significant corneal disease, a history of interstitial lung disease/pneumonitis, active immune disease, or prior treatment with an anti-TROP2-ADC. Pts are randomized in a 1:1 ratio to receive either Dato-DXd (6 mg/kg) (Module 1) or Dato-DXd (6 mg/kg) combined with durvalumab (1120 mg) (Module 2), both administered intravenously every 3 weeks until disease progression or unacceptable toxicity. Each arm will include 25 pts and is designed using the Bayesian optimal phase 2 (BOP2) design. An intermediate analysis will be performed after 12 pts in each module. The primary endpoint is the objective response rate (ORR) at six months, determined and assessed every six weeks using RECIST v1.1 by the investigator. Secondary endpoints include investigator-assessed duration of response (DOR), progression-free survival (PFS), clinical benefit rate (CBR), OS, safety, patient-reported outcomes (EORTC QLQ-C30 and QLQ-BR45), and treatment-emergent antidrug antibodies (ADA). Tumor and blood samples are longitudinally collected at baseline, on treatment

(C1D3 or C2D3), and at the end of treatment. Planned exploratory analyses include treatment-specific biomarkers/mechanisms of response and resistance using high-throughput imaging mass cytometry, RNA sequencing, and whole exome sequencing, on tumor samples, circulating tumor DNA (ctDNA), and circulating tumor cells (CTCs). Additionally, patient-derived organoids will be generated to test and develop novel treatment strategies. In modules 1 and 2, saliva and mouth swab will also longitudinally collected to determine predictors of oral mucositis in patients treated with Dato-DXd. Study enrollment started in June 2024 and is currently ongoing.
Clinical trial information: EU CT Number: 2023-503606-36-00

P2-10-29: Cascade Testing in Racially/Ethnically Diverse Relatives of Patients with Breast or Ovarian Cancer (CASSIE)

Alissa Michel, Nicole Collins, Erik Harden, Eileen Fuentes, June Hou, Elana Levinson, Rita Kukafka, Meghna S. Trivedi, Katherine D. Crew,

Background: About 5-10% of breast cancers and 15% of ovarian cancers are attributed to germline pathogenic variants (PVs) in genes such as BRCA1 or BRCA2. Cascade testing, the process of informing at-risk family members of a PV detected in the proband and offering genetic counseling/testing, is a significant public health intervention which can reduce the burden of disease through targeted early detection and prevention strategies. Several studies have demonstrated that uptake of cascade testing is low, ranging from 15-57%, with testing more commonly pursued when the proband is White. Barriers include time constraints during clinical encounters, lack of contact and emotionally distant relationships with family members, geographic barriers, fear of a positive result and medical mistrust among racially/ethnically diverse patients. To address these barriers, we have developed a patient-facing web-based decision aid (DA), RealRisks, which is available in English and Spanish and has been rigorously tested in a randomized controlled trial (RCT) of genetic testing uptake among diverse women with a family history of breast or ovarian cancer.
Study Design: We are conducting a pilot cluster-RCT of the RealRisks DA and direct access to genetic counseling/testing services to increase cascade testing. We will enroll 30 probands diagnosed with breast or ovarian cancer and a known PV in a hereditary breast and ovarian cancer (HBOC) gene. They will invite 1-4 female first-degree relatives (FDRs) (60 total) who have not undergone germline genetic testing to participate. Cluster randomization will occur at the proband level with stratification based upon U.S. or foreign-born. Female FDRs will be assigned to a standard of care (SOC) notification letter alone or in combination with RealRisks and access to genetic counseling/testing services based upon randomization assignment of the proband. RealRisks consists of interactive modules to collect family history and elicit personal preferences on genetic testing. Probands and FDRs will complete surveys at baseline and 3 months. A subset of probands and FDRs will participate in semi-structured interviews to better understand barriers and facilitators to cascade testing.
Eligibility criteria: Eligible probands include: 1) men or women diagnosed with Stage 0-IV

breast or ovarian cancer; 2) PV in a high or moderate-penetrance HBOC predisposition gene (ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, EPCAM, MLH1, MSH2, MSH6, NF1, PALB2, PMS2, PTEN, RAD51C, RAD51D, TP53) identified within the past year; 3) at least 1 female FDR who has not undergone germline genetic testing. Eligible FDRs include: 1) women, age ≥18 years; 2) FDR of patient with breast or ovarian cancer and known PV; 3) English or Spanish-speaking; 4) able to provide consent.
Outcomes: Our primary endpoint is genetic testing uptake at 3 months among FDRs. Secondary endpoints include genetic testing knowledge, genetic testing intention/decision, informed choice and decision conflict among FDRs at baseline and 3 months. Through qualitative analysis, we will assess barriers and facilitators to communication of genetic test results to family members, experiences with RealRisks, and access to genetic counseling/testing and downstream cancer screening/preventive services.
Statistical methods: We will have >80% power to detect a difference in cascade testing uptake of 20% in the control arm and 60% in the intervention with a 1-sided alpha of 0.05, assuming an intraclass correlation coefficient (ICC) of under 0.20 to account for clustering and 10% dropout.
Current/target accrual: The trial will be activated in August 2024.
Discussion: Results from this pilot trial will inform a larger multicenter RCT to reduce disparities in cascade testing uptake for HBOC syndrome.

P2-10-30: Classifying for HER2 Dependence to De-Escalate Neoadjuvant Chemotherapy in Patients with HER2+ Early Breast Cancer Undergoing HER2 Double-Blockade - CHERRY-PICK Trial (LACOG 0721)

Sérgio Daniel Simon, Carlos Barrios, Jorge Canedo, Laura Testa, José Bines, Luciana Castro Garcia Landeiro, Antonio Llombart, Cristina Matushita, Karina Hiromoto Oikawa, João Nunes de Matos Neto, Katsuki Tiscoski, Marcelle Goldner Cesca, Nicole Machado Rossi Monteiro, Susana Ramalho, Pablo Barrios, Rafaela Gomes de Jesus, Gustavo Werutsky

Background: HER2-positive breast cancer (BC) represents 20% of BC subtypes and is marked by high proliferation and aggressive behavior due to HER2 gene amplification. Chemotherapy combined with anti-HER2 blockade is the standard of care treatment neo/adjuvant setting for HER2+ early BC. The relevance of HER2 as a therapeutic target underscores the importance of accurate HER2 testing. HER2 heterogeneity is associated with resistance to HER2-targeted neoadjuvant therapy, and thus de-escalation of standard therapeutic regimens will depend on accurate tests and HER2 enriched selected tumors. More recently, 18F-FDG-PET identified patients with HER2-positive, eBC who benefited from chemotherapy-free dual HER2 blockade with trastuzumab and pertuzumab, and in which a PET-based, pCR-adapted strategy was associated with an excellent 3-year iDFS. The CHERRY-PICK clinical trial aims to evaluate an anti-HER2 chemo-free neoadjuvant regimen using a fixed-dose combination of pertuzumab and trastuzumab (PHESGO),

targeting a HER2 enriched population, selected by standard biomarkers (HR status and HER2 score) using a PET/CT response based strategy for pCR.
Trial Design: CHERRY-PICK (LACOG 0721) is a nonrandomized, phase II, single-arm study assessing the efficacy of neoadjuvant pertuzumab and trastuzumab (PHESGO) and de-escalating chemotherapy in patients with HER2+ enriched tumors through a PET/CT response based pCR-adapted strategy. The study will enroll women aged 18 to 80 years who have an ECOG performance status of 0 or 1. Eligible participants must present with clinical stage T1c-T2 N0-N1 BC. Tumors must be classified by immunohistochemistry at a central pathology review before enrollment as HER2 3+ score and estrogen receptor (ER) negative, or low (≤10%), and progesterone receptor (PR) negative (<1%). At baseline for image evaluation, patients must have a PET/CT SUVMax of ≥ 2.5 at primary tumor and tumor size of at least 10mm.
Initial dose of PHESGO is 1,200 mg pertuzumab, 600 mg trastuzumab, and 30,000 units hyaluronidase administered subcutaneously over approximately 8 minutes followed every 3 weeks by a dose of 600 mg pertuzumab, 600 mg trastuzumab, and 20,000 units hyaluronidase administered subcutaneously over approximately 5 minutes. After 3 cycles of PHESGO patients will perform PET/CT for response evaluation.
Patients achieving PET/CT response (≥40% reduction in the baseline SUVMax) will continue treatment for 5 additional cycles, completing a total of 8 cycles of neoadjuvant PHESGO therapy. After surgery, patients with pCR will complete 1 year of PHESGO and those with non-pCR will receive adjuvant T-DM1 or standard of care chemotherapy plus PHESGO, as per physician choice. Patients without PET/CT response after cycle 3 will be discontinued from the study and will receive treatment according to institutional standard of care.
The primary objective is to evaluate the pathological complete response (pCR) rate in patients who demonstrate a PET-CT response after 3 cycles. Approximately 63 participants will be enrolled to achieve a final sample size of 44 participants evaluable for the primary endpoint, considering a 20%-30% PET-CT non-responder rate. Secondary objectives include PET-CT response rate, objective response rate by PERCIST and RECIST 1.1, invasive disease-free survival (iDFS), event-free survival (EFS), overall survival (OS), safety, cardiotoxicity, and health-related quality of life (HRQoL). Baseline characteristics will be analyzed using descriptive statistics. The pCR rate will be reported as percentage, with a 95% confidence interval calculated using the Clopper-Pearson method. Time-to-event outcomes will be estimated using the Kaplan-Meier method. Comparisons of these outcomes will be performed using stratified log-rank tests. The trial is open for accrual, with the first site activated in June 2024 and a total of 11 centers planned to participate in Brazil.
Trial Registration: NCT06068985

P2-11-01: Comprehensive spatially resolved single-cell analysis of immunotypes in triple-negative breast cancer revealed the central role of intratumoral MHC class II expressions

Yi Liu

Background: Several studies demonstrated the central role of preexisting immune responses and outcomes in triple-negative breast cancer (TNBC). Emerging studies described 3 distinct tumor-immune microenvironments, termed immunotypes, based on the amount and locations of tumor-infiltrating lymphocytes (TILs), namely immune inflamed (IN), immune excluded (IE), and immune desert (ID). We previously demonstrated that patients with IE tumors had poor outcomes despite having high sTIL. Here, we further evaluated tumor and immune cell characteristics associated with each immunotype.
Methods: NanoString Digital Spatial Profiling (DSP) and CosMx, a spatial multi-omics single-cell imaging platform, were performed in 75 samples from the Mayo Clinic (MC) TNBC cohort (Leon-Ferre BCRT 2018). Firstly, tumors with sTIL quantified by H&E ≤ 30% were classified as ID. The rest of the tumors with high sTIL > 30% were categorized according to the intratumoral CD8 protein expression by DSP, with IE having intratumoral CD8 in the lower median and IN having intratumoral CD8 in the upper median. Chi-square test, gene set enrichment, Cox regression, and Kaplan-Meier analysis were used. Differential expression listed as log 2-fold change (FC) was estimated from the linear mixed model with significance defined as two-sided $p< 0.05$.
Results: In the proteomic DSP-multiplex analysis, intratumoral CD34, GZMB, PTEN, and SMA were significantly more abundant in ID, whereas only B2M and PD-L1 were more abundant in IE. As expected, T cell markers (CD3, CD8, CD4) and their activation markers (ICOS, GZMB) were significantly higher in the intratumoral compartment of IN. Immune checkpoint proteins, including PD-L1, STING, Tim-3, and VISTA, but not CTLA4, were higher in IN samples. IDO1, CD20 (B-cells), and CD68 (macrophage) were more abundant in IN, whereas CD34 (stem cells and/or mast cells) and CD56 (a potential NK cell marker) were not differentially expressed in the intratumoral compartment of IN. Only fibronectin (FN) and smooth muscle actin (SMA) were more abundant in ID. In the CosMxTM single-cell spatial analysis, GSEA analysis demonstrated significant enrichment of the GOBP termed Antigen Processing and Presentation in IN (FDR < 0.001). We further identified 19 genes that were differentially expressed in tumor cells at BY.adj $p<0.05$ across the three immunotypes. 13 out of 19 transcripts were involved in antigen presentation, including transcription factors CIITA and NLRC5, the MHC components HLA-A, HLA-B, HLA-C, HLA-DRA, HLA-DRB1, HLA-DPA1, HLA-DPB1, and HLA-E, the peptide antigen transporters TAP1 and TAP2, and the MHC II invariant subunit protein CD74. Using Kaplan-Meier analysis, all MHC II components HLA-DPA1, HLA-DPB1, HLA-DQA1, HLA-DQB1, HLA-DRB1, and HLA-DRB5 were associated with outcome at log-rank $p<0.05$, and only HLA-B was associated with outcomes (p 0.028). However, HLA-DRA expressions in immune cells, including B cells, macrophages, total dendritic cells (mDC and pDC), and total T-cells (T CD4, T CD8, and Treg), were not associated with outcome.
Conclusions: Using comprehensive spatially resolved single-cell analysis, we demonstrated the central role of intratumoral MHC class II expression associated with inflamed phenotype. Intratumoral MHC class II expressions were associated with significantly improved outcomes but not the MHC expressions in immune cells. Strategies to increase intratumoral MHC expression may improve outcomes for this group of patients in the future.

P2-11-02: Is Adjuvant Chemotherapy Needed in Small Node-Negative Triple Negative Breast Cancer?

Joon Suk Moon, Tae Kyung Yoo, Woong Ki Park, Jai Min Ryu, Sae Byul Lee, Jisun Kim, Il Yong Chung, Beom Seok Ko, Hee Jeong Kim, Jong Won Lee, Byung Ho Son, Jeong Eon Lee, Jonghan Yu, Byung Joo Chae, Se Kyung Lee, Yeon Hee Park, Ji Yeon Kim, Sung Bae Kim, Jin Hee Ahn, Jae Ho Jeong, Hye hyun Jeong, Kyung Hae Jung, Jeong Eun Kim

Background: The efficacy of adjuvant chemotherapy in small node-negative triple-negative breast cancer (TNBC), specifically T1a/bN0 remains unclear. However, recent studies have highlighted that tumor-infiltrating lymphocytes (TILs) are associated with better survival outcomes in TNBC patients. As a result, a few TIL-based clinical trials are now being conducted. This study aims to evaluate the need of adjuvant chemotherapy in patients with T1a/bN0 TNBC according to TIL levels.
Methods: Patients who underwent primary surgery for T1a/bN0 TNBC between 1995 and 2020 at two tertiary hospitals (Asan Medical Center, Samsung Medical Center) were retrospectively reviewed. Clinicopathological features were compared according to receipt of adjuvant therapy. Kaplan-Meier survival analysis and Cox proportional hazard models were applied to determine the impact of adjuvant chemotherapy on recurrence-free survival (RFS). Subgroup analysis was performed according to tumor size, TIL level and chemotherapeutic regimen.
Results: A total of 712 patients were included in this study. Among them, 371 (52.1%) patients underwent adjuvant chemotherapy. Patients who underwent adjuvant chemotherapy were significantly younger compared to patients who did not undergo chemotherapy (mean age 50.7 years vs 55 years, t-test p-value <0.001). Patients with a high-grade tumor, larger tumor, and high Ki-67 were more likely to have undergone chemotherapy. Whereas patients with a low TIL (≤ 30%) tumors were more likely to not have chemotherapy. Most of the patients had only adriamycin-included chemotherapeutic regimens (N=256, 69%), and only 9 (2.4%) patients underwent a taxane-included regimen. Other chemotherapeutic regimens include CMF and Didox. During a median follow-up of 72 months, 58 (8.1%) patients had a locoregional recurrence or distant metastasis. Adjuvant chemotherapy was found to have no significant impact on RFS (5-year survival rate 93.9% no chemotherapy vs 93.0% chemotherapy, log-rank test p-value 0.59). After adjusting for age, histologic grade, tumor size, Ki-67, and TIL level, patients who underwent chemotherapy had no significant difference in RFS compared to patients who did not receive chemotherapy (hazard ratio 1.12, 95% confidence interval 0.564-2.226, p-value 0.746). Subgroup analysis according to tumor size (T1a, T1b), TIL (≤ 30%, >30%), and chemotherapeutic regimens (only adriamycin and/or taxane) also showed that adjuvant chemotherapy had no significant impact on recurrence.

Conclusion: In the overall small node-negative TNBC patient population, adjuvant chemotherapy did not significantly impact recurrence. Avoidance of chemotherapy in T1a/bN0 TNBC patients can be considered. Further clinical studies are needed to evaluate the efficacy of adjuvant chemotherapy in patients with small node-negative TNBC.

P2-11-03: Quantification of Breast Cancer 1 gene (BRCA1) promoter methylation in individuals with and without cancer using cell-free DNA

Francesca Menghi, Margaret Antonio, William Cance, Tracy Nance, Edison T. Liu

Introduction: BRCA1 promoter hypermethylation (BRCA1meth), which is a driver of homologous recombination deficiency (HRD), is observed in up to 25% of triple negative breast cancers (TNBCs) and ovarian carcinomas (OvCas). BRCA1meth is associated with worse outcome compared to BRCA1 mutations (Menghi et al., PMID: 35857626), and, when found in individuals without cancer (i.e. constitutional BRCA1meth), it is associated with increased risk of breast and ovarian cancer (Lonning, et al., PMID: 36074460). Current methodologies to determine the presence of BRCA1meth in a cancer sample require tissue biopsy and have not been adopted for standard clinical assessment. The GRAIL cell-free DNA (cfDNA)-based targeted methylation platform is a robust, biopsy-free, scalable assay that was optimized to distinguish cancer methylation patterns between different cancer signal origins. Here, we describe the GRAIL platform's ability to detect and quantify BRCA1meth.

Methods: As part of the CCGA study (NCT02889978), clinical data were recorded and plasma samples were collected and processed on GRAIL's targeted methylation platform from 2,958 patients with cancer prior to any treatment, and from 2,790 individuals without cancer. Samples were evaluated from patients with a variety of cancers: breast, ovarian, cervical, uterine, lung, prostate, head and neck, kidney, bladder, stomach, esophageal, colorectal, and hematological malignancies. A dilution series of contrived samples was analyzed to establish analytical characteristics of BRCA1meth detection using the GRAIL assay.

Results: When applied to contrived samples, the GRAIL platform was able to detect BRCA1meth at an LoD95 of <1% (as measured by BRCA1meth fraction = methylated molecules / total molecules).

When applied to a cohort of 2,790 individuals without cancer, we found 4% of individuals harbored evidence of BRCA1meth in the fractional range of 0.4% to 37%, with the majority of individuals (81%) having <5% BRCA1meth fraction, similar to surveys using peripheral blood cell DNA (Lonning et al., PMID: 36074460). Consistent with recent data of constitutional BRCA1meth prevalence in umbilical cord blood of newborns (Nikolaienko, et al., PMID: 38053165), we see lower incidence of BRCA1meth in males without cancer (3%)

compared to females without cancer (5%, p=0.01).

BRCA1meth was significantly enriched in the cfDNA of patients with TNBC and OvCa compared to female individuals without cancer (17/112 (15%), adjusted p=0.001 for TNBC; 14/101 (14%), adjusted p=0.01 for OvCa), in concordance with previous assessments of BRCA1meth prevalence across different tumor types (Menghi et al., PMID: 35857626). In TNBC and OvCa, the per-sample BRCA1meth fraction ranged from 0% to 54% and was correlated with the methylation-based estimate of tumor fraction in both TNBC (R=0.68, p=0.0052) and OvCa (R=0.65, p=0.03). High BRCA1meth fractions (up to 16-21%) were observed in four individuals with uterine, colorectal, bladder, or kidney cancer. This suggests that BRCA1 deficiency may be implicated in these rare cases, which would imply HRD, making them candidates for specific treatments.

Finally, across tumor types that affect both sexes, we found consistently lower percentages of BRCA1meth in male vs. female patients, reflecting the differential rates of constitutional BRCA1meth across the two sexes. This suggests that the dynamics of BRCA1 promoter methylation and its consequences for the development of cancer may differ by sex.

Conclusions: This work shows that the GRAIL platform, as a single blood-based assay, can sensitively detect and quantify BRCA1meth from cfDNA, which may inform cancer susceptibility in non-cancer bearing individuals and may also have potential treatment selection implications for cancer patients.

P2-11-04: Incidence and pattern of central nervous system recurrence in TNBC according to response after neoadjuvant treatments

Thomas Grinda, Alyssa R. Martin, Melissa E. Hughes, Chiara Corti, Sara M. Tolaney, Ayal A. Aizer, Jose Pablo Leone, Nancy U. Lin, Sarah L. Sammons

Background: Response to neoadjuvant treatment (NAT), assessed by pathological complete response (pCR) or the Residual Cancer Burden Index (RCB), is significantly associated with recurrence-free and overall survival in patients (pts) with early-stage triple-negative breast cancer (TNBC). However, distant recurrence sites may vary based on NAT response, with a predominance of CNS recurrences in pts with pCR observed in the KEYNOTE522 trial. This has not yet been confirmed in real-world data (RWD).
Methods: In this retrospective RWD study, we describe the CNS recurrence rate at metastatic diagnosis (dg) in Stage I-III TNBC (defined as ER <1%, PR <1%, and HER2 negative by ASCO-CAP guidelines) pts treated with NAT according to pCR and RCB. Patients with bilateral or multifocal cancer were excluded. We used a prospectively maintained institutional database of patients at a single institution supplemented by review of electronic health records. Time to CNS recurrence was calculated from the time of breast surgery to CNS recurrence defined as diagnosis of CNS metastases with or without non-CNS recurrence within 3 months of initial diagnosis of recurrence. CNS metastases include brain

metastases (BM) and/or leptomeningeal disease (LMD). Medians with ranges; cumulative incidences were from Kaplan-Meier comparisons used Fisher's test and log-rank test.
Results: From a total of 630 pts with TNBC who received NAT followed by breast surgery between 2015 and 2022, 37 were excluded with bilateral or multifocal cancer and 593 were included. The median age at initial diagnosis was 51.2 years (yrs) (21.0 - 89.5). Of these pts, 477 (80%) received anthracyclines, 523 (88%) taxanes, 176 (30%) platinum, and 124 (21%) immunotherapy as part of their NAT.
Among them, 214/593 (36%) achieved pCR or RCB0, 78/593 (13%) were classified as RCB1, 207/593 (34%) as RCB2, and 71/593 (12%) as RCB3; 23 pts who did not achieve pCR had an unknown RCB score.
With a median follow-up of 2.8 years (95% CI: 2.6 – 3.1 years), 102 patients experienced distant or local recurrence, with 24 (23%) cases occurring in the CNS. Among pts who achieved pCR, 6/9 (67%) recurrences occurred in the CNS, compared to 18/93 (19%) patients without pCR who had CNS recurrence (p = 0.005). Based on the RCB score, proportion of CNS recurrence were 6/9 (67%) for RCB0, 3/9 (33%) for RCB1, 8/37 (28%) for RCB2, and 7/40 (17%) for RCB3.
Among patients with CNS recurrence, 4/6 (67%) with pCR versus 18/18 (100%; p= 0.054) without pCR had parenchymal BM; 4/6 (67%) versus 2/18 (11%; p=0.018) had LMD. Isolated CNS recurrence was more common in the pCR group; 5/6 (83%) versus 3/18 (17%; p=0.007). Additionally, 3/4 (75%) patients with pCR and 5/18 (28%; p=0.12) without pCR had a single BM as the CNS recurrence. Also, among patients with CNS recurrence, those with pCR were numerically more clinical stage III: 4/6 (67%) vs 6/16 (33%; p=0.19).
The median time to CNS recurrence was 1.62 yrs (0.57-4.66) for patients with pCR and 1.03 yrs (0.35-1.72) for those without pCR. According to RCB 1, 2 and 3 score, median time to CNS recurrence were 0.88 yrs (0.35 - 1.02), 1.12 yrs (0.53 - 1.71), 0.93 yrs (0.38 - 1.72). Cumulative incidence of CNS recurrence at 1 and 2 yrs for pts with pCR was 0.97% (CI95% 0.0 - 2.3) and 1.52% (CI95% 0.0 - 3.22); for pts without pCR was 2.26% (CI95% 0.70- 3.80) and 5.49% (CI95% 2.98 - 7.93), respectively (log-rank: p= 0.2).
Conclusion: Although uncommon, the proportion of pts with relapsed disease with CNS as the first site of recurrence was significantly higher in pts achieving pCR compared to those with residual disease following NAT for TNBC, though there was no statistically significant difference in the cumulative incidence of CNS recurrence by pCR status. Isolated brain relapse was more common among patients with pCR. These findings highlight the critical need for strategies to identify pts at risk for CNS events and to develop effective CNS prevention approaches in high-risk pts.

P2-11-05: Accurate and cost-effective reconstruction of TNBC heterogeneity through 3D digitization of core needle biopsies

Jeffrey Sheridan, Jaiji George Chen, Junxiang Xu, Christina Ennis, Emma Kelley, Neal Kewalramani, Wonyl Choi, Jason Weiss, Gerald Denis, Naomi Ko, Ruben Dries

Objective: Increasing evidence suggests that the tumor microenvironment (TME) of patients with triple negative breast cancer (TNBC) is hallmarked by extensive inter and intra-tumor heterogeneity. Deeper insights into the biological basis of this heterogeneity are needed to elucidate the aggressive nature of TNBC. Early attempts to stratify TNBC patients using bulk or single-cell transcriptomics have shown promise to understand differences in clinical outcomes and provide a personalized medicine approach. However, most examples limit themselves to a single 2D tissue slice per patient. Unfortunately, such an approach represents only a fraction of a 3D core needle biopsy, which is the only available tissue source to examine the treatment naïve TNBC microenvironment.
Recently, spatial omics technologies demonstrated superior results for determining heterogeneity as these tools simultaneously profile the intact TME architecture and spatially resolved transcriptomes. Constructing 3D datasets by sectioning tissue and profiling each slice ($n > 40$) is feasible, but cost-prohibitive and impractical. An innovative digitization workflow that infers transcript localization across 3D datasets without probing each tissue slice would reduce costs and maximize tissue usage, whilst subsequently enhancing our understanding of tissue composition in the treatment naïve TNBC biopsy. Our goal is to facilitate building a comprehensive and large-scale map depicting TNBC heterogeneity from difficult-to-access tissue sources that could shed the much-needed light on TNBC.
Method: We sectioned and imaged a treatment-naive core needle biopsy of TNBC into 48 serial slices, with 8 for spatial transcriptomics (Visium, 10X Genomics) equally spaced and 40 for H&E staining. Image coloration was normalized in a semi-automatic manner, and sections were registered on the associated H&E images using VALIS to create a 3D representation of the tissue. Transcripts from spatial transcriptomic sections were enhanced at super-resolution and mapped across serial sections using iSTAR. 3D spatial transcriptomic data analysis and quantitative comparisons with in-silico 2D slices was performed using the Giotto Suite ecosystem.
Results: We generated a fully digital and super-enhanced (20 μm pixels) 3D spatial transcriptomics dataset from a single core needle TNBC biopsy by integrating image registration with spatial transcriptomics. Transcripts were projected across tissue sections using spatial interpolation and deep learning methods that learn the spatial and histology relationships for genes, thereby providing a comprehensive and super-resolved 3D representation. We observed that specific 3D structures, such as stromal plasma infiltrates and tertiary lymphoid structures, can be more accurately identified from the full 3D digital biopsy. We also illustrate how spatial gene expression patterns, key signaling pathways, and cellular architecture are organized in three dimensions, which cannot be easily inferred from 2D datasets alone. Importantly, systematic analysis comparing 3D versus 2D in-silico generated slices provides a quantitative framework that can be used to determine the limitations and power of spatial transcriptomic data analysis in 2D.
Conclusion: This study demonstrates the feasibility of incorporating spatial transcriptomics and 3D registration methods into standard spatial analyses, enabling a detailed understanding of the spatial organization within a core needle TNBC biopsy and leading to informed insights on tissue architecture and function. Our approach facilitates a data-driven

approach to better understand the strengths and limitations of profiling tumor heterogeneity in core needle biopsies of breast cancer. Finally, our approach enables researchers to make more informed research designs for large-scale projects, maximizing the usage of precious and often difficult-to-obtain patient samples.

P2-11-06: Neoadjuvant chemotherapy plus camrelizumab vs. chemotherapy in patients with locally advanced immunomodulatory triple-negative breast cancer: a prospective, randomized, open-label, phase 2 trial

Li Chen, Shu-hao Jiang, Guang-Yu Liu, Ke-Da Yu, Jiong Wu, Gen-Hong Di, Wen-Juan Zhang, Xiao-xi Ma-lin, Qian-nan Liang, Yu Shen, Zhong-Hua Wang, Jun-Jie Li, Zhi-Ming Shao

Background: Blockade of the PD-L1/programmed cell death protein 1 checkpoint improves the efficacy of classical chemotherapy in the neoadjuvant treatment of triple-negative early breast cancer (TNBC) but results in adverse events. Treatment approaches for immune-sensitive diseases and the efficacy of adding camrelizumab to chemotherapy regimens is unclear, especially in TNBC patients with a high tumor burden.
Methods: This open-label, randomized, phase 2 study randomly assigned (1:1) 90 patients ≥ 18 years with stage II–III histologically documented immunomodulatory TNBC (CD8 ≥10%) were randomly assigned (1:1) to receive chemotherapy with or without intravenous 200 mg camrelizumab every 2 weeks. Chemotherapy comprised nab-paclitaxel (100 mg/m^2)and carboplatin at a dose based on an area under the concentration–time curve of 1.5 mg per milliliter per minute once every week for 3 weeks for a 28 days per cycle within the first 12 weeks, followed by epirubicin (90 mg/m^2) and cyclophosphamide (600 mg/m^2) every 2 weeks for 8 weeks, followed by surgery. The primary endpoint (pathological complete response, pCR) was evaluated using an intention-to-treat approach. This study is registered with ClinicalTrials.gov (NCT05582499).
Findings: Between October 2022 and September 2023, 156 patients were recruited and assessed for eligibility. Of the 90 eligible patients, 45 were randomly assigned to receive camrelizumab plus chemotherapy, and 45 was assigned to receive chemotherapy, with 76.7% having stage III disease. At the data cutoff (March 30, 2024), the pCR rate was 62.2% (28/45 patients) in the camrelizumab–chemotherapy group and 42.2% (19/45 patients) in the chemotherapy group (rate difference: 20.0% [95% CI, -0.8 to 39.2]; P=0.058). Treatment-related adverse events of grade 3 or higher occurred in 33 patients (73.3%) in the camrelizumab-chemotherapy group and in 32 patients (71.1%) in the chemotherapy group. Bulk transcriptomic analysis indicated that patients who received immunotherapy and achieved pCR had significantly greater baseline levels of CD8+ T cells than did those who did not achieve pCR(non-pCR).
Interpretation: In immunomodulatory TNBC patinets with a high tumor burden, neoadjuvant treatment with camrelizumab in combination with nab-paclitaxel plus

carboplatin and anthracycline-based chemotherapy significantly improved pCR rates with an acceptable safety profile.

P2-11-08: Spatial transcriptomic analysis for tumor infiltrating immune microenvironment modulation by neoadjuvant pembrolizumab with chemotherapy for patients with triple negative breast cancer

Kyunghee Park, Junghoon Shin, Jin Seok Ahn, Jeong Eon Lee, Jonghan Yu, Jai Min Ryu, Se Kyung Lee, Byung Joo Chae, Seok Won Kim, Seok Jin Nam, Wong Yang Park, Yoon La Choi, Yeon Hee Park

Introduction: Adding pembrolizumab to conventional neoadjuvant cytotoxic chemotherapy (NAC) improved pathologic complete response rate (pCR) and event free survival (EFS), which has become practice changing treatment. Furthermore, EFS benefit has been maintained even in non-pCR patients. Here, we are to explore the role of pembrolizumab in terms of tumor microenvironment using a spatial transcriptomic analysis.
Methods: We examined a prospective cohort of patients for residual TNBC after NAC with Visium Spatial Gene Expression (Visium V4 Slide - FFPE v2, 10X Genomics). Data was preprocessed with Spacer Ranger, aligned to GRCh38, and analyzed using the Seurat R package. Expression data was normalized and batch effect corrected with SCTransform and RunHarmony. Cell types and Hallmark pathway scores were determined with AddModuleScore. Differential gene expression and gene set enrichment analysis was performed using FindMarker in Seurat and ClusterProfiler. Broader cell types were deconvoluted using a reference with the spacexr R package. Tumor borders were assessed with the SpaCET R package.
Results: In total, 20 cases of residual TNBCs were analyzed. Of 20 cases, sixteen TNBCs had been treated with pembrolizumab (PEM) plus NAC and four with only NAC. In residual cancer burden (RCB) class, four were class I (three in PEM+NAC and one in NAC), fifteen in class II (twelve in PEM+NAC and three in NAC) and one in class III (PEM). Four patients have experienced distant metastasis after standard adjuvant treatment (three in PEM+NAC and one in NAC group).
In DEG analysis, we found CXCL9, CXCL10 and CXCL13 increased in PEM+NAC whereas CCL18 and CD36 in NAC group (FDR <0.01, respectively). GSEA result was shown that interleukin 18(IL18) and interferon gamma (IFNG) response pathway was significantly up-regulated in PEM+NAC group compared to those in NAC group. Cell type scores of CD4+T cell, CD8+T cell, M1 macrophage (Mac) and cancer cell were higher in PEM+NAC group, whereas M2 Mac, myCAF as well as iCAF were higher in NAC group (FDRs < 0.01). The distance between cancer and cytokines including CXCL9 and CXCL10 were closer in PEM+NAC group compared to the that in NAC group (FDRs <0.005). Otherwise, the distance from cancer cell to IFNG, IFNA and CCL5 were not different between PEM+NAC and NAC groups.
Furthermore, we analyzed the interaction between cancer cells and immune cells. In tumor associated Macs, CXCL9 and CXCL10 expressed Mac were nearer by cancer cells in

PEM+NAC group than NAC group even though SPP1 Mac also closer to cancer cells in PEM+NAC group compared to NAC group (Ps <0.05). Moreover, CD69 and PDCD1 expressed exhausted CD8+ T cells were farther from cancer cell in PEM+NAC group compared to distance in NAC group. However, there was no different distance from cancer cells to IFNG and IFN alpha expressed CD8+ T cells between two groups.
Conclusion: After PEM+NAC, residual TNBC more closely interacted CXCL9+/CXCL10+ macrophages even though SPP1+ macrophages with hypoxia also be near to tumor cells compared to those in NAC only. In addition, PEM+NAC expelled exhausted CD8 T cells from cancer in this spatial transcriptomic analysis. Based on these finding, we suggested that adding pembrolizumab to NAC would modulate tumor infiltrating immune cells, which may contribute better survival outcomes.

P2-11-09: Adding Carboplatin to neoadjuvant chemotherapy (NACT) in early triple-negative breast cancer (eTNBC): a systematic review and meta-analysis

Beatrice Ruffilli, Ida Taglialatela, Francesca D'Avanzo, Valentina Rossi, Benedetta Conte, Francesca Vezzoli, Giorgia Ferrari, Luca Boni, Alessandra Gennari

Background: Triple negative breast cancer (TNBC) is characterized by a poor prognosis and a high risk of early relapse. The inclusion of platinum agents in neoadjuvant regimens has been associated with an improvement in pathological complete response rate (pCR) in this subset of patients. However, the use of carboplatin (CBDCA) is still challenging due to inconsistent long-term outcome improvements and the risk of its chronic toxicity. This meta-analysis attempts to assess the impact of the addition of carboplatin to chemotherapy regimens in the neoadjuvant setting in eTNBC.
Methods: A systematic review and meta-analysis was conducted by searching MEDLINE, PubMed and the principal oncology meetings articles and abstracts from 2014 to 2024 with no restriction of language. The research was performed through MeSH terms. Phase II-III randomized studies evaluating the addition of carboplatin to neoadjuvant chemotherapy (NACT) in early Triple-Negative Breast Cancer (eTNBC) reporting response rate and survival outcomes were included. Case reports, reviews and observational studies were excluded. Pathological complete response (pCR) was the primary endopoint; Disease-free survival (DFS) was the secondary endpoint of our investigation. For the primary endpoint (pCR) a random-effects model was used for data analysis, whereas Odds Ratio (OR) was extracted and converted into logOR as outcome measure. Heterogeneity using I2 statistics and publication bias using Fail-Safe N test were assessed. For what concerns the secondary endpoint, a mixed-effects model was used for data analysis, whereas Hazard ratios (HR) and 95% confidence interval (CI) were extracted and converted into logHR and corresponding standard error to obtain the Summary HR (SHR). Heterogeneity was assessed using I2 statistics and publication bias using Egger's regression test. The data analyses were performed with Jamovi 2.4.11 software.
Results: Overall, 30 studies were retrieved of which 9 clinical trials were eligible for this

meta-analysis. Five studies (BrighTNess, GeparSixto, GS5-01, BR 15 1 PEARLY, NACATRINE) completely satisfied the inclusion criteria and were included, with a total of 2956 patients. The addition of CBDCA to NACT was associated with a significant improvement in pCR rate: OR 1,63 [95% CI: 1.3-2.0, p<0.01]; a low heterogeneity (I2=20.4%) with a possible publication bias was detected (Fail-Safe N=45.000, p<0.001). Platinum-based NACT significantly increased DFS with a SHR 0,74 [95%CI: 0.6-0.9, p<0.001], (I2 =24.74%, no publication bias p=0.567).
Conclusions: NACT has a major role in the treatment of EBC. The addition of CBDCA to NACT resulted into a significant improvement in pCR rate and DFS. Given the well-known higher platinum-sensitivity of TNBC and its impact on long-term outcomes, carboplatin should be a standard component of NACT in high risk eTNBC.

P2-11-10: Assessing the Differential Response to Immunotherapy in BRCA1/2 Mutation Carriers with Triple-Negative Breast Cancer

Minna Lee, Natalia Polidorio Machado, Varadan Sevilimedu, Lauren Perry, Giacomo Montagna, Monica Morrow, Nour Abuhadra, George Plitas, Stephanie Downs-Canner

Background: The addition of pembrolizumab to standard neoadjuvant chemotherapy (NAC+P) for patients with triple-negative breast cancer (TNBC) has been shown to result in higher rates of pathologic complete response (pCR) and longer event-free survival compared to neoadjuvant chemotherapy alone (NAC). Alterations in the DNA damage response and homologous recombination pathways may differentially affect the tumor-immune microenvironment and therefore influence response to immunotherapy. It is not known whether BRCA1/2 mutation carriers with TNBC have a differential response to immunotherapy compared to noncarriers. Our objective was to compare pCR rates between BRCA1/2 carriers and noncarriers with TNBC undergoing NAC compared to NAC+P.
Methods: 341 women with stage II-III TNBC treated with NAC+P based on the KEYNOTE 522 (KN522) regimen from 8/2021-5/2024 were compared to 433 consecutive patients who received NAC prior to 7/2021. Demographic and clinicopathological characteristics, and BRCA1/2 mutational status were collected. pCR rates, defined as no disease in the breast and axilla (ypT0/is pN0), were compared between BRCA1/2 carriers and noncarriers across treatment regimens using Chi square tests. Logistic regression was used to evaluate the association between BRCA1/2 status and pCR.
Results: Of non-KN522 patients, 76 (18%) were BRCA1/2 carriers and of KN522 patients, 56 (16%) were BRCA1/2 carriers. Overall, BRCA1/2 carriers were younger, had a lower BMI), and were more likely to be White. There was no difference in histology, grade, presence of lymphovascular invasion, clinical T or N stage, or chemotherapy regimen between carriers and noncarriers. The pCR rates in the non-KN522 group were 50% for BRCA1/2 carriers compared to 36% for noncarriers (p=0.021). In the KN522 group, pCR rates were 68% for BRCA1/2 carriers compared to 55% for noncarriers (p=0.073). Among mutation carriers treated with KN522, the pCR rate was 69% (31/45) for BRCA1 and 60% (6/10) for BRCA2 carriers. On multivariable analysis for the entire cohort, BRCA1/2 status

(OR 1.55, 95% CI 1.03-2.34, p=0.036), receipt of KN522 (OR 2.13, 95% CI 1.71-3.12, p<0.001), younger age at diagnosis (OR 0.98, 95% CI 0.97-0.99, p=0.002), and high grade (OR 9.42, 95% CI 4.01-27.6, p<0.001) were associated with pCR. Among patients receiving KN522, only high grade was associated with pCR (OR 17.4, 95% CI 5.03-110, p<0.001); BRCA1/2 status, age, BMI, race, and stage were not associated with pCR.
Conclusion: BRCA1/2 carriers with TNBC had better response to NAC compared to noncarriers. This was also observed in patients who received NAC+P, although this did not reach statistical significance. Additional work with a larger sample size of carriers may further delineate the differential response to NAC+P. This will be increasingly important for BRCA1/2 carriers as we investigate optimal escalation and de-escalation strategies, particularly when immunotherapy is combined with alternative therapies (i.e., PARP inhibitors).

P2-11-11: Clinicopathological features predictive of neoadjuvant immune checkpoint inhibitor benefit in triple-negative breast cancer

Shipra Gandhi, Gary Tozbikian, Oluwole Fadare, Samira Syed, Briana To, Dionisia Quiroga, Song Yao, Kristopher Attwood, Yisheng Fang, Thaer Khoury

Background: The KEYNOTE-522 (KN-522) regimen [chemotherapy (CT) + immune checkpoint inhibitor (ICI)] is the treatment of choice for patients with triple-negative breast cancer (TNBC) in the neoadjuvant setting. Addition of ICI could be associated with life-threatening immune related adverse events (irAEs). There is an unmet need to identify a subgroup of TNBC patients who would benefit from ICI, while sparing its use in the majority where CT alone may be sufficient. Our study aimed to compare the pathological complete response (pCR) rate between two matched cohorts (CT + ICI vs. CT alone), identify clinicopathologic variables that would predict benefit from ICI and study association of irAE with pCR.
Methods: Patients treated with CT + ICI (n=128) were 1:1 matched to patients treated with CT alone (n=128) on age range (10 years), race, clinical-AJCC stage, and histologic type [metaplastic vs. no special type] from four US academic institutions. Additionally, data on Nottingham grade, degree of necrosis, and percentage of tumor infiltrating lymphocytes (TILs) was collected from pre-treatment core needle biopsy (CNB). To identify the clinicopathologic features of patients who could benefit from ICI, multivariable logistic regression models were used. Data on incidence of any grade irAEs was collected and its association with pCR was also analyzed using multivariable logistic regression models.
Results: pCR was achieved in 64/128 (50%) patients treated with CT + ICI vs. 46/128 (35.9%) treated with CT alone (p = 0.02). The optimal threshold to predict pCR for TILs was 30% for both CT + ICI and CT alone groups, with AUC of 0.78 and 0.73, respectively (p<0.001 for both). In the CT group, lower TILs in CNB, non-Black race, metaplastic histology and higher degree of necrosis were associated with non-pCR; where the corresponding ROC curve had an AUC of 0.83. Patients who received CT were categorized into quartiles (Q) based on the predicted risk of non-pCR (Q1 representing the lowest risk,

Q4 representing the highest risk of non-pCR (34/128 or 26.6%), and Q2 and Q3 representing intermediate levels of risk). In the Q4, the pCR rate with CT alone was only 2.9% (1/46) while it was 20% (6/64) in the CT + IT cohort (p=0.044). The following variables were associated with Q4 vs. Q1-3: non-Black race (96.9% vs. 88%, p=0.04), metaplastic histology (29.7% vs. 1.6%, p<0.01), lymph node (LN) positive disease (54.6% vs. 50%, p<0.01), Nottingham grade 2 (32.8% vs. 6.3%, p<0.01), and lower mean TILs (12.8 +/- 15.0 vs. 36.7 +/- 26.5, p<0.01). The incidence of any grade irAEs was 32% (41/128) in patients treated with CT + ICI. Among patients with an irAE, 63.4% achieved pCR vs. 43.7% without irAE who achieved pCR (p=0.04). There was a higher likelihood of pCR in patients treated with CT + ICI who experienced irAE (OR=3.34, 95% CI 1.17-9.58) while controlling for age, AJCC stage, nottingham grade, race, TILs, and number of ICI doses.
Conclusions: In our real-world multicenter study, the pCR rate with neoadjuvant CT + ICI was lower than that reported in KN-522, with a similar irAE rate. We identified a subgroup of patients with TNBC likely to benefit from addition of neoadjuvant ICI to CT: those with metaplastic histology, non-Black race, LN positive disease, nottingham grade 2, or low TILs (<30%). Occurrence of any irAE was associated with increased likelihood of achieving pCR. Our results warrant validation in larger cohorts.

P2-11-12: Use of the prognostic H&E stromal tumor-infiltrating lymphocytes score and the predictive 27-gene IO score to identify patients with stage I TNBC who may benefit from immune checkpoint inhibitor-based, chemo de-escalated curative-intent therapy.

Erin Hong, Yaping Wu,Tyler J Nielsen, Amanda K Cottam, Kara Gilbert, Kirsten Glass, Brock L Schweitzer, Douglas Hanes, Alan Su, David B Page

Background: Chemotherapy plus immune checkpoint inhibitor (ICI) is the standard curative therapy for stage II/III TNBC, whereas chemotherapy without ICI remains the standard for stage I (T1c) TNBC. Stage I TNBCs may be immunogenic and have excellent outcomes with less/no chemo, highlighting a potential opportunity for a less toxic, ICI-based curative approach. In a Dutch registry, stage I TNBCs with high H&E stromal tumor-infiltrating lymphocytes [sTILs-hi; ≥75%] had excellent (2%) 3-year distant recurrence or death incidence despite not receiving chemo, whereas stage I TNBCs with intermediate [sTILs-int; 30-75%] or low [sTILs-lo; <30%] had 11% and 27% 3-year distant recurrence (de Jong et al, J Clin Oncol 2022; 40:2361-2374). The sTIL score is not consistently predictive of ICI benefit, whereas the DetermaIOTM 27-gene IO score RT-PCR assay has been shown to predict ICI benefit in the neoTRIP randomized trial and in other datasets. We hypothesize that the prognostic sTIL score could be harmonized with the predictive 27-gene IO score to identify patients with stage I TNBC who would most likely benefit from chemo de-escalation and an ICI-based curative approach.
Methods: We evaluated outcomes, H&E sTILs (scored by a trained pathologist using the International TILs Working Group method), and IO score using samples from stage I (T1c) TNBCs (n=57) treated at our institution from 2010-2022. sTILs and IO score measurements

were repeated in matched biopsies v. surgical excisions when available (n=34 with no intervening therapy). Cumulative incidence of distant recurrence or death was calculated from the time of resection. sTILs and IO scores were described using the above thresholds reported by de Jong, et al. For matched biopsy/surgery specimens, averaged scores were reported.
Results: The 3-year distant recurrence or death incidence was: 7% (n=4/55) for the entire cohort; 20% (n=3/15) for no chemo & 5% for chemo (n=2/42); and 0% (n=0/2) for sTILs-hi, 0% (n=0/15) for sTILs-int & 10% (n=4/38) for sTILs-low. The proportion of IO positive scores in this stage I TNBC cohort was lower (IO+ 18%, n=10/57; mean: -0.28, stdev 0.29) compared to IO scores from previously reported stage II/III TNBC cohorts (neoTRIP: IO+ 42% [Dugo et al., 2022], neoPACT: IO+ 52% [Sharma et al., 2023]). IO scores and sTIL scores across matched biopsy versus surgical excisions were concordant [ICC(3,k): 0.88 & 0.9]. IO scores were moderately correlated with sTILs (r2=0.67), however IO+ tumors were found across all sTILs strata (TILs-lo: n=1/38, 2%; TILs-int: n=7/17, 41%; TILs-hi: n=2/2, 100%).
Conclusions: This dataset reaffirms excellent outcomes for T1c, chemo-treated TNBC, and highlights a potential role for chemo-deescalated, ICI-based therapy for patients with IO+ and sTIL-lo/int tumors who are predicted to benefit from ICI but who still are at high risk of recurrence without systemic therapy. A clinical trial is warranted to evaluate efficacy of ICI in T1c TNBC, and to test the utility of IO score for determining ICI benefit in this setting.

P2-11-13: Retrospective validation of digital twin-based prediction of personalized triple negative breast cancer response to neoadjuvant therapy regimens

Chengyue Wu, Ernesto A.B.F. Lima, Casey E. Stowers, Zhan Xu, Clinton Yam, Jong Bum Son, Jingfei Ma, Gaiane M. Rauch, Thomas E. Yankeelov

Introduction: Neoadjuvant therapy is standard of care for locally advanced triple-negative breast cancer (TNBC), yet only 50-65% achieve a pathological complete response (pCR). Personalizing therapeutic regimens remains a challenge. We have developed MRI-guided digital twins (mathematical models predicting patient responses to neoadjuvant chemotherapy (NAC)) to address this need [1,2]. This study aims to validate digital twins by virtually replicating results from previous clinical trials investigating the efficacy of various chemotherapy regimens.

Methods: This study employed 105 TNBC patients from the ARTEMIS trial (NCT02276433) [3] who received 4 cycles (4×) of Adriamycin/Cytoxan (A/C) every 2-3 weeks, followed by 12 cycles (12×) of weekly Taxol (T). Each patient had multi-parametric MRI to monitor tumor anatomy, perfusion, and cellularity. Personalized digital twins were created by calibrating a biology-based mathematical model to each patient's MRI data collected before, after 2 cycles, and at the end of A/C [1]. The calibrated digital twin has been shown to predict the response of patient's tumor to both the actual and alternative NAC regimens [2].

The accuracy of predicted response to the actual regimen was validated in prior work [1]. To further validate the accuracy of predicted response to alternative NAC regimens, we simulated the response of the individual patients in our cohort to the regimens investigated in three landmark clinical trials (INT C9741 [4], ECOG 1199 [5-6], and SWOG S0221 [7]) that compared A/C and T administrative schedules in locally advanced breast cancer, and determine if our digital twin-based methodology can recapitulate the trial observations.
INT C9741 compared two A/C-T regimens: 1) tri-weekly A/C-T: 4× A/C per 3 weeks → 4× T per 3 weeks, and 2) dose-dense A/C-T: 4× A/C per 2 weeks → 4× T per 2 weeks. The trial found dose-dense A/C-T significantly improved the disease-free and overall survival (DFS/OS) compared to tri-weekly A/C-T.
ECOG 1199, along with recent meta-analyses [8], compared three T regimens combined with tri-weekly A/C: 1) tri-weekly Taxol: 4× A/C per 3 weeks → 4× T per 3 weeks, 2) bi-weekly Taxol: 4× A/C per 3 weeks → 4× T per 2 weeks, and 3) weekly Taxol: 4× A/C per 3 weeks → 12× T weekly. Weekly and bi-weekly Taxol provided similar DFS/OS superior to tri-weekly Taxol, especially for TNBC [6].
SWOG S0221 compared four different A/C-T regimens: 1) Arm 1: 6× A/C per 2 weeks → 6× T per 2 weeks, 2) Arm 2: 15× A/C weekly → 6× T per 2 weeks, 3) Arm 3: 6× A/C per 2 weeks → 12× T weekly, 4) Arm 4: 15× A/C weekly → 12× T weekly. All regimens showed similar DFS over the population, with a non-significant DFS/OS improvement in TNBC patients with bi-weekly A/C-T (Arm 1).

Results: For INT C9741, our digital twin predictions yielded a pCR rate of 49.52% and 73.33% for tri-weekly and dose-dense A/C-T, respectively, with a significant difference ($P < 0.001$) via $\chi 2$ test. This result was consistent with the trial observation on dose-dense A/C-T.
For ECOG 1199, our digital twin predictions yielded pCR rates of 49.52%, 60.00%, and 55.24%, respectively, for the tri-weekly, bi-weekly, and weekly T regimens, with no significant difference ($P > 0.1$). The weekly and bi-weekly T led to higher pCR rates than the tri-week T, consistent with the trial observations.
For SWOG S0221, our digital twin predictions yielded pCR rates of 79.05%, 72.38%, 73.33%, and 69.52% for the four regimens, with no significant difference. Arm 1 had the highest pCR rate, again consistent with the trial outcome.

Conclusion: Our digital twin predictions matched previous clinical trial observations on various NAC regimens, supporting their use in tailoring NAC for TNBC patients. This method can also be beneficially used for designing adaptive clinical trials.

P2-11-14: Treatment Patterns and Safety of Adjuvant Therapy After Chemoimmunotherapy for Early-Stage Triple-Negative Breast Cancer in a Real-World Scenario: The Neo-Real Study

Renata Bonadio, Isadora Sousa, Flávia Balint, Ana Carolina Comini, Monique Tavares, Fernanda Madasi, Jose Bines, Rafael Ferreira, Daniela Rosa, Candice Santos, Zenaide Souza, Daniele Assad-Suzuki, Júlio Araújo, Débora Gagliato, Carlos Henrique dos Anjos, Bruna Zucchetti, Anezka Ferrari, Mayana de Brito, Renata Cangussu, Maria Marcela Monteiro, Paulo M. Hoff, Laura Testa, Maria del Pilar Estevez-Diz, Romualdo Barroso-Sousa

Background: The KEYNOTE-522 trial established neoadjuvant pembrolizumab plus chemotherapy (P+CT) followed by adjuvant pembrolizumab as the standard of care for stage II-III triple-negative breast cancer (TNBC). Nevertheless, numerous doubts were raised in clinical practice on how to integrate this regimen with other treatment standards such as adjuvant capecitabine (C) or olaparib (O). This study aims to evaluate treatment patterns and safety outcomes of adjuvant therapies following neoadjuvant P+CT using real-world data (RWD).

Methods: The multicentric Neo-Real study evaluates patients with TNBC treated with neoadjuvant P+CT since July 2020 across ten cancer centers. The objective of this analysis is to describe the treatment patterns in the real-world and to analyze the safety associated with these treatments, focusing on grade ≥ 3 adverse events (AE) and rates of drug discontinuation due to AE.

Results: To date, 410 patients have been included in the Neo-Real study, with 349 having a pathologic report following surgery and 185 concluding all the adjuvant therapy phase. Median age was 43 years; 69.5% had stage II and 25.8% stage III disease. Pathologic complete (pCR) response was achieved in 62.5% (n = 218) of patients and residual disease was found in 37.5% (n = 131). Among patients with pCR, 14% (n = 31) did not receive any adjuvant therapy, and 86% (n = 187) received Pembrolizumab alone (P). Among those with residual disease and a BRCA wild-type/unknown status (n=114), 26.3% (n = 30) received adjuvant P alone, 54.4% (n = 62) received P plus capecitabine (P+C), 10.5% (n = 12) capecitabine alone, 4.4% (n = 5) other regimens (including clinical trials), and 4.4% (n = 5) received no adjuvant therapy. Among those with a BRCA mutation and residual disease (n=12), 75% (n = 9) received pembrolizumab plus olaparib (P+O), 16.7% (n = 2) P+C, and 8.3% (n = 1) olaparib alone.
Rates of grade ≥ 3 AE were 6.3% with P, 16.3% with P+C, and 14.3% with P+O (P=0.057). The most common grade ≥ 3 AE were immune-related AE (6.3%) with P, diarrhea (6.1%) and hand-foot syndrome (8.2%) with P+C, and anemia (14.3%) with P+O. Drug discontinuation due to toxicity during adjuvant therapy occurred in 5.4%, 12.7%, and 10% of the cases, respectively (P=105).
The immune-related grade ≥ 3 AE with adjuvant P consisted of endocrine disorders (2.8%), hepatitis (1.4%), pneumonitis (0.7%), colitis (0.7%), arthritis (0.7%), and skin toxicity (0.7%). Notably, considering all the course of pre- and post-surgery therapy, 23.7% of the

immune-related AE occurred during the adjuvant phase.

Conclusions: In a real-world scenario, most patients treated with neoadjuvant chemoimmunotherapy continued adjuvant pembrolizumab after achieving pCR, while adjuvant capecitabine and adjuvant olaparib were frequently used in combination with pembrolizumab for those of residual disease. Combined adjuvant strategies showed higher rates of grade ≥ 3 AE and drug discontinuation. The efficacy of the combined adjuvant strategies remains to be determined.

P2-11-15: Axillary Pathologic Complete Response in Triple-Negative Breast Cancer Patients with Mammary Pathologic Complete Response: A Systematic Review

Deize Azevedo Pereira, Milena Martello Cristófalo, Jonathan Yugo Maesaka, Yedda Nunes Reis, Gabriela Bezerra Nóbrega, José Maria Soares-Jr, Edmund Chada Baracat, José Roberto Filassi

Background: Neoadjuvant chemotherapy plays a crucial role in breast cancer by providing prognostic information through assessment of systemic treatment response. Response patterns can indicate which patients may have better survival outcomes and may benefit from less invasive therapies. Considering mammary and axillary responses, patients with HER2-positive and triple-negative subtypes exhibit higher rates of pathologic complete response (pCR). This study aimed to evaluate the rate of axillary pCR in triple-negative breast cancer patients achieving mammary pCR.
Methods: This systematic review was conducted following the PRISMA protocol and was registered in PROSPERO (ID: 498121). PubMed, Embase, and Web of Science databases were searched. MESH Terms used were: ((((triple negative breast cancer) and (neoadjuvant chemotherapy)) and (lymph node)) and (axilla response)) and (breast response). Article screening was performed independently by two evaluators using the Rayyan platform. Pathologic complete response (pCR) was defined as the absence of invasive disease in the breast and axilla, with or without residual in situ disease after neoadjuvant chemotherapy (ypT0/ypTis/ypN0). Axillary pCR also included the absence of isolated tumor cells and micrometastases. Studies evaluating mammary and axillary pCR after neoadjuvant treatment in breast cancer patients, including triple-negative tumors, were included without restrictions on chemotherapy type or surgical procedures. Methodological quality assessment was conducted using the Newcastle-Ottawa Scale for cohort studies.
Results: As of November 2023, 180 studies were retrieved, with ten cohort studies meeting the inclusion criteria, totaling 7,206 patients, of whom 30% had triple-negative tumors. Each of the 10 pre-selected articles, all cohort studies, underwent bias assessment using the Newcastle-Ottawa Scale. All 10 selected articles scored 6 or higher, indicating acceptable quality in their methodology and enabling inclusion in this systematic review. Among these, 42% had clinically positive axilla (cN+) prior to neoadjuvant chemotherapy, confirmed by cytologic examination in 419 cases and clinical or pathological examination in 2,575 cases.

Axillary pCR rates were consistently higher than mammary pCR rates across the studies. In 9 out of the 10 selected articles, the rate of axillary pCR was higher than the rate of mammary pCR; in one of them, the rate was similar. In none of the evaluated articles was the mammary response rate higher than the axillary. The overall rates of pCR were 33.4% in the breast (ranging from 19 to 48%), 49.3% in the axilla (ranging from 25 to 92%), and 26.9% (ranging from 14 to 38%) for both sites combined in the triple-negative population. Conclusion: Despite high chemosensitivity in triple-negative breast cancer, rates of mammary pCR are consistently lower than the rates of axillary pCR. Factors beyond tumor subtype likely influence response patterns, indicating the need for further research to identify predictive biomarkers and optimize treatment strategies.

P2-11-16 Characterization of disseminated tumor cells (DTCs) in patients with triple-negative breast cancer (TNBC)

Anne Eckardt, Laura Weydandt, Annekathrin Höhn, Bahriye Aktas, Ivonne Nel

Background: Despite successful treatment of the primary tumor, recurrence occurs in about 30% of breast cancer patients. One possible reason might be micro-metastases, so-called disseminated tumor cells (DTC) in the bone marrow (BM), which split off from the primary tumor in early stages of the disease. The most aggressive subtype is triple negative breast cancer (TNBC), which is hormone-receptor negative (<1% ER/ PR) and HER2 negative (IHC Score 0, 1 or 2 and CISH-). The majority of TNBCs are of high grade and show a high proliferation rate. Patients usually receive chemotherapy but have an increased risk of recurrence and poor prognosis. Particularly patients that do not achieve pathological complete remission (pCR) after chemotherapy might require targeted treatment approaches. Little is known concerning the characteristics of DTCs and their role in TNBC patients.
Methods: BM aspirates were collected from the anterior iliac crest of 80 patients with primary (n=67) or recurrent (n=13) TNBC during surgery. After density gradient centrifugation, cell suspensions were transferred onto glass slides and subjected to a sequential multi-parameter immunofluorescence staining procedure, detecting pan-cytokeratin (CK), vimentin (vim), and for exclusion of hematopoietic cells CD45 in a first panel. Cells were digitalized and detected using the Zeiss Axioscan 7 scannig microscope. After enzymatic release of the fluorochromes, a second antibody panel including HER2, Ki67 and PD-L1 was applied to the same slides, followed by scanning and detection. Nuclei were identified using DAPI within the mounting media in both staining steps. We analyzed 2 x 106 cells per patient.
Results: The DTC positive rate was 56% (n=45) among the cohort. In total, we detected 253 DTCs resulting in a median number of 4 DTCs per patient. Of the 64 patients treated with NACT, 35 were DTC positive and had a decreased pCR rate (54%) compared to DTC negative patients (n=29; pCR rate: 69%). Concerning epithelial-to-mesenchymal transition, phenotype characterization revealed that 14 patients showed epithelial DTCs (CK+/Vim-)

only, 45 cases had epithelial (CK+/Vim-) as well as mesenchymal (CK-/vim+) DTCs and DTCs with mixed characteristics (CK+/vim+). One patient displayed mesenchymal DTCs only (CK-). Based on the phenotypical (panel 1) and therapeutic (panel 2) marker expressions, we found 20 different DTC subpopulations. The majority of epithelial DTCs (CK+/vim-) revealed no expression of PD-L1, Ki67 or HER2 (68%). However, DTCs with hybrid characteristics (CK+/vim+) displayed increased numbers of Ki67+ (85%) and PD-L1+/Ki67+ DTCs (30%). The most frequently occurring profile was CK+/vim+/PD-L1-/ Ki67+/ HER2- (n=75 cells). Interestingly, the mesenchymal DTCs (CK-/vim+) revealed elevated DTC numbers with PD-L1+/Ki67+/HER2± (45%) which increased up to 80% in the CK-/vim- DTCs. HER2 positive cells were predominantly found in non-epithelial DTCs (CK-). Conclusion: Our data indicate that the process of EMT might be linked to the occurrence of DTC subpopulations positive for Ki67, PD-L1 and HER2 which could be therapeutically relevant. Further, our results rise the question whether DTCs are dormant in TNBC patients.

P2-11-17: Atezolizumab in combination w/ polychemotherapy w/ or without a pretherapeutic immune therapy window in patients w/ early triple negative breast cancer (eTNBC) & low tumor burden – prospective data from the randomized neoadjuvant neoMono trial

Cornelia Kolberg-Liedtke, Johannes Schumacher, Ramona Erber, Michael Braun, Peter A. Fasching, Eva-Maria Grischke, Christian Schem, Michael P. Lux, Mustafa Deryal, Oliver Hoffmann, Bernhard Heinrich, Georg Kunz, Kristina Lübbe, Petra Krabisch, Arndt Hartmann, Philip Raeth, Sabine Kasimir-Bauer, Hans-Christian Kolberg

Background: Neoadjuvant chemotherapy in combination with an immune checkpoint inhibitor (ICI) is standard of care in cases of high-risk (tumor size ≥ 2 cm and/or N+) early triple negative breast cancer (eTNBC). In contrast, node negative patients with tumors < 2 cm are currently treated with chemotherapy alone. In fact, based on a large series of real-world data the benefit of chemotherapy in TNBC smaller than 10 mm is in question. Overall, the optimal management of node negative patients with T1c tumors is still an unanswered question.
The neoMono trial prospectively analyzed whether the addition of a preceding Atezolizumab monotherapy window prior to Atezolizumab and neoadjuvant chemotherapy (CTX) improves pCR rates among patients with early TNBC (eTNBC). The results of the primary endpoint analysis have been reported last year at this meeting. While the trial did not demonstrate significant superiority of the immune therapy window regarding pCR rates, impressive pCR rates in the PD-L1 positive population (91.5% in the experimental arm A and 82.2% in the control arm B) as well as in the PD-L1 negative population (56.1% in arm A and 64.5% in arm B) were observed.
Here we present a subgroup analysis including only patients with eTNBC and low tumor burden (defined as tumors smaller <= 2 cm (i. e. cT1c) and cN0).

Methods: NeoMono is a phase 2 randomized multicenter trial planned to recruit a maximum

of 458 female and male pts with primary TNBC (defined as ER/PR < 10% and HER2 negative) with tumor stages cT1c – cT4d (cN0 and cN+) in 34 study sites. PD-L1 status had to be identifiable by central pathology by means of the VENTANA PD-L1 (SP142) assay and was defined by PD-L1 expression on immune cells (IC). Neoadjuvant treatment in both study arms consisted of Atezolizumab 1200 mg every 3 weeks in addition to neoadjuvant CTX (12 x Carboplatin/Paclitaxel q1w followed by 4x Epirubicin/Cyclophosphamide q3w), in arm A preceded by an Atezolizumab monotherapy window of 840 mg once two weeks prior to initiation of combination therapy. The neoMono statistical design uses Bayesian posterior probabilities (uniform prior distribution) and logistic regression. In this subgroup analysis we included only patients with tumors smaller than 2 cm and node negative disease.

Results: 57 pts in arm A and 51 in arm B were included in this subgroup analysis. Demographics and baseline characteristics were balanced between both study arms. Among patients with PD-L1 (IC) tumors (PD-L1 (IC) positive defined as ≥ 1%) pCR rates were 100% in arm A and 90% in arm B. The corresponding pCR rates for PD-L1 (IC) negative tumors (PD-L1 (IC) negative defined as <1%) were 65.9% in arm A and 76.3% in arm. In multivariate analysis (including therapy arm, PD-L1 status, grade 3 and age) only PD-L1 (IC) status (OR 8.46; p <0.044) interacted significantly with pCR.

Conclusion: To our knowledge our analysis is the largest prospective dataset regarding patients with eTNBC and low tumor burden treated with neoadjuvant chemotherapy and an immune checkpoint inhibitor. No significant differences were seen between treatment arms although numerically PD-L1 positive patients showed increased benefit from the immune therapy window. pCR rates were higher compared to the overall study population which may be attributed particularly to smaller tumor size.
We acknowledge that the neoMono trial did not include a chemotherapy only arm, therefore, no conclusions regarding a benefit of the addition of an ICI in general to neoadjuvant chemotherapy can be drawn.
Our result underscore the need to further evaluate the clinical efficacy of combined neoadjuvant chemo- and ICI-therapy in patients with eTNBC and low tumor burden.

P2-11-18: Patterns of Treatment in Older Patients with Early-Stage Triple Negative Breast Cancer

Mohammad Abbas, Asmaa El-Mouden, James Jing, Alex Cai, Stephanie M. Wong, Mark Basik, Jean-Francois Boileau, Karyne Martel, Miranda Bassel, Sarkis Meterissian, Ipshita Prakash

Background: Triple negative breast cancer (TNBC) comprises approximately 15-20% of breast cancer diagnoses in patients over 70 years of age. Chemotherapy has been the mainstay of treatment for both early and advanced stages of TNBC and is associated with a clear survival advantage for older patients with this aggressive subtype. Despite an aging population and an increase in the incidence of breast cancer in older patients, there remains

a knowledge gap in the global treatment patterns of older patients with TNBC.
Methods: A retrospective cohort study was conducted at two academic cancer centers in Canada. Adult women with stage I-III triple negative breast cancer were included from 2005 to 2023. Patients were stratified by age < 70 years (younger cohort), and ≥70 years (older cohort). Demographic, clinical, and histopathologic data were extracted from the institutional databases. Descriptive statistics were used to summarize the data and the Kaplan-Meier method was used to provide survival estimates.
Results: A total of 731 patients were included with a median follow-up time of 49 months (IQR 24-79). The median age was 57 years (IQR 47-67); 20.8% of patients (n=152) were 70 years and older, whereas 79.2% (n=579) were < 70 years. Median tumor size was 22 mm (IQR 16-34) with 36.0% (n=263) having positive lymph nodes at diagnosis. Neither of these characteristics was significantly different between age groups (p=0.99, p=0.17 respectively). In terms of baseline health status, 87.5% (n=133) of the older patients had an Eastern Cooperative Oncology Group score of 0 or 1. Of the older patients, 95.4% (n=145) underwent breast surgery compared to 99.5% (n=576) of younger patients (p < 0.001). Similarly, 69.1% (n=105) of older patients underwent chemotherapy compared to 94.0% (n=544) of younger patients (p < 0.001). Immunotherapy in the early-stage setting was also differentially administered based on age group, with 5.3% (n=8) of older patients receiving it compared to 16.8% (n=97) of younger patients (p < 0.001). Chemotherapy use amongst patients ≥70 years increased over time with 41.7% receiving chemotherapy in the 2005-2010 time period as compared to 76.5% in 2015-2022 (p=0.01). Additionally, use of neoadjuvant chemotherapy (NAC) increased throughout the time period of interest with no older patient receiving NAC in the 2005-2010 interval versus 49.0% receiving NAC in 2015-2022 (p<0.001). The 5-year breast cancer-specific survival (BCSS) in the entire cohort was 89.7% (95%CI 87.2-92.3%). Five-year BCSS in older patients was 87.6% and 90.2% for the younger subgroup (p=0.64). Five-year overall survival was 77.2% in the older subgroup versus 87.5% in the younger subgroup (p<0.0001).
Conclusion: In the largest Canadian cohort of patients with early-stage TNBC to date, our analysis showed that older patients continue to be undertreated compared to their younger counterparts. However, despite the age-related differences in treatment patterns, 5-year BCSS did not significantly differ by age and was higher than 85% in women ≥70 years. This excellent outcome is likely driven by the increased use of chemotherapy and preference for neoadjuvant sequencing over time in this patient population highlighting the importance of systemic therapy in older patients with TNBC.

P2-11-19: Unique kinetics of myeloid derived suppressor cell (MDSC) accumulation associated with immune related adverse events (irAEs) in patients with early stage triple negative breast cancer (eTNBC) receiving neoadjuvant chemo-immunotherapy

Alberto J. Montero, Naji Mallat, Patricia Rayman, Paul Pavicic, Jennifer Powers, Sherwin DeSouza, Corey Speers, Megan Kruse, Zahraa AlHilli, C. Marcela Diaz-Montero

Background: The KEYNOTE (KN)-522 trial established pembrolizumab in combination with chemotherapy as the standard of care for the treatment of eTNBC (clinical stage II-III). This trial demonstrated that the addition of pembrolizumab to standard anthracycline-platinum-taxane neoadjuvant chemotherapy was associated with a clinically and statistically significant improvement in pathological complete response (pCR) rates and event-free survival compared to chemotherapy alone. Pembrolizumab is a programmed cell death protein 1 monoclonal antibody, known to cause irAEs in a significant subset of patients— in the KN-522 trial the rate of any grade and >3 grade irAEs were approximately 34% and 13%, respectively. The addition of pembrolizumab does add significant toxicity to standard chemotherapy, which can lead to early discontinuation of curative intent treatment. Therefore, identification of early predictors of irAEs and ways to mitigate them is very important. We hypothesized that an increase in circulating MDSC levels is an early marker of irAEs associated and that MDSCs differ phenotypically and functionally from tumor driven MDSCs. Accumulation of MDSCs has been previously reported to correlate with stage and inversely correlate with response to systemic therapy.

Methods: PBMCs were isolated at baseline, Cycle 1 Day 1, Cycle 1 Day 8, Day 1 Cycles 2-4, and after surgery from n=40 eTNBC patients treated with the KN-522 chemotherapy regimen. Phenotypic characterization of MDSCs was performed by high parameter flow cytometry. Data was concatenated and visualized in UMAPs using FlowJo. Kinetics of MDSC accumulation during treatment was assessed and associated with irAEs defined as: adverse events that associated with exposure to an immune checkpoint inhibitor (ICI) and consistent with an immune phenomenon. Phenotypic characteristics of MDSCs from metastatic TNBC patients at baseline and MDSCs from non-metastatic TNBC at the time of irAEs were compared.

Results: Twelve out of 40 patients (30%) on study had one of the following documented iRAEs: hypothyroidism (n=4), hepatitis (n=3), adrenal insufficiency (n=2), colitis (n=1), myocarditis (n=1), and hemophagocytic lymphohistiocytosis (n=1). Levels of MDSCs increased during treatment among non-metastatic patients undergoing ICI, and this surge was more prominent among patients experiencing irAEs. In eTNBC patients with irAE associated MDSCs, we observed marked differences in the PMN-MDSC phenotype when compared to MDSCs from metastatic TNBC patients (tumor derived MDSCs). One key finding was significantly higher CX3CR1 expression, the receptor for fractalkine, among irAE associated MDSCs vs. tumor derived MDSCs. Interestingly, accumulation of CX3CR1+ PMN-MDSCs was also found to be the prominent MDSC subtype in the patient who developed severe grade 4 hemophagocytic lymphohistiocytosis.

Conclusions: Our results highlight a potential contribution of a unique subset of PMN-MDSCs to the pathogenesis of irAEs that could involve signaling by fractalkine and provide a potential target of therapeutic intervention.

P2-11-20: Discovering Co-driver Genes and Pathways of Mutant TP53 in Breast Cancer by CRISPR Screening and Multi-omics Approaches

Lilian Nwachukwu, Anasuya Pal, Yining Zheng, Laura Gonzalez-Malerva, Duatin Grief, Lydia Sakala, Jin Park, Joshua LaBaer

In the United States, breast cancer is one of the leading causes of cancer death in women. Triple-negative breast cancer (TNBC) is the most aggressive of all molecular subtypes of breast cancer. It is highly heterogeneous and difficult to target and treat due to its lack of targetable receptors. Our aim is to identify new molecular targets that could aid the treatment of TNBC cases and reduce cytotoxicity of the current therapeutic regimen. The TP53 gene, a known tumor suppressor is the most frequently mutated gene in triple-negative breast cancer occurring in >80 % of TNBC cases.

Statistical pathway analysis from RNA-Seq and ChIP-Seq done on the MCF10A mammary epithelial cell lines expressing the 10 most clinically prevalent p53 mutants identified the Hippo pathway to be dysregulated when associated with aggressive cellular phenotypes. Upon suppression of the upstream Hippo tumor suppressor pathway, the activation of a series of genes promoting cancer hallmark phenotypes ensues. A cell-based TEAD reporter assay showed transcriptional activity of TEAD to be higher in MCF10A cells expressing more aggressive p53 mutants compared to the cell lines with less aggressive mutants. Knockdown of the TAZ protein decreased the invasiveness of the invasive p53 mutant expressing cell lines.

We hypothesized that, in addition to neo-morphic activities of different p53 mutants, the heterogeneity in clinical phenotypes observed in TNBC is due to functional interactions of the driver mutation in p53 with other functionally important co-existing mutations and dysregulated pathways, called ‘co-drivers’.

To identify potential functionally important ‘co-driver’ mutations that cause cancer progression and heterogeneity in clinical phenotypes, a genome-wide screen was performed using lentiviral CRISPR screen library on the invasive MCF10A-p53-R273C-MycOE cell line. In vivo experiments showed that injection of the library-transduced cells yielded tumor in mice. PCR and whole-exome sequencing of the tumor showed frameshift mutations in the enriched EVC2 (EvC Ciliary Complex Subunit 2), NR1D1 (Nuclear Receptor 1D1), and ARAF (a Ras-activating RAF family kinase) genes. Confirming the hits from screening, knockout of these genes in R273C-MycOE cells also showed increased cell invasion.

In parallel, in vitro screens carried out using CRISR knock-out library on the least aggressive MCF10A-p53-Y234C cells identified potential co-drivers. Knockout of GCNT1 and FGD6 genes in MCF10A-p53-Y234C cells increased cell invasion and induced dephosphorylation and activation of TAZ. TEAD activity was also found to be higher in these knock-out cells compared to the Y234C cells. Knockdown of the TAZ protein showed decreased TEAD

activity in the FGD6 and GCNT1 knock-out cells and substantially decreased cell invasion.

We have carried out functional characterization of the TP53 mutations in TNBC and confirmed the cellular phenotypes for specific p53 mutants obtained from the in vitro and in vivo screens. We are validating these identified 'co-driver' genes and targets to discover the molecular mechanisms affecting phenotypic heterogeneity of the p53 mutants and investigating the mechanisms through which Hippo pathway drives the progression of TNBC, as well as assessing the pathway as a target for potential therapy for TNBC with specific TP53 mutations.

P2-11-21: Characterisation of treatment and outcomes for adenoid cystic carcinoma as a distinct clinical sub-type of triple negative breast cancer

Fiona Britton, Steven Churchill, Paul Bishop, Guy Betts, Joseph Haigh, Emily Heathcote, Anne Armstrong, Robert Metcalf

Background: Adenoid cystic carcinoma (ACC) most commonly arises within the salivary glands but can also occur in other glandular tissue including the breast. ACC of the breast (ACCB) represents c.0.1% of breast cancer diagnoses and typically has triple negative receptor status; however the biology and clinical course are very different from triple negative invasive ductal/lobular carcinomas. ACC is typically a slow growing disease with high rates of recurrence many years after diagnosis. Furthermore, ACC has very low response rates to cytotoxic chemotherapy. We report a single institution case series of patients with ACCB, over 26 years and present their management and outcomes.
Methods: Search of an institutional pathology database for diagnoses of ACCB from 1990 to 2020 was conducted to identify patients. A retrospective review of their patient records was undertaken, including a summary of clinical and pathological characteristics, description of curative-intent management and outcomes.
Results: Sixteen ACCB patients were identified who all presented with early breast cancer; T1 (n=7), T2 (n=6), T3 (n=3). Two patients had nodal disease (N1) at diagnosis. Median age at diagnosis was 65 years (range 34 to 91 years). All patients underwent upfront surgical resection with either mastectomy (6/16) or wide local excision (WLE) (10/16), and both patients with known lymph node involvement had axillary lymph node clearance. Six patients received adjuvant chemotherapy with anthracycline and taxane based regimens. Eleven patients went on to receive adjuvant radiotherapy, including 9 WLE patients and 2 mastectomy patients.
Two-year survival was 100%, with no patients experiencing local or distant recurrence. Metastatic recurrence was identified in 7 (44%) patients, including both patients with lymph node involvement at diagnosis. Median time to first recurrence was 74 months (range 27 to 127 months), while median overall survival from recurrence was only 9 months (range 3 to 15 months). Only two patients received systemic anti-cancer therapy for the treatment of metastatic disease, and one patient had known metastatic disease monitored for 15 months with surveillance imaging. One patient had a mastectomy for local

recurrence and a solitary lung metastasis resected, remaining on surveillance with no evidence of disease 33 months later. The other six patients have all died from their metastatic disease. Survival data is based on a minimum follow-up of five years. Five-year survival was 87.5% (14/16), with a median overall survival of 89.5 months.
Conclusions: ACCB is a rare breast cancer subtype and follows a different clinical course to IDC/ILC; ACCB specific management and follow-up should be considered to reflect this. These patients experienced disease recurrence at later timepoints. Previous case studies report better outcomes for ACCB patients when compared to typical triple negative breast cancer, however the majority of ACCB patients recur more than 5 years after diagnosis. Clinicians should be aware of a greater propensity to late follow up for ACCB patients.

P2-11-22: Tolerance of Neoadjuvant Chemotherapy in Combination with Immunotherapy in Older Patients with Triple Negative Breast Carcinoma: The MSKCC Experience

Abha Kulkarni, Diana Lake, Charlie White, Yuan Chen, Mithat Gonen, Koshy Alexander, Larry Norton, Mark Robson, Jasmeet Singh

Background: Triple-negative breast cancer (TNBC) comprises 20% of breast cancer subtypes and has elevated risk of recurrence and mortality. In patients with early-stage TNBC, neoadjuvant chemotherapy (NAC) is standard of care. Among patients treated with NAC, pathologic complete response (pCR) at surgery portends a favorable prognosis. The KEYNOTE 522 (KN-522) trial reported improved pCR, event free survival, and overall survival using immunotherapy with an anthracycline, taxane, and carboplatin-based regimen. However, the median age in KN-522 was 49 years and 90% of the enrolled population was ≤65 years of age. Due to persistent underrepresentation of patients ≥65 years in clinical trials, tolerance and toxicity patterns of the standard KN-522 regimen are not well understood in this subgroup. In this study, we aim to assess real-world feasibility of the KN-522 regimen in patients ≥65 years by studying the impact of treatment modification on clinical outcomes. Methods: We conducted a retrospective analysis of patients age ≥65 with non-metastatic TNBC treated at Memorial Sloan Kettering Cancer Center (MSKCC). Patients were excluded if they received a portion of their care elsewhere or were found to have metastatic disease prior to initiation of NAC. Percent completion of drugs was summarized using mean and interquartile range and its association with pCR, defined as absence of invasive carcinoma on surgical pathology (ypT0N0 or ypTisN0), was assessed using Wilcoxon rank sum test. Fisher's exact test was used to compare the pCR rate between patients who completed ≤85% and >85% of the KN-522 regimen, a threshold that prior studies suggest may affect clinical outcomes. Results: We identified 55 patients ≥65 who began treatment with the KN-522 regimen. Ages ranged from 65 to 85. Of these 55 patients, 2 (4%) had stage I, 40 (73%) had stage II, and 13 (24%) had stage III disease. Only 27 (49%) patients completed >85% of the planned treatment, while only 5 (9.1%) completed the full KN-522 regimen. In 12 (22%) patients, one or more drugs were not administered (cyclophosphamide 10 [18%], anthracycline 9 [16%], carboplatin 3 [5.5%], taxane 1 [1.8%],

pembrolizumab 1 [1.8%]). Of 52 patients who began the carboplatin and taxane portion of the regimen, 29 (56%) received carboplatin weekly while 22 (42%) received it every 3 weeks. Toxicity required dose reduction in 7 (13%) and treatment discontinuation in 27 (52%) of one or both drugs. Of 45 patients who began the anthracycline and cyclophosphamide portion of the regimen, toxicity required dose reduction in 4 (9%) and treatment discontinuation in 10 (22%) of one or both agents. pCR was observed in 24 (44%) patients. The pCR rate did not differ significantly between those who received ≤85% and >85% of the treatment regimen (13 [46%] vs 11 [41%], p=0.8). Grade 3 or higher anemia, neutropenia, and thrombocytopenia were present in 22 (40%), 28 (64%), and 10 (25.5%) patients, respectively. Six (10.9%) had febrile neutropenia. Twelve (21.8%) had immunotherapy-related toxicity, the most common of which were thyroid dysfunction (4, 7.3%), hepatotoxicity (3, 5.5%), and pneumonitis (3, 5.5%). Toxicity required hospitalization in 16 (29%) patients. There were no treatment-related deaths. Conclusion: Treatment completion rate for the standard KN-522 regimen in patients ≥65 years of age was less than 10%, with less than half of patients completing >85% of the planned treatment regimen. The pCR rate observed in this population appeared to be lower than previously reported with this regimen but was not significantly different between those who received ≤85% and >85% of the planned treatment. There is a need for better tolerated chemotherapy and immunotherapy combination regimens in older patients.

P2-11-23: Impact of age on neoadjuvant chemo-immunotherapy (IO) administration and outcomes in patients with early-stage triple-negative breast cancer (TNBC)

Alexis LeVee, Bethania Santos, Megan Wong, Nora Ruel, Heather McArthur, Joanne Mortimer

Introduction: Although patients diagnosed with early-stage triple negative breast cancer (TNBC) are commonly diagnosed before age 50, the impact of age on efficacy and toxicity of recent innovations in standard-of-care curative intent therapy are not well-defined. For example, subgroup analyses from KEYNOTE-522, wherein 11% of the population was aged ≥65y, demonstrated an overall benefit with pembrolizumab (pembro) in addition to neoadjuvant chemotherapy (NAC) in patients aged ≥65y and age <65y; however, the older cohort had an inferior pathologic complete response (pCR) rate of 54.3% vs. 66.2% in the younger cohort, with corresponding event-free survival (EFS) hazard ratios of 0.79 and 0.61, respectively. The aim of this analysis is to examine whether differences in management of older patients with early breast cancer exist and to identify appropriate patients who would benefit from neoadjuvant chemo-immunotherapy (IO).
Methods: Patients with early-stage TNBC diagnosed between 7/1/2021 and 12/31/2023 for whom treatment with the KEYNOTE-522 regimen was planned standard-of-care therapy were identified from 2 institutional databases. Patients were excluded if they did not receive at least 1 cycle of NAC, at least 1 cycle of neoadjuvant pembro, or did not undergo definitive surgery. Univariate and multivariate analysis was performed using logistic

regression to identify factors associated with pCR.
Results: Of the 264 patients (263 female/1 male) included in the analysis, the median age was 52.9 (range 20.8-87.7). 51 (19.4%) patients were age ≥65y, and 213 (80.6%) patients were <65y. Hypertension was more common in patients age ≥65y compared to those <65y (66.7% vs. 21.6%), as was hyperlipidemia (64.7% vs. 23.0%) and type 2 diabetes (33.3% vs. 13.6%) [p<0.001]. Although tumor size, nodal status, and grade were similar between the two age groups, patients age ≥65y were more likely to be diagnosed with non-ductal histologies (17.5%) compared to age <65y (5.1%) [p=0.005]. Patients age ≥65y received fewer cycles of NAC compared to age <65y, with a median of 7 cycles (2-8) and 8 cycles (2-8), respectively (p<0.0001). Similarly, patients age ≥65y received less cycles of neoadjuvant pembro compared to age <65y, with a median of 7 cycles (1-11) and 8 cycles (1-11), respectively (p=0.003). The number of carboplatin and taxane cycles were similar between the two age groups (p=0.34 and p=0.60, respectively). Although the median number of anthracycline-cyclophosphamide (AC) cycles was the same in both age groups [4 (0-4)], the distribution of AC cycles varied: 52% of patients age ≥65y vs. 78% of those age <65y completed 4 cycles of AC, while 36% of patients age ≥65y vs. 12% of those age <65y received 0 AC cycles (p=0.0003). Patients age ≥65y had inferior pCR rates compared to patients age <65y: 49.0% vs. 63.4%, respectively (p=0.059). Although the 65y cutoff was not predictive of pCR, we observed a considerable advantage in patients age <50y vs. those age ≥50y, both in the univariate and multivariate setting. Multivariate analysis showed that younger age (<50y vs. ≥50y) (odds ratio (OR) 1.94; 95% confidence interval (CI), 1.11-3.38; p=0.02), the absence of type 2 diabetes (OR 2.08; 95% CI 1.03-4.18; p=0.04), and higher grade (3 vs. ≤2) (OR 2.18; 95% CI 1.07-4.42; p=0.03) were independent predictors of pCR.
Conclusion: This study suggests that older patients with early TNBC are less likely to receive the planned course of neoadjuvant chemo-IO which may, in turn, impact pCR rates. Overall, older patients received fewer cycles of both neoadjuvant pembrolizumab and NAC, with AC most frequently discontinued. Further studies to identify the optimal treatment regimen for patients aged ≥65y with TNBC are needed.

P2-11-24: Racial and ethnic disparities in treatment outcomes of patients with early-stage triple-negative breast cancer following neoadjuvant chemoimmunotherapy

Megan Wong, Alexis LeVee, Bethania Santos, Nora Ruel, Heather McArthur, Joanne E. Mortimer

Introduction: Triple-negative breast cancer (TNBC) disproportionately impacts patients (pts) of select racial/ethnic groups, particularly evidenced by the higher incidence and poorer outcomes among African American pts with triple-negative disease. Since the KEYNOTE-522 trial did not report differences in pathologic complete response (pCR) by racial/ethnic groups following neoadjuvant chemotherapy (NAC) with or without pembrolizumab, it is critical to confirm the benefit of adding pembrolizumab to NAC in all pt populations. Our study sought to determine the impact of race/ethnicity on the clinical

management and treatment outcomes of NAC with pembrolizumab to confirm the generalizability of KEYNOTE-522 and to identify differences in outcomes according to race/ethnicity. Methods We performed a retrospective chart review of pts with early-stage TNBC receiving NAC with pembrolizumab from 2 institutional databases (City of Hope and University of Texas Southwestern). Pts included in the study were diagnosed with early-stage TNBC from 7/1/2021 to 12/31/2023, received at least 1 cycle of NAC with pembrolizumab, and underwent definitive surgery. Descriptive statistics were used to help understand the differences in clinicopathologic, treatment, and response variables across race/ethnicity groups. The Chi-squared test was used to compare categorical data and the Kruskal-Wallis test compared continuous data across the race/ethnicity categories.
Results: 264 pts (263 females and 1 male) were included in this study, with 116 (43.9%) pts identifying as non-Hispanic White (NHW), 61 (23.1%) as Hispanic/Latino (HISP), 43 (16.3%) as Black/African American (AA), and 34 (12.9%) as Asian. The remaining 10 (3.8%) pts were of other/unknown ancestry. At diagnosis, there were no differences in age, prevalence of hyperlipidemia, prevalence of type 2 diabetes, clinical tumor size, clinical nodal stage, histology, and tumor grade between the racial/ethnic groups ($p>0.2$). However, BMI ($p=<0.0001$) and obesity ($p=0.004$) varied significantly across racial/ethnic groups of pts receiving neoadjuvant chemoimmunotherapy. Asian pts had the lowest median BMI at 24.9 (interquartile range [IQR] 22.2-29.1) and the lowest prevalence of obesity (23.5%), whereas AA pts had the highest median BMI at 33.9 (IQR 26.4-37.5) and highest rate of obesity (62.8%). Similarly, the prevalence of hypertension varied by race/ethnicity ($p=0.0008$). Hypertension was more common AA pts (53.5%) than Asian (23.5%), HISP (24.6%), and NHW pts (24.1%).
During NAC, the receipt of ≥75% of carboplatin and taxane doses were similar across racial/ethnic groups ($p=0.06$). There was also no difference in the number of doses received of pembrolizumab ($p=0.6$) and doxorubicin with cyclophosphamide ($p=0.4$).
While pCR rates were not significantly different by race or ethnicity ($p=0.3$), AA (51.1%, 95% confidence limit [CL] 35.6-66.7) and Asian (50.0%, 95% CL 35.3-70.6) pts had the lowest rates of pCR, whereas HISP (67.2%, 95% CL 55.0-79.3) and NHW (63.8%, 95% CL 54.9-72.7) had the highest rates of pCR.
Conclusion: Although not statistically different, our study found that AA and Asian pts had the lowest rates of pCR following NAC plus pembrolizumab, whereas HISP and NHW had the highest rates of pCR. Since the limited number of Asian and AA pts may contribute to this lack of significance, further research with larger sample sizes of these groups is needed. In addition, the presence of obesity and hypertension was different among racial/ethnic groups, highlighting that underlying health disparities exist in the NAC setting. Understanding these disparities underscores the importance of including diverse pt populations in clinical trials to ultimately optimize treatment outcomes for all pts with TNBC.

P2-11-25: Comparison of Outcomes Among Women with Triple-Negative Breast Cancer Treated with Neoadjuvant Chemotherapy According to Age

Regina Matar-Ujvary, Kristina Fecanji, Varadan Sevilimedu, Giacomo Montagna, Mary L. Gemignani

Background: Triple-negative breast cancer (TNBC) subtype and women diagnosed with breast cancer at a young age (<40) have worse outcomes despite a higher rate of achieving pathologic complete response (pCR) following neoadjuvant chemotherapy (NAC). We sought to identify whether young age contributed to worse outcomes in a contemporary group of TNBC patients treated with NAC.
Methods: A retrospective review of an institutional database identified women with TNBC who underwent NAC followed by surgery from 2010-2019. Clinicopathologic, treatment, and outcomes variables were compared between women <40 and ≥40 years of age at diagnosis. Multivariable models were used to identify factors independently associated with locoregional recurrence (LRR) and distant recurrence (DR), and survival.
Results: We identified 515 women with median age of 51 (range 21-82); 104 (20%) were <40 and 411 (80%) were ≥40 years of age. Compared to women ≥40, younger women presented at a similar clinical stage (of all patients, 6.4% were stage 1, 65% stage 2, and 29% stage 3) and had similar rates of lymphovascular invasion (25%) and extracapsular extension (9.4%). Younger women were more likely to have a high-penetrance gene mutation (35% vs 14%), breast pCR defined as ypT0/is (55% vs 34%), negative pathologic nodal status (81% vs 64%), higher overall pCR rate (47% vs 25%), undergo a mastectomy (75% vs 47%) and less likely to receive adjuvant radiotherapy (70% vs 84%)(all p<0.01). A smaller proportion of women <40 underwent an axillary lymph node dissection (16% vs 25%), but this difference was only marginally significant (p=0.053). There was no difference in type of chemotherapy regimens between groups, with nearly 87% of women receiving an ACT-based regimen. At a median follow-up of 2.8 years (interquartile range 1.6-4.7), there were 36 ipsilateral LRR events. The 5-year LRR rate was 7.9% in women <40 (95% confidence interval [CI] 1.4-14%) versus 8.7% in women ≥40 (95% CI: 5.5-12%) and did not differ between groups (p=0.6). There were 79 total DR events; the 5-year DR rate was 15.2% in women <40 (95% CI 7.4-22.4%) versus 18.4% in women ≥40 years (95% CI 14-22.5%) and did not differ between groups (p=0.6). Fifteen (14%) women in the <40 group died of disease versus 77 (19%) in the ≥40 group (p=0.2). On multivariable analysis, lymphovascular invasion, nodal positivity, and having residual disease were significantly associated with increased risk of breast-cancer mortality. Age, race, and type of surgery were not significantly associated with any of the outcomes.
Conclusion: Young women with TNBC were more likely to be gene carriers and to undergo mastectomy, although they presented with similar clinical stage and were more likely to achieve a pCR from NAC. Young age at diagnosis was not an independent predictor of recurrence and survival outcomes in women with TNBC treated with NAC. Further studies assessing the impact of neoadjuvant chemo-immunotherapy on outcomes in young women are needed.

P2-11-26: Adjuvant chemotherapy in lymph node-negative, T1 triple-negative breast cancer

Jesus Anampa, Alvaro Alvarez Soto, Samilia Obeng-Gyasi, Rachel B. Jimenez, Xiaonan Xue

Introduction: Adjuvant chemotherapy improves overall (OS) and disease-free survival in early-stage triple-negative breast cancer (TNBC) after upfront surgery. However, the role of adjuvant chemotherapy in small, node-negative TNBC has not been formally assessed in clinical trials, and high-quality data is scarce. To better understand this issue, we designed this study to evaluate the benefit of adjuvant chemotherapy in a nationwide dataset.
Methods: This is a retrospective study using the National Cancer Database (NCDB). We collected data on T1N0M0 TNBC patients treated with upfront surgery diagnosed between 2010 and 2019. Kaplan-Meier methods and cox proportional models were used to compare OS between chemotherapy and no chemotherapy cohorts. Logistic regression analysis was used to identify variables associated with chemotherapy use.
Results: In patients with T1N0M0 TNBC, adjuvant chemotherapy improved OS (HR, 0.51; 95% CI, 0.47 – 0.55; p<0.001). The benefit of adjuvant chemotherapy was evidenced across all tumor sizes but with different absolute improvements in OS; the 5- year OS rates for chemotherapy vs. no chemotherapy were 98% vs. 93%, 96% vs. 89%, and 93% vs. 80% for patients with T1a, T1b, and T1c tumors, respectively. Compared to NH white, NH Black women had the same odds of chemotherapy use (OR, 1.01; 95% CI, 0.94 – 1.10; p=0.75) but derived less benefit from chemotherapy (HR, 0.64; 95% CI, 0.54 – 0.76; p<0.001). Despite no difference in chemotherapy benefit in OS across age subgroups, old patients had lower odds of chemotherapy use (OR, 0.19; 95% CI, 0.18 – 0.21; p<0.001).
Conclusions: We report that adjuvant chemotherapy improves OS in patients with T1N0M0 TNBC. However, the magnitude of the benefit is larger for T1c tumors than for T1b and T1a tumors. Patients with T1aN0 had good prognosis with or without chemotherapy; thus, informed decision-making weighing risks, benefits, and comfort level is especially critical in this group.

P2-11-27: A Phase 3, Randomized Study of Adjuvant Sacituzumab Tirumotecan (sac-TMT) Plus Pembrolizumab vs. Treatment of Physician's Choice in Patients With TNBC Who Received Neoadjuvant Therapy & Did Not Achieve a Pathological Complete Response at Surgery

Heather McArthur, Jing Wei, Jaime Mejia, Wilbur Pan, Javier Cortes

Background: Trophoblast cell surface antigen 2 (TROP2) expression is higher in triple-negative breast cancer (TNBC) than in other breast cancer subtypes, and the high expression is associated with poor prognosis. Sacituzumab tirumotecan (also known as sac-TMT/MK-2870/SKB264) is a novel antibody-drug conjugate composed of anti-TROP2 antibody coupled to a cytotoxic belotecan derivative via a novel linker with an average drug to antibody ratio of 7.4. In a previous phase 3 study (OptiTROP-Breast01), sac-TMT

monotherapy provided statistically significant and clinically meaningful improvement in PFS (hazard ratio [HR], 0.31; 95% CI, 0.22-0.45; P < 0.00001) and OS (HR, 0.53; 95% CI, 0.36-0.78; P = 0.0005) compared with physician's choice of chemotherapy in patients with heavily pretreated advanced TNBC. The current standard of care for patients with newly diagnosed high-risk early-stage TNBC is neoadjuvant pembrolizumab plus chemotherapy followed by adjuvant pembrolizumab monotherapy after surgery. However, there is a high unmet need for patients who do not achieve pathological complete response (pCR) after receiving the current standard of care regimen as these patients experience higher rates of disease recurrence and mortality when compared with those who achieve a pCR. The current study (NCT06393374) evaluates adjuvant sac-TMT plus pembrolizumab versus treatment of physician's choice (TPC; comprised of pembrolizumab with or without capecitabine) in patients with TNBC who received neoadjuvant therapy and did not achieve a pCR at surgery.
Methods: This phase 3, randomized, multicenter, open-label study is enrolling patients aged ≥18 years with centrally confirmed TNBC per the most recent American Society of Clinical Oncology/College of American Pathologists guidelines. Eligible patients have non-pCR after ≥5 cycles of neoadjuvant pembrolizumab plus chemotherapy, including ≥1 cycle of anthracycline-based neoadjuvant therapy. All patients must provide tissue from the surgical specimen for TROP2 assessment (central testing) and be able to continue on adjuvant pembrolizumab. Randomization must be conducted within 12 weeks from surgical resection; the window for randomization may be extended on a case-by-case basis after consultation with the sponsor. Patients are randomized (1:1) to receive pembrolizumab 400 mg Q6W for 5 doses plus sac-TMT 4 mg/kg Q2W for 12 doses (arm 1) or TPC with pembrolizumab 400 mg Q6W for 5 doses alone or with capecitabine 1000-1250 mg/m2 BID on days 1-14 and days 22-35 every 42 days for 4 cycles (2 weeks on, 1 week off; arm 2) until completion of therapy or disease recurrence, another malignancy requiring active treatment, unacceptable toxicity, or patient withdrawal. Randomization is stratified by residual tumor and lymph node status, TROP2 expression, and intention to use capecitabine. The primary endpoint is invasive disease-free survival (iDFS). Secondary endpoints are overall survival (OS), distant recurrence-free survival (DRFS), patient-reported outcomes (PROs), and safety. Enrollment began in Q2 2024.

P2-11-28: Intra-arterial chemotherapy for triple-negative breast cancer: a systematic review

Mariano Belfort Santos, Maria Luiza Cedraz, Raissa Vesper, Andreza Pita, Maialu Carneiro, Ana Maria Teixeira

Introduction: Triple-negative breast cancer (TNBC) is defined by the absence of estrogen receptors (ER), progesterone receptors (PR), and human epidermal growth factor receptor 2 (HER2). This subtype is known for its aggressive behavior and poor prognosis, marked by rapid progression and a heightened risk of distant metastasis. The lack of effective targeted endocrine therapies and anti-HER2 treatments contributes to high mortality rates and

limited options for patients. One promising strategy is intra-arterial neoadjuvant chemotherapy, which aims to deliver treatment directly to the tumor site. This technique involves catheterizing the main artery supplying the breast tumor, allowing localized delivery of chemotherapeutics. This method enables a substantial concentration of the drug at the tumor site, leading to greater anticancer efficacy compared to traditional intravenous infusion. Currently, this technique is being evaluated in clinical trials, especially for its efficacy in locally advanced cases via the superior epigastric artery. Preliminary results indicate that this neoadjuvant approach exhibits mild toxicity profiles and significant therapeutic potential for treating locally advanced TNBC.
Methods: This review evaluates the efficacy of intra-arterial chemotherapy in treating TNBC by analyzing recent studies and outcomes. A comprehensive literature search was conducted using the Boolean strategy: ("triple-negative breast cancer" OR "TNBC") AND ("intra-arterial chemotherapy" OR "superselective intra-arterial chemotherapy" OR "intra-arterial"). The search was performed in PubMed and Embase, including studies published from 2000 to 2023.
Results: In reviewing three studies on breast cancer treatment, distinct outcomes were observed across therapeutic approaches. In the Jinsong He et al. study, the intra-arterial group exhibited a clinical complete remission (cCR) rate of 19.15% and a partial remission (PR) rate of 27.66%, resulting in an overall response rate (ORR) of 46.0%. The control group had a cCR of 6.38% and a PR of 23.40%, leading to an ORR of 29.0%. The H. Y. Jin et al. 2016 study on intra-arterial chemoinfusion in locally advanced TNBC reported a cCR of 33.3%, PR of 51.0%, and a notably high ORR of 84.3%. This study also found a pathological complete remission (pCR) rate of 31.3% and a disease control rate (DCR) of 98.0%. The He J-S et al. 2009 study on targeted chemotherapy reported an ORR of 91.6%, compared to 85.0% in the control group. Notably, skin ulceration was the most common toxicity, affecting 21.6% of patients, with two patients (3.9%) experiencing grade 3/4 ulcerations, effectively managed with topical care.
Conclusion: TNBC remains a challenging subtype characterized by its aggressive nature and limited treatment options due to the absence of effective targeted therapies. The reviewed studies highlight the potential of intra-arterial neoadjuvant chemotherapy as a promising strategy for delivering high concentrations of chemotherapeutics to tumor sites, resulting in improved response rates compared to conventional treatments.

P2-11-29: IMPACT OF GERMLINE MUTATIONS ON pCR IN TRIPLE NEGATIVE BREAST CANCER PATIENTS TREATED WITH PEMBROLIZUMAB PLUS CHEMOTHERAPY: THE TIGER STUDY

Andrea Botticelli, Simona Pisegna, Simone Scagnoli, Armando Orlandi, Daniele Alesini, Giuliana D'Auria, Domenico Bilancia, Marianna Giampaglia, Francesco Pantano, Ilaria Portarena, Matteo Vergati, Patrizia Vici, Agnese Fabbri, Federica Mazzuca, Francesca Salvatori, Giorgia Arcuri, Carla Maria Gullotta, Francesca Sofia Di Lisa, Denise Drittone, Paolo Sciattella, Alessandra Fabi

Background: In high risk early triple negative breast cancer (TNBC), the integration of pembrolizumab into chemotherapy regimens has enhanced clinical outcomes in neadjuvant setting. However, there is a paucity of data regarding its efficacy in routine clinical settings, and the therapeutic response in germline mutation carriers remains inconclusive. This retrospective study aims to describe outcomes and safety in patients (pts) with early TNBC who received neoadjuvant pembrolizumab in a real-world context.

Methods: Clinical, pathological and germaline evaluation data of patients with early TNBC treated with neoadjuvant chemio/immunotherapy were retrospective collected from 10 italian referral hospitals. CTCAE v5 guidelines were used for toxicity grading. Logistic regression assessed the effect of clinical variables on AEs and response, adjusting for covariates.

Results: One hundred twenty one (121) patients (pts) were included, with a median age of 50 years (26-79). Body mass index (BMI) was <18.5 in 3 pts, from 18.5 to 24.9 in 75, 25-29.9 in 21, >30 in 17 and not available (NA)in 4, respectively. 74 pts had stage II TNBC and 47 stage III. G3 disease was reported in 93 pts, G2 in 18 and not known in 10, respectively. Nodal status was N0 in 59 pts, N1-N2 in 59, and NA in 3 pts. Overall, 19% of pts fell into clinical T2 or higher TNBC (n=24). G3 or greater AEs in the combined phases were experienced by 28% of pts (n=35) and AEs led to discontinuation in 12% of cases (n=15). 74/121 pts received up to 8 Pembrolizumab cycles. Germline alterations were detected in 26 pts (21%). Among them, 19 patients presented BRCA1/2 germline mutations, while 7 pts showed other than-BRCA germline alterations (1 PALB2, 1 MRE11, 1 RAD51, 1 TINF2, 1 FANCD2, 1 ATM and 1 BRIP1, respectively). Globally 94/121 patients received surgery and, of them, 56 achieved pCR (60%). In germline mutated subgroup, pCR rate was 80% (n=20/25). In the pts population that received surgery, the presence of germline mutations was significantly associated with higher probability of pCR (OR 3.6, p=0.01). At multivariate analysis, correlation between pCR and germline alterations was confirmed (p=0.02). No significant association was found between pCR and toxicity and other variables [stage, nodal status, grading, BMI class, treatment discontinuation and pembrolizumab cycles number (p>0.05)].

Conclusions: Efficacy of neoadjuvant pembrolizumab plus chemotherapy was confirmed in our Italian real-world population. Toxicity and discontinuation rate were comparable with that previously reported. Carrier pts with germline alterations, both BRCA1/2 and other than-BRCA1/2, showed a significant higher pCR rate when compared to wild type population.

P2-11-30: RAD51AP1 Inactivation Induces Synthetic Lethality of PARP Inhibitors in Breast Cancer Patients Irrespective of BRCA1/2 mutation

Jabunnesa Khanom, Sonia Batan, Nanditi N. Thangaraju, Tulshi Patel, Subha Sundaram, Snigdha Ganjikunta, Breanna Kennedy, Puttur D. Prasad, Muthusamy Thangaraju

Introduction: Triple-negative breast cancer (TNBC), an aggressive variant of breast cancer (BC), is characterized by a lack of expression of estrogen receptor (ER-), progesterone receptor (PR-), and HER2/Neu amplification. TNBC shares striking similarities with basal-like as well as BRCA1-mutation-associated BC. Approximately 70% of BCs arising in BRCA1-mutation carriers and 23% of BCs arising in BRCA2-mutation carriers are associated with the TNBC phenotype. TNBC accounts for 15-20% of all BC subtypes and is considered the most lethal subtype due to the lack of targeted therapy and the development of resistance to existing chemotherapies. Recently, poly (ADP-ribose) polymerase inhibitors (PARPi), Olaparib (AZD2281), and Talazoparib (BMN673) have been shown to offer an attractive new therapeutic avenue for the treatment of TNBC patients who carry BRCA mutations. BRCA1/2 is involved in homologous recombination (HR)-mediated DNA damage repair and PARPi induces synthetic lethality in patients who have HR deficiency (HRD). The concept of synthetic lethality is based on the observation that when single-strand break (SSB) occurs the cells can repair it efficiently by DNA recombinases and cancer cells will survive. However, if a double-strand break (DSB) occurs the cells are a lot less efficient in repairing the cells and will go to cell death. The repair of DSBs mainly relies on homologous recombination (HR), and BRCA1 and BRCA2 are crucial proteins involved in the HR repair pathway. Therefore, FDA-approved PARPi for the treatment of TNBC patients who carry BRCA mutations. Although PARPis induce synthetic lethality in BRCA-mutant MBC, PARPis had no response in patients who do not have BRCA-mutations, which accounts for ~80% of the total TNBC. Therefore, targeting the DDR pathway is one of the most promising approaches to enhance the synthetic lethality of PARPi in TNBC patients. We have recently identified that RAD51AP1 (RAD51-Associated Protein 1), a DNA damage repair protein that plays an important role in HR. RAD51AP1 enhances RAD51 recombinase activity by binding to damaged DNA strands and increases the catalytic activity of RAD51. RAD51 is a recombinase that catalyzes HR which is essential for maintaining DNA integrity in both normal and tumor cells. Like BRCA1, RAD51AP1 is also a DNA repair protein, and it plays a specific role in HR that is dispensable in cells with a lower burden of DNA damage such as normal cells. However, it is crucial in DNA damage repair and cell survival when the burden is high as seen in cancer cells and cells treated with DNA-damaging agents.
Objective: To test the hypothesis that RAD51AP1 inactivation will induce synthetic lethality of PARPi in both BRCA1/2 mutant wild-type and TNBC as well as in ER-positive breast (ER+BC) cells.
Methods: We have used two ER+BC cell lines (T47D, express wild type BRCA1, and MCF7, loss of single BRCA1 allele) and two TNBC cell lines (SKBR7, express wild type BRCA1, and HCC1937, express mutant BRCA1, 5382insC). We obtained PARPi Olaparib and Talazaparib (Selleckchem). We also used genetically engineered mouse models (GEMM) of ER+BC (MMTV-Wnt1-Tg), ER-negative BC (ER-BC, MMTV-Neu-Tg), and TNBC (C3(1)-TAg) in wild-type and Rad51ap1 knockout (Rad51ap1KO) background. All animals were housed and handled according to approved protocols established by the Augusta University (AU) Animal Care and Use Committee and NIH guidelines.
Results: Analysis of RAD51AP1 expression in different BC subtypes shows significantly higher RAD51AP1 expression in basal TNBC when compared with other BC subtypes such

as luminal A, luminal B, and HER2+. This high expression of RAD51AP1 is associated with a poor prognosis. RAD51AP1 expression promotes tumor growth in both ER+BC and TNBC cell lines. RAD51AP1 knockdown limits tumor growth and induces synthetic lethality of PARPi in both ER+BC and TNBC cell lines irrespective of BRCA1/2 mutation. We recapitulated these findings in GEMM of ER+BC, ER-BC, and TNBC.
Conclusion: Overall, our results provide a novel therapeutic strategy to induce the synthetic lethality of PARPi for the treatment of TNBC patients irrespective of BRCA1/2 mutations.

P2-12-01: Survival Outcomes after Pathologic Complete Response with Neoadjuvant Endocrine Therapy vs. Neoadjuvant Chemotherapy

Tori Chanenchuk, Samantha M. Thomas, Astrid Botty van den Bruele, Akiko Chiba, Kendra J. Modell Parrish, Hannah E. Woriax, Maggie L. DiNome, Kelly E. Westbrook, Jennifer K. Plichta

Background: Neoadjuvant systemic therapy has emerged as the standard of care for many patients with breast cancer potentially leading to surgical downstaging and providing insight into treatment response and prognosis. Neoadjuvant therapies can result in pathologic complete response (pCR), which is predictive of long-term outcomes; patients who attain pCR are consistently found to have better survival outcomes than those with residual disease. Select patients with estrogen receptor positive (ER+) tumors may receive either neoadjuvant chemotherapy (NAC) or neoadjuvant endocrine therapy (NET). Although the role of NAC has been well established for various breast cancer subtypes, NET has become a more appealing option for patients with ER+ disease. As such, we sought to assess survival outcomes in those with early-stage ER+ breast cancer who received either NET or NAC, and achieved pCR.
Methods: All patients diagnosed with ER+/HER2- stage I-III breast cancer in 2010-2021, who received neoadjuvant therapy followed by surgery, and achieved pCR, were selected from the National Cancer Database. Patients were stratified by type of neoadjuvant systemic therapy: NAC vs NET. The Kaplan-Meier method was used to estimate overall survival (OS) and log-rank tests were used to test for differences in OS between groups. Cox Proportional Hazards models were used to estimate the association of NAC vs NET with OS, after adjustment for demographics, disease characteristics, surgery, radiation and immunotherapy; hazard ratios (HRs) and 95% confidence intervals (CIs) are reported.
Results: We identified 3313 patients meeting eligibility criteria: 3148 received NAC and 165 NET. The median follow-up for the entire cohort was 82 months. Patients who received NAC were significantly younger [median age (IQR): NAC 49y (41-58) vs NET 64y (57-69); $p<0.001$], more likely to have a comorbidity score of 0 (NAC 89.3% vs NET 81.2%, $p=0.004$), and more likely to have private insurance (NAC 68.9% vs NET 44.2%, $p<0.001$). There were no significant differences between the NAC and NET patients based on race/ethnicity, income level, education level, or community type (all $p>0.05$). Expectedly, NAC patients were more likely to have larger tumors [median tumor size (IQR): NAC 3 cm (2-4.3) vs NET 1.3cm (0.7-2.8); $p<0.001$), ductal histology (NAC 92.6% vs 81.2%, $p<0.001$), and grade 3 tumors (NAC 70.2% vs 10.3%, $p<0.001$), while NET patients were more likely to have T1

(NAC 22.1% vs NET 67.9%, p<0.001) and N0 disease (NAC 46% vs NET 95.8%, p<0.001). The median time from start of treatment to surgery was 159 days for the NAC cohort, and 147 days for the NET cohort (p=0.23). In the unadjusted Kaplan-Meier analysis, there was no significant difference in OS between NAC vs NET [5-year OS: NAC 0.935 (95% CI 0.926-0.944) vs NET 0.916 (95% CI 0.856-0.951); log-rank p=0.08]. After adjustment for demographics, disease characteristics, and other treatments, there was no association between OS and the study groups (NAC vs NET; p=0.63).
Conclusions: Patients with ER+/HER2- early-stage breast cancer who achieved pCR had similar overall survival, regardless of whether they were treated with NAC or NET. As such, pCR appears to have similar prognostic value regardless of the type of systemic therapy used to obtain this favorable outcome.

P2-12-02: Risk of recurrence in real-world (RW) NATALEE- and monarchE-eligible populations of patients with HR+/HER2- early breast cancer (EBC) in an electronic health record (EHR)-derived database

Paolo Tarantino, Hope S. Rugo, Giuseppe Curigliano, Joyce O'Shaughnessy, Wolfgang Janni, Komal Jhaveri, Jason Mouabbi, Adam Brufsky, Erika Hamilton, Ruth O'Regan, Julia Kim, Liz Santarsiero, Murat Akdere, Fen Ye, Henry Owusu, Stephanie L. Graff

Background: The phase 3 NATALEE and monarchE trials showed statistically significant invasive disease–free survival benefits with the addition of a CDK4/6 inhibitor to endocrine therapy (ET) in patients with HR+/HER2− EBC. This analysis reports patient characteristics and efficacy outcomes in the NATALEE- and monarchE-eligible populations in a US RW EHR-derived database.
Methods: De-identified data from the Flatiron Health US EHR database (January 2011-November 2023) were analyzed. Patients with stage I to III HR+/HER2− EBC who were aged ≥18 y when diagnosed, had undergone breast cancer resection, had initiated adjuvant ET, and met disease eligibility characteristics for NATALEE or monarchE were included in the analysis. NATALEE eligibility was defined as stage II/III disease (AJCC 8th edition) irrespective of nodal status, with additional criteria for stage IIA T2N0 disease (grade [G] 2 with Ki-67 ≥20% or high genomic risk; G3). monarchE eligibility was defined as ≥4 positive lymph nodes (LNs) or 1 to 3 positive LNs and G3 and/or tumor size of ≥5 cm (cohort 1) and 1 to 3 positive LNs and Ki-67 of ≥20% (G<3 and tumor size <5 cm; cohort 2). N1mi disease was also allowed in monarchE. Invasive breast cancer–free survival (iBCFS) and distant recurrence–free survival (DRFS) were assessed based on STEEP v2.0 criteria.
Results: Overall, 2534 patients were NATALEE eligible (NATALEE population [NAT]), while 1157 were monarchE eligible (monarchE population [monE]). Median age was 61 y in NAT and 60 y in monE. Approximately half of patients in NAT had previously received chemotherapy (1312 [51.8%]), while nearly two-thirds of monE patients had prior chemotherapy (735 [63.5%]). Most patients in NAT had stage II disease (stage II, 1843 [72.7%]; stage III, 691 [27.3%]), while most patients in monE had stage III disease (stage I, 37 [3.2%, all T1N1mi]; stage II, 484 [41.8%]; stage III, 636 [55.0%]). In both populations,

most patients had N1 disease (NAT: N0, 604 [23.8%]; N1, 1462 [57.7%]; N2/3, 468 [18.5%]; monE: N0, 0; N1, 689 [59.6%]; N2/3, 468 [40.4%]).
The median follow-up from initial diagnosis was 55.1 months in NAT and 53.4 months in monE. Risk of invasive breast cancer recurrence or death was clinically meaningful in both NAT and monE, with 3- and 5-y iBCFS rates of 89.2% and 81.4% in NAT and 83.4% and 72.1% in monE, respectively. 5-y iBCFS rates decreased with increasing stage (NAT: stage II, 87.1%; stage III, 66.5%; monE: stage I, 97.3%; stage II, 80.1%; stage III, 64.9%) and nodal status (NAT: N0, 86.4%; N1, 85.3%; N2/3, 63.8%; monE: N1, 78.2%; N2/3, 63.8%). Risk of distant recurrence or death was considerable in both NAT and monE, with 3- and 5-y DRFS rates of 90.4% and 83.1% in NAT and 85.2% and 74.6% in monE. 5-y DRFS rates by stage and nodal status had trends similar to those of iBCFS rates; however, the rates were comparable for N0 and N1 in NAT (NAT: stage II, 88.7%; stage III, 68.6%; N0, 87.4%; N1, 87.4%; N2/3, 65.0%; monE: stage I, 97.3%; stage II, 83.1%; stage III, 67.2%; N1, 81.6%; N2/3, 65.0%). Patients who did not receive chemotherapy had slightly better 5-y iBCFS rates (NAT: 83.3% vs 79.7%; monE: 75.1% vs 70.6%) and DRFS rates (NAT: 85.3% vs 81.1%; monE: 78.0% vs 72.9%) than those who received chemotherapy.
Conclusions: This RW analysis reflective of the current treatment landscape shows that approximately twice as many patients with HR+/HER2− EBC met NATALEE vs monarchE eligibility criteria. The relatively high incidences of distant recurrences within 5 y in the NATALEE- and monarchE-eligible populations receiving the current standard of care highlight the notable risk of early recurrence in these patients and the need for risk reduction strategies.

P2-12-03: The effect of Abemaciclib plus fulvestrant on overall survival in hormone-receptor positive, HER2-negative breast cancer that progressed on endocrine therapy – Comparing Real-World outcomes in England to MONARCH 2

Emma Kipps, Jack Anderson, Peter Clark, Katherine Thackray, Martine Bomb, Sarah Lawton

Introduction: Abemaciclib plus fulvestrant was approved for use in Europe following the publication of the Monarch-2 trial. The National Institute for Health and Care Excellence recommended reimbursement through the Cancer Drugs Fund (CDF) for all patients with hormone-receptor positive, HER2-negative breast cancer that had progressed on endocrine therapy. During this time, the National Disease Registration Service (NDRS) collected real-world evidence on patient characteristics and outcomes. We compared the results from the Monarch-2 trial to the Systemic Anti-Cancer Therapy (SACT) dataset within NDRS to evaluate the generalisability of the Monarch-2 trial to real-world treatment settings in the NHS.
Methods: The SACT dataset linked to BlueTeq identified all patients with a CDF application for abemaciclib with fulvestrant between April 2019 and December 2019 in England, with follow-up until 25 March 2024. Baseline characteristics reported include gender, age group,

Eastern Cooperative Oncology Group performance status (ECOG PS) and previous endocrine therapy status as reported by the treating clinician, and summary measures were calculated for these characteristics. The primary endpoint was overall survival (OS). Monarch-2 was a global, randomised, placebo-controlled, double-blind phase 3 trial which enrolled patients between August 2014 and December 20151. The patient inclusion criteria were more restrictive in the Monarch-2 trial. This study compared results from the real-world SACT cohort to those from the Monarch-2 trial.
Results: 1,113 applications for abemaciclib with fulvestrant were received through the CDF; after deduplication and exclusions (to restrict to patients who received treatment funded through the CDF and whose treatment ascertainment was complete in the SACT dataset) this related to 876 patients, compared to 669 patients in the Monarch-2 trial. The median age of the real-world cohort was 65 years, compared to 59 years in the Monarch-2 trial. All patients in the Monarch-2 trial were female, while 1% (N=11) of the real-world cohort was male. The median OS in the real-world prescribing setting was 25.9 months [95% CI: 23.7, 28.4], compared with the Monarch-2 trial median OS of 46.7 months. While the Monarch-2 trial consisted exclusively of patients with ECOG PS of 0 or 1, 8% (N=71) of the real-world cohort had an ECOG PS greater than 1, however sensitivity analysis showed that OS in the real-world cohort restricted to patients with ECOG PS 0-1 was consistent with the OS for the overall real-world cohort.
Conclusion: The trial data is not generalisable to the real-world setting for this cohort of patients as the median OS in this real-world cohort was 20 months less than the median OS reported in the Monarch-2 trial.

P2-12-04: Impact of Weight and Weight Variation in Adolescent and Young Adult (AYA) Women with Invasive Breast Cancer

Nerea Lopetegui-Lia, Emily C. Zabor, Kenda Alkwatli, Ahmed Mohamed, Hassan Elmaleh, Alex Milinovich, Anukriti Sharma, Blaine Martyn-Dow, Kevin M Pantalone, Daniel Rotroff, Halle CF Moore

Background: Breast cancer (BC) is the most common malignancy in adolescent and young adult (AYA) women age 15-39, and the incidence continues to rise each year (1, 2). The reason for this remains unknown, but one potential etiology includes the increasing incidence of obesity (1). Studies in premenopausal women have demonstrated that a high body mass index (BMI) prior to BC diagnosis is associated with worse clinical outcomes (3). The prognostic value of weight gain after BC diagnosis remains unclear (4) as its impact on recurrence risk and overall survival has been inconsistently reported, with limited data among the AYA population (5).
Our aim was to describe the clinical-pathological characteristics of AYA women diagnosed with BC, its association with weight change, and the impact of weight variation during the initial treatment period on patient outcomes.
Methods: This retrospective study included patients with invasive stage I-III BC, age 15-39 at the time of diagnosis, that received treatment at the Cleveland Clinic between 1996 and

2023. Data was collected via computerized data extraction and manual chart review. The analysis was limited to patients who had both a pre-diagnosis (within 1.5 years (y) before diagnosis) and post-diagnosis (up to 1.5y after diagnosis) BMI measurement so that change in BMI could be calculated. A BMI reduction of ≥2 units was considered clinically meaningful weight loss and a BMI increase of ≥2 units was considered clinically meaningful weight gain. A change in BMI < 2 units was considered no change or stable weight. Continuous and categorical variables were summarized using median IQR and N (%), respectively. The Kruskal-Wallis test was used to test for differences according to BMI change categories in continuous variables, and either Fisher's exact test or the Chi-squared test was used to test for differences according to BMI change in categorical variables, as appropriate. The Kaplan-Meier method was used to estimate 5y overall survival (OS) probability, the log-rank test was used to test for differences according to weight change and hazard ratios (HR) were estimated using univariable Cox regression.
Results: A total of 345 patients were identified for analysis. 339 patients (98%) were ≥25 years, 5 were age 19-24, and one was ≤18 years. The median pre-diagnosis BMI was 25 kg/m2 (22,31). Stable weight was observed in 242 patients (70%), 52 (15%) experienced weight loss, and 52 (15%) had weight gain during the first 1.5y of treatment from the time of diagnosis.
While the measurement and analysis of weight changes focused on the initial BC treatment period, median follow-up time among survivors was 6.8y. During follow-up, 51 patients died from any cause. The 5y OS probability of patients with weight gain, weight loss, and stable weight were 66%, 85%, and 90%, respectively (log-rank P=0.006). Patients with weight gain had a statistically significant increased hazard of mortality as compared to those with no change and with weight loss combined, HR 2.71 (95% CI: 1.44-5.10), P=0.005
Discussion: Overall survival probability was reduced in AYA women with early stage BC that experienced weight gain during the initial treatment period. Approximately 70% of patients had no significant change in BMI during their initial BC treatment course, despite undergoing loco-regional and systemic therapies. These results support counselling AYA women regarding the risk of reduced survival associated with weight gain during the initial BC treatment period. Future research is necessary to examine the impact of longer-term weight changes on the risk of BC recurrence and mortality.

P2-12-05: Retrospective Study of Drug-Induced Interstitial Lung Disease in Breast Cancer Patients Treated at Mayo Clinic between the Years of 2018-2023 (Real World Experience)

John Fanous, Farah Raheem, Alejandro Diaz-Arumir, Ana Zamora Martinez, Claire Yee, Lida Mina

Background: Breast cancer treatment has seen significant advancements in recent years, particularly with the introduction of immune checkpoint inhibitors, antibody-drug conjugates, and CDK 4/6 inhibitors. Despite these improvements, side effects remain a major concern. Drug-induced interstitial lung disease (DIILD), a subtype of diffuse

parenchymal lung disease, occurs at different rates with different drugs posing a significant challenge for the treating medical oncologist. Understanding the real-world incidence of DIILD with newer breast cancer drugs is essential for enhancing patient outcomes.
Methods: In this retrospective study, we reviewed patients diagnosed with DIILD at Mayo Clinic Comprehensive Cancer Center from January 2018 to December 2023. Using Mayo Clinic's informatics tool, Mayo Data Explorer, with keywords "drug-induced," "pneumonitis," "lung injury," and "interstitial lung disease," and ICD codes for breast cancer (n=304), 101 patients were identified. All cases were reviewed by a pulmonologist to confirm the diagnosis. Patients with alternative diagnoses were excluded. Pneumonitis grading was based on NCI CTCAE v6.0 guidelines. Statistical analyses included Kruskal-Wallis tests and Fisher's exact tests.
Results: Among the 101 breast cancer patients with DIILD, 89% were white, the median age was 62.7 years (IQR: 54-69.9), and 94.1% had good performance status (ECOG 0-2). Median BMI was 27.9 (IQR: 23.3-32.9), with 33.7% having a smoking history. Comorbidities included prior radiation (51.5%), lung disease (COPD 6.9% & asthma 15.8%), prior COVID-19 infection (24.8%), and CKD (16.8%, with 11.8% stage IV/V). Tumor characteristics: 61.4% were estrogen positive 25.7% HER2 positive and 12.9% triple negative. Disease stages: 47.5% of patients were in early-stage (stages I-III), while 56.4% were metastatic (stage IV).
Forty-five patients required hospitalization, five required intubation (11.4%), and there were three deaths (all associated with fam-trastuzumab deruxtecan). Common culprit drugs included fam-trastuzumab deruxtecan (20%), everolimus (15.8%), abemaciclib (12.9%), and pembrolizumab (11.9%). Median time to DIILD diagnosis: 111 days (IQR: 69-210) with specific median times of 173.5 days for fam-trastuzumab deruxtecan, 95.5 days for everolimus, 205 days for abemaciclib and 85 days for pembrolizumab.
Regarding treatment, 78.2% received high-dose corticosteroids, 1% mycophenolate, and 7.9% other treatments. Seventeen patients were rechallenged with the culprit medication and 47% experienced recurrence. More than half (57.4%) resolved within six months, with a median resolution time of 62.5 days (IQR: 41-110).
We analyzed for predictors of grade severity, with DIILD severity defined as low-grade (grades 1-2, 56.4%) and high-grade (grades 3-5, 43.6%). COPD was the only significant predictor, with COPD being more common in patients with higher ILD grade (13.6% vs. 1.8%, p=0.041). Of note, a history of prior COVID-19 infection was not predictive of DIILD severity.
Conclusion: This study provides real-world experience on DIILD in breast cancer patients, identifying common culprit drugs and highlighting an association of higher ILD grading with COPD. The variability in time to DIILD diagnosis underscores the need for vigilant monitoring. High-dose corticosteroids were effective, but rechallenge posed a high recurrence risk, indicating the complexity of managing DIILD. Future research is needed to identify individualized genomic predictors of lung toxicity.

P2-12-06: Key factors influencing patient preferences for BRCA testing and adjuvant therapy in HER2-negative early breast cancer

Kathryn Mishkin, Kathleen Beusterien, Josh Lankin, Emily Mulvihill, Kathryn Krupsky, Alexandra Gordon, Xiaoqing Xu, Qixin Li, Jaime Mejia, Kim Hirshfield, Jagadeswara Rao Earla

Background: PARP inhibitors (PARPis) have survival benefits for women with high-risk HER2-negative early breast cancer (eBC) with germline BRCA mutations (BRCAm). Identifying patients eligible to receive PARPis can be challenging, as many individuals who are BRCAm carriers are unaware of their status, despite increasing availability of genetic testing. This study sought to identify factors that influence patient preferences for BRCA testing and adjuvant therapy.
Methods: Women (≥18 years) in the United States with HER2-negative eBC were recruited between October 2023 - March 2024 via an online research panel to complete a cross-sectional survey. The survey included a Best-Worst-Scaling (BWS) exercise to identify barriers/facilitators to BRCAm testing among 16 factors. Two Discrete Choice Experiments (DCE) were included: one to evaluate preferences for BRCA testing by prompting patients to select between 2 hypothetical scenarios varying on 5 testing-related attributes (i.e., eligibility for targeted treatment, delays due to testing, information sharing with family, preventive surgery options, and out-of-pocket costs [OOPC]) and another to assess the influence of 7 treatment attributes on patients' preferences for adjuvant therapy (i.e., invasive disease-free survival, whether the treatment is targeted, risk of nausea, risk of serious side effect [SSE], regimen, treatment duration, and monthly treatment OOPC) versus no treatment. Attributes included in the BWS and DCE exercises were informed by qualitative interviews with 20 healthcare providers and 12 patients. BWS and DCE attribute preference weights were calculated using hierarchical Bayesian modeling.
Results: Women (N=360) on average were 61 years old and 77% were White; most resided in the South (37%) and Midwest (23%). Most women were first diagnosed with breast cancer after 2017 (72%), 61% were never tested for BRCAm or unsure of their status/testing history. Roughly one-third received adjuvant chemotherapy and another third received neoadjuvant chemotherapy. Relative to the other factors in the BWS, the top facilitators for BRCA testing were the possibility of test results showing eligibility for targeted therapy that may prevent or delay metastasis, having no OOPC for testing, and physician recommendation. OOPC of $250, potentially delaying treatment by 3-4 weeks and concerns that test results could lead to denial of life insurance/higher premiums were the top three barriers. The DCE evaluating preferences for BRCA testing showed that, on average, decreasing OOPC from $250 to no cost was most important, followed by learning if preventive surgery should be considered to prevent new cancer, and learning about eligibility for targeted treatment. The DCE on preferences for adjuvant therapy showed that 77% of the time, patients chose treatment over opting out, regardless of the combination of adjuvant treatment attributes shown. On average, reducing treatment OOPC from $900 to $0 influenced treatment choice most, followed by reducing risk of SSE from 77% to 24%, and having a BRCA-targeted treatment.
Conclusions: Patients reported that a key benefit of BRCA testing was using the results to

inform treatment decisions. Yet, OOPC may act as a barrier to testing. Patients' decision to receive adjuvant therapy was influenced by the perceived effectiveness and tolerability of the therapy, and like BRCA testing, financial burden was a concern. Comprehensive patient-provider discussions regarding the benefits of testing including eligibility for innovative treatment may be an effective strategy for increasing BRCA testing and enhancing shared treatment decision-making. Selection of effective adjuvant treatment likely requires balanced consideration of medication tolerability and financial burden to the patient.

P2-12-07: Effectiveness of Predictive Calculators for Breast Cancer Recurrence: A Comparative Study with the 21-Gene Score

Iris Otoya, Cindy Calle, Zaida Morante, Natalia Valdiviezo, Yomali Ferreyra, Katia Roque, Hugo Fuentes, Norma Huarcaya, Tatiana Vidaurre, Carlos Castañeda, Bruno Muñante, Carlos Munive, Mariano Lopez-Pereyra, Julio Abugattas, José Cotrina, Silvia Neciosup, Henry Gómez

Background: In patients with early-stage breast cancer who have hormone receptor-positive and human epidermal growth factor receptor 2-negative (HER2-) tumors, the utility of adjuvant chemotherapy is determined by a recurrence score based on the expression of 21 genes. The limitations of using this recurrence score include the high cost and the long waiting time for results. Nomograms/calculators have been developed to predict the results of the 21-gene recurrence score, taking into account clinicopathological variables established in clinical practice as prognostic and/or predictive. The aim of this study was to evaluate the correlation between the recurrence score based on the expression of 21 genes and the calculators from the University of Tennessee (TUC) and Johns Hopkins University (JHUC).
Methods:We retrospectively reviewed clinical records from 408 patients diagnosed with early-stage breast cancer at Instituto Nacional de Enfermedades Neoplásicas (INEN, Peru) and Oncosalud with available ODX recurrence scores. ODX-RS were compared with scores from the Tennessee University calculator (TUC) and Johns Hopkins University (JHUC) using a confusion matrix to validate those nomograms with our cohort. We performed a comparative analysis of clinical characteristics between low-risk (RS ≤ 25, n=342) and high-risk (RS > 25, n=66) groups, followed by univariate and multivariate logistic regression to identify predictors of low-risk ODX scores. Statistical significance was set at $p<0.05$.
Results: In our study, the median age was 58 years, with a higher proportion of >50 years in the low risk group (p=0.027). High-risk patients had higher median tumor size and Ki67 expression (p=0.018 and p<0.001), with significant differences also noted in surgery type, histologic type, Elston grade, and PR status. Meanwhile, negative recurrence status was similar in both groups. Significant predictors for low recurrence risk included histologic type, Elston grade, PR status, and Ki67%. Lobular carcinoma (OR 5.15, 95%CI 1.43-33.2, p=0.032) and PR positive (OR 4.98 95%CI 2.42-10.3, p<0.001) were associated to a lower risk of recurrence compared to ductal carcinoma and PR negative. Patients with higher Elston grades and Ki67% were less likely to have low recurrence risk. Patients demonstrate a high specificity but extremely low sensitivity with the TUC. This indicates that it misses a

significant number of true positives (low-risk patients correctly identified as low-risk), the low AUC values also indicate poor performance regardless of age group (≤ 50: 0.297, > 50: 0.344). Patients showed significantly improved performance with the JHUC, where we excluded 262 patients due to indeterminate outcomes. The rate of true positives for both age groups is higher (>83%) with greater sensitivity and specificity. AUC values (≤ 50: 0.802, > 50: 0.75) also reflect robust performance across different age cohorts.
Conclusions: Only the established Johns Hopkins University calculator demonstrated good performance in correctly stratifying our patients. This highlights the need for further refinement and validation in predictive models across diverse patient populations to optimize medical decisions.

P2-12-08: Real world progression-free survival after CDK4/6 inhibitors plus endocrine therapy: results from the multicenter SISTER study

Pier Paolo, Maria Berton Giachetti, Stefania Morganti, Sara Gandini, Fabiola Giudici, Antonio Marra, Eleonora Nicolò, Emma Zattarin, Chiara Corti, Laura Boldrini, Annarita Verrazzo, Caterina Sposetti, Maria Grazia Razeti, Ambra Carnevale Schianca, Roberta Scafetta, Bianca Malagutti, Beatrice Taurelli Salimbeni, Paola Zagami, Roberta Caputo, Claudio Vernieri, Elisabetta Munzone, Simone Scagnoli, Andrea Botticelli, Matteo Lambertini, Mario Giuliano, Michelino De Laurentiis, Giulia Viale, Giampaolo Bianchini, Giuseppe Curigliano, Carmine De Angelis, Carmen Criscitiello

Background: Endocrine therapy (ET) combined with CDK4/6 inhibitors (CDK4/6i) is the standard first-line treatment for ER+/HER2- metastatic breast cancer (mBC). However, the optimal treatment after disease progression on ET + CDK4/6i remains unclear.
Aim: This study aims to evaluate real-word progression-free survival (rwPFS) with various treatments in a post-CDK4/6i setting, with real-word overall survival (rwOS) as a key secondary endpoint.
Design and Setting: The multicenter SISTER study included patients with ER+/HER2- mBC who received ET-based or chemotherapy (CT)-based therapy after progressing on ET + CDK4/6i between July 2015 and May 2023. rwPFS and rwOS were analyzed based on treatment type, clinicopathological characteristics and duration of prior CDK4/6i therapy. Descriptive analyses included patient demographics, disease and treatment characteristics.
Results: Following progression on CDK4/6i, 221 patients (43.7%) received ET-based therapy and 56.3% received CT-based therapy. The ET-based group included 114 patients (22.9%) who received everolimus + exemestane (Eve+Exe) and 100 (20%) who received ET alone. The CT-based group included 106 patients (21.2%) who received intravenous (iv) CT and 179 (35.9%) who received oral CT. At a median follow-up of 4.75 months (IQR, 2.82-9.31) from the post-CDK4/6i treatment start, the median rwPFS in the overall population was 5.44 months (95% CI 4.59-5.97). Median rwPFS was 5.28 months (95% CI 4.36-5.74) and 6.43 months (95% CI 4.36-5.74) in patients who received CDK4/6i as first- or second-line therapy, respectively. No statistically significant difference in median rwPFS was found between CT-based (5.83 months, 95% CI 5.27-6.69) and ET-based (4.29 months, 95% CI

3.90-5.67, p=.54) groups post-CDK4/6i progression. Patients with visceral involvement had a worse median rwPFS (5.31 months, 95% CI 4.22-5.80) compared to those without (6.43 months, 95% CI 4.69-7.64, p=.0009). Patients on oral CT had better median rwPFS (6.89 months, 95% CI 5.28-8.72) than those on iv-CT (5.44 months, 95% CI 3.70-5.97, p=.005). Patients treated with CDK4/6i for at least 12 months had similar median rwPFS (5.57 months, 95% CI 4.23-6.46) compared to those treated for less than 12 months (5.31 months, 95% CI 4.36-6.16, p=.24). The overall population's median rwOS was 24.26 months (95% CI 21.70-27.46). Patients on ET had a better median OS compared to those on CT (31.74 months, 95% CI 24.79-38.66 vs 20.79 months, 95% CI 18.23-23.93, p=.00089). In a multivariate model for PFS, age was inversely correlated with progression risk (HR 0.99, 95% CI 0.98-0.99, p=.028), while de novo metastatic disease (HR 1.24, 95% CI 1.00-1.53, p=.047) and visceral involvement (HR 1.45, 95% CI 1.17-1.80, p=.008) were independently associated with higher risk. Longer prior CDK4/6i treatment duration was associated with a lower progression risk (HR 0.99, 95% CI 0.98-1.00, p=.049). Compared with oral CT, the use of iv-CT, Eve+Exe or ET only was associated with a higher progression risk (HR 1.43, 95% CI 1.10-1.87, p=0.008; HR 1.40, 95% CI 1.08-1.82, p=.011; HR 1.39, 95% CI 1.06-1.81, p=.016, respectively). Patients with a known BRCA1/2 mutation (16/103, 15%) had a significantly shorter median rwPFS (3.95 months, 95% CI 3.25-5.31) compared to those with wild type BRCA1/2 (5.97 months, 95% CI 4.10-6.92, p=0.033) and median rwOS (26.9 months, 95% CI 23.1-NA) compared to non-mutants (mOS not reached, p=.34).
Conclusions: This study identified visceral involvement and a shorter CDK4/6i therapy duration as independent prognostic factors for poorer survival outcomes. CT-based therapy demonstrated superior rwPFS for patients with brief prior CDK4/6i therapy and those with visceral metastases. Patients receiving oral CT showed improved rwPFS compared to iv-CT. These findings suggest that treatment strategies should consider the type of progression and prior treatment duration to optimize patient outcomes in ER+/HER2- mBC.

P2-12-09: Clinical, genetic and immunological features, HER2-low expression and treatment patterns in a large population of male breast cancer patient with long-term follow up

Fabio Girardi, Carlo Alberto Giorgi, Francesca Porra, Gaia Griguolo, Cristina Falci, Giovanni Faggioni, Eleonora Mioranza, Christian Zurlo, Anna Chiara Cattelan, Monica Marino, Valeria Faso, Maria Vittoria Dieci, Valentina Guarneri

Background: Male breast cancer (BC) is a rare entity, accounting for 1% of all BC diagnoses. It is characterized by distinct biological and clinicopathologic features, often driving more unfavorable clinical outcomes as compared to female BC, thus posing impelling clinical challenges.
Methods: We collected clinical and biological data from a large retrospective cohort of male patients (pts) with BC diagnosis. Relapse-free survival (RFS, pts with stage I-III at diagnosis) and overall survival (OS, all pts) were adopted as survival endpoints according to STEEP v2.0 definitions. Tumor-infiltrating lymphocytes (TILs) were assessed on primary tumors,

relapses or both, complying with the recommendations by the International TILs Working Group.
Results: We included 157 pts. Median age at BC diagnosis was 65.1 years.
The population exhibited high rates of cardiometabolic comorbidities (65.6%) associated with major medication burden (24.3% pts with ≥5 drugs/day).
We reported relevant rates of second malignancies (28.6%) and family history of cancer (69.1%). Among pts undergoing genetic testing, rates of germline mutations in BRCA1, BRCA2 and PALB2 genes were 1.3%, 17.3% and 2.7%, respectively.
Our male BC population was enriched for HR+/HER2- subtype (91.3% vs HER2+ 8% vs triple-negative 0.7%). Of HR+/HER2- BC pts with advanced BC (n=35), 82.9% had HER2-low phenotype on primary and/or recurrent tumor.
Among HR+/HER2- BC pts, 15.9% received CDK4/6i+ET (adjuvant, n=1; advanced BC, n=19). Among BRCA+ pts (n=14), 21.4% received PARP-inhibitors (adjuvant, n=1; advanced BC, n=2).
Of pts receiving CDK4/6i for advanced BC, 94.7% received palbociclib; the ET backbone was aromatase inhibitor (AI) in 78.9% and fulvestrant in 21.1% of cases. Median PFS with CDK 4/6i+AI and CDK 4/6i+fulvestrant was 22.8 and 11.9 months, respectively. Grade 3 adverse events (AEs) occurred in 41.2% of pts (grade 3 neutropenia 41.2%, grade 3 thrombocytopenia 5.8%). No grade 4-5 AEs nor treatment discontinuations due to AEs were recorded.
After a median follow up of 9.1 years, 5-yr RFS and 5-yr OS rates in HR+/HER2 subgroup were 70.9% and 81.5%, respectively. Patients with BRCA1/2-PALB2 germline mutations experienced a trend for poorer OS than those tested negative (5-yr OS in mutated versus non-mutated: 81.7% vs 93.0%, p=0.068). Among all pts experiencing OS event (known cause of deaths, n=37), 40.5% died from other causes than BC (including: other malignancies, 27.0%; cardiovascular event, 8.1%). Among pts with OS event and previous BC distant relapse (n=25), 16% died from non-BC causes.
Finally, TILs were available for 77 pts; median (Q1-Q3) TIL levels were 2.0% (1-5%) overall, 2.0% (1-5%) in primary tumor and 1.0% (0-5%) in metastatic samples. No pts exhibited a lymphocytic predominant phenotype. TILs did not retain any prognostic role.
Conclusions: We confirmed, in one of the largest available series, that male BC represents a distinct clinical entity as compared to female BC, with unique challenges and clinical needs. The high burden of comorbidities and second malignancies drove a substantial risk of non-BC-related mortality, even in pts with advanced BC. In addition, a signal for a negative prognostic impact of gBRCA1/2-PALB2 mutations was captured. Data regarding CDK4/6i-based treatment were reassuring both in terms of efficacy and safety. A substantial proportion of men with advanced HR+/HER2- BC showed HER2-low phenotype, thus arising the need to generate solid data regarding trastuzumab deruxtecan efficacy/safety specifically in male BC. Finally, as expected also given the enrichment for HR+/HER2- phenotype, male BC was associated with weak immune infiltration.
Our results advocate for more inclusive criteria in clinical trials and for the generation of high-quality real-world data.

P2-12-10: Dynamic Changes in Breast Cancer Immunochemistry Biomarkers at Recurrence and Their Impact on Survival

Katia Roque, Iris Otoya, Natalia Valdiviezo, Zaida Morante, Yomali Ferreyra, Silvia Neciosup, Henry Gomez, Tatiana Vidaurre, Hugo Fuentes, Raymundo Flores, Pedro Contreras, Marco Laura, Gonzalo Ziegler, Jose Cotrina, Jorge Dunstan, Ramon Andrade de Mello, Carlos Castañeda

Introduction: Variations in the expression of estrogen receptor (ER), progesterone receptor (PgR), human epidermal growth factor receptor 2 (HER-2), Ki-67, and histological grade (HG) between primary and recurrent/metastatic lesions have been reported as prognostic factors in breast cancer (BC). This study aims to evaluate the impact of discordance in these markers on overall survival (OS) and to describe the behavior of tumor-infiltrating lymphocytes (TiL) and T-cell infiltration.
Methods: This study is a retrospective analysis of 132 non-advanced breast cancer patients who experienced confirmed recurrence or metastasis at the Instituto Nacional de Enfermedades Neoplásicas between 2011 and 2022. Descriptive analysis assessed the expression levels of ER, PgR, HER-2, Ki-67, and histological grade in both primary and metastatic tumors. In a subset of 21 patients, CD8 (SP16) and CD163 (EP324) staining was performed on diagnostic and recurrence samples, and TiLs were evaluated by an independent pathologist. Fisher's exact and Pearson's Chi-squared tests were used to identify significant differences between primary and recurrent/metastatic tumors. For survival analysis, the Kaplan-Meier curve and the Cox regression model were employed to estimate the relative risk (HR – Hazard Ratio). A p-value of less than 0.05 was considered statistically significant.
Results: Median age at diagnosis was 49.6 yo, and most patients were diagnosed at stage III (62%). 15.7% of patients experienced a loss of ER at recurrence, while 14.6% acquired ER expression ($p<0.001$). Additionally, 48.6% of patients experienced a loss of PgR at recurrence, while 13.6% acquired PgR expression ($p<0.001$). 41.3% of patients changed from HER2-zero to HER2-low ($p<0.001$). Regarding histological grade, 73% of patients increased from HG1 to HG3, and 81.3% increased from HG2 to HG3 ($p=0.009$). There were no significant differences between the median Ki-67 at diagnosis and the median at recurrence (42.05% vs 42.14%, $p=0.98$).
Overall, 55.5% (n=73) of patients changed the subtype of breast cancer at recurrence ($p<0.001$). For the luminal subtype, 11% changed to the HER2 subtype and 1.4% to the Triple Negative (TN) subtype. For the HER2 subtype, 15.8% changed to the luminal and 15.8% to TN subtypes. Only 3.8% of patients changed from TNBC to the HER2 subtype and 7.7% to the luminal subtype.
Regarding the subgroup analysis for TiL, CD8 and CD163, the median levels at diagnosis were 42.94%, 28.89%, and 44.71%, respectively. At recurrence, the median levels were 47.78% for TiL, 30.50% for CD8, and 41.00% for CD163. No significant differences were found between primary and recurrent/metastatic lesions (TiL $p=0.55$, CD8 $p=0.79$, and CD163 $p=0.57$).
Median overall survival (OS) was 99.3 months (CI 82-118). Finally, the survival analysis

demonstrated that patients who did not lose ER (HR 0.49; CI 0.29-0.81, p=0.005) or PR (HR 0.5; CI 0.28-0.88, p=0.016) expression had better OS. No significant differences were found for the other variables.
Conclusions: Patients who maintained expression of ER and PR showed significantly improved overall survival, underscoring the critical prognostic value of hormone receptor status. It is noteworthy that no significant differences were found in the levels of Ki-67 between primary and recurrent/metastatic lesions. In our series, the levels of TiL, CD8, and CD163 in recurrent tumors remained relatively stable compared to the primary tumors.

P2-12-11: Lobular breast cancer: diagnostic complexity and delays to surgery.

Hannah Lennon, Eaman Javed, Ruzan Reem, Hiba Fatayer, Vijay Sharma, Julia Henderson, Mohamed Lafi, Anupama Shrotri, Asha Shivaram, Lee Martin

Introduction: Lobular breast cancers account for up to 15% of breast cancers but can be diagnostically complex and often require increased investigation burden. We investigated characteristics and outcomes of lobular breast cancer.
Methods: We performed a retrospective cohort study of consecutive diagnoses of lobular breast cancer at two high-volume surgical centres in Liverpool, UK between March 2023-March 2024. Clinical, histological, imaging and treatment pathway data were collected. Outcomes in terms of time to surgery were computed and compared using Kaplan-Meier plots. Mean (SD) or median (IQR) are presented throughout and p-value <0.05 was considered statistically significant.
Results: For the 12-month period, a new primary diagnosis of lobular breast cancer was diagnosed in 87 women with a median age of 65 years (36-96) and 25/87 (28.7%) were detected via the NHS screening programme. 3/87 (3.5%) first presented as metastatic disease (all 3 as gastrointestinal metastases). 71/87 (81.6%) were classical lobular cancer subtype, 11/87 (12.6%) were pleomorphic and 5/87 (5.7%) were mixed lobular/ductal. 59/87 (67.8%) underwent MRI, the mean tumour size on MRI was 43.7 mm (SD 28, range 6-140mm). Tumour size on MRI was similar to the tumour size on final histology (43.7mm vs 39.3mm, p=0.31), however was consistently larger than USS (43.7mm vs 25.1mm, p<0.001) and mammogram (43.7mm vs. 22.6mm, p<0.001).
25/60 (41.7%) undergoing MRI required second look imaging with 17 (68%) requiring further image-guided biopsy, of which 5 were positive for malignancy (PPV=20%).
Time from diagnosis to surgery for patients going direct to surgery was significantly longer for the lobular breast cancer patients compared with total new cancers going direct to surgery (66 days vs. 55 days, p=0.004).
In total, 32 (36.7%) patients had neoadjuvant endocrine therapy, 21 patients received neoadjuvant endocrine treatment as a bridging therapy to surgery (median 44 days, range 13-179 days) and 11 patients received neoadjuvant endocrine therapy for downstaging, for a duration of 9-12months. 10 frail and/or co-morbid patients were treated with primary

endocrine therapy only, age range 77-96 years.
Oncotype testing was undertaken in 30 patients, recurrence score range 3-25.
38/51(74.5%) patients underwent breast conserving surgery of which 8/38 (21.1%) required further surgery 4/8 (50%) underwent completion mastectomy. Pre-operative imaging consistently underestimated pathological tumour size in these patients.

Conclusion: In lobular breast cancer, MRI demonstrates strong correlation with final pathological tumour size with greater accuracy than mammography and/or USS but generates a high volume of incidental findings requiring further investigations. We observed a clinically relevant and statistically significant delay to surgery in patients with lobular breast cancer. Further work is needed to improve efficiency in care pathways in lobular breast cancer, as this may improve patient outcomes.

P2-12-12: Impact of the addition of pembrolizumab to neoadjuvant chemotherapy in triple negative breast cancer in Ireland: a retrospective, multi-centre, real-world study

Karine Ronan, Laurann Rabbitt, Karolina Weiner-Gorzel, Benjamin Mathewson, Lisa Prior, Jennifer Westrup, Janice Walshe, Michaela Higgins, Hannah O Connor, Beth Costello, Shahid Iqbal, Catherine Kelly, Maccon Keane, Sonya Chew, Emily Harrold

Background: The 60-month follow up data from the phase III KEYNOTE 522 (KN522) trial reported that the addition of pembrolizumab (pembro) to chemotherapy improved event free survival (EFS) and increased the rate of pathological complete response (pCR).1 As a result, the KN522 regimen is standard of care for stage II/III TNBC. The KN522 trial reported that immune-mediated adverse events (IRAEs) ≥ grade 3 occurred in 12.9% of pts in the pembro arm and 1.0% of pts in the chemo only arm.2

Methods: We conducted a retrospective observational cohort study of patients (pts) with TNBC, stage II-III, who received paclitaxel and carboplatin followed by doxorubicin plus cyclophosphamide, associated with pembro, as per the KN522 trial, between January 2023 and May 2024 at five Irish institutions. We examined the real-world pCR rate and IRAEs.

Results: 67 patients (pts) started the KN522 regimen. The median age was 49 years (range 32-77). 47 pts (70%) had T1-2 tumours, 19 pts (28%) had T3-4 tumours, data was unavailable for 1 pt. 38 pts (57%) had node positive disease.
16 pts (23%) experienced an IRAE of ≥ grade 3 during treatment. 13 pts (19%) experienced an IRAE ≥ grade 3 in the neoadjuvant phase and 3 pts (4%) experienced an IRAE ≥ grade 3 in the adjuvant phase. The most common ≥ grade 3 IRAEs observed were hepatitis (n=6, 9%); nephritis (n=4, 6%) and colitis (n=3, 4%). 34 pts (51%) were hospitalized at least once during treatment. 13 pts were hospitalized on more than once occasion, and a total of 54 hospitalisations were recorded for the group during treatment. To date, 3 pts have been hospitalised during the adjuvant phase.

Of the 40 pts who had undergone surgery at the time of data analysis, 26 pts (65%) had a pCR. Among those pts who experienced a pCR, a higher proportion had stage II disease (n=20, 77%) compared with the pts who did not experience a pCR (n=9, 64%), although this was not statistically significant (p=0.469). There was a lower instance of ≥ grade 3 IRAEs observed among pts who experienced a pCR (n=4, 15%) compared with those who did not experience a pCR (n=5, 36%), however this was not statistically significant (p=.234). A lower number of patients who experienced a pCR were hospitalised during the neoadjuvant phase of treatment (n=12, 46%) compared with pts who did not experience a pCR (n=8, 57%). The median number of cycles of pembro received among patients who experienced a pCR was 8 (range 1-10), compared with a median of 7 cycles among patients who did not experience a pCR (range 2-10).

Conclusion: We found a high pCR rate among pts who completed the neoadjuvant phase of treatment. The IRAEs observed were in line with the known side effects of the agents. IRAEs ≥ grade 3 were higher in our real-world cohort compared with KN522 published data.2 Higher rates of IRAEs ≥ grade 3 have been reported among other real-world cohorts.3 We found a high rate of hospitalization in our cohort, which is also in line with published real-world data.4 The hospitalization rates observed with this regimen are higher than hospitalisation rates with neoadjuvant chemotherapy alone, which range from 6.2%-10% for pts aged <65 years and 12.7%-24% for pts ≥65 years.5 In this cohort, pts who experienced a pCR had a higher frequency of stage II disease and lower rates of ≥grade 3 IRAEs compared with those who did not experience a pCR, although this did not reach statistical significance. This real-world study supports trends observed in other similar studies and highlights the complexity of managing the toxicities arising from the addition of immunotherapy to standard neoadjuvant chemotherapy.

P2-12-13: Clinico-Pathological Characteristics and Incidence Trends of Breast Cancer in Young Women: A 10-Year Single Institution Retrospective Study

Francisco Javier Muñoz i Carrillo, Benjamin Walbaum, María Rey, Carme Crous, Clara Rodrigo, Esther Sanfeliu, Fara Brasó-Maristany, Isabel Garcia-Fructuoso, Elia Seguí, Raquel Gómez-Bravo, Barbara Adamo, Tomás Pascual, Olga Martínez-Sáez, Francesco Schettini, Núria Chic, Montserrat Muñoz, Aleix Prat, Maria Vidal

Introduction: Women diagnosed with breast cancer (BC) before age 40 (YWBC) experience a substantially higher risk of recurrence and mortality than their older counterparts. The global trends in BC incidence and mortality among YWBC are scarcely described, although recent studies suggest a rise among certain high-income countries.

Material and methods: We conducted a retrospective analysis including all consecutive newly diagnosed BC patients (NBC) between January 2014 and December 2023 at Hospital Clinic of Barcelona, Spain. Clinical and immunohistochemistry characteristics (estrogen

receptor [ER], progesterone receptor [PR], HER2 status and Ki67 expression) determined BC subrogated subtypes: hormone receptor-positive (HR+)/HER-2 negative (HER2-), HER2-positive (HER2+) and triple negative (TN). YWBC incidence (YI) was defined as the yearly ratio between YWBC and NBC. Our primary objective was to report the YI over the years and determine if there was any variation. We also assessed incidence differences among immunohistochemical subtypes, as well as the YI in very young BC pts (≤ 35 years, VYWBC). Incidence difference across years was evaluated using the Kruskal–Wallis test, with a significance p-value <0.05.

Results: A total of 262 YWBC pts were included, accounting for 9.6% of NBC over the 10-year period, ranging from a minimum of 7.38% in 2020 to a maximum of 14.02% in 2018. When analyzing YI over the years, we observed an initial increase until 2018, followed by a decline and stabilization at a steady percentage, with no statistically significant differences (p=0.44). With a median age of 37 years (range: 18 to 40 years), the majority (76.33%) were diagnosed at early stages (i.e., stage II or less). Stages II and III represented 38.50%, whereas 6.11% were metastatic at diagnosis, without significant variations throughout the period (p=0.44). Most YWBC were ER-positive (66.41%), PR-positive (53.05%), HER2-negative (62.6%), and had a Ki67 >20% (52.29%). Most tumors were HR+ (54.23%) throughout the entire period, with minimal variation across the years. The proportion of HR+ vs HR-negative (HR-) tumors remained stable over the 10 years studied (p=0.44). HER2+ tumors accounted for 23.66% of YWBC, ranging from 10.34% (2023) to 43.48% (2018). On the other hand, TN tumors represented 21.76% of the cases, with a range from 5.56% (2014) to 41.38% (2023) during the period, again with no significant change. VYWBC represented a steady 4% of NBC, with a non-significant tendency to decrease in recent years (reaching 1.84% in 2023). Stages II and III represented 38.51%, without significant changes throughout the period (p=0.437). Across subtypes, HR+ tumors were 47.19%, HER2+ 24.57% and TN, 27.03%. Interestingly, among YWBC, VYWBC represented a third of the new cases, peaking in 2020, followed by a numerical non-significant reduction in incidence (p=0.44).

Conclusions: YWBC incidence has remained stable over the years. In our population, the YI is consistent with previous studies, ranging from 5-10% depending on the country, and slightly higher than the YI reported for Spain (6.6% in 2022). Both in YWBC and VYWBC, no variation was observed regarding stage and subtypes over time. Overall, these results indicate that over the past ten years there have not been significant changes in the YI, nor a trend towards more aggressive phenotypes among YWBC at our institution.

P2-12-14: Adverse events in patients treated with neoadjuvant chemo/immunotherapy for triple negative breast cancer

Jessica Sharpe, Chih-Yuan Hsu, David Choi, Ekaterina Proskuriakova, Sara Zelinskas, Mateo Campana Montalvo, Hollie Sheffield, Jennifer G. Whisenant, Keaton Gaffney, M. Scott

Thompson, Kim Blenman, Lynn Symonds, Nisha Unni, Dionisia Quiroga, Karine Tawagi, Cesar Santa-Maria, Yu Shyr, Laura Kennedy

Background: Triple negative breast cancer (TNBC) accounts for 15% of newly diagnosed breast cancer cases and has higher risks of distant recurrence and death compared to other subtypes. The current standard-of-care regimen for locally advanced disease from the KEYNOTE-522 (KN-522) trial combines neoadjuvant chemotherapy (carboplatin, paclitaxel, doxorubicin, and cyclophosphamide) with neoadjuvant and adjuvant pembrolizumab. This regimen increased rates of pathologic complete response (pCR) and event-free and overall survival but had higher rates of adverse events (AEs). Of note, patient race was not reported in KN-522. Our goals were to examine rates of AEs, hospitalizations, and suspected immune-related adverse events (irAEs) in TNBC patients undergoing neoadjuvant chemo/immunotherapy in a diverse academic center population more representative of a real-world patient population.

Methods: TNBC patients who received neoadjuvant treatment with pembrolizumab were retrospectively identified through pharmacy treatment records at 7 academic medical centers across the U.S. Electronic medical record review was conducted, and de-identified data were managed using electronic data capture tools. Descriptive statistics were used to report all variables, and total rates of AEs, grade 3+ AEs, and hospitalization rates for patient groups were estimated with 95% confidence intervals (CIs) calculated by 5000 Monte Carlo simulations. Fisher's exact test was used to compare event rates between groups, and two sample proportions test was used to evaluate the difference in proportions between any two groups.

Results: At the time of analysis, 137 patients had data collected from 4 sites. Median age was 48 years old. All identified as female. Racially, 59% identified as white, 34% as black, and 7% as other. Ethnically, 7% identified as Hispanic/Latino. 75% were overweight/obese based on initial BMI. 61% achieved a pCR following neoadjuvant treatment, and 4 (3%) died from progressive/metastatic disease at the time of data collection. 89% had a reported AE, and 36% had a grade 3+ AE. The most common grade 3+ AE was myelosuppression, and 70% required growth factor support at some point during neoadjuvant therapy. The most common suspected irAEs were dermatitis (20%), hypothyroidism (18%), arthralgias/myalgias (18%), diarrhea (15%), hepatitis (11%), and adrenal insufficiency (5%). 12% also had cardiac or thrombotic AEs. 24% were treated with systemic steroids for a suspected irAE, and only 58% received a full course (8 doses) of neoadjuvant pembrolizumab due to toxicity concerns. Pembrolizumab was permanently discontinued in 58% of patients with very few (6%) re-challenged once stopped. 31% were hospitalized during treatment, with the majority hospitalized during neoadjuvant therapy. Neutropenic fever was the most common admitting diagnosis, and 29% of hospitalizations had an irAE reported. There were no statistically significant differences in AE or hospitalization rates between white versus black patients or between patients with normal BMIs compared to overweight/obese patients, although there was a trend towards significance in overweight but not obese patients having lower rates of grade 3+ AE ($p=0.07$) compared to patients

with normal BMIs.

Conclusions: This study presents an analysis of AEs in a more diverse and representative of the real-world patient population receiving neoadjuvant chemo/immunotherapy for TNBC. Rates of pCR and AEs were similar to those reported in KN-522. However, a large proportion of patients stopped pembrolizumab early due to a suspected irAE and did not complete adjuvant treatment. Additionally, high rates of hospitalization and myelosuppression suggest that incorporating growth factor support may benefit TNBC patients receiving neoadjuvant treatment. Our study is ongoing with final data collection pending; this will be reported in the future.

P2-12-15: Trends in Antiemetic Use in Patients Receiving Fam-trastuzumab Deruxtecan-nxki for Metastatic Breast Cancer: A Retrospective Analysis of Data from the IntegraConnect PrecisionQ De-Identified Database

Stephan Rosenfeld, Vikram Gorantla, Rushir Choski, Debra Patt, Anupama Vasudevan, Anna Rui, Dawn Brenneman, Mike Gart, Prateesh Varughese, Brandon Wang, Lisa Morere,Simon Blanc

Background: Clinical practice guidelines recommend treatment with 3-4 antiemetic drugs for regimens with high emetic risk, such as fam-trastuzumab deruxtecan-nxki (T-DXd). This study uses real-world data to characterize the real-world use of antiemetics in patients with metastatic breast cancer (mBC) and explores the impact of antiemetic treatment on T-DXd outcomes. Methods: This was a retrospective, observational analysis of data from patients in the IntegraConnect PrecisionQ real-world de-identified database, enriched with information obtained by curation. The study included adults (age ≥18 years) with a confirmed diagnosis of mBC who initiated treatment with T-DXd between December 20, 2019 and December 31, 2023. The index date was the date of T-DXd initiation and follow-up was through May 20, 2024. Antiemetic classes were defined using data obtained within the first 7 days of T-DXd initiation using National Comprehensive Cancer Network (NCCN) criteria. Outcomes included time to treatment discontinuation (TTD), the rate of dose reductions for T-DXd, and the rate of antiemetic use over time in patients receiving T-DXd. Also included were demographics and clinical characteristics. Data are presented using descriptive statistics. Results: Overall, 2,132 patients were included in the analyses, most were female (98.4%) and white (62.2%). The median (interquartile range [IQR]) age at diagnosis was 59 (50, 67) years and the median (IQR) age at treatment was 63 (54, 71) years. Most patients (82.4%) had an Eastern Cooperative Oncology Group (ECOG) score of 0-1; 13.9% were ECOG 2 and 3.7% were ECOG 3+. A total of 113 patients received no antiemetics, 136 received 1 antiemetic class, 1090 received 2 antiemetic classes, and 793 received 3-4 antiemetic classes. Over a median follow-up duration (IQR) of 16.3 (11.0, 28.0) months, 11.0 (5.7, 21.0) months, 13.8 (7.0, 19.7) months, and 9.1 (5.9, 13.8) months for each group, respectively, the number of patients who discontinued/died was 96 (85.0%), 94

(69.1%), 745 (68.3%), and 433 (54.6), respectively. The median (95% confidence interval [CI]) TTD was 7.0 (5.6, 8.3) months, 7.6 (5.5, 12.4) months, 8.3 (7.6, 9.2) months, and 9.0 (8.0, 9.6) months for patients treated with 0, 1, 2, and 3-4 antiemetic classes, respectively. At 6 months, treatment probability (95% CI) was 58.6% (48.8, 67.1), 55.2% (46, 63.4), 59.6% (56.5, 62.5), and 61.5% (57.9, 64.8), respectively; and at 18 months it was 15.4% (9.1, 23.3), 22% (13.8, 31.6), 26.1% (23.2, 29.2), and 30.2% (25.4, 35.2), respectively. The number of patients receiving 3-4 antiemetics has been increasing since the end of 2021, and in 2023, more patients were receiving 3-4 antiemetic classes (n=574) than 2 antiemetic classes (n=294). In an analysis of patients who were on T-DXd for ≥6 months (n=1027), the rate of dose reduction decreased with the number of antiemetic classes (32.7% for 0-1 classes, 27.5% for 2 classes, 24.9% for 3+ classes). Conclusion: In this analysis of real-world data, persistence on T-DXd treatment increased with the number of antiemetic classes administered. Following the NCCN guideline update, patients receiving T-DXd are now treated with 3 or more antiemetic classes. The requirement for dose reduction appears to be reduced when more antiemetic classes are used.

P2-12-16: A PROSPECTIVE RANDOMIZED PLACEBO-CONTROLLED TRIAL EVALUATING EFFECT OF A WIDE SPECTRUM MICRONUTRIENTS SUPPLEMENT ON CANCER RELATED FATIGUE IN BREAST CANCER PATIENTS TREATED WITH ADJUVANT/NEO-ADJUVANT THERAPY

Alessandra Fabi, Luisa Carbognin, Silvia Rotondaro, Stefania Russo, Giulia De Pieri, Andrea Fontana, Sara Donati, Carmelo Bengala, Laura Velutti, Rebecca Pedersini, Andrea Antonuzzo, Paolo Bossi, Maria Sole Rossato, Germano Tarantino

Background: Fatigue is the most common symptom experienced by patients during the cancer trajectory from diagnosis to the end of life. Several studies in breast cancer (BC) patients confirm that fatigue is the most reported symptom (88-91%). Women with BC are the highest users of complementary therapies, including use of micronutrients, to prevent or reduce the Cancer-related fatigue (CRF) severity. This highlights how there is still today the need for non-pharmacological treatments that are able to relieve CRF in breast cancer (BC) patients. There is no unanimous consensus on the use of micronutrients in CRF and randomized controlled studies are needed to define the effect of these substances. Recently a nutritional supplement containing 19 nutrients including amino acids such as arginine and carnitine, highly absorbed minerals such as Sucrosomial® iron, magnesium, zinc and selenium, group B vitamins, and plant extracts as Panax ginseng and Eleutherococcus senticosus (Apportal®) demonstrated a significantly improvement of post-Covid related fatigue and to ameliorate muscle strength and physical performance in subject suffering from long-Covid syndrome. Besides, a recent cohort study including 458 individuals who reported fatigue from different causes (not Covid related) showed that the intake of APPORTAL® significantly improves both mental and physical fatigue (under submission).
Study Objectives: The primary objective of this study is to investigate if BC patients

undergoing adjuvant or neo-adjuvant therapy can have a beneficial effect from Apportal® supplementation. Secondary objectives are evaluating if the supplementation with APPORTAL® can improve patients' nutritional status, muscular strength, and quality of life (QoL).
Trial design: This is a randomized, placebo controlled, multicenter study with two parallel groups of patients. Patients with BC, suffering from fatigue after at least one cycle of adjuvant or neo-adjuvant chemotherapy will receive APPORTAL®, (Pharmanutra SpA, Italy), 1 sachet per day or placebo for 8 weeks. Visits were scheduled at baseline and after 4-8-12 weeks, assessing fatigue (BFI questionnaire), physical status, blood nutritional markers, quality of life (QoL), muscular strengths, compliance and adverse events.
Major Inclusion Criteria: - Females aged 18 or higher - Patients diagnosed with histologically confirmed BC - Patients having done at least one cycle of adjuvant or neo-adjuvant chemotherapy - ECOG performance status ≤1 at screening - CRF of moderate-severe intensity (NRS > 4) - Patients able to follow the recommendations on the physical exercise to do - Patients who accept to use adequate contraceptive methods, if they are of child-bearing potential.
Sample Size
92 patients randomized 1:1 ratio into Treatment group (APPORTAL® plus physical exercise) and Placebo group (Placebo plus physical exercise).
Estimated Dates for Completing Accrual
Patient recruitment will be completed by mid-2025. First patient was enrolled in December 2023.
Trial Registration Number
NCT 06137833

P2-12-17: A Phase 1, First-in-Human study of autologous monocytes engineered to express an anti-HER2 chimeric antigen receptor (CAR) in participants with HER2 overexpressing solid tumors

Yara Abdou, Felicia Cao, Paula Pohlman, Richard Maziarz, Hemant Murthy, Yuan Yuan, Anuradha Krishnamurthy, Kim Reiss Binder, James Isaacs, Aiwu He, Pooja Advani, Daniel Blumenthal, Kenneth Locke, Jeanette Wetzel, Michael Klichinsky, Thomas Condamine, Eugene Kennedy, Davendra Sohal

Background: Myeloid cells are actively recruited to the solid tumor microenvironment (TME) and have the potential to mediate tumor control via phagocytosis, TME remodeling, and T cell activation. We previously developed human chimeric antigen receptor macrophages (CAR-Macrophage) and have shown potent anti-tumor activity in pre-clinical solid tumor models1. The anti-HER2 CAR-Macrophage cell therapy product, CT-0508, was evaluated in a Phase 1 trial as a monotherapy and in combination with pembrolizumab. Clinical data have demonstrated preliminary safety, feasibility, and validated the mechanism of action. We have developed a next-generation CAR monocyte (CAR-Monocyte) platform to increase the available dose, improve tumor trafficking and engraftment, and

shorten the manufacturing and vein-to-vein time as compared to CAR-Macrophage therapy. CT-0525 is an autologous anti-HER2 CAR-Monocyte cell therapy based on CD14+ monocytes engineered with an Ad5f35 adenoviral vector to express an anti-HER2 CAR. Pre-clinical studies have demonstrated the feasibility, phenotype, pharmacokinetics, durable CAR expression, cellular fate, antigen specificity, and anti-tumor activity of CT-0525. Pre-clinical studies have shown that CT-0525 differentiated into pro-inflammatory CAR-Macrophages in vivo and controlled tumor growth. The CT-0525 manufacturing process takes one day and enables the production of up to 10 billion cells from a single apheresis. CT-0525 is being investigated in a first-in-human, open-label, multi-center, Phase 1 study in participants (pts) with HER2 overexpressing solid tumors.
Methods: This Phase 1, first-in-human study evaluates the preliminary safety, feasibility, tolerability, trafficking, TME activation, and initial evidence of efficacy of the investigational CAR-Monocyte product, CT-0525, in pts with locally advanced unresectable/metastatic solid tumors overexpressing HER2. Pts previously treated with anti-HER2 therapies are eligible for this dose escalation study. Filgrastim mobilized autologous CD14+ monocytes are collected by apheresis, followed by manufacturing and cryopreservation. CT-0525 will be administered without conditioning chemotherapy. The 1st cohort of pts will receive 3 x 109 CT-0525 CAR positive monocytes administered in one infusion intravenously. If tolerated as per the modified toxicity probability interval algorithm (mTPI), the 2nd cohort of pts will receive up to 10 x 109 CT-0525 CAR positive monocytes in one infusion. A minimum of 3 evaluable pts is required at each dose level. Primary endpoints include assessment of safety and tolerability, as well as manufacturing feasibility. Secondary endpoints include initial evidence of efficacy. Correlative assessments include pre- and post-treatment biopsies and blood samples for safety, immunogenicity, pharmacokinetics, tumor trafficking, TME modulation, epitope spreading, and other translational biomarkers. This clinical trial (NCT06254807) is currently enrolling at multiple sites across the United States.

P2-12-18: A Randomized Phase 2 Non-inferiority Trial of (Z)-endoxifen and Exemestane + Goserelin as Neoadjuvant Treatment for Premenopausal Women with ER+/HER2-Breast Cancer (EVANGELINE)

Matthew Goetz, Vera J. Suman, Arezoo Mirad, Harjinder Singh, Sandra S. Hammer, Lida Mina, Pooja Advani, Roberto Leon-Ferre, Karthik Giridhar, Felipe Batalini, Daniel Flora, Jason M. Jones, Nusayba A. Bagegni, Katie N. Hunt, James Jakub, Mara Piltin, Amy Degnim, James N. Ingle, Judy C. Boughey, Sarah A. Buhrow, Joel M. Reid, Matthew Schellenberg, John R. Hawse, Steven C. Quay

Background: Ovarian function suppression (OFS) when combined with tamoxifen or an aromatase inhibitor is the standard of care for premenopausal women (preMW) with estrogen receptor positive (ER+) human epidermal growth factor receptor 2 negative (HER2-) breast cancer (BC) based on SOFT (Francis 2022) and TEXT (Pagani 2022) clinical

trials and confirmed in a metanalysis (EBCTCG 2022). However, estrogen deprivation in preMW is associated with significant morbidity and up to 40% of premenopausal women with ER+/HER2- BC are intolerant of OFS. For these women, tamoxifen monotherapy is the only FDA approved option where long-term patient outcomes are known to be sub-optimal. Therefore, there is substantial room to improve endocrine therapy for preMW with ER+/HER2- BC. (Z)-endoxifen is one of the most active anti-estrogen tamoxifen metabolites, with preclinical data demonstrating superiority to tamoxifen and letrozole in aromatase expressing xenograft models and evidence for antitumor activity in early phase clinical trials in patients with prior progression on endocrine therapy including tamoxifen. In addition to its ability to potently block ERα, (Z)-endoxifen at clinically achievable concentrations inhibits protein kinase C beta 1 (PKCβ1), resulting in downstream AKT inhibition and apoptosis. It is hypothesized that (Z)-endoxifen, when delivered as monotherapy at doses that dually target both ERα and PKCβ1, will potently inhibit BC proliferation while obviating the need for OFS in premenopausal women. If successful, this innovative approach could spare women with endocrine sensitive BC from the side effects of OFS.
Methods: To further study (Z)-endoxifen in preMW, a multicenter study in the United States, with possible expansion to other countries was designed (EVANGELINE; NCT05607004). This is a Phase 2, open-label, randomized, neoadjuvant study with a pharmacokinetic (PK) run-in phase in preMW with Stage IIA or IIB ER+/HER2- incident BC. Subjects are randomized 1:1 to either exemestane plus goserelin or (Z)-endoxifen monotherapy. The primary objective of the PK-run is to determine the dose that inhibits PKCβ1 and in the randomized Phase II is to determine whether the endocrine sensitive disease (ESD) rate (defined as Ki-67 ≤ 10% after 4 weeks of neoadjuvant therapy) with (Z)-endoxifen is non-inferior to exemestane plus goserelin. Subjects will be enrolled with the intent of surgical treatment in the involved breast after completing 6 months of neoadjuvant treatment. Safety, tolerability, response rates and surgical outcomes will be assessed. Disease progression will be monitored throughout study participation. Paired tumor biopsies and blood sampling will allow for a robust biomarker evaluation. Enrollment to the 40mg PK Run-was completed in June 2023 (n=7), and accrual to the 80mg PK Run-in will be complete by August 2024. The randomized portion of the trial is expected to commence in Fall 2024.

P2-12-19: A Randomized Phase II Window-of-opportunity Trial of Ruxolitinib in Patients with High Risk and Premalignant Breast Conditions

Julie Nangia, Shaun Bulsara, Tao Wang, Amy Ku, Derek Thomas, Ingrid Meszoely, Parijatham S. Thomas, Catherine Parker, Sheldon Feldman, Carla Fisher, Kristalyn Gallagher, Gaorav Gupta, Alastair Thompson, Kristen Otte, Carolina Gutierrez, Chandandeep Nagi, George Miles, Susan Hilsenbeck, Yi Li, C. Kent Osborne, Mothaffar Rimawi

Background: Current medications to prevent breast cancer (BC) are the antiestrogens tamoxifen, raloxifene, anastrozole and exemestane which can prevent 50% of ER+ BC. However, because they can have side effects and require 5 years of continuous use, women

who are yet cancer-free are often reluctant to take them. Furthermore, antiestrogens do not prevent ER- BC. Therefore, it is urgent that we develop alternative prevention drugs that require only a short-term treatment and are suitable for preventing both ER+ and ER- BC. No prevention strategies have been developed for ER- or HER2+ subtypes, the most virulent forms of the disease.

Ruxolitinib is a small molecule which selectively inhibits the activities of Janus Associated Kinases (JAK); activated JAK phosphorylate STATs leading to modulation of gene expression. In animal models, ruxolitinib prevents progression of premalignant breast lesions to invasive BC. Studies in several human tissue types suggest that there are anticancer "barriers," namely apoptosis and senescence, which are erected in early lesions to prevent the progression to cancer. We hypothesize that the JAK2-STAT5 pathway in human premalignant lesions promotes the progression of these lesions to malignancy by lowering the apoptosis anticancer barrier; therefore, inhibition of this pro-survival pathway could reduce the load of premalignant lesions in the breast and thus lower BC risk. We are conducting a window-of-opportunity trial through the Translational Breast Cancer Research Consortium (TBCRC) to test whether short-term ruxolitinib treatment of subjects with premalignant lesions will result in increased apoptosis.

Trial Design: This is a phase II, double-blind, placebo-controlled clinical trial. Our target population consists of patients with premalignant breast lesions requiring surgical excision. Subjects will be randomized 1:1 to receive either ruxolitinib 20 mg twice daily or placebo for ~15 days after which they will proceed with standard of care surgical excision within 12 hours of the last dose.

Key Eligibility Criteria: 1) Breast biopsy showing atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ, or ductal carcinoma in situ requiring surgical excision

2) Adequate hematologic and organ function

3) Willing to not use concomitant strong CYP3A4 inhibitors

Statistical Methods: The primary endpoint is change in apoptosis, as measured by cleaved caspase-3 staining, in surgical samples relative to baseline biopsy. Lesions of different types will be characterized separately, and the participant's most advanced lesion present at baseline will be used for the primary analysis. The difference in changes between groups will be evaluated using the Wilcoxon rank sum test.

The secondary objectives primarily focused on the effects of ruxolitinib treatment on biomarkers. The secondary endpoints include pre- and post-treatment pSTAT5, TUNEL, Ki67, BCLxL, MCL1, BCL2, PRLR, pSTAT3, and serum prolactin levels. Changes in these markers will be compared between groups using the Wilcoxon rank sum test.

Accrual:

We expect to enroll 100 subjects from 7 sites in the US in order to obtain 70 evaluable subjects. Currently there are 80 subjects enrolled.

P2-12-20: A Real-World Study of the Effectiveness and Safety of Trastuzumab Deruxtecan (T-DXd) in HER2-low Metastatic Breast Cancer (mBC) among Racial and Ethnic Minorities and Older Populations in the United States

Mackenzie Henderson, Candice Drinkwater, Danielle Potter, Divi Alagappan, Victoria de Giorgio-Miller, Shahid Ashfaque, Gargi Patel, Kellie Ryan, Cecilia Orbegoso Aguilar, Armen A. Ghazarian

Background: Approximately 45-55% of all primary breast cancer (BC) cases are classified as human epidermal growth factor receptor 2 low (HER2-low). Currently, trastuzumab deruxtecan (T-DXd) is the only approved HER2-targeted therapy for HER2-low metastatic BC (mBC). In the US, Black/African-American and Hispanic women have more advanced BC stage at diagnosis, less favorable tumor characteristics, and a lower chance of receiving guideline concordant care compared to non-Hispanic white women. Similarly, women ≥65 years of age have higher BC incidence and mortality, are more likely to be under-treated, and are less likely to comply with treatment compared to younger women. Given these health inequities, we sought to further evaluate the safety and effectiveness of T-DXd among racial/ethnic minorities and older patients in the HER2-low mBC setting.

Specific Aims: The primary objective of this study is to assess the effectiveness of T-DXd measured by real-world progression-free survival among HER2-low mBC patients treated with T-DXd, stratified by race, ethnicity, and age group. Secondary objectives are twofold: (1) describe demographic/clinical characteristics and prior anticancer therapy among HER2-low mBC patients and (2) assess the real-world targeted safety profile of T-DXd among HER2-low mBC patients, both stratified by race, ethnicity, and age group. Targeted adverse events (TAEs) include interstitial lung disease/pneumonitis, left ventricular dysfunction, neutropenia/febrile neutropenia, and nausea/vomiting. As an exploratory objective, we will assess the effectiveness of T-DXd using additional endpoints including real-world overall survival, real-world time to next treatment, and real-world time to treatment discontinuation.

Eligibility criteria: To be included in the Source Population, patients must be ≥18 years old with HER2-low mBC. Major exclusion criteria include history of a non-BC primary cancer, history of HER2 positive disease, and having neither race nor ethnicity data. The T-DXd Treated Cohort will include the subgroup of patients from the Source Population who receive T-DXd during the study period.

Study Design: This is a non-interventional, retrospective cohort study conducted in the real-world setting. The data source is the Guardian Research Network (GRN), a de-identified electronic medical record database covering US oncology and non-oncology care. The planned study period is from August 2022 to December 2026. All necessary variables will be obtained from structured data elements or curation of unstructured data elements, as needed (e.g., physician notes, radiology reports). Present and target accrual. A sample size

projection for the T-DXd Treated Cohort was completed based on current patient accrual in GRN with assumptions for T-DXd uptake. At the time of this analysis, 60 patients fulfilled all eligibility criteria for inclusion in the T-DXd Treated Cohort, and approximately 450 patients are projected to be eligible for inclusion in this cohort through the end of the study period.

Statistical Methods: All analyses will be descriptive; no hypothesis testing is planned. The Source Population will be used to summarize demographics, clinical characteristics, and treatment patterns. Effectiveness endpoints will be analyzed using a time-to-event approach (Kaplan-Meier estimator). The proportion of patients with each TAE will be summarized and select TAE characteristics will be described. All analyses will be conducted overall and stratified by race, ethnicity, and age group (≤65, >65, and >75 years).

P2-12-21: A Video Intervention to Improve Patient Understanding of Tumor Genomic Testing in Patients with Metastatic Breast Cancer: Primary Results of a Prospective Intervention Trial

Deloris Veney, Lai Wei, Amanda E. Toland, Carolyn J. Presley, Tasleem J. Padamsee, Clara N. Lee, Heather Hampel, William J. Irvin, James Kim, Michael J. Bishop, Shelly R. Hovick, Leigha Senter, Daniel G. Stover

Background: Tumor genomic testing (TGT) has become standard-of-care for all patients with metastatic breast cancer (MBC). Guidelines for patient education prior to TGT from the American Society of Clinical Oncology (ASCO) and the American College of Medical Genetics (ACMG) are not widely followed. We have previously demonstrated disparities in general genomic knowledge across race and income. The purpose of this study was to evaluate the impact of a concise (3-4 minute) video for patient education prior to TGT in a prospective interventional trial. We report the results of the MBC cohort (ClinicalTrials.gov NCT05215769).
Methods: We created a base animated video incorporating culturally diverse images, available in English and Spanish, applicable to any cancer type, with MBC-specific content included for patients with MBC. From March 2022 to June 2024, a total of 54 patients with MBC were enrolled at a single tertiary academic institution, and three community cancer centers. Participants completed validated survey instruments immediately prior to video viewing (T1), immediately post-viewing (T2) and after receipt of their own TGT results (T3). Instruments included: 1) 10-question objective genomic knowledge/understanding (GKU); 2) 10-question video message-specific knowledge/recall (VMSK); 3) 11-question Trust in Physician/Provider (TIPP); 4) attitudes around TGT. The primary objective was to assess change in VMSK between T1 and T2. A cohort of fifty patients provided 90% power to detect an effect size of 0.47 in change of recall accuracy from pre- to post-video using two-sided Wilcoxon signed-rank test with alpha of 0.05. The associations of VMSK, GKU, and TIPP with categorical demographic variables were explored with Kruskal-Wallis test.
Results: To date 50 of the 54 patients with MBC enrolled have completed surveys at all

timepoints. The MBC cohort had a median age of 57; all were female; most were Caucasian (49/54, 91%); most were married/in domestic partnership (41/54, 76%). For the primary endpoint, there was a significant increase in VMSK ($p<0.001$) but there was no significant change in GKU ($p=0.89$) or TIPP ($p=0.59$). Improvement of VMSK was consistent across demographic groups, including race/ethnicity, age, income, and education. Of the 10-questions in the VMSK survey, results for four questions significantly improved after viewing the video, including questions informing the likelihood of TGT impact on treatment decision, incidental germline findings, and cost of testing. However, the improvement seen was not consistently sustained at T3 in seven of ten questions. Higher baseline genomic knowledge was significantly associated with higher participant income.
Conclusions: A single viewing of our concise, 3-4 minute, broadly applicable video incorporating culturally diverse images administered prior to TGT significantly improved VMSK across all demographic groups. While video content recall regressed over time, patient's perception of the merits of TGT and their TIPP remained unchanged. This approach can be a valuable tool for empowering patients and educating them on the risks, benefits, and limitations of TGT in alignment with ASCO and ACMG guidelines.

P2-12-22: A multicenter, single-arm, phase II clinical trial of oral CDK4/6 inhibitor darciclib in combination with endocrine therapy in adjuvant treatment for hormone receptor-positive, HER2-negative female breast cancer.

Jie Ouyang, Yifen Wu, Pengfei Qian, Jinsong He, Hao Hu, Shi Tang, Qing Zhang, Heng Huang, Shuqin Xie, Zhuohong Liang, Ailing Zhang, Hong Hu, Xiaobo Wu, Heng Tian, Ying Cao, Yongxia Wang, Zhibiao Zhang, Yufang He, Ting Yang

Background: Although the role of endocrine therapy in the adjuvant treatment of HR+/HER2- breast cancer has been established, Early HR positive and HER2 negative breast cancer show a long-term risk of recurrence. Studies have shown that about 20% of patients experience recurrence and metastasis after receiving adjuvant endocrine therapy for 5 years. CDK4/6 inhibitor combined with endocrine therapy for HR+/HER2- breast cancer has been proven to have synergistic effects. Previous studies have shown that Abemaciclib and ribociclib can reduce the risk of recurrence and increase iDFS in early high-risk HR positive breast cancer, but conventional doses lead to excessive adverse events and patients interrupt treatment. Compared with different CDK4/6 inhibitors combined with AI as first-line treatment of advanced HR+ breast cancer, dalpiciclib achieved the highest ORR. It was found that dose reduction had no significant identifiable negative impact on the progression-free survival evaluated in the study. This study will be evaluated the effectiveness and safety of a small-dose dalpiciclib combined with endocrine therapy in hormone receptor-positive, HER2-negative breast cancer in women.
Methods: This multicenter, single arm, phase II clinical trial(ChiCTR2400080962) will enroll 317 women with hormone receptor-positive early breast cancer from Jan 2024 to Dec 2025.

Eligible patients are aged ≥18 years and ≤75 years, either postmenopausal or pre/perimenopausal. Histologically confirmed stage II-III (a) IIA-N0: Grade 2 with high risk [Ki67≥20% or high-risk gene characteristics], Grade 3, N1 ; (b) Anatomical stage IIB: N0 or N1;(c) Anatomical stage III: N0, N1, N2, or N3. HR positive defined as ER positive: Positive staining tumor cells accounting for ≥10% of all tumor cells (confirmed by the pathology department of the research center), regardless of PR expression status.
Patients will receive dalpiciclib 100mg daily for 21 days followed by a 7-day break(every 28 days as a cycle) for 3 years. All patients receive standard endocrine therapy for 5-10 years after standard postoperative adjuvant chemotherapy and/or adjuvant radiotherapy. The primary endpoint is Intermediate Disease-Free Survival(IDFS), while the secondary endpoints including Disease-Free Survival(DFS), Distant Disease-Free Survival(DDFS),Overall Survival(OS).The safety of patients will be assessed by the quality of life rating scale (EORTIC QLQ-C30).
Conclusions: This multicenter, single-arm, phase II clinical trial will provide valuable insight into the efficacy and safety of a small-dose dalpiciclib in combination with endocrine therapy in adjuvant treatment for hormone receptor-positive, HER2-negative female breast cancer. If proven effective and well-tolerated, this regimen may offer a more convenient treatment option for this patient population, potentially improving quality of life and treatment adherence.

P2-12-23: A phase 2 trial combining tiragolumab and atezolizumab with neoadjuvant or first line chemotherapy for triple negative breast cancer (SKYLINE)

Francois-Clement Bidard, Romain-David Seban, Laurence Champion, Nina Jehanno, Anne Vincent-Salomon, Irene Buvat, Julien Fouque, Toulsie Ramtohul, Agathe Peltier, Diana Bello-Roufai, Florence Coussy, Fatima Mechta-Grigoriou

Introduction: TIGIT is an immune inhibitory receptor that is a member of the Ig superfamily and that acts to limit anti-tumor immune responses in the context of the tumor microenvironment. TIGIT expression has been shown to be elevated in the tumor microenvironment in many human tumors and is coordinately expressed with other immune checkpoints such as PD-1/PD-L1. Prior works identified that expression of both PD-1 and TIGIT at the surface of CD4+ T lymphocytes is increased in presence of an immunosuppressive subset of cancer-associated fibroblasts (CAF) which express FAP (Fibroblast Activated Protein). Interestingly, new advanced metabolic imaging tracers, such as FAPI-46, could allow whole body imaging and quantitative mapping of FAP+ CAF and might represent a predictive marker of immunotherapy efficacy.
SKYLINE is a phase 2 trial exploring the use of an anti-TIGIT therapy, tiragolumab, in combination with anti PD-L1 atezolizumab and chemotherapy in patient with triple negative breast cancer (TNBC), as neoadjuvant (cohort A) or first line (cohort B) therapy.
Methods: SKYLINE (NCT06175390) is an ongoing trial in at Institut Curie Hospitals (France), prospectively enrolling 160 patients with TNBC (ER & PR<10%, HER2-). In cohort

A, patients with stage II-III TNBC undergo neoadjuvant therapy that consists in a sequential use of nab-paclitaxel, carboplatin, atezolizumab and tiragolumab at standard doses for four 3-weeks cycles, followed by AC, atezolizumab and tiragolumab for four 3-weeks cycles, before curative surgery. Patients in cohort A could also receive additional atezolizumab and tiragolumab in the adjuvant setting. In cohort B, patients with de novo or relapsed stage IV TNBC receive nab-paclitaxel, atezolizumab and tiragolumab (4-weeks cycles) until disease progression or unacceptable toxicity. The study primary objective focuses on anti-tumor efficacy: pCR rate and 6-months PFS rate in cohorts A and B, respectively. Multiomics characterization of repeated tissue samples, blood samples and imaging (including next generation imaging with 68Ga-FAPI-46 PET/CT) is planned to better understand and predict the efficacy of immuno-chemotherapy in patients with TNBC.

Acknowledgments
SKYLINE is promoted by Institut Curie and supported by Roche, Institut Roche and ANR as part of the PIA France 2030 with the funding of the CASSIOPEIA RHU (ANR-21-RHUS-0002).

P2-12-24: A phase I/Ib trial of the CDK4/6 antagonist ribociclib and the HDAC inhibitor belinostat in patients with metastatic triple negative breast cancer and recurrent ovarian cancer with response prediction by genomics (CHARGE).

Talicia Savage, John G Lamb, Elyse D'Astous, Shashank Sama, Kristen Kelley, Christos Vaklavas, Namita Chittoria, Lauren Mauro, Kathleen Harnden, Takada Harris, Adam L Cohen, Theresa L Werner

Rationale: Metastatic triple negative breast cancer (TNBC) and recurrent ovarian cancer have poor prognoses with survival rates of approximately twenty-three months and thirty-two months, respectively. New treatment paradigms for these malignancies are needed. In Vivo studies have demonstrated promising results in single agent activity of histone deacetylase inhibitors (HDACi) against TNBC. In vitro studies have demonstrated cell cycle inhibition with the use of CDK4/6 inhibitors (CDKi) and synergistic inhibition with the combination of both HDACi and CDKi. We hypothesized that the CDKi ribociclib (RIB) plus the HDACi belinostat (BEL) would be well-tolerated and effective in people with metastatic TNBC or recurrent ovarian cancers.
Research objectives: This open-label, multi-center, phase I study follows a modified 3+3 dose escalation design allowing independent escalation of the dose of each of the agents with a ten-person expansion cohort at the maximum tolerated dose (MTD) level. Dose escalation was open to patients with TNBC or ovarian cancer, and only TNBC will be enrolled in the dose expansion. The first cohort at dose level 0 was RIB 200 mg daily and BEL 600 mg/m2 daily on days 1-5 of a 28-day cycle. The RIB dose could be escalated to 400mg on days 8-28, and the BEL could be escalated to 1000mg/m2 daily on days 1-5 of the 28 day cycle. The primary objective of this trial was to assess the maximum tolerated dose

of RIB in combination with BEL in patients with metastatic triple negative breast cancer or recurrent ovarian cancer. The secondary objectives were to assess the frequency, severity, and type of adverse events (AEs), and serious adverse events (SAEs). Here we report the final safety results from the 3+3 dose escalation cohort.
Results: We enrolled three patients (two ovarian, one TNBC) at dose level 0: RIB 200 mg daily + BEL 600mg/m2 days 1-7 with no dose-limiting toxicities (DLTs).
Three patients (one ovarian, two TNBC) were enrolled at dose level 1B: RIB 200 mg daily + BEL 1000 mg/m2 days 1-5 [increased dose of BEL compared to dose level 0]. Two patients experienced a DLT (one prolonged QTc, one allergic reaction).
Six patients (three ovarian, three TNBC) were enrolled at dose level 1A: RIB 400 mg days 8-28 + BEL 600 mg/m2 days 1-5. One patient experienced a DLT (prolonged QTc). Therefore, the MTD has been established at dose level 1A: RIB 400 mg days 8-28 + BEL 600 mg/m2 days 1-5.
The most common side effects experienced in at least 50% of patients were fatigue, dyspnea, constipation, headaches, and nausea with most AE being grades 1 or 2.
Conclusions: The maximum tolerated dose for this regimen has been determined to be 400 mg RIB on days 8-28 with 600mg/m2 BEL dosing on days 1-5. EKG monitoring is needed due to risk of QTc prolongation. We saw no unexpected or IRB reportable serious adverse events, and no indications of significant liver toxicity. The trial has now proceeded to dose expansion and efficacy assessment.

P2-12-25: A phase III trial evaluating De-escalation of Breast Radiation (DEBRA) following breast-conserving surgery of stage 1, HR+, HER2-, RS ≤18 breast cancer: NRG-BR007

Julia R. White, Reena S. Cecchini, Eleanor E.R. Harris, Eleftherios P. Mamounas, Daniel G. Stover, Patricia A. Ganz, Reshma Jagsi, Stewart J. Anderson, Carmen Bergom, Valérie Théberge, Mahmoud El-Tamer, Richard C. Zellars, Dean A. Shumway, Guang-Pei Chen, Thomas B. Julian, Norman Wolmark

Background: Approximately 50% of newly diagnosed invasive breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as the Oncotype DX® have identified patients (pts) with reduced risk of distant metastasis and without benefit from chemotherapy added to endocrine therapy (ET), freeing them from excess toxicity. Genomic assays are also recognized as prognostic for in-breast recurrence (IBR) after breast-conserving surgery (BCS) and could similarly allow de-escalation of adjuvant radiotherapy (RT). Reducing overtreatment is of interest to pts, providers, and payers.
Methods: We hypothesize that BCS alone is non-inferior to BCS plus RT for IBR and breast preservation in women intending ET for stage 1 invasive breast cancer (ER and/or PR-positive, HER2-negative with an Oncotype DX Recurrence Score [RS] of ≤18). Stratification is by age (<60; ≥60), tumor size (≤1 cm; >1-2cm), and RS (≤11, >11-18/MammaPrint Low). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods

(moderate or ultra hypo- or conventional-fractionated whole breast RT with/without boost, or APBI) with ≥5 yrs of ET (tamoxifen or AI) or Arm 2 with ≥5 yrs of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 (≤2 cm), pN0, age ≥50 to <70 yrs, s/p BCS with negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER and/or PR-positive (ASCO/CAP), HER2-negative (ASCO/CAP), and Oncotype DX RS ≤18 (diagnostic core biopsy or resected specimen). A "low risk" MammaPrint is permissible if completed as part of usual care prior to screening. Primary endpoint is IBR (invasive breast cancer or DCIS). Secondary endpoints are breast conservation rate, invasive in-breast recurrence, relapse-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in IBR of 4% at 10 yrs to judge omission of RT as non-inferior (10-yr event-free survival for RT group is 95.6% v 91.6% for the omission-of-RT group). BR007 is powered to detect non-inferiority with 80% power and a one-sided α=0.025, assuming that there would be a ramp-up in accrual in the first two years (leveling off in Yrs 3-5); 1,670 pts (835 per arm) are required for randomization. Conservative loss to follow-up is 1%/yr. Some T1a pts screened may have Oncotype DX scores >18, making them ineligible for the study. In the accrual process, 1,714 pts will be required to register to ensure that our final randomized cohort is 1,670 pts.
As of July 3, 2024, 1,033 pts have been screened and 927 randomly assigned.
NCT #: NCT04852887.
Support: U10 CA180868, -180822, UG1 CA189867.

P2-12-26: A phase Ib study of novel combination (New) of low dose oral cyclophoSphamide (S) To potentiate axatilimab (A) + retifanlimab (R) in treating metastatic Triple negative breast cancer (NEW START)

Joshua Haney, Diego A. Pedroza, Angela Marx, Angela Alexander, Rebecca Tidwell, Azadeh Nasrazadani, Rachel Layman, Vicente Valero, Huiming Sun, Anthony Lucci, Susie Sun, Carisa Le-Petross, Gary Whitman, Rahul Sheth, Savitri Krishnamurthy, Chelain Goodman, Michael Stauder, Wendy A. Woodward, Jeffrey Rosen, Bora Lim

Background: A large proportion of triple negative breast cancer (TNBC) patients (pts) will have residual disease detected post-neoadjuvant systemic therapy (NAST), which is associated with a significant risk of recurrence within 2-3 years following surgery. Moreover, if resistance develops to first-line therapy, the response rate to second or higher lines of therapy is poor (5-10% historically), representing a vast unmet need. Evidence suggests that one mechanism causing resistance is associated with the tumor immune microenvironment (TIME), particularly low T cell infiltrates and high levels of tumor-associated macrophages (TAMs). This led to the hypothesis that eradicating TAMs could re-sensitize NAST-resistant TNBC to tumor growth inhibition. Preclinical models using the preclinical version of axatilimab + low dose cyclophosphamide (CTX) successfully depleted macrophages and treated several primary TNBC models. However, intratumoral

heterogeneity within lung metastasis was observed following treatment cessation, along with elevated PD-L1 levels. Suspecting elevated PD-L1 levels as the likely cause of T cell exhaustion, an immune checkpoint blockade drug was added, which showed higher efficacy and prolonged the overall survival of mice bearing established lung metastasis. Given the target relevance in inflammatory breast cancer (IBC), the TNBC and low ER/PR IBC will also be included due to the high infiltration of TAMs and resistance to chemotherapy. After successful pre-clinical models, we propose a phase 1b study to demonstrate safety, response, and to find the optimal biologic dose (OBD) of CTX and axatilimab, along with standard dose retifanlimab to facilitate studies of efficacy. Axatilimab is a monoclonal antibody (mAb) with a high affinity against CSF-1R. Targeting CSF-1R is expected to reduce the circulating levels of pathogenic macrophage precursors and inhibit their activation in tissues. Retifanlimab is a mAb that targets PD-1, currently FDA approved for use in merkel cell carcinoma. It is designed to block checkpoint inhibitory interactions and sustain the function of PD-1–expressing cells. Methods: Up to 24 pts will be enrolled in cohorts of 3 pts. Pts will receive a fixed dose of retifanlimab, one of two dosage levels of CTX, and one of three dosage levels of axatilimab. The utility-based Bayesian optimal interval (U-BOIN) design will be used to determine the OBD weighing both dose limiting toxicities and objective responses. We will study baseline and follow-up biopsy after pharmacodynamics window (4 weeks +/- 7 days) to test exploratory biomarkers such as TAMs, epithelial-mesenchymal transition features, and other TIME cells. Tumor staging will be done at baseline and after every 2 cycles, each cycle defined as 4 weeks. All tumor responses will be evaluated by iRECIST 1.1. The study was sponsored by Incyte and the UT MD Anderson Cancer Center Morgan Welch Inflammatory Breast Cancer Clinic and Research Program. Key inclusion criteria: - Metastatic or locally recurrent unresectable malignancy lacking standard curative treatments - Histologically or cytologically confirmed non-IBC TNBC, defined as ER<1%, PR<1% and HER2 negative per ASCO CAP 2018 guideline, OR - IBC confirmed according to international consensus criteria that is ER<20% and PR<20% - At least 1 week since prior chemotherapy or radiation therapy - Age ≥18 years - Has at least one measurable lesion per RECIST 1.1 - ECOG performance status ≤ 2 - Adequate organ and marrow function. Key exclusion criteria: - Unrecovered >Grade 1 adverse events due to prior anti-cancer therapy, with some exceptions - Evidence of progression in treated brain metastases. The primary endpoints are OBD, dose limiting toxicity, and objective response. The secondary endpoints include clinical benefit, duration of response, progression-free survival, 2-year overall survival, pharmacodynamic markers, and detailed safety and tolerability of the triple combination.

P2-12-27: A phase Ib study of the safety, tolerability, biological effect, and efficacy of allogenic natural killer cells in combination with trastuzumab and pertuzumab in patients with refractory HER2-positive metastatic breast cancer.

Santiago Escrivá-de-Romaní, Vladimir Galvao, Maria Castro-Henriques, Ascensión Lopez-Díaz de Cerio, Aura Muntasell, Carlos Vilches, Miguel López-Botet, Maria del Carmen Ochoa, Susana Inmaculada Inoges, Sara Santana, Marta Rotxes, Pere Barba, Julia Lostes, Gabriela Ene, Sonia Servitja, Guillermo Villacampa, Susana Muñoz, Darío López, Xenia Villalobos, Silvia Martin Lluesma, Cristina Saura, Joan Albanell, Elena Garralda, Ignacio Melero, Maria Martinez-Garcia

Background: Survival of HER2-positive (HER2+) metastatic breast cancer (MBC) patients (pts) has improved with targeted therapies, but there is still a need of developing new therapeutic approaches. Double blockade alone with trastuzumab (T) and pertuzumab (P) showed significant clinical activity. T and P exert part of their activity based on antibody dependent cell mediated cytotoxicity (ADCC), mediated by natural killer cells (NK). Through the binding of the CD16 receptor of the NK cell to the Fc domain of T, NK cells can eliminate tumor cells covered by these antibodies. Furthermore, ADCC activation of an innate immune response induces cytokine secretion and antigen release, which may trigger an adaptive immune response against tumor antigens. Solid tumors usually present poor NK infiltration due to limited homing and immunosuppressive microenvironment. Our hypothesis is that the effect of T and P can be improved by regulating the efficiency of the ADCC activity through the infusion of ex-vivo activated allogenic NK cells. We propose a proof-of-concept phase I clinical trial for pts with HER2+ MBC refractory to antiHER2 therapies, to test the infusion of allogenic NK cells in order to enhance the ADCC of T and P to overcome this resistance and improve clinical outcome.
Methods: This is a single arm, open label, multi-center, proof of concept investigator-initiated phase Ib trial to assess the safety and the tolerability of NK adoptive cell therapy (NK-ACT) and T+P when used in combination in refractory HER+ MBC. A total of 6 pts will be included in the safety lead-in phase. If signs of both clinical and biological activity are seen, and no more than 1 treatment-limiting toxicity (TLT) is observed, the study will expand with 14 additional pts. The NK investigational cell product comprises a live cell suspension of allogenic NK cells obtained from peripheral blood from a healthy donor, that will be infused on Day 2 at a minimum dose of 5x107 NK and a maximum dose limit of 5x108 NK. IL-2 will be administered on Days 2 (within 24h after NK infusion), 4 and 6 as a subcutaneous dose of 5x105 UI/m2. A preparative IV single-dose cyclophosphamide (600mg/m2) is given between Days -3 and -5 before NK cell infusion. On day 1, T is given at a dose of 8mg/kg IV for the loading dose, and 6mg/kg IV for the maintenance dose and P at a dose of 840mg IV for the loading dose, and 420 mg IV for the maintenance, both every 3 weeks, until disease progression, unacceptable toxicity or study termination.
Major eligibility criteria: HER2+ pts as per ASCO/CAP guidelines; ECOG performance status ≤1; measurable disease; received at least two lines in the metastatic setting including

trastuzumab/pertuzumab and an anti-HER2 ADC; progressed to previous therapy; normal organ and marrow function; patient has potential NK allogenic donors. Key exclusion criteria: Prior treatment with adoptive cellular therapy; Symptomatic or untreated primary or metastatic CNS malignancy. The primary objectives are to assess the safety and the tolerability of NK-ACT and T/P when used in combination. The secondary objective is to evaluate the initial clinical activity of NK-ACT concomitant with T/P. Exploratory objectives include describing the mechanisms of action and assessing biomarkers of the immunomodulatory effect and anti-tumor activity of the combination of NK-ACT and T/P. Statistical methods: no formal hypothesis testing and no formal sample size calculation. The safety lead-in phase will include the first 6 pts. If no more than 1 TLT is observed amount those pts, the study will expand with 14 additional pts.

P2-12-28: A prospective randomized, controlled study to evaluate device efficacy for cutting and/or coagulation of tissue during mastectomy procedures.

Jessica Montalvan, Margarita Riojas-Barrett, Bernardo Martinez Leal, Nelly A. Hernandez, Ivan Marin, Logan Healy, Elizabeth Bonefas, Alastair M. Thompson, Marco Maricevich, Sebastian Winocour, Stacey A. Carter

Background/Purpose: The ConMed HelixAR Electrosurgical Generator with Argon Beam Coagulation Technology (CHEST) trial focuses on patients undergoing unilateral or bilateral mastectomy with immediate breast reconstruction including breast implants, tissue expander placement, or autologous flap. The study design compares time to hemostasis between two devices: the HelixAR Electrosurgical Generator (HEG) and the Conventional Electrosurgical Coagulation (CEC) system. To evaluate the device effectiveness between the HelixAR Electrosurgical Generator and Conventional Electrosurgical Coagulation systems for cutting and/or coagulation of tissue during mastectomy and reconstruction surgery, we report their implementation in a randomized clinical trial. The study is powered to show superiority of the HEG to the CEC as it relates to the primary objective of time from post-mastectomy to hemostasis. The HEG is designed to deliver argon gas and high frequency electrical current compared to the CEC delivering high frequency electrical current only. The key efficacy measure is post-mastectomy time to hemostasis with the secondary endpoints of wound infection, drain duration, total drain output, blood loss and device related adverse events. The study hypothesizes that the time for post-mastectomy hemostasis is significantly less for the HEG than the CEC. Additional hypotheses include overall fewer device related adverse events, lower blood loss, and reduced operative time. Methods: This ongoing 1:1 randomized controlled trial plans to enroll 82 patients undergoing mastectomy with reconstruction. The population includes women with breast cancer and/or high risk of developing breast cancer from genetic mutations and family history. Exclusion factors include known history of bleeding diathesis or coagulopathy, advanced refusal of blood transfusion, active systemic or cutaneous infection or inflammation. Participants are randomly allocated to either the HEG or the CEC at the time

of surgery. The surgeons are instructed to use the randomized device throughout the procedure with primary endpoints focused on evaluating device efficacy for cutting and coagulation. Subjects are monitored for 2 months post-operatively to assess perioperative outcomes.
Results: At the time of abstract submission, 80 patients were enrolled, with 39 allocated to HEG and 40 to the CEC (1 pending randomization). 48 subjects experienced an adverse or serious adverse event including bruising, infections, and wound dehiscence. It has been determined that none of these reported events are related to device use. Preliminary findings indicate a marked reduction in hemostasis time with the HEG compared to the CEC.
Conclusion: The trial demonstrates the feasibility of conducting a randomized controlled trial at a single center in a complex operative setting comparing two FDA approved surgical devices. The final analysis will show whether the HEG improves hemostasis in women undergoing mastectomy with reconstruction.

P2-12-29: A randomized clinical trial comparing ctDNA-directed therapy change with standard of care in patients with metastatic triple negative breast cancer (mTNBC)

Jessica Sharpe, Ben H. Park, Vandana G. Abramson

Background: Despite treatment advances in mTNBC, most patients presenting for first-line therapy will require cytotoxic chemotherapy (CT). Sacituzumab govitecan (SG) is an antibody-drug conjugate to the Trop-2 antigen that is expressed in the majority of TNBCs. SG is approved as second- or third-line therapy for patients with mTNBC per the phase III ASCENT trial, but its utility as a first-line treatment is unknown. ctDNA correlates with cancer burden and response to local and systemic therapies, but there is not an approved use for quantitatively monitoring patients' ctDNA levels during treatment. Previous studies showed a direct correlation between a patient's ctDNA mean variant allele frequency (VAF) and tumor burden as well as response or resistance to treatment. We hypothesize that a lack of a significant decrease in ctDNA VAFs shortly after initiating a first-line CT for mTNBC could serve as a biomarker of de novo resistance and could warrant a change of therapy earlier than conventional imaging studies would normally dictate. This study therefore evaluates switching to SG in mTNBC patients without a 50% decrease in ctDNA VAFs less than one month after starting a first-line CT with the goal of improving progression-free survival (PFS) and overall survival (OS) and of decreasing toxicity by stopping an ineffective treatment earlier.

Methods: In this two-arm randomized clinical trial, 120 patients will receive standard of care (SOC) physician's choice CT. Patients will be randomized 1:1; one group will undergo SOC treatment with conventional staging imaging to guide treatment decisions, while the other group will undergo ctDNA evaluation on cycle (C) 1 days (D) 1 and 15 of treatment. If the mean ctDNA VAF on-treatment does not decrease by 50% on C1D15, patients will change SOC CT to SG. Both groups will undergo radiological assessment every 9 weeks.

ctDNA will be banked on C4D1, C7D1, and at the end of treatment. Patients with a biopsy-confirmed new diagnosis of mTNBC that is PD-L1 negative (CPS <10) or who are otherwise not eligible for immune checkpoint inhibitor therapy are eligible for this study. Patients will not have received prior treatment for mTNBC and must have an ECOG PS of 0-2 as well as measurable disease by RECIST. The primary endpoint is PFS. This study has 80% power to detect a 2-month difference in PFS between patients treated with a ctDNA-guided therapeutic approach compared to patients assessed by conventional imaging alone (one-sided type 1 error of 10%). Key secondary endpoints include evaluating the overall response rate (RECIST v1.1), PFS2, and OS. Correlative studies include assessing ctDNA-defined clonal mutation profiles and their predictive value and correlating changes in ctDNA with standard imaging. This study (NCT05770531) is open at Vanderbilt University Medical Center and will open at 7 other sites through the ACCRU network. Six patients have been enrolled as of 6/2024.

P2-12-30: A randomized phase III clinical trial of acupuncture for chemotherapy-induced peripheral neuropathy treatment (ACT)

Ting Bao, Mingxiao Yang, Ivana Lopez-Nieves, Anna M. Tanasijevic, Lauren Piulson, Mehul Shrivastava, Matthew Weitzman, Iris Zhi, Jun J. Mao

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and potentially dose-limiting side effect of neurotoxic chemotherapy among people who experience cancer. CIPN presents as pain, numbness, tingling, and motor weakness, which worsens quality of life and can disrupt active treatment regimens. Currently, duloxetine is the only ASCO-recommended painful CIPN treatment after chemotherapy completion. However, due to its undesirable side effects, such as fatigue, sleep disturbance, and digestive symptoms, there is a pressing need for more well-tolerated, evidence-based interventions. Based on our pilot study that demonstrated the feasibility and preliminary efficacy of acupuncture in relieving CIPN pain, we developed the ACT trial to evaluate the effect of acupuncture on improving pain and other related symptoms among cancer survivors with CIPN pain.
Methods: ACT is a prospective phase III multicenter, parallel two-arm randomized clinical trial at Dana-Farber Cancer Institute (DFCI) and Memorial Sloan Kettering Cancer Center (MSK) (ClinicalTrials.gov Identifier: NCT04917796). ACT aims to determine the efficacy of an eight-week electroacupuncture (EA) treatment vs. sham acupuncture (SA) on improving CIPN symptoms severity in cancer survivors. We plan to enroll 250 participants to detect an effect size of at least 0.45 for the primary pain outcome at 12 weeks post-randomization between EA vs. SA, with 80% power and a 1% Type I error rate, assuming a 10% loss to follow-up. Major eligibility criteria include adults who 1) have no evidence of disease or stable diseases, 2) have completed neurotoxic chemotherapy such as platinum agents, taxanes, vinca alkaloids, and bortezomib at least three months before enrollment, and 3) have a clinical diagnosis of CIPN with moderate to severe pain, defined as a score of at least four on the Brief Pain Inventory (BPI) average pain item. Participants will be randomly

allocated to receive ten real or sham acupuncture treatments over eight weeks at two centers and their regional clinics. Aside from patient-reported outcome measures (i.e., BPI, Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity, EORTC Quality of Life Questionnaire-CIPN 20), we conduct quantitative sensory testing to assess changes in sensory function. The primary study endpoint is week 12, and the secondary study endpoint is week 24.
Progress: 1) We transitioned this trial to a multicenter trial in June 2024, with DFCI as the coordinating center and MSK as a subsite; 2) The DFCI site started patient enrollment in June 2024; 3) The DSMB last reviewed the trial in December 2023 and suggested that the trial continue as planned at MSK; 4) As of July 9, 2024, a total of 149 of the planned 250 participants have been enrolled. Accrual completion is expected by December 2024.

P3-01-01: Innovative Approaches to Breast Cancer Awareness: The Impact of Virtual Navigation and Future Digital Solutions

Manisha Salinas

Background: Breast cancer remains a significant public health challenge, with persistent disparities in screening and outcomes among Black women. Black women are more likely to be diagnosed at later stages and have higher mortality rates compared to White women. These disparities are often due to barriers such as limited access to healthcare, lack of awareness, and socioeconomic factors. Innovative digital solutions are critical for bridging these gaps and enhancing breast cancer awareness, screening behaviors, and survivorship in underserved communities.
Objective: This study aims to evaluate the impact of virtual health navigation on breast cancer awareness and to introduce a forthcoming mobile application designed to support breast cancer survivorship using AI and digital health tools.
Methods: We employed a mixed-methods approach, utilizing a virtual platform to deliver educational sessions on breast cancer risk factors, mammography, and preventive behaviors. Participants' knowledge, attitudes, and screening intentions were assessed through pre- and post-intervention surveys. Qualitative insights were gathered from focus group discussions to understand participants' experiences and perceptions.
Results: The virtual navigation program significantly increased participants' knowledge and awareness regarding breast cancer. Baseline surveys indicated that only 25% of participants had undergone mammography screening in the past year. Post-intervention surveys revealed that 75% of participants intended to undergo mammography screening within the next year, demonstrating a threefold increase in screening intentions. Additionally, 94% of participants found the virtual sessions beneficial, and 88% reported high satisfaction with the platform. Qualitative findings highlighted enhanced engagement and understanding of breast cancer risks, with 77% of participants expressing a desire to seek further information on breast cancer prevention and early detection post-intervention. These results emphasize the program's success in improving education and prevention behaviors, setting the stage for enhanced survivorship support.

Future Directions: Building on these successful outcomes, we are developing a mobile application designed to extend support into the survivorship phase for minority women. This app will leverage AI and digital health tools to provide personalized health information, follow-up screening reminders, and virtual support groups. By offering continuous support, the app aims to help survivors maintain their health post-treatment and address ongoing disparities in breast cancer care.
Conclusion: The integration of virtual navigation and digital health tools represents a transformative approach to enhancing breast cancer awareness, screening behaviors, and survivorship among Black women. This research demonstrates the significant potential of innovative digital solutions in addressing healthcare disparities. By developing a mobile application focused on breast cancer survivorship, we are positioned to provide continuous, personalized support that can significantly reduce disparities and improve health outcomes. The implications of this work highlight the critical role of targeted digital health interventions in fostering a more equitable healthcare landscape, ultimately leading to better outcomes for underserved populations.

P3-01-02: Impact of race, socioeconomic status and clinicopathological features on clinical outcomes in triple negative breast cancer in the ECOG-ACRIN EA1131 trial

Moriah Forster, Fengmin Zhao, Sarah Bell, Ingrid A. Mayer, Carlos L. Arteaga, William F. Symmans, Ben H. Park, Brian L. Burnette, Amye J. Tevaarwerk, Sofia F. Garcia, Karen L. Smith, Della F. Makower, Margaret Block, Kimberly A. Morley, Chirag R. Jani, Craig Mescher, Shabana J. Dewani, Bernard Tawfik, Lisa E. Flaum, Erica L. Mayer, William M. Sikov, Eve T. Rodler, Lynne I. Wagner, Angela M. DeMichele, Joseph A. Sparano, Ruth C. Carlos, Antonio C. Wolff, Kathy D. Miller, Sonya Reid

Background: Racial disparities in breast cancer outcomes persist despite a decline in overall breast cancer mortality. Black women have a higher incidence of triple negative breast cancer (TNBC), worse social determinants of health (SDOH), and quality of cancer care, which contributes to racial survival disparities. The EA1131 study evaluated patients with clinical stage II-III TNBC with residual disease after completion of neoadjuvant chemotherapy to determine whether invasive disease-free survival (IDFS) would be improved with adjuvant platinum compared with capecitabine. Herein we report a post hoc analysis of EA1131 to evaluate whether racial disparities were observed among patients with residual TNBC.
Methods: Our study population included Black and White patients in EA1131. Race was self-reported; participants who identified as part of a racial group with <15 patients or unknown race were excluded from this analysis (n=39). Our primary objective was to evaluate clinicopathological features, basal-subtype, SDOH, and survival outcomes by race in EA1131. The Agency for Healthcare Research Quality (AHRQ) neighborhood socioeconomic index (nSES) was calculated using residential zip codes linked to county level data on occupation, income, poverty, wealth, education, and crowding. Binary and

categorical data were analyzed with Fisher's exact test to evaluate differences in baseline characteristics by race. Cox regression analysis was used to estimate hazard ratios for DFS and overall survival (OS), adjusting for treatment arm, intrinsic subtype (basal vs non-basal), tumor grade, clinical stage prior to neoadjuvant treatment, pathologic stage after neoadjuvant treatment at the time of surgery, BMI, nSES index, and insurance type.
Results: Of 415 patients enrolled in EA1131, 376 were included in this analysis (308 White [82%] and 68 Black [18%]). Most patients had basal-subtype TNBC (77%), grade 3 disease (71%), pathologic stage II disease (49%), private insurance (70%), and a BMI ≥30 (49%). There were no racial differences in grade, clinical or pathological stage. Black patients were more likely to have basal-subtype TNBC (89% vs 75%; p=0.009) and a BMI ≥30 (62% vs 46%; p=0.026) compared to White patients. Black patients were more likely to be in the lowest nSES index quartile (39% vs 22%; p=0.008) and have Medicaid (32% vs 13%; p<0.001), while White patients were significantly more likely to have private insurance (73% vs 57%; p=0.013). The median DFS for White patients was 42.6 months compared to 25.1 months for Black patients, but this numerical difference was not statistically significant (p=0.24). There were also no significant differences in DFS or OS by race (HR 1.03, 95% CI: 0.65-1.61 and HR 0.67, 95% CI: 0.36-1.22, respectively), after adjusting for potential confounders.
Conclusion: Black patients with residual TNBC enrolled on EA1131 were more likely to have more aggressive basal-subtype tumors, to be obese, and to have lower socioeconomic status. Despite these factors, no significant differences in survival by race were observed. While this analysis was limited due to sample size, one possibility is that enrollment in a clinical trial, by minimizing differences in treatment received, has the potential to mitigate racial inequities in care. Larger studies are necessary to confirm these findings.

P3-01-03: The impact of race on outcomes of immune checkpoint inhibitor in triple-negative breast cancer patients: NCDB data analysis

Andrew Liu, Nadine Norton, Keith Knutson, Saranya Chumsri

Background: Immune checkpoint inhibitor (ICI) in combination with chemotherapy has become the standard of care for early-stage and first-line metastatic triple-negative breast cancer (TNBC) patients. TNBC disproportionately affected African Americans and Hispanic patients. Previous studies prior to ICI approval in TNBC demonstrated racial disparity with worse outcomes in these groups of patients. However, the impact of race on the outcomes of TNBC patients treated with ICI remains unknown. In this study, we analyzed the National Cancer Database (NCDB) to evaluate the clinical characteristics and outcomes of TNBC patients from different racial groups.
Methods: The NCDB patient database from 2004-2017 was used. Continuous variables were summarized using sample mean and standard deviation, and categorical and discrete variables were summarized using count and percentage of patients. Independent samples t-test or ANOVA were used to compare continuous variables, and categorical and discrete variables were compared using a chi-square test. Patient survival by race was calculated

using the Kaplan-Meier method. Associations of race with death were evaluated using unadjusted Cox regression models with death as the outcome. Hazard ratios (HRs) were estimated. All statistical tests were two-sided. Statistical analyses were performed using R Statistical Software.
Results: A total of 2015 patients were included, consisting of 71.4% White, 19.7% African American, and 8.9% Hispanic. The African American and Hispanic cohorts had more patients < 60 years old than the White cohort, representing 63.9%, 66.1%, and 56.8%, respectively ($p = 0.005$). African Americans and Hispanics also had more patients with Charlson-Deyo scores above 0 compared to Whites, representing 17.2%, 16.1%, and 10.6% of their respective cohorts ($p = 0.003$). African Americans and Hispanics tended to receive treatment at academic centers compared to Whites, representing 47.0%, 55.2%, and 34.0%, respectively ($p < 0.001$). Additionally, a greater proportion of African Americans and Hispanics received treatment in metro areas compared to White patients, representing 93.3%, 96.0%, and 85.5% of their respective cohorts ($p < 0.001$). There was no significant difference in insurance coverage between races ($p = 0.333$). In contrast, the different race cohorts presented similar distributions of clinical features, with no significant differences in tumor grade ($p = 0.276$), tumor size ($p = 0.285$), lymph node status ($p = 0.422$), lymphovascular invasion status ($p = 0.088$), clinical and pathologic staging ($p = 0.096$), and whether they received chemotherapy ($p = 0.230$), radiation therapy ($p = 0.587$), and surgery ($p = 0.242$). For stage II-III TNBC, there were 538 White, 142 African American, and 62 Hispanic patients who received at least 1 dose of ICI. Using Kaplan-Meier analysis, African American patients ($n = 142$) had significantly worse overall survival (OS) compared to whites (HR = 1.362, $p = 0.012$). For patients with Stage IV TNBC receiving ICI, there were 108 Whites, 30 African American, and 12 Hispanic patients. There was a trend toward worse outcomes in African American patients when compared to whites (HR = 1.950, $p = 0.210$). There was no significant difference in patient survival when comparing Hispanic/other patients with whites in any stage of TNBC while receiving ICI (HR = 0.956, $p = 0.777$ for Stage II and III; HR = 2.089, $p = 0.200$ for Stage IV).
Conclusion: Despite similar clinical characteristics, African-American TNBC patients receiving ICI had significantly worse outcomes compared to Whites. Future studies are needed to further validate these results and elucidate the biological basis for the racial disparity observed with ICI treatment in TNBC patients.

P3-01-04: Racial and ethnic disparities in the development of second primary solid tumor malignancies in breast cancer survivors

Kriti Ahuja, Malak Alharbi, Jayasree Krishnan, Zunairah Shah, Shipra Gandhi, Arya Mariam Roy

Background: Cancer is the second most common cause of death in the United States and breast cancer (BC) is projected to be the most common cancer diagnosis in 2024. Further, BC, lung/bronchus, colorectal and pancreatic cancers are projected to contribute to nearly 50% of all cancer deaths. Prior SEER analysis of early-stage BC survivors demonstrated a

statistically significant increase in the development of lung, tongue, salivary gland, gastric, colon and genitourinary cancers compared to the general population. However, very little is known about the racial differences in the development of second primary malignancies (SPM) in BC. Hence, we investigated the development of solid tumor SPM in BC survivors across different racial and ethnic groups.
Methods: We conducted a retrospective analysis of the Surveillance, Epidemiology and End Results (SEER) 17 registries database and identified the cases diagnosed with BC as their primary malignancy between the years 2000 to 2021. These cases were followed for several years, and the standardized incidence ratios (SIR) for the development of SPMs in BC were calculated. The analysis was stratified by the following races and ethnicities: Non-Hispanic Whites (NHW), Non-Hispanic Blacks (NHB), Non-Hispanic American Indian/Non-Hispanic Alaska Native (NHAI/NHAN), Non-Hispanic Asian or Pacific Islander (NHAPI), Hispanic (H).
Results: A total of 703991 NHW, 105014 NHB, 4712 NHAI/NHAN, 90295 NHAPI and 118500 H were included in the SPM analysis. The risk of developing solid tumor SPMs after BC was increased in all groups with SIR ranging from 1.14 in NHW to 1.83 in NHAI/NHAN ($p<0.05$). Within this, all groups had a statistically significant increased risk for developing second primary BC and endocrine malignancies, particularly thyroid cancer. The mean age for developing second primary BC ranges from 61.2 years (y) in Hispanics to 67.99 y in NHW. The total SIR for second primary BC was highest in NHBs (NHW – 1.31, NHB 2.07, NHAI/NHAN – 1.84, NHAPI 1.85, H – 1.58, $p<0.05$), which peaks (SIR: 2.61, $p<0.05$) at a latency of 10+ years after initial BC diagnosis. NHAPI were at the highest risk for development of thyroid cancer (SIR 2.22), followed by Hispanics (SIR 1.96), NHAI/NHAN (SIR 1.91), NHB (SIR 1.63) and NHW (1.4) ($p<0.05$). Further, there was a statistically significant increase in the risk for developing kidney and pancreatic cancers in various groups. The total SIR for kidney cancer was highest in NHAI/NHAN at 2.57, followed NHAPI at 1.55, NHB at 1.44, H at 1.4 and NHW at 1.1 ($p<0.05$)). Pancreatic cancer was relatively more common in BC survivors among NHAI/NHAN (SIR 1.76) and NHAPI (SIR 1.49) ($p<0.05$). NHAI/NHAN BC survivors seem to be particularly prone to developing SPMs with elevated SIRs such as – other oral cavity and pharynx (40.3), larynx (10.97), melanoma of skin (12.54), skin excluding basal and squamous (9.18), anus, anal canal and anorectum (5.48), cecum (2.86), colon, rectum and anus (1.79) and lung/bronchus (1.78) (all $p<0.05$). Interestingly, Hispanic BC survivors were more prone to stomach cancer with SIR 2.23 ($p<0.05$). There was also a higher incidence of salivary gland and soft tissues malignancies including the heart in all groups except NHAI/NHAN ($p<0.05$).
Conclusion: There is a statistically significant increase in the development of solid tumor SPMs across all races and ethnicities, with a disproportionate increase in the NHAI/NHAN (head and neck, skin and GI cancers), NHAPI (thyroid, BC, kidney and pancreas) and NHB (BC) emphasizing the importance of survivorship care that is accessible to all races and ethnicities. Further, there is a need to tailor the survivorship practices to each race and ethnicity depending on their specific risk for certain malignancies.

P3-01-05: The Effect of Individual and Neighborhood-level Socioeconomic Disparities in Advanced and Early-Onset Female Breast Cancer

Anumita Chakraborty, Lauren Correia, Jill Hasler, Gaetano Romano, Antonio Giordano, Shannon Lynch, Aruna Padmanabhan

Background: Race is a significant factor in the diagnosis and outcomes of breast cancer (BC); Black women are diagnosed with more aggressive disease, and have higher mortality from BC compared to White women. Race may be a surrogate for other social determinants of health (SDOH), which may explain observed disparities. Further study is needed to assess the effect of all 5 domains of SDOH (education access and quality, health care access and quality, neighborhood and built environment, social and community context, and economic stability) on BC. In the absence of individual-level information, neighborhood-level socioeconomic status (nSES) can be useful in determining patterns of disparity. This study aims to determine associations between early-onset BC and advanced-stage BC at diagnosis across all 5 domains of SDOH using both individual and nSES measures.

Methods: A retrospective analysis of female patients who presented to Fox Chase Cancer Center and Temple University Hospital between January 1st, 2018-December 31st, 2022, was conducted. Patient demographics (age, race, insurance, address, family history of cancer) and clinical characteristics (stage, receptor phenotype) were obtained. Patient addresses were used to geocode patients to a US Census Tract corresponding to known nSES variables obtained from the US Census Bureau, the Centers for Disease Control and Prevention, and the SEER Database. Primary outcomes included early-onset BC (defined as diagnosis <45 years) and advanced disease (AD; defined as stages 3 and 4 at diagnosis). Data was analyzed via univariate logistic regression models to compare patient, clinical, and neighborhood characteristics. Multivariate logistic regression models controlling for age at diagnosis, year of diagnosis, insurance, BC phenotype, and family history of cancer were used to assess associations between individual variables or nSES and the outcomes. Lasso regression controlling for race, insurance, and family history of BC was used to assess for significant associations between nSES variables and outcomes.

Results: 5172 female patients were diagnosed with BC, of which 1248 (24.1%) patients were Non-Hispanic Black, 3023 (58.4%) Non-Hispanic White, 151 (2.9%) Asian/Pacific Islander, 419 (8.1%) Hispanic and 331 (6.4%) Other/Unknown. Mean age at diagnosis was 60.1 years. 374 (7.2%) patients were diagnosed with ER-/PR-/HER2- breast cancer (TNBC). 641 (12.4%) patients were diagnosed with early-onset BC, and 744 (14.4%) patients had AD at diagnosis. On multivariate analysis, patients with Medicaid and Medicare had higher odds of being diagnosed with AD compared to those with private insurance (OR 2.116 [1.494-2.998], p<0.001; and OR 1.383 [1.013-1.888], p=0.041, respectively). Hispanic patients had lower odds of AD compared to non-Hispanic White patients (OR 0.544 [0.322-0.917], p=0.022). Patients with TNBC and ER-/PR-/HER2+ disease had increased odds of AD at diagnosis (OR 3.391 [2.543-4.521], p<0.001; and OR 1.382 [1.019-1.874], p=0.037, respectively). Patients with TNBC and ER-/PR-/HER2+ disease also had increased odds of

early-onset disease (OR 1.756 [1.256-2.455], p=0.001; and OR 1.427 [1.036-1.966], p=0.029, respectively). Lasso regression indicated the nSES variables of Technical/Professional/Managerial Employment, Household Income, and Index of Concentration at the Extremes (ICE; high-income White vs. low-income Black) was associated with advanced vs. localized disease at diagnosis.

Conclusion: Patients with Medicare and Medicaid have higher risk of AD at diagnosis compared to patients with Private insurance. Patients with TNBC and ER-/PR-/HER2+ BC have higher risk of both AD at diagnosis and early onset disease. Lasso regression indicates that rate of Technical/Managerial/Professional Employment, Household Income, and ICE (high-income White vs. low-income Black) within a patient's census tract is associated with advanced vs. localized disease.

P3-01-06: Differences in health-related quality of life among breast cancer survivors by Hispanic origins

Eunkyung Lee, Brian Sukhu, Meera Lakshmanan, Jongik Chung, Michael J. Rovito, Robert B. Hines, Victoria Loerzel

Background: Breast cancer is the most frequently diagnosed cancer and the second-leading cause of cancer-related death in American women. With prolonged survival, health-related quality of life (HRQOL) has become the primary concern of the survivors, and Hispanic women are more vulnerable than other race/ethnic groups. Despite many interventions available for the Hispanic population, they still report worse HRQOL than other groups, which warrants investigation of subpopulations that have their own culture, lifestyle, and health beliefs, which challenges healthcare providers in helping them improve their HRQOL. Therefore, this study assessed intra-disparities in HRQOL by their Hispanic origin.
Methods: The Florida Statewide Cancer Registry, a trusted source of cancer data, facilitated the patient recruitment process for this population-based epidemiologic study. Following state-mandated recruitment procedures, up to two invitation letters and four phone calls were made to gauge potential participants' interest. Surveys were then sent to interested participants according to their preferred mode (mail or online) and language (English or Spanish). The Functional Assessment of Cancer Therapy – Breast (FACT-B) was utilized to assess five domains of HRQOL: physical, social, emotional, and functional well-being, as well as breast cancer symptoms. Total and domain scores were calculated. Higher scores indicate better HRQOL. Scores were compared across Hispanic origins using ANOVA tests.
Results: A total of 365 women completed surveys; participants included 33 Colombians, 24 Cubans, 22 Dominicans, 20 Mexicans, 198 Puerto Ricans, and 68 in the other category. The mean FACT-B total score was 104.0 (SD 24.7), with a significant difference among Hispanic subgroups ($P < 0.001$), the highest score from Cubans (mean 117.6, SD 17.2) and the lowest score from Dominicans (mean 93.7, SD 24.2). As the total score was highly correlated with all five domain scores (r ranging between 0.59 – 0.85, all $P < 0.0001$), similar results were observed from ANOVA tests for five domains. In addition to Hispanic origin, factors such as

income, education level, marital status, smoking status, alcohol consumption, laterality, cancer stage, treatment type, and surgery type were all associated with the total and domain scores.
Conclusions: The study has shown intra-disparities in HRQOL among Hispanic breast cancer survivors. These disparities, which could be explained by differences in sociodemographic and clinical characteristics of Hispanic subgroups, present a significant challenge. However, the insights gained from this study can be used to develop culturally tailored intervention programs that have the potential to significantly improve the HRQOL of Hispanic breast cancer survivors.

This study was supported by the Florida Breast Cancer Foundation Scientific Grant and the University of Central Florida Office of Research to EL.

P3-01-07: Breast Cancer Survival According to Health Insurance Coverage in Brazil: Results from the Prospective AMAZONA III Study (GBECAM 0115)

Daniela Dornelles Rosa, José Bines, Carlos Barrios, Gustavo Werutsky, Eduardo Cronemberger, Geraldo Silva Queiroz, Vladmir Cordeiro de Lima, Ruffo Freitas-Junior, José d'Oliveira Couto, Karla Emerenciano, Heloisa Resende, Susanne Crocamo, Tomás Reinert, Brigitte Van Eyil, Yeni Nerón, Vanessa Dybal, Nicolas Silva Lazaretti, Rita de Cássia Costamilan, Diocésio Alves Pinto de Andrade, Clarissa Mathias, Giovana Zerwes Vacaro, Giuliano Borges, Alessandra Menezes Morelle, Carlos Sampaio, Max Mano, Rafaela Gomes de Jesus, Sergio Daniel Simon

Background: Breast cancer (BC) is the most commonly cancer diagnosed in women in Brazil. Prior analysis of AMAZONA III study showed that Brazilian patients with public health coverage were diagnosed with symptomatic disease, later stages, and more aggressive BC subtypes when compared to privately insured patients. The aim of this study is to evaluate the impact of BC subtypes and type of health insurance in clinical outcomes of stage I-III BC from a large, prospective, cohort study in Brazil.
Methods: AMAZONA III study (GBECAM 0115) is a prospective cohort study that included patients newly diagnosed with invasive BC during the period of January 2016 to March 2018 within 22 sites in Brazil, including patients covered by public and private health systems. Here we present survival data from patients with stages I to III BC. Data were collected from medical visits and information from type of health insurance, public or private, were extracted from medical charts. BC subtypes were classified according to estrogen receptor (ER) status, progesterone receptor (PgR) status, and HER-2 status analyzed in local laboratory as follows: Luminal (ER and/or PgR positive and HER2 negative), HER2 positive (any ER/PgR and HER2 positive) and Triple negative (ER and PgR negative, HER2 negative). The 5-year disease-free survival (DFS) and overall survival (OS) rates were assessed by Kaplan-Meier analysis and hazard ratios with 95% CI from Cox regression. Trial Registration: NCT02663973.

Results: A total of 2,839 patients were included in this analysis, of whom 1771 (62.4%) had public insurance, 1569 (55.3%) were postmenopausal, 1413 (59.4%) had luminal tumors, 613 (25.8%) had HER2-positive (HER2+) and 352 (14.8%) triple-negative (TN) BC. After a median follow-up of 60.6 (60.4-60-8) months, there were 521 (15.1%) DFS events and 353 (12.4%) OS events. The 5-year DFS (5yDFS) was 91% in the private and 75% in the public system (HR 3.1, [95% CI, 2.4-3.99], p<0.0001). DFS was similar for stage I patients in the public and private systems (p=0.276). For stages II and III BC, 5yDFS was higher in the private when compared to the public system (89.4% vs. 79.6%, respectively, for stage II, p=0.0039; and 80.8% vs. 55.6%, respectively, for stage III, p<0.0001). The 5-year OS (5yOS) according to insurance coverage were 94.4% for private and 80.3% for public coverage (HR 3.91, [95% CI, 2.82-5.42], p<0.0001). Five-year OS (5yOS) was 98.2% for stage I, 88.2% for stage II, and 68% for stage III BC (p<0.0001). According to BC subtype, 5yOS was 90.2% for luminal, 83% for HER2+, and 72.7% for TN BC (p<0.0001). For stage I, 5yOS was 99% for both luminal and HER2+ BC and 89.8% for TN BC (p=0.005). There were no differences in OS according to insurance coverage in stage I, 99.1% in private vs. 97.2% in public system (p=0.27). For stage II, 5yOS was 92.1% for luminal, 86.7% for HER2+ BC, and 77.2% for TN BC (p<0.0001). There were no differences in OS according to insurance coverage in stage II BC. For stage III, 5yOS was 73.3%% for luminal, 68.4% for HER2+ BC, and 57.5% for TN BC (p=0.0028). 5yOS was worst for stage III BC treated in the public system when compared with the private system (63.2% vs. 88.9%, respectively; HR 4.21 [95% CI, 2.29-7.75], p<0.0001).
Conclusion: The AMAZONA III study demonstrated that patients from the public health system have worse clinical outcomes in Brazil. When stratified by BC stage similar DFS were noted in stage I disease but patients with stage II and III had better outcome in private health system. Patients with stage III BC from the public health system have worse OS when compared to privately insured patients. Overall, BC subtypes demonstrated significant impact on DFS and OS outcomes regardless of the insurance coverage. This study demonstrates inequities in early BC clinical outcomes in Brazil that may be influenced by timely diagnosis and treatment, different locoregional and systemic therapies, limited access to novel therapies, among others, which must be further investigated.

P3-01-08: The prevalence of biomarker alterations, treatment patterns, and survival in metastatic triple-negative breast cancer by race: A national cohort study

Pegah Farrokhi, Leah Park, Weston Schmutz, Samantha L. Thompson, Clara Lam, Bryan Iorgulescu, David Stenehjem

Background: The prevalence of triple-negative breast cancer (TNBC) is higher in Black women than in White women. However, in the era of precision oncology, treatment decisions informed by diagnostics and outcomes by race in patients with metastatic TNBC (mTNBC) are not well understood. This study assessed the prevalence of biomarker alterations, treatment patterns, and clinical outcomes in Black and White patients with

mTNBC in the United States (US) who received next-generation sequencing (NGS)-based testing.
Methods: This observational cohort study utilized the nationwide, electronic health record (EHR)-derived, de-identified Flatiron Health–Foundation Medicine Clinico-Genomic Database (primarily community oncology settings). Adult patients with mTNBC diagnosed from January 2017 to March 2022 were included and followed until September 2022. Patients who lacked race data, participated in a clinical trial, or had <6 mo of follow-up were excluded. All patients had NGS-based tumor tissue testing and/or liquid biopsy. The current portion of the study included only patients with mTNBC and assessed BRCA, PIK3CA, AKT1, and PTEN alterations. Pathogenic variants, or those likely to be pathogenic, were used to identify alteration status. BRCA1/2 results were available with no distinction between somatic and germline mutations. Programmed cell death ligand 1 (PD-L1) expression was not included in the NGS panel test, but this information was extracted from linked EHR data if documented in the physician notes. PD-L1 expression was categorized as positive for a combined positive score (CPS) of ≥10. Descriptive statistics were used to summarize biomarker alterations and treatment patterns. The Kaplan–Meier method and a Cox regression analysis were used to assess overall survival (OS) from diagnosis of mTNBC.
Results: Of 670 patients with mTNBC, 185 (28%) were Black and 485 (72%) were White. Median time from mTNBC diagnosis to NGS testing was similar in both groups (2.1 vs 1.8 mo; p=0.09). Compared with White patients, Black patients had a higher prevalence of BRCA1/2 alterations (12% vs 7%; p<0.04), but there were no significant differences in the prevalence of PIK3CA (19% vs 22%; p=0.5), PTEN (15% vs 17%; p=0.4), or AKT1 (2% vs 5%; p=0.13) alterations; there were too few patients (~15%) with PD-L1 CPS test results available in the database to discern differences. A total of 530 patients received first-line (1L) therapy: 81% of Black patients and 79% of White patients. Among patients who received 1L treatment, there was no significant difference between Black and White patients for the use of programmed cell death protein 1/PD-L1 inhibitor–based regimens (19% vs 27%; p=0.08) or chemotherapy (70% vs 63%; p=0.09). Median OS from mTNBC diagnosis was numerically, but not significantly, shorter in Black than White patients, respectively (13.7 vs 18.9 mo; p<0.15). After adjusting for baseline characteristics, treatments, and biomarkers, a nonsignificant trend toward a shorter OS remained in Black patients compared with White patients (HR 1.19; 95%: CI: 0.94–1.51; p=0.14).
Conclusions: In this US study involving patients with mTNBC who received NGS testing, Black patients were almost twice as likely to have somatic/germline BRCA1/2 alterations and, therefore, may benefit from poly (ADP-ribose) polymerase inhibition. Overall, although there was a trend toward worse survival outcomes for Black patients compared with White patients, significant differences were not observed. Future studies, with larger sample sizes, more complete and comprehensive testing results, and assessment of potential testing disparities, are needed to better understand ongoing disparities in treatments and outcomes in mTNBC by race.

P3-01-09: Feasibility of providing rural patients with telehealth consultation coupled with in-person intervention at tertiary oncology center

Natasha Hunter, Eric Konnick, Alexandra Iancu, William Gwin, Shaveta Vinayak, Rachel Yung, Jennifer Specht, Hannah Linden

Background: Progress in precision oncology diagnostics and treatment is proceeding at a rapid pace, but patients in geographically remote areas are being left behind, owing to lack of resources and infrastructure. Work performed by our group has demonstrated that nearly half of patients with presumed metastatic breast cancer (MBC) in Washington do not undergo biopsy at cancer recurrence, contrary to standard guidelines. One barrier to patients being offered this procedure is a lack of availability of high-quality bone biopsy for patients with bone-dominant disease in rural areas, owing to the technical demands of the procedure and subsequent pathologic analysis. Fred Hutch/UW Comprehensive Cancer Center (FHCC) serves all of Washington as its formal catchment area, with nearly 800,000 patients living in non-metro areas, and also the only comprehensive cancer center in a five-state region known as WWAMI (Washington, Wyoming, Alaska, Montana and Idaho).
Methods: In 2021-2023, we conducted a pilot feasibility study to bring patients to FHCC for high quality bone biopsy with genomic sequencing, the results of which could make them eligible for life-extending targeted therapy. We reached out to community oncology providers across the five state WWAMI region, describing our study and offering bone biopsy plus liquid biopsy to eligible patients. The PI obtained licensing in the relevant states to allow telehealth visits across state lines. Community providers referred patients, who met via telehealth with the PI for a comprehensive second opinion including review for study eligibility. A research coordinator then helped the patient arrange travel and accommodations for each patient and a caregiver. The patient was sent a blood draw kit to present to their local phlebotomy site for liquid biopsy and shipping to FCC molecular pathology lab. The primary aim of this study was to demonstrate logistical feasibility along with patient willingness to come for the procedure and send a blood sample drawn to our molecular pathology lab.
Results: We provided telehealth second-opinion consultations for 10 metastatic breast cancer (MBC) patients in remote sites (Washington, Alaska, Idaho and Montana), and subsequently referred them for high-quality bone biopsy with molecular evaluation at FHCC. Results from these samples are currently under analysis, and will be reported in a separate publication, combined with data from local Seattle patients enrolled in a similar study comparing bone to liquid biopsy. Average distance traveled was 390 miles, range 61 to 890, median 315. Patients spent an average of two nights in Seattle, and every patient was accompanied by a caregiver. Average reimbursement for travel, meals and accommodation was $1500. Accrual was limited by COVID-19 travel restrictions, so that patients enrolled in study and able to travel were lower than anticipated when the study was designed.
Discussion: This pilot trial demonstrated that patients were interested in traveling to a tertiary urban center for state-of-the-art interventions, and that these could be performed

with manageable cost, and a potentially scalable infrastructure. The fact that COVID-19 licensing restrictions were waived for telehealth visits between the relevant states during the period of the study obviated the need for PI licensing, but also emphasized the benefit that could be offered to patients were those regulations changed permanently to allow telehealth opinions to occur. Given that FHCC is surrounded by four states without a tertiary referral center, it is worth considering how changes in licensing regulations could lower barriers to enrollment in clinical trials for these rural populations. Expanded studies are required to explore the potential for this model in screening for clinical trials in combination with offering interventions not available at rural sites.

P3-01-10: Racial and ethnic disparities in the development of hematological second primary malignancies in breast cancer survivors

Kriti Ahuja, Malak Alharbi, Jayasree Krishnan, Zunairah Shah, Shipra Gandhi, Arya Mariam Roy

Background: Breast cancer continues to be one of the most commonly diagnosed malignancies. With improved survival in early-stage breast cancer due to significant advancement over the decades, survivorship care and monitoring for second primary malignancies (SPMs) have become increasingly important. A recent study has demonstrated significant increase in risk for developing SPMs including leukemia in stage I and II breast cancer survivors at a latency of 2 years. It is unclear whether the development of these SPMs is also due to shared abnormalities in underlying molecular pathways or is solely related to treatment. Therefore, we are investigating the development of second primary hematological malignancies in breast cancer survivors, stratifying them based on the race and receipt of chemotherapy.
Methods: We conducted a retrospective analysis of the Surveillance, Epidemiology and End Results (SEER) 17 registries database and identified the cases diagnosed with breast cancer as their primary malignancy between the years 2000 to 2021. These cases were followed for several years, and the standardized incidence ratio (SIR) for development of SPMs in breast cancer were calculated. The cohort was divided into two groups based on the receipt of chemotherapy (CT vs no/unknown CT). The analysis was stratified by the following races and ethnicities: Non-Hispanic Whites (NHW), Non-Hispanic Blacks (NHB), Non-Hispanic American Indian/Non-Hispanic Alaska Native (NHAI/NHAN), Non-Hispanic Asian or Pacific Islander (NHAPI), Hispanic (H).
Results: A total of 703991 NHW, 105014 NHB, 4712 NHAI/NHAN, 90295 NHAPI and 118500 H were included in the SPM analysis. We observed a statistically significant increase in development of leukemia across all racial and ethnic groups that received CT, however, NHAI/NHAN and NHAPI were observed to have the highest risk at total SIR of 3.44 and 3.45 respectively ($p<0.05$) (NHW: 1.87, NHB: 2.27, H: 1.83 $p<0.05$). There was a statistically significant increase in development of acute myeloid leukemia (AML) in patients who received CT across all racial and ethnic groups except NHAI/NHAN. Although the history of CT is said to increase the risk of therapy related AML, the effect of CT was different across

different racial and ethnic groups, being the highest in NHAPI, followed by NHB with overall SIR of 5.16 and 4.27 respectively as compared to NHW at 3.61 and Hispanics at 3.56 ($p<0.05$). This was primarily due to elevated SIR ($p<0.05$) at a latency of 1-5 years as follows: NHAP: 8.85, NHB: 7.4, H: 7.37, NHW 6.36. Among AML, the risk was observed to be elevated for Acute monocytic leukemia and the SIR was observed to be highest in NHB at 18.86 (H: 13.04, NHAPI 11.79, NHW 8.13, $p<0.05$). Further, even among the patients with no/unknown CT status, there was a statistically significant increase in development of AML across all groups except NHAI/NHAN. This was highest in NHAPI at an overall SIR of 1.94 and NHB at 1.84. It was highest at a latency of 1-5 years with SIR in NHB at 2.57 and NHAPI 2.44, $p<0.05$ (H: 1.95, NHW: 1.39, $p<0.05$). NHAI/NHAN were found to have a statistically significant increase in Myeloma in the No/unknown CT group at overall SIR of 3.91, with 7.25 ($p<0.05$) at a latency of 10+ years.

Conclusion: Breast cancer survivors exhibit an increased susceptibility to certain hematological malignancies across diverse racial and ethnic backgrounds. While all patients receiving CT understandably face a heightened risk of developing AML, this risk is particularly pronounced among NHAPI and NHB populations, warranting further investigation. Furthermore, an elevated risk of AML persists in the no/unknown CT population, with NHAPI and NHB groups showing the highest susceptibility, indicating a potential genetic predisposition warranting further study.

P3-01-11: Racial Disparity in the Screening and Diagnosis of Breast Cancer in the Public Health System (SUS) in Brazil

Juliana Francisco, André Mattar, Marcelo Antonini, Renata de Toledo Rodovalho, Mariana Reginato Dias Lorencinho, Janaína Rosenburg Gioseffi, Fernanda Cristina dos Santos Simão, Nina Victoria Menezes de Melo, Antonio Luiz Frasson, Eduardo de Camargo Millen, Fabricio Palermo Brenelli, Felipe Zerwes, Francisco Pimentel Cavalcante

Background: The effectiveness of screening and early diagnosis of breast cancer (BC) can significantly vary among different population groups and racial disparity can be a critical factor that influences access and quality of health services, including BC screening and diagnosis.

Objectives: To evaluate the racial disparity in screening and diagnosis of breast cancer within the Unified Health System (SUS) between the years 2015 and 2022 in Brazil.

Methods: A cross-sectional ecological observational study was made utilizing public data from the Outpatient Information System, Hospital Information System, and Mortality Information System of the Department of Informatics of the Unified Health System, as well as data from the Hospital Cancer Registry (RHC) of the National Cancer Institute. For RHC data, the period from 2015 to 2021 was analyzed due to the lack of updated and consolidated data for 2022. Mammography coverage rate was evaluated in biennial periods: 2015/2016; 2017/2018; 2019/ 2020; and 2021/2022. The proportions of early diagnosis (stages 0, 1, and 2) and late diagnosis (stages 3 and 4) were calculated. The time between the specialist consultation and receiving the diagnosis and the time between receiving the

diagnosis and starting the treatment was evaluated. Records with incomplete, invalid or missing data were excluded from the analysis.
Results: Over 18 million screening mammograms were performed on women aged 50 to 69 in SUS and because of Covid-19 pandemic there was a significant reduction in the number of mammograms, with a 41.5% decrease in 2020 and an 18.9% decrease in 2021 compared to 2019. In 2022, there was a slight increase of just over 1% in the number of mammograms compared to 2019. Regarding race/ethnicity, 52.4% of screening mammograms were performed on white women, 28.5% on brown women, 5.8% on black women, 13.4% on yellow women, and only 0.1% on indigenous women. The impact of the Covid-19 pandemic on mammography coverage is evident: the country's coverage ranged from 26.3% in the 2015-2016 biennium, 25.1% in 2017-2018, to 18.4% between 2019-2020, and 20.5% in 2021-2022. Analyzing staging it was observed that approximately 38% of breast cancer cases were diagnosed in advanced stages of the disease and the proportion of stage 3 or 4 diagnoses for white women was 35.5%, brown and black women had proportions of 44.2% and 46.5%, respectively. From 2015 to 2021, early diagnosis in white women decreased from 65.2% (2015) to 59.7% (2021). In brown women, the percentage of early diagnosis was 54.8% in 2015, increasing to 58% in 2021. For black women, these percentages were 54.9% and 52.6% for 2015 and 2021, respectively. The average number of days between the specialist consultation and receiving the diagnosis was 36 days and white women had a shorter average time (37 days) compared to black and brown women (51 days). Additionally, 65.5% of white women were diagnosed within 30 days, while this proportion was lower for black women (58.9%) and brown women (61.1%). The proportion of black women who started treatment after 60 days (65.5%) was higher than that of white women (60.8%) and brown women (59.7%). Furthermore, the average number of days until treatment initiation for brown women was 167 days, while black and white women had averages of 169 and 201 days, respectively.
Conclusions: The incidence of breast cancer among the black population in Brazil reflects the complex interactions between biological, social, and economic factors. Addressing these disparities effectively requires a collective effort from public policies, health institutions, and civil society. Only through integrated and inclusive approaches will it be possible to ensure that all women, regardless of their race or ethnicity, have equal access to quality healthcare and thus improve the impact on breast cancer survival rates and quality of life.

P3-01-12: Enhancing Adherence to Hormone Therapy among Latina Breast Cancer Patients Impacted by Social Determinants of Health through a Bilingual, Culturally Tailored Mobile App and Patient Navigation

Patricia Chalela, Vivian Cortez, Sandra Sivak, Armida Flores, Martha de la Mora, Zully Garcia, Byeong Choi, Edgar Muñoz, Asra Aslam, Mauren Duran, Cliff Despres, Alyssa Gonzales, Virginia Kaklamani, Kate Lathrop, Marcela Mazo Canola, Devasena Inupakutika, David Akopian, Amelie G. Ramirez

Background: Hormone therapy (HT) is highly effective for nearly all breast cancer patients with hormone receptor-positive tumors, which account for approximately 80% of all breast cancer diagnoses. Long-term use of HT significantly reduces cancer recurrence rates and cuts the risk of mortality nearly in half during the second decade after diagnosis. Despite these proven benefits, approximately 33% of women prescribed HT do not adhere to their medication as recommended (<80%). Latina patients are disproportionately impacted by Social Determinants of Health (SDoH), which hinder their adherence to HT, placing them at a higher risk of breast cancer recurrence, lower quality of life, increased medical costs due to disease progression and treatment, and greater risk of cancer-related mortality.
Objective: The goal of this randomized controlled study is to assess the effectiveness of the existing bilingual, culturally tailored, and interactive HT Helper app, in combination with patient navigation (PN), on improving adherence to HT among Latina breast cancer patients experiencing SDoH barriers, i.e., income, health insurance, education, health literacy, and language, impacting their medication adherence.
Study Design: The proposed 4-year study involves a parallel 3-group randomized controlled trial with 5-time assessments (baseline, 3, 6, 12, and 18 months) and will enroll 159 Latina breast cancer patients who are prescribed HT and are attending the breast clinic at the Mays Cancer Center (MCC) at UT Health San Antonio. Group 1 will receive a) the HT Helper app; and b) patient navigation (PN). Group 2 will receive patient navigation only. Group 3 will receive the usual care and information provided by the MCC's breast clinic to patients undergoing oral HT. Intervention components are based on Social Cognitive Theory and elements of Motivational Interviewing.
Methods: We will compare the effectiveness of 3 groups on HT adherence: 1) the HT Helper app + PN group vs. the PN alone group vs. the usual care group, and will assess the effect of each study condition on patient self-efficacy to identify HT side effects, use self-care to manage side effects, and communicate with the medical team. We hypothesize that the HT Helper app + PN and the PN alone groups will have greater rates of HT adherence and higher patient self-efficacy than the usual care group, with the HT Helper app + PN achieving better results than both PN alone and the usual care groups.
Conclusion: This theory-based, multilevel intervention will increase patient education, enhance self-efficacy, facilitate communication with the medical team and coordination of resources to address SDoH barriers and help patients develop self-care skills and optimal adherence to HT, ensuring patients the most equitable treatment outcomes possible, including improvement in quality of life, survival, and life expectancy.

P3-01-13: Race and response to neoadjuvant chemotherapy for nonmetastatic breast cancer using the SEER database.

Alvaro Alvarez Soto, Wenqi Gan, Jesus Anampa, Susan Tannenbaum

Background: Pathological complete response (pCR) is a surrogate for improved overall survival (OS) and cancer-specific survival (CSS) in patients with nonmetastatic high-risk breast cancer (BC) who received neoadjuvant chemotherapy (NACT). Multiple cohort

studies have suggested racial disparities in the odds of achieving pCR between Non-Hispanic White (NHW) and Non-Hispanic Black (NHB) patients. Those studies were based on local databases or the National Cancer Database (NCDB), which is a hospital-based dataset. The goal of our study is to investigate racial disparities in the odds of achieving pCR along with disparities in CSS and OS between NHW and NHB women using SEER, a nationwide, population-based NCI database that represents around 48% of all the new cancer diagnosis in the US.

Methods: We identified female NHW and NHB patients aged ≥18 years old who were diagnosed with BC between 2010-2018 and who received NACT. We excluded patients with in-situ disease only, metastatic disease, neoadjuvant radiation use, patients who did not have surgery, and patients in which BC was not their first primary. SEER defined pCR as the absence of all primary tumor or residual in situ cancer only, and non-PCR was defined as patients who had no or partial response to neoadjuvant chemotherapy.

To estimate differences in the odds of achieving pCR between races, we used a logistic regression analysis adjusted for tumor biology, treatment-related, and demographic variables. Hazard ratios of breast cancer-specific mortality and all-cause mortality calculated using Cox regression models, stratified by race and pCR status. We created survival curves using Multivariate Cox models.

Results: We identified 8,355 NHW patients and 2,071 NHB patients diagnosed with stage I-III pathologically confirmed BC who received NACT between 2010 and 2018. There were 2,945 NHW and 668 NHB with hormone receptor positive (HR+)/HER2-, 2,085 NHW and 394 NHB with HR+/HER2-, 1,124 NHW and 245 NHB with HR-/HER2+, and 2,201 NHW and 764 NHB with TNBC.

Baseline characteristics were significantly different between groups. In terms of demographics, NHW women were older (age ≥55; 46.6% vs. 38.6%), more frequently married (63% vs. 37.7%), and had higher income (income ≥ 60,000 USD; 41.2% vs. 23.7%). In terms of tumor biology, NHW were less frequently TNBC (26.3% vs. 36.9%) and high-grade tumors (56.9% vs. 66.2%). A delay in diagnosis to chemotherapy ≥2 months was seen less frequently in NHW than in NHB (18.3% vs. 29.1%).

After adjusting for all covariates, we found no difference in the odds of achieving pCR between NHW and NHB women (OR=0.89, 95% CI 0.80 – 1.00). Subsequent stratified analysis for each clinical BC subtypes, showed no differences in the odds of achieving pCR between NHB and NHW for HR+/HER2-, HR-/HER2+, or TNBC, (OR=1.07, 95% CI 0.86 – 1.32), (OR=0.81, 95% CI 0.60 – 1.10), and (OR=0.85, 95% CI 0.71 – 1.01), respectively. For women with HR+/HER2+, NHB women had lower odds of achieving pCR as compared to NHW, (OR=0.78, 95% CI 0.63 – 0.98).

No differences in the risk of death from any cause was found in NHB patients who achieved pCR compared to NHW who achieved pCR (HR=1.10, 95%CI 0.85 – 1.42). However, NHB who did not achieve pCR had worse OS compared to NHW without achieved pCR (HR=1.32, 95%CI 1.17 – 1.49). Those results were more prominent in the HR+ groups. Similar results were seen for CSS.

Conclusions: We found no differences in the odds of achieving pCR between NHB and NHW patients with nonmetastatic BC. After stratifying by BC subtype, only NHB patients with

HR+/HER2+ tumors were less likely to achieve pCR. All-cause mortality was similar between NHW and NHB that achieved pCR. However, in patients with no pCR, NHB had a higher risk of death than NHW. Biologic or socio-economic factors might explain these disparities in patients with no pCR.

P3-01-14: DARC/ACKR1, Duffy-Null and African ancestry influence on immune response in triple negative breast cancer

Yanira Guerra, Stevens Patino, Kenya Bynes, Danielle Doucette, Emma Guyonnet, Brian Stonaker, Julie Sahler, Avery August, Jason White, Lisa Newman, Melissa Davis

Breast cancer (BC) related mortality remains approximately 40% higher among African American women, where women of African ancestry are more frequently diagnosed with the more aggressive molecular subtype of BC, triple negative BC (TNBC). We have previously reported that increased west African ancestry is associated with TNBC diagnoses, and that the African ancestry-specific Duffy-null allele (Fy-) is a risk factor for TNBC diagnoses compared to other BC subtypes. Fy- is an ancestral allele that provides immunity from Plasmodium vivax malaria and is found at frequencies of >90% across Sub-Saharan African populations, and >60% among African Americans. Fy- removes erythrocytic expression of the Duffy Antigen Receptor for Chemokines gene, recently renamed Atypical Chemokine Receptor 1 (DARC/ACKR1). DARC/ACKR1 functions to modulate systemic chemokine levels, and via expression on endothelial cells influences immune cell diapedesis into tissues. In the context of BC, Fy- individuals retain DARC/ACKR1 expression on endothelial cells, and we have recently reported variable DARC/ACKR1 expression on breast tumor epithelial cells using bulk transcriptomics and immunohistochemistry-based methods. Our preliminary work conducted among women of African ancestry suggests that immune cell infiltration is correlated to DARC/ACKR1 epithelial expression. Currently, we aim to describe the combined impact of DARC/ACKR1 on immune response in both the tumor microenvironment and circulation dependent on DARC/ACKR1 expression status.
To determine Fy- impact on circulating inflammatory markers of BC patients, we have conducted Luminex multiplex assays to detect and quantify over 40 circulating chemokines and cytokines. Fy- status was determined by WGS of germline, or single-plex PCR genotyping methods. We previously reported univariate associations with CCL2, CXCL2 and CXCL11. In models adjusting for BMI and TNBC status, significant associations with CCL2 and CXCL11 are retained, where we also report significance in univariate and fully adjusted models with CCL1, CCL19, MIF and Resistin. Our ongoing work is evaluating levels associated with Fy- among African Americans only in univariate and adjusted models, and exploring how these profiles may change between molecular subtypes, including TNBC.
We have quantified the circulating and tumor immunological/inflammation profiles of (n=100+) TNBC patients using Luminex multiplex assays and tumor-specific transcriptomics. We have discovered associations with (1) Fy- status and chemokine levels in the tumors versus circulation, and (2) differential levels of chemokines in tumors or

circulation based on DARC/ACKR1 expression in the breast tumors. To better define these phenotypes spatially, we have utilized imaging mass cytometry to profile breast tumors with varying levels of DARC/ACKR1 expression on the tumor epithelial cells. DARC/ACKR1 positive tumors have increased levels of immune cells infiltrating, with increases in T cell, B cell and macrophage populations. This aligns with our previous reports using bulk transcriptomics data, specifically where we showed an African ancestry associated gene signature enriched in immune response pathways. We are currently working to quantify the spatial resolution of these phenotypes.
In conclusion, African ancestry women are more frequently diagnosed with TNBC with aggressive tumor phenotypes that are hard-to-treat. The mechanisms driving this aggressive tumor progression likely involve systemic inflammation. DARC/ACKR1 expression helps regulate systemic inflammatory profiles, which are altered among Fy- patients. We are working to define the impact of these DARC-regulated systemic profiles on the tumor microenvironment among TNBC patients, associated with Fy- DARC status. Specifically, DARC/ACKR1 driven immune profiles may provide new opportunities to for treatment to better serve this population of women.

P3-01-15: Exploring the Impact of Race, Ethnicity, and BMI on Neoadjuvant Hormonal Treatment Outcomes

Traci King, Priscila Barreto Coelho, Youley Tjendra, Judith Hurley, Sofia George

Introduction: Neoadjuvant hormonal therapy (NHT) is a potential treatment strategy for estrogen receptor-positive (ER+) breast cancer (BC) in postmenopausal women. Despite its clinical benefits, utilization of NHT varies significantly and anecdotal experience suggests that treatment responses may vary across different patient populations.

Methods: This is an IRB approved retrospective cohort study of 170 consecutive postmenopausal patients with ER+/HER-2 negative BC who received neoadjuvant hormonal therapy (NHT) at a single institution from 1/2005 to 6/2018. All subjects were treated with anastrozole 1 mg daily until maximal clinical response. In a subset of 96 patients with surgical pathology available for review by a single pathologist, quantitative ER and PR were measured by decile and Ki67 was categorized as low (0-15%), intermediate (16-30%) and high (>30%). BMI was classified as <18.5 (underweight), 18.5-24.9 (normal), 25-29.9 (overweight), and ≥30 (obese). Comparative analyses assessed the correlation between race, ethnicity, BMI, and clinical outcomes.

Results: The median age at diagnosis was 62 (range 46-91), and median size of the breast mass was 5.3 cm (range 1.5-19.0 cm). At start of treatment, 27% of patients were stage IIA, 29% IIB, 22% IIIA, and 18% IIIB. The majority of patients were White (77%) and Hispanic (71%). 23% of patients were Black. Regarding BMI, 37% were in the normal range, 38% were overweight, and 25% obese. Pathology review showed that the large majority of tumors had 91-100% ER positivity (66%) or 81-90% ER positivity (19%). PR positivity was

more variable with only 21% at 91-100% PR positivity and 35% of patients with <50% PR positivity on IHC. The largest amount of patients (48%) were Ki67 low, 17% were intermediate, and 34% were Ki67 high.
Higher BMI was associated with higher ER expression (p=0.007) and higher Ki67 (p=0.042). There was no association between ER/PR expression and race or ethnicity.
The median duration of NHT was 6 months, with treatment durations extending up to 28 months. Pathological complete response (PCR) was observed in 3 tumors. All patients with a PCR were stage IIB at diagnosis, White, Hispanic, and overweight. Progression of disease occurred in 10 patients of which 40% were Black, 60% were Hispanic, 30% were overweight, and 40% were obese. Although pCR can be used as a surrogate endpoint for response to neoadjuvant therapy, there is no standard method of determining a significant response to NHT. In our cohort, the decision to give adjuvant chemotherapy was individualized for each patient based on the perceived response to NHT. The patients given adjuvant chemotherapy were felt to be at higher risk of relapse than those who received adjuvant hormonal therapy alone. Overall, 61% of patients required adjuvant chemotherapy after NHT. White women were more likely to receive adjuvant chemotherapy than Black women 66% vs 45% (p=0.019). There was a significant correlation between higher Ki67% and the need for adjuvant chemotherapy (p=0.030), but not between degree of ER positivity, PR positivity, or BMI.

Conclusion: The use of NHT potentially prevented adjuvant chemotherapy use in 39% of postmenopausal women with ER+/HER-2 negative BC. There appear to be disparities in response to NHT based on race but not on BMI or ethnic group. Additional research is needed to investigate molecular underpinnings between race/ethnicity/BMI and response to NHT.

P3-01-16: Evaluation of the Combination of Vepdegestrant, a PROTAC Estrogen Receptor (ER) Degrader, Plus Palbociclib in CDK4/6 Inhibitor-Resistant WT ER and ER Y537S Mutant Patient-Derived Xenograft (PDX) Models

Jessica The, Nanni Huser, Alissa Wynne, Christopher Kuhlberg, Bernadette Pascual, Ian Taylor

Background: Vepdegestrant is an oral PROteolysis TArgeting Chimera (PROTAC) ER degrader that directly ubiquitinates and degrades wild-type ER and clinically relevant mutants. Vepdegestrant demonstrated superior ER degradation and antitumor activity compared with the selective ER degrader, fulvestrant, in endocrine-sensitive and resistant xenograft models and has shown substantial ER degradation and promising clinical benefit in heavily pretreated patients with ER+/HER2- breast cancer. Inhibitors of cyclin-dependent kinase 4 and 6 (CDK4/6) are now standard of care (SOC) in combination with endocrine therapy (ET) in patients with ER+/HER2- advanced breast cancer, demonstrating significantly increased progression-free (and with some combinations, prolonged overall

survival) compared with ET alone. Previously, our studies revealed evidence of synergistic interactions between vepdegestrant and CDK4/6 inhibitors (palbociclib, abemaciclib and ribociclib) in ER+ breast cancer cells.
Methods: Here, we evaluated the mechanism underlying the synergy of vepdegestrant and palbociclib in vitro. Since resistance to CDK4/6 inhibitors eventually occurs, we also evaluated the combination of vepdegestrant and palbociclib in 2 CDK4/6 inhibitor-resistant PDX models, ST941-PBR (ESR1 Y537S) and ST1799-PBR (ESR1 WT).
Results: In vitro studies revealed enhanced apoptosis in vepdegestrant plus palbociclib treated ER+ breast cancer cells, underpinning the synergistic interactions between vepdegestrant and palbociclib. In vivo, as a single agent, vepdegestrant is highly efficacious in both CDK4/6 inhibitor-resistant models (ST941-PBR 101% TGI, ST1799-PBR 76% TGI) unlike fulvestrant (ST941-PBR 2% TGI, ST1799 PBR-11% TGI) which showed minimal efficacy. In combination with palbociclib, vepdegestrant displayed greater anti-tumor activity (ST941-PBR 107% TGI, ST1799-PBR 84% TGI) than that observed with vepdegestrant alone (ST941-PBR 101% TGI, ST1799-PBR 76% TGI) or fulvestrant plus palbociclib (ST941-PBR 23% TGI, ST1799-PBR 12% TGI) in both CDK4/6 inhibitor-resistant models tested. No significant body weight loss in mice was observed with the combination treatment.
Conclusions: These data suggest that in vitro, the combination of vepdegestrant and palbociclib leads to enhanced apoptosis in ER+ breast cancer cells and in vivo, vepdegestrant alone or vepdegestrant plus palbociclib is superior to fulvestrant alone or fulvestrant plus palbociclib, respectively, in the CDK4/6 inhibitor-resistant setting.

P3-01-17: Transcriptomic and phenotypic profiling of circulating tumor cells from metastatic breast cancer patients

Michela Palleschi, Tania Rossi, Sara Bandini, Michele Zanoni, Michela Cortesi, Erika Bandini, Andrea Rocca, Giulia Gallerani, Ivan Vannini, Meropi Plousiou, Lorenzo Gerratana, Giovanni Tallini, Giovanni Martinelli, Ugo De Giorgi, Paola Ulivi

Background: Metastatic breast cancer (MBC) is considered an incurable disease and understanding the molecular mechanisms at the basis of tumor progression has become mandatory. Circulating tumor cells (CTCs) constitute a population of rare cells that are shed in the bloodstream by primary and metastatic tumors and migrate towards distant organs. The molecular characterization of CTCs is a powerful tool to better investigate the mechanisms underlying metastasis. In this study, we combine phenotypic and transcriptional profiling of CTCs isolated from MBC patients to infer the mechanisms involved in their biology, also in relation to the metastatic site and their phenotypic features.
Methods: Blood samples for CTC analysis were collected from luminal MBC patients recruited in the KENDO study (Protocol code: IRST174.19); CTCs were enriched using the RosetteSep CTC Enrichment Cocktail and frozen until downstream analyses as viable cells. To validate the antibody staining for phenotypic analysis, tests were conducted using the

cancer cell line SKBR-3. In brief, SKBR-3 cells were spiked in peripheral blood of a healthy volunteer and enriched using RosetteSep CTC Enrichment Cocktail. Enriched SKBR-3 and patients' CTCs were incubated with antibodies targeting CD45 (leukocyte marker) and epithelial markers (E-tag; EpCAM, E-cadherin) for phenotypic analysis using the DEPArray NxT platform. For transcriptomic profiling, single CTCs were isolated as single, viable cells. Libraries were prepared using the QIAseq UPX 3' Transcriptome Kit and sequenced using MiSeq on V3-150 cycles cartridges. Bioinformatic and statistical analyses were carried out using the CLC Genomic Workbench.
Results: Through feasibility analysis conducted on SKBR-3 cells, we demonstrate that our workflow involving phenotypic analysis on DEPArray NxT is an efficient tool to identify cancer cells (CD45-/E-tag+) and white blood cells (WBCs; CD45+/E-tag-). In MBC samples, we detected different cell populations: WBCs (CD45+/E-tag-), CTCs (CD45-/E-tag+), and dual-positive CTCs (CD45+/E-tag+; dpCTCs). Transcriptomic profiling was successfully performed on 37 single CTCs isolated from 7 patients. The transcriptional profile of CTCs is consistent with breast malignancy for different databases including ClinVar2019, DisGeNet, and Human Phenotype Ontology. Moreover, Gene Set Enrichment analysis highlighted pathways associated with synapse organization and calcium channel activity, suggesting the implication of the interplay between cancer cells and neurons in metastasis. Compared to a commercial RNA, CTCs express at high levels transcripts associated with cancer dissemination and genome architecture (i.e., STAG2 and H2AFZ). In CTCs from patients with bone metastasis we detected the expression of genes associated with metastatic osteotropism (i.e., S100A4, VAPA, HMGB1), while CTCs from a single patient with gastric metastasis expressed genes associated with gastric cancer metastasis and cell redox homeostasis. Transcriptional profiling of dpCTCs revealed the expression of transcripts encoding for members of the CD47/SIRPα axis, supporting their macrophage-cancer cell fusion origin, and increased glycogen biosynthetic and metabolic activity.
Conclusions: Our data suggest the potential of CTC based transcriptomics in providing new insights on the clinical-biological evaluation of MBC and its mechanisms underlying metastatic cascade and organotropism. In addition, our data provide hints for the characterization of dpCTCs, a poorly studied population whose role in metastasis is still far to be fully elucidated.

P3-01-18: Clinical validation of image-based AI predictive biomarkers for precision neoadjuvant triple-negative breast cancer treatment (PEAR-TNBC): Interim results from Cohort A

Peter Hall, Matthew Williams, Eleonora Peerani, Elli Tham, Francesco Iori, George de Fraine, Kerrie Loughrey, Andreas Kaffa, Thomas Richardson, Carolina Liberal, Angeliki Velentza-Almpani, Demi Wiskerke, Farah Sangkolah, Aston Crawley, Jay Kearney, Edgar Molina, Nourdine Bah, Marios Tasoulis, Cliona Kirwan, Susan Cleator, Steve Chan, Duleek Ranatunga

Background: Pathological complete response (pCR) to neoadjuvant therapy strongly predicts the risk of recurrence and death in triple-negative breast cancer (TNBC). There are

multiple neoadjuvant regimens available for TNBC but no biomarkers to match patients to treatments. Pear Bio has developed a functional precision medicine test coupling an organ-on-a-chip with a computer vision (CV) pipeline through which an individual patient's response to different treatments can be monitored simultaneously ex vivo using time-lapse 3D microscopy. The results are available within 1 week of the biopsy being received.
PEAR-TNBC (NCT05435352) is an ongoing prospective, two-cohort, observational trial to assess the accuracy of the Pear Bio test in predicting pCR to neoadjuvant treatment in TNBC patients. Here we report the interim results from Cohort A of the trial.
Methods: To be eligible, patients need to have ≥10mm tumor, stage I-III, TNBC, planned for neoadjuvant treatment (chosen by the treating oncologist) followed by surgery and be willing to undergo a study-specific core needle biopsy. To be evaluable, the tumor sample needs to be successfully cultured in the 3D ex vivo assay and the patient has to complete at least 4 cycles of neoadjuvant chemotherapy. The primary endpoint is the accuracy of the Pear Bio test in predicting pCR (ypT0/Tis ypN0), defined as specificity, with secondary outcomes as sensitivity, and positive and negative predictive values.
The Pear Bio test is run in parallel with the patient's treatment and the treating oncologist is blinded to the results.
We used the change in dead cell count between Day 0 and Day 3 as the metric to predict pCR, optimised the cut-off by plotting a Receiver Operating Characteristic (ROC) curve, and calculated the area under curve (AUC) for the ROC curve, as well as other measures of classification performance. The treatment responses in the test to different regimens were ranked and compared to the response seen in the patient with the regimen chosen by the treating oncologist.
Results: Cohort A recruitment began on 27th May 2022 and completed on 4th July 2024, having recruited 34 patients from five UK sites. Four patients had to be excluded (one bacterial contamination, one declined NAC, two yielded too few cells) and 18 were still awaiting clinical outcomes. In the 12 evaluable patients, median age was 53 (IQR: 42 – 64) years and median tumor size was 27mm (IQR: 20 – 34). One patient was node positive; seven patients were Stage 1 – 2B, one stage 3A and four undetermined staging. Seven patients received the KEYNOTE-522 regimen, four received AC-CarboTaxol and one EC-CarboTaxol. The median number of cycles of neoadjuvant therapy received was 8.5. Nine patients achieved a pCR at surgery.
The AUC for predicting pCR was 0.81 (p=0.046), with the Pear Bio test correctly predicting outcomes in 10 of the 12 patients.
For the three patients who did not achieve a pCR, the assay suggested that other regimens may have been more effective.
Discussion: We have presented interim results of a novel functional precision medicine assay to predict pCR in patients with TNBC receiving neoadjuvant therapy. We have shown the successful culture of tumor cells and demonstrated intra- and inter-patient variation in response to different therapies. The assay shows promise in predicting pCR, although the number of patients analyzed is small currently. The trial data continues to mature, and Cohort B is now recruiting. Future trials will run the Pear Bio test prior to therapy selection,

guiding the choice of regimen to assess the test's ability to increase pCR rates or de-escalate treatment safely.

P3-01-19: Proteomics-based degradome analysis of mammary tumor adjacent adipocyte reveals adipocyte-derived peptide MASP6 promotes breast cancer cell invasion and migration

Shuhan Zhao, Jinghui Peng, Yue Huang, Yiqin Xia, Yuhan Dai, Huilin Chen, Jiangdong Jin, Yifan Wu, Yangyang Cui, Ziyi Fu, Yongmei Yin, Shui Wang, Hui Xie

Breast cancer is the most common female malignancy all over the word, at a risen rate of over 1.7 million cases per year globally, where metastasis is the leading cause of death. Accumulating epidemiological evidence indicates that abnormal fat status such as obesity is an important risk and poor prognostic factor for breast cancer. Adipose, a significant component of the stromal tissues, also a type of metabolically active endocrine organ, is the most abundant stromal constituent in the mammary gland surrounding breast cancer. In addition, a growing number of studies have confirmed that adipocytes adjacent to invasive cancer cells, known as cancer-associated adipocytes (CAAs), participate in the regulation of breast cancer progression. Breast tumor adjacent adipocytes have the potential to drive the malignancy of tumor cells by secreting hormones, proinflammatory cytokines, and accelerating tumor metabolic reprogramming. Despite of the diversity effects of adipokines on breast cancer, adipocytes secreted protein derived peptidome remains a black hole to our knowledge, since degradome has been expanding its roles in biology and pathology. In addition to glucose and lipid metabolic products, the fragments/peptides cleaved from extracellular matrix and membrane proteins degradation by proteinase or hydrolase at the level of cancer-tissue microenvironment, are supposed to carry cancer-specific information and further reveal the reciprocal interconnected network of tumor and surrounding stroma tissues, which could be a potential anti-tumor therapeutic target. In addition, little evidence proved that adipocyte-derived peptide could participate in cancer metastasis progression. In this study, we aim to assess the biological effects of breast tumor adjacent adipocyte secreted protein derived peptides on breast cancer cells from multiple angles, and systematically analyze the degradome characters, expecting to realize a basic understanding of its role in the development and progression of breast cancer. Here we found a novel adipocyte-derived peptide MASP6 that may affect the invasive and migrative ability of breast tumor, which is of great significance for exploring new targets for breast cancer.

In order to explore the underlying mechanism of communication between breast cancer and adipose tissue, we isolated adipocytes from adipose tissues adjacent to breast tumor (TAA) and breast benign lesions (BAA) and collected the supernatant. The results showed that peptides of adipocyte secreted degradome could increase breast cancer malignancies dominantly. LC-MS/MS and bioinformatic analysis data showed there are about 100 identified peptides contribute to aberrant cell adhesion of tumor cells through regulating focal adhesion. Sparklingly, 2 lipophilic peptides are identified stable, creating sustained

effect on tumor cells.What's more, wound healing test showed that MASP6, one of the adipocyte-derived peptide, promoted the invasive and migrative ability of breast tumor cells. Dual-luciferase assay, quantitative real-time polymerase chain reaction (qRT-PCR) and western blots verified that the expression of Matrix Metalloproteinase (MMP-2/9) was increased after MASP6 treated in breast cancer cells. Mouse xenograft model demonstrated that MASP6 enhanced tumor metastasis in vivo. The PI3K/Akt signal pathway was stimulated after MASP6 treatment. Nuclear and cellular protein extraction, indirect cellular immunofluorescence revealed that MASP6 could enter into cytoplasm and activate nuclear factor kappa B (NF-κB-p65) via promoting its nuclear translocation.
In conclusion, our results confirmed mammary gland surrounding adipocytes induce malignancies of breast tumor cells, and delineated the interaction network between secreted degradome of adipocytes and tumor cells, which are believed to afford novel insights into breast cancer therapy.

P3-01-20: A novel, semi-automated Pipeline for HER2 Quantification on CTCs in breast cancer patients. Is cytopathology of peripheral blood a new diagnostic option?

Nadia Bayou, Sarah Henretta, Laura Arcos Munoz, Elisabetta Molteni, Caterina Gianni, Mara Serena Serafini, Amanda Strickland, Eleonora Nicolo`, Letizia Pontillo, Jyothi Manohar, Olivier Elemento, Massimo Cristofanilli, Carolina Reduzzi

Introduction: The Human Epidermal Growth Factor Receptor 2 (HER2) plays a central role in breast cancer (BC). Nowadays, the assessment of HER2 status and the selection of patients eligible for anti-HER2 therapy rely on immunohistochemistry (IHC) and in situ hybridization on tissue biopsy, an invasive approach, unable to capture intratumor heterogeneity and dynamic of HER2 expression. Circulating tumor cells (CTCs) offer an alternative material to evaluate HER2 expression in real-time, through a simple blood draw. Limitations to the use of CTCs for HER2 assessment derive from limited sensitivity in detection methods and lack of standardization.To overcome these limits, we developed a semiautomated pipeline combining label-independent CTC enrichment and HER2 expression quantification and we compared it to the gold-standard CellSearch®, in a cohort of patients (pts) with metastatic BC (mBC).
Methods: Blood samples (7.5 mL) were collected in EDTA tubes from mBC pts enrolled at Weill Cornell Medicine and processed within 1 hour for CTC analysis. CTCs were captured using Parsortix™ and stained for epithelial (EpCAM, cytokeratins [CK]), leukocyte (CD45) and HER2 markers as well as for nuclear staining. CTCs were identified as nucleated cells, EPCAM/CK+ and CD45-. For each CTC, 4 color digital images were processed with the automated post-processing developed tool: a combination of an open-source image analysis software CellProfiler and a custom MATLAB code allowing for CTC identification and HER2 expression categorization into high, low and no expression. A second aliquot for each sample was processed in parallel with CellSearch® for comparison.
Results:A total of 16 whole blood samples from mBC pts were collected: 5 at baseline

(31%), 4 at progression (25%) and 7 at restaging (44%). The study cohort included 5 pts (31%) with HER2+ BC, 5 pts (31%) with hormone receptor-positive (HR+)/HER2- BC, and 6 pts (3%) with HR-/ HER2- BC.By using our pipeline, CTCs were identified in all the samples, whereas CellSearch® analysis detected CTCs in 77% of samples (10/13 of evaluable samples).A total of 320 CTCs were detected in the 16 CTC-positive samples by our pipeline, versus 368 CTCs detected by CellSearch® in 10 CTC-positive samples. We were able to detect HER2+ CTCs in all the 16 processed samples (100%), while CellSearch® only did in 4/13 of the evaluable samples (31%). Among all detected CTCs, 142/320 were HER2+ (44.4%) by using our pipeline, compared to 40/368 (10.9%) identified by CellSearch®. Of the CTCs detected with our pipeline, 81.7% (116/142) had a high HER2 expression and 18.3% (26/142) a low expression. Our pipeline was therefore able to identify HER2+ CTCs in 11/11 (100%) of pts with a HER2 negative status on tissue as opposed to 2/9 (22.2%) of the samples processed by CellSearch®. Interestingly, in addition to EPCAM+/CK+ CTCs, with our pipeline we were also able to identify 83 cells with low/negative EPCAM/CK expression. These cells were CD45-negative and 12% of the cases presented a HER2 expression.
Conclusion: The current study showed the feasibility of a real-time HER2 assessment on CTCs enriched from mBC pts. The developed pipeline was able to count and identify HER2-positive CTCs with higher efficiency than the gold-standard CellSearch® overall and interestingly, also in the HER2-negative subgroup. This is a preliminary analysis that should be confirmed in larger cohorts. HER2 marker is a therapeutic target and an accurate and real-time assessment of the HER2 status could be used to better guide treatment in a larger cohort of patient with advanced breast cancer with any detectable HER2 expression that can be effectively treated with antibody-drug conjugates.

P3-01-21: Gene expression changes following pre-operative letrozole therapy among postmenopausal women with estrogen-receptor positive HER2/neu-negative invasive breast cancer

Simone Dekker, Pritha Chanana, Matthew Fitzgibbon, Jennifer M. Specht, Hannah M. Linden, Meghan R. Flanagan

Introduction: Pre-operative endocrine therapy is an evolving area with the advantage of gaining information on tumor response early the treatment course. There is limited data on how pre-operative endocrine therapy affects tumor gene expression. Our goal was to characterize changes in gene expression associated with pre-operative letrozole therapy among postmenopausal women with estrogen-receptor positive (ER+) HER2/neu-negative (HER2-) breast cancer. Approximately 75% of ER+ breast cancers are androgen receptor (AR)+, and there is emerging evidence that the balance between ER and AR signaling is a critical determinant of tumor growth. This study examines changes in overall gene expression, as well as gene expression related to ER and AR signaling.
Methods: Our study population included 33 post-menopausal females with mean age of 65 years and ER+/HER2- breast cancer who underwent surgical resection of the tumor after

receiving neoadjuvant letrozole (median days of treatment = 23 (IQR 21-30 d)). Patients had pT3 and pN2a disease or less, and grade 1 (66.6%) or grade 2 (33.3%) disease. Most patients had ER > 90% by IHC (91% of population). Gene expression was assessed on the initial diagnostic biopsy and the operative specimen. Samples were sequenced on an Illumina NextSeq P4 flowcell. Alignment was performed against the iGenomes hg38 reference genome using STAR v-2.7.10b, with quality checks using FastQC and RSeQC. We used STAR2's –quantMode flag with Gencode v38 gene definitions to perform gene expression quantification and generate counts, followed by edgeR to perform the differential expression analysis in R. A significance threshold of log2FC >= 1 or log2FC <= -1 at 5% FDR was used to define the genes of interest.
Results: 14971 genes were analyzed, of which 347 genes were differentially expressed following letrozole therapy. 203 genes were significantly downregulated, such as SERPINA6 (log2FC -4.2), CYP2A6 (log2FC -3.9), IGSF1 (log2FC -2.7), PDZK1 (log2FC -2.7), TMC3 (log2FC -2.6). The five most upregulated genes include FOSB (log2FC 5.2), FOS (log2FC 4.3), DUSP1 (log2FC 3.7), RGS1 (log2FC 3.6), and ATF3 (log2FC 3.1). 41 genes related to ER/AR signaling were significantly differentially expressed following letrozole treatment, of which the majority were related to AR signaling (37 genes). Most genes related to AR signaling were significantly downregulated (92%), such as PDZK1 (log2FC -2.7), TROAP (log2FC -2.1), NOY1R (log2FC -2.1), PGR (log2FC -1.9), and ESPL1 (log2FC -1.9).
Discussion: This study revealed modulation of gene expression after short-term pre-operative letrozole therapy. We are currently examining pathway level changes associated with pre-operative letrozole treatment to better understand how aromatase inhibitors impact AR signaling. Additionally, our team is investigating whether our observed changes in gene expression are associated with quantitative AR receptor expression by IHC and other outcome measures, such as changes in the proliferation marker Ki67. Further studies should aim to understand how aromatase inhibitors impact AR signaling and the potential impact on the efficacy of endocrine treatment and overall patient outcomes.

P3-01-22: Pilot Feasibility Study of ctDNA Testing in Breast Cancer and its Association with Pain, Stress and Anxiety

Mrinalini Ramesh, Yasmin Fakhari Tehrani, Arya Mariam Roy, Kristopher Attwood, Shipra Gandhi

Background: Molecular residual disease (MRD) assessment by circulating tumor DNA (ctDNA) has shown great promise in predicting therapeutic effects and recurrence risk. Prior studies have demonstrated that colorectal cancer patients with ctDNA negativity have superior disease-free survival compared to those with detectable ctDNA. We aimed to determine whether there was any association between ctDNA detection and clinical outcomes in breast cancer patients. Our study also investigated the association between ctDNA levels, stress, anxiety, and pain experienced by patients in this cohort. In particular, we wanted to investigate whether ctDNA positivity impacted stress and anxiety levels in these patients.

Methods: A prospective study was designed to obtain the ctDNA levels in patients treated in the breast clinic at Roswell Park Comprehensive Cancer Center from 2022 to 2024. This was done by obtaining peripheral blood with serial ctDNA analysis using a personalized, tumor-informed assay (Signatera™). Patient demographics, distress thermometer screening scores, pain scale scores, vital signs, absolute neutrophil count, and active benzodiazepine/antidepressant/antipsychotic use were compared to ctDNA status using the mean, median, and standard deviation for continuous variables, and frequencies, and percentages for categorical variables. Pain scores were obtained on a numerical scale of 1-10 with acceptable pain defined as a score less than their pain scale result. Comparisons were made using the Mann-Whitney U and Fisher's exact tests, as appropriate. The association between ctDNA, measures of pain, stress, and anxiety with recurrence were also assessed.

Results: A total of 49 patients with stage I-III breast cancer had ctDNA testing performed in the adjuvant and neoadjuvant setting after completion of locoregional and systemic treatment from 2022-2024, with 16% stage I, 45% stage II, and 39% stage III. The patient age at diagnosis ranged from 33 to 76 with a median age of 56. Of these 49 patients, 7 had detectable levels of ctDNA, including 3 patients with stage III cancer, 2 with stage II, and 2 with stage I. The median number of ctDNA tests collected was 4 with a range of 1 to 12. Testing was performed every 3 months. The study also included 7 stage IV patients who had detectable levels of ctDNA for the same period. The median age of stage IV patients was 53 years with a range of 34 to 74. ctDNA level was tested every 2 months. The median number of ctDNA collected was 6 with a range of 3 to 13. ctDNA was higher in patients with T3 versus T1 (226 MTM/mL vs 100.8 MTM/mL,0.034), and M1 versus M0 (271.5 MTM/mL vs 47 MTM/mL, <0.001). ctDNA was also positively correlated with the progression of disease on imaging ($p < 0.001$). Additionally, patients with well-controlled pain had significantly lower ctDNA expression compared to patients with uncontrolled pain (42.4 MTM/mL vs 183.3 MTM/mL, p=0.007). No association of ctDNA positivity with anxiety or distress was observed.

Conclusion: This pilot study shows the feasibility of testing ctDNA in clinical practice and explores its association with symptoms and outcomes. Further analysis with a patient population followed for a longer period will be required to understand the impact of ctDNA testing on the well-being of patients with breast cancer.

P3-01-23: MELK controls stromal components through fibronectin modulation in highly aggressive breast cancers.

Mohd Mughees, Alex Tan, Jian Wang, Savitri Krishnamurthy, Senthil Damodaran, Debu Tripathy, Wendy A. Woodward, Kevin Dalby, Chandra Bartholomeusz

Background: Triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC) have limited therapeutic options due to advanced stage at diagnosis, high rate of metastasis, and lack of actionable targets. In a previous study, we showed that MELK is a potential target in highly aggressive breast cancers; a driver of cell stemness, and promotes epithelial-mesenchymal transition and metastasis in a TNBC xenograft model. Fibronectin (FN1) produced by mesenchymal cells has been implicated in breast cancer metastasis, and previous studies have shown that FN1 expression is higher in TNBCs than in HER2-positive or hormone-receptor-positive breast cancers. Studies have also shown that an increase in FN1 can lead to the formation of extracellular fibronectin fibrils, which promote directional cancer cell motility. We previously showed that inhibition of MELK using siRNA against MELK and using a MELK inhibitor reduced the expression of FN1 in vitro and in a xenograft mouse model, suggesting that MELK kinase activity may be important for maintaining FN1 levels in TNBC. We hypothesized that MELK promotes the expression of FN1, which is involved in reorganization of the extracellular matrix.
Methods and results: To determine if MELK promotes transition to mesenchymal-like stromal components, we used qPCR to evaluate the expression of FN1 in MDA-MB-231 clones with CRISPR-based MELK knockout. The clones C3 and C28 showed 0.54-fold ± 0.03-fold ($p \leq 0.01$) and 0.76-fold ± 0.01-fold ($p \leq 0.001$) reduction in expression of FN1 compared to Cas9 control cells. To determine if MELK promotes the motility and invasion of TNBC through FN1, we performed a migration assay by plating MELK-knockdown and MELK-inhibitor-treated TNBC/IBC cells in FN1-coated migration chambers. When MELK was knocked down using three siRNAs against MELK in MDA-MB-231 cells, the relative percentage of migration was reduced by 69.01% ± 0.03, 44.53% ± 0.05, and 11.80 ± 0.10, respectively, in the MELK-knockdown cells compared to the control cells transfected with non-targeting siRNA ($p \leq 0.001$). Similarly, treatment of MDA-MB-231 and SUM149 cells with the MELK inhibitor 30e reduced the relative percentage migration by 30.45% ± 0.10 and 20.00% ± 0.14 compared to the respective DMSO-treated controls ($p \leq 0.05$) for both comparisons. To evaluate the effect of MELK on stromal organization, we used the 3D Spheroid BME Invasion Assay to measure the invasion of MDA-MB-231 cells in the presence of FN1 and MELK-In-30e. The presence of FN1 enhanced the invasion of these cells compared to the control cells, and inhibition of MELK with MELK-In-30e reduced the invasion of these cells compared to the DMSO-treated control cells. To pave the path for clinical translation of MELK inhibitors, we evaluated three MELK inhibitors (MELK-In-17, MELK-In-30e, and OTS167) to find the inhibitor with the highest efficacy and lowest toxicity alone or in combination with paclitaxel in the murine TNBC 4T1 mouse model. All the treated groups exhibited a reduction in tumor growth compared to the vehicle-treated group. The MELK–In–30–treated group exhibited significant inhibition in tumor growth compared to the OTS167-treated group ($p=0.002$). The combinations of MELK inhibitors with paclitaxel did not show any synergism with respect to tumor growth inhibition.
Conclusions and Future Directions: Our results showed that MELK promotes FN1 expression, which may be involved in stromal reorganization and contribute to tumor progression in TNBC. Currently, we are evaluating MELK inhibitors with other rational combination therapies in a triple-negative IBC xenograft model.

P3-01-24: Triple negative and non-triple negative breast cancer have distinct metabolic characteristics associated with divergent survival outcomes

Sarabjot Pabla, Shipra Gandhi, Maria-Fernanda Senosain, Hardik Parikh, Erik Van Roey, Shuang Gao, Yamuna Pulivendula, Paul DePietro, Jeffrey M. Conroy, Stephanie B. Hastings, Kyle C. Strickland, Rebecca A. Previs, Eric Severson, Brian J. Caveney, Marcia Eisenberg, Taylor J. Jensen, Shakti Ramkissoon, Heidi Ko

Introduction: Triple negative breast cancer (TNBC) is an aggressive breast cancer subtype associated with high histologic grade and poor prognosis. TNBC is also known to be associated with modified metabolic activities of both tumor and stromal cells in the tumor microenvironment, potentially as a mechanism to enhance tumor development and survival in low-nutrient conditions. Here we aimed to investigate the differences in the metabolic activity of TNBC vs. non-TNBC and their impact on survival.
Methods: Comprehensive immune profiling, including the expression of 395 immune-associated genes measured by RNA-seq, and PD-L1 expression testing by IHC, was performed on 149 real-world breast cancer samples. 52 samples were, by definition, triple negative for ER, PR, and HER2 overexpression. Based on Reactome pathway database data, mRNA expression signatures of carbohydrate (7 genes), lipid (10 genes), protein (29 genes), vitamin/cofactor (6 genes), and overall (32 genes) metabolism were calculated by averaging the normalized gene expression of each gene set. Samples were grouped into high (greater than or equal to median expression) and low (less than median expression) groups for each metabolic signature. Statistical comparisons of biomarkers between groups were performed using the Wilcoxon Rank-Sum test for continuous variables and Fisher's Exact Test for categorical variables ($p \leq 0.05$ for significance). Survival differences were quantified by Kaplan-Meier analysis ($p \leq 0.05$ for significance).
Results: In general, TNBC demonstrated greater overall metabolic activity ($p=0.001$), including greater lipid ($p=5.8\times10\text{-}5$), protein ($p=0.0053$), and vitamin/cofactor ($p=0.04$) metabolism. However, there was no significant difference in carbohydrate metabolism between TNBC and non-TNBC. Among TNBC cases, only higher vitamin and cofactor metabolism was associated with better overall survival (OS) (61 months vs. 37 months, $p=0.029$), while carbohydrate, lipid, protein, and overall metabolic activity were not significantly associated with OS. For non-TNBC cases, high overall metabolic activity was associated with better OS (180 months vs. 78 months, $p=0.011$), as was high carbohydrate (147 months vs. 79 months, $p=0.0053$), high lipid (162 months vs. 73 months, $p=0.016$), and high protein metabolism (148 months vs. 73 months, $p=0.026$).
Conclusions: We found that, in general, TNBC is more metabolically active than non-TNBC, though the survival effects of this difference vary depending on the specific aspect of cellular metabolism being measured, with some signatures associated with OS in TNBC and others in non-TNBC. An improved understanding of the metabolic environment of breast cancer as it relates to both triple negative status and differences in patients may facilitate a more nuanced characterization of tumor subtypes, aiding in the development of treatment strategies taking this aspect of the tumor microenvironment into account.

P3-01-25: Molecular and immunological characterization of HER2-low, HER2 ultra-low, and HER2-null male breast cancer

Dario Trapani, Sachin Kumar Deshmukh, Sharon Wu, Joanne Xiu, Priya Jayachandran, Nancy U. Lin, Giuseppe Curigliano, Milan Radovich, Maryam Lustberg, Stephanie L. Graff, George W. Sledge Jr, Sara M. Tolaney, Jose P. Leone

Background: Human epidermal growth factor receptor 2 (HER2) gene expression is an important predictive and prognostic biomarker in breast cancer (BC), which also guides treatment recommendations. The expression of HER2 is a continuum from null to positive and includes HER2-low and ultra-low as targets for anti-HER2 antibody–drug conjugates (ADC). However, HER2-low and ultra-low have not been studied in male BC. Here, we analyze whether there are any differences in molecular and immunological features between HER2-low, ultra-low and HER2-null/negative expression in males with BC.
Methods: 199 male breast tumor samples were included in this study. HER2-null expression was defined as infiltrating cancer cells completely free of HER2 immunohistochemistry (IHC) staining. HER2 ultra-low expression was defined as ≤10% cancer cell showing incomplete and faint/weak membrane staining. HER2-low expression was defined as HER2 (IHC) 1+ or 2+ with negative chromogenic in situ hybridization (CISH) assay. HER2-positive expression was defined as HER2 IHC 3+ staining or 2+ with positive CISH assay. Mutations and gene expression were detected by next-generation sequencing (NextSeq; WES, NovaSeq) and Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ), respectively; tumor mutational burden (TMB) totaled somatic mutations per tumor (high>10 mt/MB). Immune cell fractions were calculated by deconvolution of WTS:Quantiseq. Statistical significance was determined using chi-square and Mann-Whitney U test and p-value <0.05 was considered significant.
Results: Of 199 samples, there were 70 (35.2%) HER2-null tumors, 49 (24.6%) HER2 ultra-low tumors, 64 (32.2%) HER2-low tumors, and 16 (8.0%) HER2-positive. The proportion of HR+ was 81.4% in HER2-null, 93.8% in HER2 ultra-low, 87.5% in HER2-low and 81.2% in HER2-positive tumors. HER2 ultra-low male BC had higher frequency of PIK3CA (44.19% vs 23.64%) compared to HER2-null and KMT2D (7.5% vs 0%) compared to HER2-low, all p<0.05. HER2-low male BC had numerically lower frequency of TP53 (8.7% vs 16.6%, p=0.2) and ESR1 (1.6% vs 5.4%, p=0.2) compared to HER2-null. No significant differences were noted in TMB-high frequency (7.1% vs 5.0% vs 6.9%) and PD-L1 positivity (22C3) (8.11% vs 9.0% vs 10.6%) between HER2 ultra-low, HER2-low and HER2-null (all p=1.0). Analysis of inferred immune cells revealed that HER2 ultra-low and HER2-low male BC had higher infiltration of B cells (6.6% vs 5.8% vs 4.9%) but lower infiltration of neutrophil (2.4% vs 2.0% vs 3.8%) (all p<0.05). HER2-low had lower expression of immune checkpoint gene LAG3 (fold change (FC): 1.6), stem cell-related genes (KLF4, POU5F1; FC: 1.3-1.7) and drug-efflux gene ABCB5 (FC: 2.2) compared to HER2-null tumors (all p<0.05). HER2 ultra-low had lower expression of drug-efflux gene ABCG2 (FC: 1.5) compared to HER2-null tumors (p<0.05). Data adjusted for HR-subtype will be presented at the meeting.
Conclusions: Our findings add valuable information to the current understanding of the HER2 spectrum in the male breast cancer, including frequency distribution and molecular

characterization. With some exceptions, HER2-low, ultra-low and null breast cancer in men shared genomic features, suggesting that the disease biology may not be different across the spectrum of what historically has been considered HER2-negative disease. Interestingly, HER2 ultra-low, HER2-low and HER2-null had differential tumor immune microenvironment that warrant further exploration.

P3-01-26: Amitriptyline potentiates Elacestrant in treating ER positive ESR1 mutant Breast cancer.

Prabhakar Pitta Venkata, Arhan Rao, Timilsina Santosh, Suryavathi Viswanadhapalli, Ratna K. Vadlamudi, Virginia G. Kaklamani, Manjeet K. Rao

Background: Breast cancer (BC) stands as the most prevalent cancer and the leading cause of cancer-related deaths among women globally, with an incidence rate of 1 in 8 women developing invasive breast cancer during their lifetime. A significant majority (80%) of these cases are Estrogen Receptor positive (ER+). The standard first-line treatment for locally advanced or metastatic ER-positive/human epidermal growth factor receptor 2 (HER2)-negative breast cancer includes endocrine therapy with aromatase inhibitors (AI) or Fulvestrant combined with a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. However, disease progression often leads to endocrine resistance, primarily due to acquired mutations in the estrogen receptor 1 (ESR1). These ESR1 mutations cause estrogen-independent ER activation, resulting in resistance to AIs but not to selective ER degraders (SERD) or selective ER modulators (SERM). Current treatment guidelines recommend continuing sequential endocrine therapy until a visceral crisis occurs or all options are exhausted, revealing a significant unmet clinical need. Repurposing existing or investigational drugs has emerged as a promising strategy for cancer treatment. Consequently, we explored the potential of repurposing the antidepressant Amitriptyline for treating ER+ breast cancer.
Methods: We employed both short-term and long-term cell viability assays, as well as apoptosis assay, to evaluate the anticancer activity of Amitriptyline across various BC cell lines. These included wild-type ERα cell lines (MCF7 and ZR75), cell lines with acquired resistance (MCF7-Tam and MCF7-LTLT), and mutant ERα cell lines (MCF7-ERα-D538G, MCF7-ERα-Y537S, ZR75-ERα-D538G, and ZR75-ERα-Y537S). To validate our in vitro findings, we employed patient-derived explants (PDEX), cell-derived xenograft, and patient-derived xenograft (PDX) models to test Amitriptyline's efficacy. Biotin/Streptavidin pull down assay followed by mass spec analysis and RNA sequencing (RNA-seq) analysis were conducted on vehicle-treated and Amitriptyline-treated breast BC cells to elucidate the target protein and mechanism of action respectively. Additionally, we investigated whether Amitriptyline could sensitize ER+ breast cancer cells to Elacestrant, an FDA approved SERD.
Results: Amitriptyline treatment significantly reduced both short-term and long-term cell viability of BC cells in a dose-dependent manner. Additionally, Amitriptyline markedly increased apoptosis in BC cells. These in vitro findings were corroborated in vivo, as Amitriptyline treatment inhibited the growth of ER+ BC in a preclinical orthotopic

syngeneic model. Furthermore, Amitriptyline significantly lowered Ki67 levels in ESR1 mutant patient-derived explants (PDEX). Notably, Amitriptyline enhanced the sensitivity of ER+ BC to Elacestrant, demonstrating highly synergistic effects. The combination of Amitriptyline and Elacestrant significantly improved cell viability, survival, and apoptosis outcomes compared to Elacestrant alone.
Conclusion: Our study highlights the potential of Amitriptyline as a safe and effective treatment option for patients with ER+ breast cancer.

P3-01-27: CYTOKINE LEVEL AND OUTCOMES OF NEOADJUVANT TREATMENT IN EARLY BREAST CANCER

Salome Khutsurauli, Ofra Maimon, Benjamin Nisman, Avital Granit Mizrahi, Shani Breuer, Nada Salaymeh, Ahinoam Gugenheim, Tamar Peretz

Background: Globally breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in women. Neoadjuvant therapy (NAT) in locally advanced breast cancer resulted the achievement of pathological complete response (pCR) which is a valid predictor of good prognosis and influence in the future also on survival both in Her2 positive and TNBC.
Correlation between neutrophil to lymphocyte ration (NLR), levels of cytokines IL6,IL8,IL10 and pCR after neoadjuvant chemotherapy remains unclear.
Patients and methods:This prospective study was conducted at Sharett Institute of Oncology and included 37 patients with locally advanced breast cancer undergoing neoadjuvant treatment.The patients were sampled for the first time on the day they started chemotherapy, in the mid cycles and at the end of the treatment.IL-6,IL-8 and IL10 were measured by an automated solid-phase chemiluminescent immunometric assay.
Results:The rate of elevated NLR above 2.05 in non-pCR was significantly higher than in those with pCR (58.3% vs. 16.7%, P=0.032). High NRL (>2.06) at the start of treatment was predictor of non-pCR (odds ratio 7.00, 95% CI 1.3-39.1, P=0.027).The difference in the rate of elevated delta NLR among responders and non-responders was not significant (16.7% and 30.4%, P=0.450).
We found that the levels of IL-6 and IL-10 were consistently low in the subgroup of BRCA1/2 carriers, while IL-6 was higher in Her2-positive tumor. Analysis of changes in cytokines during NAT showed that elevated IL-6 above 4.8 pg/ml after first treatment was found to be a significant predictor of pCR.A significant correlation was found between IL-6 and IL-10. The changes of IL-10 showed similar to IL-6 kinetics during neoadjuvant treatment both in responders and non-responders, however difference between two subgroups did not reach statistical significance. For IL-8, no statistically significant findings were found.
We also collected saliva samples in order to check cytokine levels.First we found that cytokine level in Saliva were almost ten times higher than in serum.IL6 level was higher in patients with family history before the treatment (p= 0.010) and in mid treatment (p=0.042).IL6 and IL10 level were higher in the mid treatment in patients with advanced

disease, such as larger tumor size with significant p value (p=0.013 for IL6 and p=0.049 for IL10).IL8 and IL10 levels were lower during and at the end of NA treatment in patients with Her2 positive disease.There was no correlation in cytokines measured between serum and saliva during neoadjuvant treatment.
Conclusion: We found association between pCR and NLR. Also elevated IL-6 was a significant predictor of pCR.Furthermore the levels of IL-6 and IL-10 remained low in BRCA ½ carriers, while IL-6 was consistently higher in Her2-positive tumor.
A significant correlation was found between IL-6 and IL-10. The changes of IL-10 showed similar to IL-6 kinetics during neoadjuvant treatment both in responders and non-responders, however difference between two subgroups did not reach statistical significance. For IL-8, no statistically significant findings were found.
No correlation was found between salivary and blood cytokine levels,with salivary levels tending to be higher.This can be caused because of food,dry mouth as a side effect of the treatment, tooth and gum infections both as a side effect of the chemotherapy and so on. But we were able to find correlation between salivary cytokines,Her2 positive disease, family history and tumor size.
From the results of the study, it can be concluded that there is a relationship between an increase in IL-6 levels and response to treatment and there is room to deepen the research and examine the possibility of introducing IL-6 as a measure of response to treatment.

P3-01-28: Therapeutic Yoga Enhances Cognitive and Metabolic Markers in Breast Cancer Survivors

Minal Sonawane, G. J. Almeida, N. T. Darby, M. C. Serra, T. Calderon, A. Lapetoda, B. Gutierrez, A. G. Ramirez, D. C. Hughes, Darpan I. Patel

Background: Cancer-related cognitive impairment (CRCI) frequently arises as a consequence of breast cancer treatments, manifesting in challenges such as impaired memory, attention, processing speed, and word finding. These cognitive deficits ranging from mild to moderate, can persist for months or even years. They can negatively impact a survivor's quality of life, mental health, and interpersonal relationships. Moreover, breast cancer and its therapies adversely affect various metabolic processes in the body influencing factors such as weight changes, fat metabolism, energy regulation, dyslipidemia, growth hormone regulation and cardiovascular health. This study aims to investigate whether a 16-week therapeutic yoga program (TYP) modulates the cognitive and metabolic biomarkers profile in plasma among heterogeneous breast cancer survivors.
Approach: Participants included in the study were adults aged 18 and older with a clinical cancer diagnosis. Informed consent was obtained from all participants. Nineteen participants completed three weekly 75-minute sessions of TYP combined with love and kindness meditation. Blood samples were collected from sixteen participants both before and after the TYP intervention. Eight neuro and metabolic biomarkers viz, Beta-NGF, BDNF, Ghrelin, IL12P70, Leptin, MCP-1, TNF-Beta, VEGF-A were measured by a U-Plex Custom Metabolic Group1 (hu) Multiplex Assay on the MESO Quickplex SQ 120MM, Model 1300.

The data was analyzed using Wilcoxen signed rank test.
Results: The participants had a mean age of 59.6 years (± 7.3 years). Over half of the cohort (56%) were classified as overweight or obese (BMI ≥ 25 kg/m^2). The majority were female (71%) and breast cancer survivors (65%), with 44% of these survivors being of Hispanic ethnicity. Statistically significant increases were observed in concentrations of BDNF (pre: 653.50 vs post: 1234.17 pg/ml; 88.85%, P=0.005) and ghrelin (pre: 576.10 vs post: 710.80 pg/ml; 23.38%, P=0.04). Notably there was a marked difference found [PDI1] in VEGF-A (45.51% increase post TYP) and MCP-1 (19.79% decrease post TYP).
Conclusion: TYP contributed to substantial improvements in cognitive biomarkers in plasma samples from breast cancer patients. Future research utilizing larger cohorts is needed to validate these results.

P3-01-29: Open, single-arm clinical trial with innovative inPROBE® technology for in vivo, real-time, quantitative HER2 expression assessment

Dariusz Stencel, Wojciech Polkowski, Andrzej Kurylcio, Przemysław Kopyto, Marcin Staniszewski, Magdalena Staniszewska

Background: The current standard of HER2 expression assessment on breast cancer (BC) cells is IHC/FISH; however the results are imprecise. This significantly implies prognosis, therapy and reimbursement, especially in relation to HER2-low and ultra-low BC subtype.
Methods: We developed a new, innovative tool for quantitative assessment of HER2 expression on BC cells. This is real-time, in vivo inPROBE®, merging molecular biology with photonics technology. We conducted an interventional, open-label, single-arm safety and efficacy clinical investigation in female BC patient aged 18 to 75 years with known HER2 status based on IHC/FISH. The primary endpoint was identification of HER2 concentration ranges detected with microprobe corresponding to HER2 receptor status identified by IHC/FISH. The key secondary endpoint was to assess the relation between inPROBE assessment in tumor mass and surrounding area in the direct tumor vicinity in HER2-positive pts.
Results: There were 22 women with confirmed BC and known HER2 status enrolled, with 18 pts. finally included in statistical analysis (6 pts. with HER2+ and 12 pts. with HER2- BC). All pts. were in good clinical stage (ECOG PS=0). Mean (SD) age was 56.6 (10.6) years, range 39-77 years. The study met its primary endpoint. The ranges of HER2 concentrations corresponding to HER2- or + status were identified, with significant difference for minimum values in Wilcoxon exact test (significantly lower for HER2- than for HER2+ BC, p=0.041). The secondary endpoint was not met, but comparison of HER2 receptor concentrations detected with the microprobe located within the tumor and in the near tumor area in overall population (HER2+ and HER2-) showed moderately significant difference (p=0.046). This group could be heterogenous, possibly including patients with truly HER2- (0), but also HER2-low expression. Safety profile of device was good and promising. No adverse events were observed.

Conclusions: The current standard IHC/FISH method for HER2 expression assessment could be questioned and advances in targeted therapy may require more sophisticated technologies. Further clinical development of inPROBE® can be continued with no risks for patients' safety. inPROBE® technology could become promising tool, providing the oncologist with new, modern, real-time, in vivo diagnostic method; thus, meeting a pressing clinical need.

P3-01-30: Precision and Repeatability of PD-L1 Detection using PD-L1 IHC 22C3 pharmDx in Breast Cancer

Emily Olander, Jaret Quiroz, Joseph Barreto, Donna Kell, M.D., Siena Tabuena-Frolli, Camilla Recke, Megan Kalpakoff

PD-L1 IHC 22C3 pharmDx (SK006) is an FDA-approved qualitative immunohistochemical (IHC) assay validated for the detection of the programmed-death ligand 1 (PD-L1) protein in multiple tumor types, including triple-negative breast cancer (TNBC). TNBC is a breast cancer (BC) subtype that is negative for estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2).
In addition to TNBC, BC also includes a collection of sub-types known as non-TNBC (ER+, PR+, and/or HER2+). While precision and repeatability of PD-L1 IHC 22C3 pharmDx have previously been demonstrated on TNBC, these performance characteristics are less known for non-TNBC. Although non-TNBC is not an FDA-approved tumor type for the device, the goal of the studies listed herein was to determine and report the precision and repeatability of PD-L1 IHC 22C3 pharmDx on TNBC and non-TNBC specimens, collectively.
To evaluate the analytical performance of PD-L1 IHC 22C3 pharmDx for BC, the following studies were executed on formalin-fixed, paraffin-embedded (FFPE) BC specimens: intra-run repeatability (n=42), day-to-day testing variability (combined precision; n=41), as well as inter- and intra-observer precision (n=61). The specimen pool included the dynamic range of PD-L1 expression (CPS = 0–100) for each study. To mimic real-world subtype prevalence, the specimen pool consisted of approximately one third TNBC and two thirds non-TNBC. All specimens were prepared and stained according to the PD-L1 IHC 22C3 pharmDx package insert. The stained slides were scored using the combined positive score (CPS) algorithm and assigned an expression status (positive/negative) at the CPS ≥ 1 cutoff. CPS was determined by dividing the number of viable PD-L1-staining cells (tumor cells, lymphocytes, and macrophages) by the total number of viable tumor cells. Totals are multiplied by 100 and displayed as integers. Intra-run repeatability was scored by three certified observers, combined precision was scored by two certified observers, and inter- and intra-observer precision studies were scored by three certified observers. Negative percent agreement (NPA), positive percent agreement (PPA), and overall agreement (OA) were calculated for each study. Acceptance criteria (AC) were predefined, requiring a 95% confidence interval (CI) with a lower bound (LB) value of ≥ 85%. Agreement was based on the binary (positive/negative) PD-L1 expression status assigned to a stained slide by an observer.

All studies met the predefined AC. Intra-run repeatability of the assay achieved CI LB values of 94.3%, 97.1%, and 96.2% for NPA, PPA, and OA respectively. Combined precision achieved NPA, PPA, and OA CI LB values of 89.5%, 95.5%, and 93.5%, respectively. Inter-observer precision resulted in CI LB values of 90.8%, 93.9%, and 93.6% for NPA, PPA, and OA, respectively. Finally, intra-observer achieved NPA, PPA, and OA CI LB values of 94.4%, 96.4%, and 96.0%, respectively.
Overall, based on 95% CI LB values and the fulfilled AC, these studies demonstrate high precision and repeatability of PD-L1 IHC 22C3 pharmDx in the detection of PD-L1 expression in breast cancer (triple negative and non-triple negative, collectively). Further, these results feed into the growing body of research demonstrating CPS as a precise and reproducible scoring algorithm across multiple tumor types. In addition to strengthening confidence in the reliability of the device and scoring algorithm, these consistent results have a potential impact on breast cancer treatment; however, additional studies are required to confirm.

P3-02-01: Is Autologous Fat Grafting a Safe Option or a Risk of Cancer Recurrence in Women with Breast Cancer Who Carry Germline Pathogenic Variants?

Lucrezia Raimondi, Cora Schumacher, Barbara Veronese, Pasquale Buonandi, Rosaria Condorelli, Elena Trevisi, Lorenzo Rossi, Corrado Parodi, Daniel Schmauss, Yves Harder, Simone Schiaffino, Nickolas Peradze, Rossella Graffeo Galbiati

Background: Autologous fat grafting (lipofilling, LF) is widely accepted for breast reconstruction after cancer surgery (breast conservative treatment and mastectomy), due to its potential to improve aesthetic outcome. However, its long-term oncological safety in breast cancer patients with pathogenic germline variants (gPV) is still not well documented. This study aims to compare the incidence of local recurrence in breast cancer (BC) patients with gPV who underwent LF compared to those who received breast reconstruction without LF.
Methods: A retrospective, single-center, case-control study has been conducted, including BC women with gPV referred to the High Cancer Risk Clinic in southern Switzerland who underwent surgery followed by breast reconstruction with or without LF. Autologous fat was aspirated using a standard tumescent solution, yet neither centrifuged nor enriched. Patient demographic details, clinical information, reconstruction procedures, and fat grafting data were systematically collected.
Results: Among 897 women with BC referred for genetic counselling and testing, 132 carried heterozygous gPVs in the following genes: 44 (33%) in BRCA1, 39 (30%) in BRCA2, 1 (1%) in BRCA1 and BRCA2, 10 (8%) in CHEK2, 4 (3%) in PALB2, 8 (6%) in ATM, 1 (1%) in CDH1, 1 (1%) in PTEN, 3 (2%) in BRIP1, 3 (2%) in NTLH1, 2 (2%) in RAD51C, 2 (2%) in NBN and 1 (1%) in TP53. In addition, variants were identified in other cancer predisposition genes based on family history: 3 (2%) in MUTHY, 1 (1%) in CDKN2A, 2 (2%) in PMS2, 4 (3%) in CFTR, 1 (1%) in MSH6, 1 (1%) in MITF and 1 (1%) in SDHA. The median

age at cancer diagnosis was 42 years (range: 21-82). Out of the women included in the study, 54% underwent mastectomy, while the remaining 46% opted for breast-conserving surgery. A total of 25 LF procedures were performed, with an average of 2 sessions per patient (range: 1-4). Median follow-up was 84 months from the primary surgery (range: 12-408 months) and 36 months from the LF (range: 12-84 months). Thirty-seven cases of locoregional recurrence were observed, including 1 (4%, a BRCA1 triple-negative breast cancer not associated with ductal intraepithelial neoplasia) in the LF group and 36 (33.6%) in the no-LF group. Fourteen of these patients underwent mastectomy, and four had contralateral prophylactic mastectomy. For this group of patients, the results of the genetic tests were distributed as follows: 14 for BRCA1, 12 for BRCA2, 2 for ATM, 3 for CHEK2, 2 for MUTYH, 1 for NTLH1, 1 for NBN, 1 for PALB2 and 1 for TP53.
Conclusions: The current evidence does not support the opinion that the use of LF in reconstruction following mastectomy or conservative surgery in gPV carriers with BC significantly increases the risk of locoregional recurrence.

P3-02-02: Genetics and Breast Cancer: Insights and Challenges from Two Years of Analysis of the Private Health System in Brazil.

Letícia Linhares, Felipe Marcondes de Oliveira Coelho, Laura de Mello Andrade, Renata Capanema Saliba Franco, Virgínia de Assis Silva, Marcela de Oliveira Sá, Renata Viana Hoffmann Monteiro Guedes, Waldeir José de Almeida Junior, Anna Dias Salvador, José Tadeu Campos de Avelar

Introduction: Approximately 10% of breast cancers are associated with hereditary genetic mutations, notably genes linked to moderate risk of breast cancer (CHEK2 and ATM), and high risk (BRCA1, BRCA2, CDH1, PALB2, PTEN, STK11, and TP53). Patients with pathogenic variants in these genes are potential beneficiaries of individualized strategies, and therefore the study of these genes is useful in managing affected families.
The aim of this study was to evaluate pre and post-genetic test data of patients with breast cancer, as well as the implications of these results on patient management and follow up.
Methods: An observational, cross-sectional, and descriptive study was conducted in a private hospital in Belo Horizonte, Minas Gerais, Brazil. Data were obtained retrospectively from breast cancer patients who underwent oncogenetic medical appointments between 01/01/2021 and 12/31/2023. Clinical information from pre and post-genetic test consultations were collected, including test results, treatment implications, and absences from post-test appointments.
Results: This study included all the 126 patients who received genetic testing indications from the oncogenetic specialist. Ages at breast cancer diagnosis ranged from 26 to 90 years. Epidemiological characteristics are summarized at table 1.Remarkably, only 55.6% of patients returned for the post-test consultation, with 14.3% of them having pathogenic results in one of these genes: BRCA1, BRCA2, TP53, CHEK2, and MUTHY (Chart 1). Treatment impacts are described in Table 3. Likely pathogenic results were identified in 2,85% of cases and variants of uncertain significance (VUS) in 45.7% (Table 2).

Five patients had pathogenic mutations in BRCA genes and were indicated for contralateral prophylactic mastectomy. One underwent breast-conserving surgery without contralateral prophylactic surgery. Bilateral prophylactic salpingo-oophorectomy was not indicated for one patient under 40 years old. Of the other four patients, three underwent oophorectomy. None used adjuvant PARP inhibitors (PARPi). The three patients with pathogenic TP53 mutations underwent contralateral prophylactic mastectomy and Li-Fraumeni syndrome screening. Patients with pathogenic mutations in MUTHY and CHEK2 were not candidates for risk-reducing surgery and received high-risk screening.
Discussion: Genetic testing could bring positive implications. A study published by Bae et al. showed that women at high-risk of breast cancer who underwent screening with mammography and MRI had better overall survival than those screened with mammography alone. Furthermore, the use of PARPi as adjuvant therapy increases progression-free survival, as well as overall survival in the early setting, which justify genetic testing in candidates for PARPi.
Confirming the impact of genetic counseling, in this present study, 90% of the patients who returned with pathogenic mutations received additional interventions due to the test results, with 80% being risk reduction surgeries.
Despite these findings, it is alarming that over 40% of our patients did not attend the post-test appointment. Considering that over 17% of our sample had a pathogenic or likely pathogenic mutation, it is concerning the number of patients that could potentially have their clinical management and counseling compromised.
A publication by Mansilla et al. also showed a low success rate for genetic counseling consistent with our data. This reflects a paradoxical trend between increasing test availability and low patient adherence to comprehensive genetic counseling. This phenomenon may be due to low patient understanding, and anxiety about the responsibility of sharing results with their relatives.
Conclusion: In a scenario of widespread genetic testing, and its positive effects, it is equally important to improve genetic counseling strategies, and implement close surveillance to maximize the benefits of oncogenetics.

P3-02-03: HEPARANASE LIQUID BIOPSY AND BREAST CANCER

Daniel Gimenes, Gislaine Patricia Andrade, Afonso Celso Pinto Nazario, Maria Aparecida da Silva Pinhal

Background: Breast cancer is a complex disease with high clinical and genetic heterogeneity and represents a public health problem worldwide, as it is among the four main causes of premature death in most countries. The molecular profile of solid tumors may be established using surgical or biopsy tissue samples. However, tissue-based tumor profiles are subject to sampling bias, provide only a snapshot of tumor heterogeneity, and cannot be obtained repeatedly. Therefore, analyses of circulating nucleic acids, blood samples, or other body fluids, commonly called liquid biopsies, can also contain tumor-derived genetic information. Liquid biopsy represents an innovative method that has gained prominence in recent years, a significant change in how we diagnose and monitor various diseases,

especially cancer. Previous studies from our group showed that circulating lymphocytes obtained from patients with breast cancer have higher glycosidase heparanase (HPSE1) expression. Objective: We aimed to investigate the expression of HPSE1 in circulating T-lymphocytes collected from blood samples of patients with breast cancer compared to the control group (women not affected by neoplasms). Methods: To obtain the mononuclear cell fraction, T-lymphocytes were extracted using Ficoll-paque (Sigma-Aldrich) from the collected peripheral blood sample. Total RNA was extracted from T-lymphocytes with Trizol (Invitrogen), following the manufacturer's instructions. After obtaining the cDNA by reverse transcription, the expression of HPSE1 was evaluated by quantitative PCR. Results: A significant increase in the expression of HPSE1 was observed in T-lymphocytes obtained from breast cancer patients compared to unaffected individuals. The results also showed higher expression according to the different molecular subtypes of breast cancer (Luminal B, HER2 positive, and triple-negative). Conclusion: We conclude that expression analyses of HPSE1 using liquid biopsies allow a non-invasive and real-time assessment, favoring prospective studies where early diagnoses and personalized treatments can be developed.

P3-02-04: Phase II, Single Arm Trial of Denosumab's Effect on Breast Density and Breast Tissue Biomarkers

Patricia Thompson, Krisha Mehta, Jie Yang, Chuan Huang, Yunhan Liao, Eduardo Scandinari Manzolli, Christina Preece, Caterina Vacchi-Suzzi, Alison Stopeck

Background: Receptor activator of nuclear factor-κB (RANK) and its ligand (RANKL) regulate bone metabolism, immune tolerance, immunity, and mammary gland biology. RANKL, induced by progesterone, prolactin, vitamin D3, PTHrP, TNF-α, prostaglandin E2, and interleukins, impacts osteoclast differentiation, lymph node formation, breast cell proliferation, and immune regulation. RANKL/RANK is essential for mammary stem and progenitor cell populations linked to progesterone and BRCA1 mutation-driven breast cancers. This pilot investigated RANKL inhibition with denosumab, a therapeutic anti-RANKL antibody, to assess effects on breast density in postmenopausal women. Methods: This single-arm, open-label pilot administered 120 mg of denosumab subcutaneously monthly for 6 doses to postmenopausal early-stage breast cancer patients. Patients may have received aromatase inhibitors. Those on SERMs were ineligible. Breast density was measured by MR imaging of the breast at baseline and after 6 months. Analysis was performed on 25 evaluable patients. The primary endpoint was the MRI-measured breast density (MRD) change from baseline to the end of study, approximately one month after last injection. A ≥5% relative decrease in breast density in ≥ 30% of participants was predefined to warrant a larger study. Results: Thirty postmenopausal women with a history of breast cancer received the intervention, 25 evaluable with 5 excluded (withdrew consent, image distortion, or ineligibility). All evaluable patients completed baseline and 6-month MRI measurements and received at least 5 doses of monthly denosumab. Median age was 60 years, median BMI was 28.5 kg/m2, and 44% were on aromatase inhibitors. Median baseline MRD was 16.2% (range 4.91-45.34%). Fourteen (56%) were characterized as

heterogeneously dense (BI-RADS c), one (4%) extremely dense (BI-RADS d), and ten (40%) as scattered fibroglandular by mammography. Excluding two high density outliers, baseline RANKL correlated with breast density (Spearman's rho = 0.51). All patients had undetectable RANKL levels after 6 months of denosumab. Relative MRD decreased by -8.19% (mean) and -6.34% (median) for the primary endpoint after 6 months. Fifteen subjects (60%, 95% CI= 42-75%) had a relative MRD decrease of ≥5%, with only two (8%) increasing. There was no significant correlation between changes in MRD and baseline MRD, age, BMI, or baseline RANKL levels. As a reference, a similar population of postmenopausal women on aromatase inhibitors (N=39) followed for 6 months, 21% had a decrease in MRD of ≥5%, 46% had no change, and 33% had an increase of ≥5%. The difference between DMAB and the ref group remained significant after multivariate adjustment (p=0.01). Denosumab was well tolerated, with no significant or unexpected toxicities. Seventeen doses were administered at home by an RN. Exploratory analyses of a subset of patients with available breast biopsies revealed potential correlations between change in MRD following denosumab treatment and baseline immune cell phenotypes including for example higher baseline RANKL+/CD8+ T cells in participants with greater decreases in MRD at 6 months (rho= -0.49, p= 0.10). Conclusions: In this pilot, therapeutic suppression of RANKL for putative breast cancer prevention was well-tolerated and could be administered at home. RANKL levels correlated with baseline breast density, and treatment for 6 months was associated with a reduction in breast density that favors effects of RANKL inhibition on breast tissue. Our results support further studies to define denosumab and RANKL's effects on breast density, including effects that may be mediated through a RANKL-positive breast immune microenvironment in postmenopausal women.

P3-02-05: Mitochondrial Metabolism-Related Features Guiding Precision Subtyping and Prognosis in Breast Cancer, Revealing FADS2 as a Novel Therapeutic Target

Yangyang Cui, Yakun Kang, Yiqin Xia, Yue Huang, Shui Wang, Hui Xie

Background: Breast cancer is one of the most common malignant tumors in women. Mitochondria are critical components within cells. Changes in mitochondrial metabolism play a crucial role in regulating tumor cells and further impacting clinical prognosis. However, their interplay in breast cancer remains a pending issue. This study aimed to reveal the relationship between mitochondrial metabolism-related genes and breast cancer by constructing risk features.

Methods: Breast cancer transcriptome chip data were obtained from TCGA and GEO, while mitochondrial gene data were downloaded from the MitoCarta3.01 database. The "ConsensusClusterPlus" package was used for clustering analysis, with subsequent processing for GSEA, GO, and KEGG pathway analyses. A prognosis model for breast cancer was established using Cox regression and LASSO algorithms. The CIBERSORT algorithm and MCPcounter algorithm were utilized to calculate each patient's immune cell infiltration level. Additionally, the expression of pivotal genes in breast cancer patient tissue specimens

and cell models was validated to verify their association with biological functions in breast cancer cells.
Results: We employed the LASSO regression algorithm to reveal mitochondrial metabolism-related genes in the TCGA BRCA dataset and identified four prognosis-related genes (MYH11, LTF, FADS2, and PSPHP1). These findings were further validated through analysis using the GEO dataset. Based on the four-gene prognosis model derived from mitochondrial metabolism, breast cancer patients with a high-risk score had shorter overall survival compared to the low RS patient group. Immunological analysis revealed that patients with higher risk scores were more likely to be unresponsive to immunotherapy but more sensitive to several conventional chemotherapies, suggesting the potential strategy of combining chemotherapy with immunotherapy to enhance the efficacy of current T cell-based immunotherapy. Univariate and multivariate Cox regression analyses validated the mitochondrial gene model as an independent prognostic indicator for predicting overall survival. They established a nomogram based on the mitochondrial gene model to predict the prognosis of breast cancer. Inpatient tissue validation, pivotal genes exhibited an expression trend consistent with the results of bioinformatic analysis. Finally, through cellular experiments, we verified the expression and function of the key gene FADS2, finding that FADS2 was highly expressed in breast cancer cell lines, and upon its knockout, the cell's invasion, migration, and colony-forming abilities were significantly reduced.
Conclusion: This work demonstrates that prognostic features based on mitochondrial-related genes are related to clinical outcomes, tumor progression, and genetic alterations. Our research findings may provide insights for developing new targets for breast cancer treatment, early intervention, and prognosis prediction.

P3-02-06: Prevalence of BRCA1/2 Mutations in Low ER Positive/HER2 Negative Breast Cancer: Clinico-Pathological Parameters and Comparisons with Unselected TNBC

Ji Won Yoo, Jinyoung Byeon, Jisun Kim, Han-Byoel Lee, Sung Gwe Ahn, Seung Ho Baek, Jeong Eon Lee, Se Kyung Lee, Byung Joo Chae, Jonghan Yu, Seok Won Kim, Seok Jin Nam, Tae-Kyung Yoo, Jai Min Ryu

Introduction: Following the 2010 ASCO guidelines' establishment of a 1% ER positivity threshold, numerous studies have identified the clinical parallels between ER low positive & HER2 negative breast cancer (Low-ER) and triple-negative breast cancer (TNBC), noting an elevated BRCA1/2 mutation incidence in Low-ER cases. Despite NCCN guidelines advocating for genetic testing in all TNBC patients, Low-ER cancers have yet to receive similar consideration. This investigation aims to assess the prevalence of BRCA1/2 mutations and associated clinicopathological features in unselected Low-ER cases, and to compare the BRCA1/2 prevalence with that observed in unselected TNBC.
Methods: This multicenter, retrospective, non-randomized single-arm study analyzed data from January 2014 to December 2022 at Samsung Medical Center, Seoul National University Hospital, Asan Medical Center, and Gangnam Severance Hospital. The study included adult

females with primary Low-ER & HER2 negative breast cancer, excluding those without biobank samples, with mixed IHC subtypes, or with synchronous breast cancers of different IHC types. Buffy coat samples from biobanks were used to supplement cases without prior BRCA1/2 mutation tests. Comparative analysis with TNBC was based on data from a previous study by Park, W.K., et al, examining BRCA prevalence in TNBC patients from June 2008 to January 2016 at Samsung Medical Center[1].
Results: Of the 268 Low-ER patients, 94 had prior genetic testing, and 174 were assessed via buffy coat analysis. BRCA1/2 mutations were detected in 13.8% of Low-ER patients, with significant variation across age groups: 43.2% in patients aged ≤40, 51.4% in those aged 41-60, and 5.4% in patients over 60 years (p=0.002). The prevalence of BRCA1/2 mutations in Low-ER patients was not significantly different from that in TNBC patients, with 12.8% of TNBC patients carrying the mutations (p=0.666). Age-stratified BRCA prevalence in the TNBC group was 33.6% for patients ≤40 years, 59.8% for those 41-60 years, and 6.6% for those >60 years, with no significant differences from the Low-ER group (p=0.328, 0.868, and 0.729, respectively). In the Low-ER group, patients with a family history of breast or ovarian cancer had a significantly higher mutation rate (51.4%) compared to those without (15.3%), with an odds ratio of 5.851 (95% CI 2.796-12.243, p<0.001).
Conclusion: The study reveals that the prevalence of BRCA1/2 mutations in Low-ER patients is comparable to that in TNBC patients. This finding supports the extension of BRCA1/2 mutation testing guidelines to include Low-ER patients, similar to those for TNBC, to enhance treatment planning.

P3-02-07: Breast Cancer Polygenic Risk Score and Patient Survival Outcomes Among Caucasians

Arya Mariam Roy, Nur Zeinomar, Haiyang Sheng, Janise M. Roh, Cecile A. Laurent, Isaac J. Ergas, Jennifer Delmerico, Qianqian Zhu, Marilyn L. Kwan, Lawrence H. Kushi, Christine B. Ambrosone, Song Yao

Introduction: Genome-wide association studies have identified many common, low-penetrance variants associated with breast cancer risk. This has led to the development of polygenic scores (PGS) to aggregate the effects of individual variants for risk prediction. However, the genetic determinants of breast cancer-related outcomes remain largely unknown. We hypothesize that breast cancer patients with high PGS are at an increased risk of experiencing a second breast-related adverse event, such as recurrence, contralateral breast cancer, or death.
Methods: The study is based on the Pathways Study, which is a prospective cohort study of breast cancer survivors enrolled shortly after diagnosis in 2006-2013 at Kaiser Permanente Northern California, with ongoing follow-up. Genome-wide genotype data were available

from 3,995 patients for calculation of 4 PGS, including PGS313, PGS4k, PGS5k and PGS6m. Scores were categorized into tertiles to investigate their associations with 7 survival outcomes including recurrence, contralateral second primary breast cancer, other second primary cancer, and death. Hazard ratios (HR) and 95% confidence intervals (CI) were derived from multivariable Cox proportional hazards regression models. The models were adjusted for age at diagnosis, race and ethnicity group, tumor stage, tumor grade, IHC subtype, surgery, radiotherapy, chemotherapy, and endocrine therapy.
Results: The median age at diagnosis was 60 (23.6-94.8) years and most (68%, n= 2696) patients self-identified as Non-Hispanic whites. Many women had estrogen receptor (ER)+ (83.4%), stage I and II tumors (89%), with 13.3% HER2+ tumors. The majority (60%) received lumpectomy and some type of adjuvant therapy (44.3% radiotherapy, 47.0% chemotherapy, and 74.6% received hormonal therapy). By December 31, 2021, the median follow-up time was 10.5 (0.2-14.2) years. In the overall cohort, there were 504 recurrences, 419 total second primary cancers (146 contralateral and 237 non-breast), and 762 deaths (352 breast cancer-specific). Among Non-Hispanic whites, there were 333 recurrences, 322 total second primary cancers (113 contralateral and 184 non-breast), and 558 deaths (224 breast cancer-specific).
In the overall cohort, breast cancer patients with high (T3) PGS313 had a higher risk of recurrence (HR 1.29, 95% CI: 1.02-1.61, p=0.04), all-cause death (HR 1.28, 95% CI: 0.96-1.31, p=0.03), total breast cancer events (HR 1.29, 95% CI: 1.04-1.54, p=0.02) and invasive breast cancer events (HR 1.34, 95% CI: 1.09-1.63, p=0.006) compared to those with low (T1) PGS313. Although breast cancer-specific death was observed to be higher among those with high PGS313 in the overall cohort, it was not statistically significant (HR 1.34, 95% CI: 0.99-1.73, p=0.007).
In the subgroup analysis, it was observed that Non-Hispanic White breast cancer patients with high (T3) PGS313 had similar higher risk of recurrence (HR 1.29, 95% CI: 1.06-1.83, p=0.04) but not contralateral breast cancer (HR 1.22, 95% CI: 0.76-1.94, p=0.58) or other second primary cancers (HR 1.01, 95% CI: 0.77-1.34, p=0.86). They also had a higher risk of all-cause death (HR 1.30, 95% CI: 0.99-1.41, p=0.04), breast cancer-specific death (HR 1.53, 95% CI: 1.08-2.15, p=0.03), and invasive breast cancer (HR 1.33, 95% CI: 1.06-1.71, p=0.02). The other three PGS were not associated with survival outcomes in either the overall or Non-Hispanic White cohorts examined.
Conclusions: Breast cancer patients with higher PGS313 scores were found to have an elevated risk of recurrence, invasive breast cancer events, and death. These results suggest that breast cancer PGS may have additional prognostic utility in patients diagnosed with the disease, indicating the need for further investigation.

P3-02-08: Incorporating Breast Radiomics and Body Mass Index to Improve Breast Cancer Risk Prediction in Minority Women

Sara Wallam, Vicky Ro, Shivangi Kwatra, Alissa Michel, Julia McGuinness, Simukayi Mutasa, Richard Ha, Katherine Crew

Introduction: Obesity and increased breast density are both independent risk factors for the development of breast cancer. However, mammographic density and body mass index (BMI) are inversely related. We previously demonstrated that an artificial intelligence (AI)-based radiomics method, such as a convolutional neural network (CNN) applied to screening mammograms, can improve breast cancer risk prediction when combined with established clinical risk factors, particularly among Black and Hispanic women. We evaluated whether the addition of BMI and CNN would improve performance of the Breast Cancer Surveillance Consortium (BCSC) model, version 2, among racially/ethnically diverse women undergoing screening mammography.
Methods: We conducted a retrospective cohort study among women, age 35-74, who underwent screening mammography at Columbia University Irving Medical Center (CUIMC) in New York, NY between 2014 and 2018 and who had available BMI data and mammograms evaluable for CNN analysis. We extracted data from the electronic health record (EHR) on age, race, ethnicity, first-degree family history of breast cancer, prior breast biopsy results, mammographic density, height, weight, and BMI. We compared the predictive performance of two hybrid models against the traditional BCSC model using area under the receiver operating characteristics curves (AUCs) and the DeLong test. Hybrid model 1 added CNN risk scores (score 0-1) to traditional BCSC clinical risk factors, and hybrid model 2 added BMI and CNN risk scores to the BCSC clinical risk factors.
Results: Among 14,558 evaluable women, mean age was 56.2 years (SD, 9.6 years) with 27.2% non-Hispanic White, 35.4% Hispanic, 9.4% non-Hispanic Black, 4.5% Asian, and 23.5% other/unknown race/ethnicity. Almost half (43.6%) of women were obese. Within five years of the baseline mammogram, 99 women were subsequently diagnosed with invasive breast cancer. Compared to the performance of the BCSC model (AUC=0.656, 95% confidence interval [CI]=0.602-0.711), hybrid model 2 (BCSC + CNN + BMI) had a significant improvement in breast cancer risk prediction (AUC=0.695, 95% CI=0.643-0.747, p=0.031). In particular, adding CNN and BMI to the BCSC model significantly improved breast cancer risk prediction among non-Hispanic Black and Hispanic women. Compared to the performance of the BCSC model among non-Hispanic Black women (AUC=0.556, 95% CI=0.341-0.770), hybrid model 1 (BCSC + CNN) and hybrid model 2 performed better (AUC=0.838, 95% CI=0.732-0.944, p=0.033 and AUC=0.846, 95% CI=0.756-0.936, p=0.019, respectively). A similar pattern was observed for Hispanic women for the BCSC model (AUC=0.600, 95% CI=0.514-0.687), hybrid model 1 (AUC=0.661, 95% CI=0.572-0.750, p=0.059) and hybrid model 2 (AUC=0.673, 95% CI=0.588-0.758, p=0.031).
Conclusions: Among women undergoing screening mammograms, the addition of BMI and CNN risk scores to the BCSC risk model improved breast cancer risk prediction, especially among racial/ethnic minorities. The new BCSC model, version 3, now incorporates BMI with improved breast cancer risk prediction, especially among obese women. More accurate breast cancer risk prediction may improve personalized screening and prevention strategies for diverse populations.=

P3-02-09: Correlation between risk groups and molecular subtype of breast cancer with metabolic syndrome and ethnicity

Sharda P. Singh, Chathurika Samudani Dhanasekara, Michael W. Melkus, Reshad S. Ghafouri, Soroush Shahrokh, Flavia Sardela de Miranda, Maria F. Mahecha, Adam Brufsky, Joyce O'Shaugnessy, VK Gadi, Cathy Graham, Mehran Habibi, William Audeh, Sahra Uygun, Lavanya Samraj, Rakhshanda Layeequr Rahman

Background: Breast cancer (BC) is the most common malignancy among women worldwide. Comprehensive genomic profiling has been widely used to identify molecular biomarkers and signatures for developing novel therapeutic strategies. BC is a complex disease; besides the genomic and molecular characterization of tumors, racial/ethnic classification and body mass index (BMI) are key determinants of treatment outcomes. To explore gene-to-phenotype relationships, we obtained transcriptomic and clinical data from 978 patient samples comprising all four BluePrint® (BP) subtypes: Luminal A, Luminal B, HER-2, and Basal, representing ~25% of each genomic subtype. We investigated the association of biomarkers of inflammation, apoptosis, oxidative stress, autophagy, and ER stress in patients with BC and correlated them with BMI, menopausal status, and ethnicity.
Method: The FLEX registry (NCT03053193) enrolled 14000 patients with stage I-III BC across 90 institutions in the United States and stratified risk groups based on the 70-gene signature (MammaPrint®, (MP)) and molecular subtype based on the 80-gene signature (BP). We obtained transcriptomic (110 genes) and clinical data from 978 patient samples, representing ~25% of each genomic subtype. Principal component analysis (PCA) was conducted using the 'PCAtools' package in R to reduce the gene expression data's dimensionality and identify major variation patterns among the samples. Analysis of variance (ANOVA) was performed between groups using the first five principal components (PCs). The family-wise error rate was set at 0.05, using the modified Holm-Bonferroni approach.
Results and Conclusion: Of the 978 patients (Caucasians:81.7%; African Americans:2.58%; other races: 5.7%), the risk or genetic profile was as follows: MP: Ultra-Low = 76 (8%), Low = 176 (18%), High1 = 315 (32%), and High-2 = 411 (42%); BP: Luminal A 250 (26%), Luminal B = 250 (26%), HER2 = 228 (23%), and Basal = 250 (26%). The mean age was 58.84±13.04, the average BMI was 30.04±7.34, and the majority were postmenopausal (n = 717, 73%). The first five PCs accounted for 63.11% of the total variance of the dataset. These five PC loadings (variable contributes) were enriched for genes associated with various cellular mechanisms, including glucose metabolism, cellular growth, resistance to cell death, angiogenesis induction, oxidative stress handling, and epigenetic modifications. Interestingly, the pairs plot comparing PC1 through PC5 showed a certain degree of clustering and PC4 (total variance of 4.59%) indicated distinct clustering for each molecular subtype. The biplot for PC1 and PC4 showed a certain degree of separation when intrinsic molecular subtypes and risk of recurrence categories were used. SOD2, KLK5, KLK7, and IL8 showed a strong positive correlation with PC4, whereas GLI1 showed a strong negative correlation with PC4. The loading plot also showed a positive loading for SOD2, indicating a significant role of SOD2 in differentiating distinct molecular subtypes. Comparisons of PCs

with clinical variables showed that PC4 was significantly correlated with all baseline clinical variables, including age ($p < 0.001$), BMI ($p = 0.001$), race ($p < 0.001$), menopausal status ($p = 0.001$), molecular subtype ($p < 0.001$), and risk of recurrence ($p < 0.001$). Additionally, PC4 was also found to be significantly correlated with tumor size ($p < 0.001$), lymph node status ($p < 0.001$), and the presence of distant metastasis ($p < 0.001$).
In conclusion, our findings demonstrate that genes in PC4 play a crucial role in discriminating known molecular profiles when different risk categories, as it is significantly associated with baseline characteristics, and risk of recurrence. Further analysis should be conducted to explore genes that contribute to PC4, such as SOD2. These results highlight the potential of SOD2 as a prognostic biomarker and a therapeutic target in breast cancer.

P3-02-10: Evaluation of a polygenic risk score as a predictor of breast cancer, triple-negative breast cancer, and early-onset disease in Hispanic women.

Holly Pederson, Matthew Kucera, Eudora Hu, Brooke Hullinger, Timothy Simmons, Elisha Hughes

Background: Hispanic women in the U.S. have a lower incidence of breast cancer (BC) when compared to non-Hispanic white (NHW) women. However, Hispanic women diagnosed with BC tend to be younger, have more advanced disease at presentation, and have a higher risk of BC mortality compared to NHW women. Some studies have suggested that these differences may be due, in part, to a higher prevalence of aggressive subtypes, including triple-negative BC (TNBC). More accurate risk prediction methods are urgently needed to identify young Hispanic women with elevated risk of BC.
Incorporating polygenic risk scores (PRS) into clinical models can substantially improve risk assessment, but most PRS have demonstrated poor performance among non-European ancestries. We previously described a multiple-ancestry PRS (MA-PRS) based on 56 ancestry-informative and 329 BC-associated single-nucleotide polymorphisms (SNPs). MA-PRS predicts overall BC risk for diverse populations by characterizing genetic ancestry at each BC SNP and applying ancestry-specific SNP risks and frequencies.
Here, we evaluated the extent to which MA-PRS improves upon clinical factors for the prediction of overall BC, TNBC, and early-onset (< 50 years of age) disease in a large, independent cohort of self-reported Hispanic women.
Methods: We examined clinical and genetic records from self-reported Hispanic women referred for hereditary cancer testing from 8/22 – 9/23 and negative for pathogenic variants in BC-associated genes. The association of MA-PRS with overall BC, TNBC and early-onset disease was analyzed using multivariable logistic regression adjusted for personal and family cancer history, age, and genetic ancestry. Analyses were conducted within the full cohort and the subpopulation of patients < 50 years old. Odds ratios (OR) are reported per standard deviation (SD) with 95% confidence intervals (CI).
Results: 12,384 Hispanic women met the study eligibility criteria. A total of 2,071 (16.7%) were diagnosed with BC. Of those, 876 (42.3%) were diagnosed with early-onset BC, 196

(9.5%) were diagnosed with TNBC, and 86 (4.2%) were diagnosed with early-onset TNBC. Most (59.7%) of those diagnosed with BC had no family history of breast or ovarian cancer. MA-PRS significantly improved upon clinical factors for the prediction of overall BC (OR 1.63; 95% CI 1.53-1.73), early-onset BC (OR 1.62; 95% CI 1.49-1.76), TNBC (OR 1.42; 95% CI 1.22-1.67) and early-onset TNBC (OR 1.48; 95% CI 1.18-1.86). This effect of MA-PRS on risk stratification compares favorably to the 1.4 OR per SD reported in the current literature for mammographic density, which is widely recognized as an important risk factor.
Conclusions: MA-PRS substantially improved upon clinical factors for the prediction of overall BC, TNBC and early-onset disease in a large cohort of Hispanic women. Incorporation of MA-PRS into BC risk assessment has the potential to improve BC survival through more accurate identification of women at high risk.

P3-02-11: CDH1 genotype exploration in phenotype-first approach with hereditary lobular breast cancer syndrome

Giovanni Corso, Elena Marino, Cristina Zanzottera, Sara Gandini, Elena Guerini-Rocco, Debora Macis, Sergio Vincenzo Taormina, Matteo Dal Molin, Giulia Massari, Paolo Veronesi, Bernardo Bonanni, Viviana Galimberti

Background: Pathogenic or likely pathogenic (P/LP) germline CDH1 variants confer a significant risk for diffuse gastric cancer (DGC) and lobular breast cancer (LBC) development within the known hereditary diffuse gastric cancer (HDGC) syndrome. Classically, LBC is part of this pleiotropic inherited cancer predisposition. However, in some circumstances, LBC can be the first (and unique) manifestation in P/LP germline CDH1 carriers, also in the absence of diffuse gastric cancer (DGC) manifestation. Recently, we introduced a newly concept, the so-called “hereditary lobular breast cancer” (HLBC) syndrome. HLBC is defined in this context by the presence of a P/LP CDH1 variant in either an isolated individual with early-onset LBC, or in women with bilateral LBC, or in a family with one or more LBC cases in first-degree or second-degree relatives, but no known DGC in either situation.
Objectives: The aim of this phenotype-genotype study was to assess the frequency of germline CDH1 variants in women with the HLBC phenotype fulfilling pre-established clinical criteria. Genomic inactivation was also analyzed in matched tumor samples in germline CDH1 variant carriers, and the association of genetic profiles with clinical-pathological data and survival. The BRCA1 and BRCA2 genes were also tested to verify a possible association (or exclusion) between CDH1 HLBC and the hereditary breast-ovarian cancer syndromes in these families. The main outcome was to define an accurate estimate of prevalence of germline CDH1 variants among patients with HLBC and the association of somatic sequence alteration with HLBC syndrome.
Methods: This cohort study was approved by the European Institute of Oncology ethical committee, and all available participants gave their written consent to be included in the study. The single-center, longitudinal, prospective cohort study was conducted from January 1, 1997, to December 31, 2021. Women with LBC observed at the European

Institute of Oncology, Milan, Italy, were included. Testing for germline CDH1, BRCA1, and BRCA2 genes was performed. Somatic and epigenetic profiling were assessed for germline CDH1 carriers, exploring intragenic loss of heterozygosity (iLOH), promoter CDH1 methylation and second somatic variant. Additional 324 genes were explored in tumor samples using the FoundationOne CDx assay. The Kaplan-Meier method and a multivariable Cox proportional hazards regression model were applied for overall and disease-free survival analysis.
Results: Of 5429 cases of primary LBC, HLBC phenotype was reported for 1867 (34.4%). A total of 394 women with LBC were available for genetic testing, among whom 15 germline CDH1 variants in 15 unrelated families were detected. Among these variants, 6 (40.0%) were P/LP, with an overall frequency of 1.5% (6 of 394). Of the 6 probands with P/LP CDH1 LBC, 5 (83.3%) had a positive family history of BC and only 1 (16.7%) had sporadic juvenile early-onset LBC (with age at diagnosis ≤45 ys). No germline BRCA1 and BRCA2 variants were identified in CDH1 carriers. An inactivating CDH1 mechanism (second hit) was revealed in 4 of 6 explored matched tumor samples (66.7%) in P/LP germline carriers. In HLBC tumor samples, structural alterations (iLOH and mutations) were identified with a higher frequency (86%), respect to epigenetic mechanisms (methylation). We noted a high accumulation of genomic aberrations in HLBC samples compared with sporadic LBCs. The P/LP CDH1 LBC variant carriers had a significantly lower age at diagnosis compared with the group carrying CDH1 variants of unknown significance or likely benign (42.5 [IQR, 38.3-43.0] vs 51.0 [IQR, 45.0-53.0] years; P=.03).
Conclusions: In this cohort study, P/LP germline CDH1 variants were identified in women not fulfilling the classic clinical criteria for HDGC screening, suggesting that detection of these variants may suggest a novel approach to test women with LBC with early age at diagnosis and/or positive family history of BC.

P3-02-12: Hereditary breast cancer risk assessment and referral at a high-volume, diverse mammography clinic

Emily L. Podany, Shaili Tapiavala, Katherine Glover-Collins, Erin Linnenbringer, Stacey Ballard, Helen Blair, Tabassum Ahmad, Amy Cyr, Meg Thaier, Jessica McDowell, Amanda Golden, Sarah Addison, Elizabeth McFarland, Lannis Hall, Foluso Ademuyiwa, Graham Colditz, Timothy Eberlein, Bettina Drake, Debbie Bennett, Katherine Weilbaecher

Background: Despite treatment innovations and decreasing cancer mortality, Black and White patients (pts) in the United States have persistent inequities in breast cancer outcomes. Non-Hispanic Black women have the highest incidence rates of breast cancer between 20 and 39 years of age. The American College of Radiology (ACR) recommends breast cancer risk assessment for all women, particularly Black women, by the age of 25. In the St. Louis metropolitan area, pts residing in the North and Eastern regions with high Black populations are more likely to have late-stage breast cancer diagnoses.
Methods: In 2023, the Breast Cancer Equity Group at Siteman Cancer Center began a program to give on-site real-time screening mammography results and a hereditary cancer

risk assessment delivered by a breast health nurse navigator to pts in North County. During the under-30-minute waiting period from completion of the mammogram to the delivery of results, the nurse navigator asked pts 5 family cancer history questions developed by medical oncology, genetics, surgical oncology, and public health researchers based on NCCN guidelines. If they would meet NCCN criteria for genetic counseling and testing, they were referred to a high-risk breast clinic. We performed retrospective chart review on all pts screened to determine screening outcomes of high-risk vs normal-risk pts and which pts were previously flagged as high-risk in the electronic medical record (EMR).
Results:
Between September 2023 and April 2024, 154 pts were seen in the same day screening mammography and breast cancer risk assessment clinic, of whom 72.1% (111/154) self-identified as Black and 19.5% (30/154) were under the age of 50. Over one third of the pts coming in for a routine screening mammogram - 34.4% (53/154) - were determined to be high-risk for breast cancer, of whom 69.8% (37/53) were Black. All pts that screened as high-risk were offered referral to the high-risk breast clinic by the navigator. 75.5% (40/53) of the high-risk pts agreed to be referred to this clinic for further evaluation. In the high-risk group, 11.3% (6/53) of the pts had a mammogram at the appointment requiring follow-up, defined as BI-RADS 0, and 3.8% (2/53) were diagnosed with breast cancer. None of the pts requiring further imaging were lost to follow-up. In the normal risk group 3.0% (3/99) had abnormal mammograms and 1.0% (1/99) were diagnosed with breast cancer. In pts under the age of 50, 50% (15/30) screened as high-risk, 73.3% (11/15) of whom were Black. 75.5% (40/53) of the high-risk pts had relevant cancer family history data already documented in the EMR, but only 9.4% (5/53) had their cancer risk mentioned in the EMR by a physician. In this high-risk cohort, whose family cancer history was generally documented in the EMR, 54.7% (29/53) were overdue for a mammogram.
Discussion: While it is imperative that we understand the socioeconomic factors behind the ongoing racial inequities in breast cancer, it is also important to consider potential differences in cancer gene mutation prevalence between Black and White pts and their associated risks for cancer development at a young age. Our findings in this population highlight the need for more widespread genetic risk screening, as over a third of the pts screened positive as high familial risk for breast cancer. It may not be enough to rely on the EMR, as most of these pts had documented family cancer history but very few were flagged as high-risk. It is also key to consider risk screening at a younger age as per ACR guidelines, as 50% of the women under age 50 were classified as high-risk by family history yet over half were overdue for a mammogram. Our future implementation science projects will focus on disseminating this risk assessment to more clinics including primary care, bolstering the existing infrastructure to further support the high-risk breast clinic, and improving communication on screening benefits in the community to improve timely screening mammography.

P3-02-13: Global disparities in breast cancer screening programs and breast cancer mortality

Syed Mahfuz Al Hasan, Debbie L. Bennett, Adetunji T. Toriola

Background: Breast cancer screening is effective in reducing breast cancer mortality. Nevertheless, there is a lack of data on whether having a national breast cancer screening program has an impact on breast cancer mortality. In this study, we performed a comprehensive assessment of the associations between breast cancer screening programs and the mortality attributable to breast cancer in the 194 countries.
Methods: Global breast cancer screening data were collected from the WHO Global Health Observatory database. Correspondingly, breast cancer mortality data were procured from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2019 database. Our analysis incorporated 48,960 data points embedded within 1632 cohorts, to estimate annual changes in breast cancer mortality at global, regional, and national levels from 2015 to 2019. We used a joinpoint regression model with a data-driven Bayesian information criterion method for calculating the annualized changes in breast cancer mortality. The significance level of the difference in mortality between countries with and without screening programs was assessed using bootstrap methods.
Results: Over the 2015-2019 period, about half of the countries (97 out of 194) reported implementing breast cancer screening programs that target the general population. Notably, countries with screening programs showed a significant annual reduction in age-standardized breast cancer mortality rates compared to countries lacking regular or consistent screening programs (mean difference: 1.18 [95% UI, 0.86-1.49]). In 2019, countries with breast cancer screening programs (18.6 deaths [95% UI 17.4-19.7] per 100,000) had 4.0 fewer deaths (95% UI: 2.0-6.1) per 100,000 population compared to countries without screening programs (22.6 deaths [95% UI 21.0-24.3] per 100,000). The reduction in mortality rates was particularly distinct among postmenopausal women aged 50-74 years, exhibiting a decline of 10.1 deaths (95% UI, 4.4-16.1) per 100,000 population in countries with screening programs. Regionally, during 2015-2019, breast cancer mortality rate in countries with regular screening programs was reduced by 1.27% (95% UI 0.13%-2.41%) per year in Sub-Saharan Africa and 0.85% (0.13%-1.57%) per year in Latin America and the Caribbean compared to the countries without such regular programs.
Conclusion: Countries with breast cancer screening programs experienced a significant reduction in breast cancer mortality. To effectively reduce breast cancer mortality on a global scale, it is imperative to encourage the adoption of national breast cancer screening programs and prioritize the expansion of screening coverage.

P3-02-14: Clinicopathogenomic analysis of Japanese metastatic breast invasive lobular carcinoma

Masaki Makita, Hiroshi Tada, Minoru Miyashita, Narumi Harada, Yohei Hamanaka, Akiko Ebata, Miku Sato, Tokiwa Motonari, Mika Yanagaki, Asumi Yamazaki, Tomomi Kon, Aru Sakamoto, Takanori Ishida

Objective: To analyze clinicopathogenomic data registered in C-CAT and to examine the genomic landscape of invasive lobular carcinoma and whether there is a significant difference between invasive ductal carcinoma (IDC) and lobular carcinoma ILC. Methods: From June 2019 to February 2024, 4084 metastatic breast cancer patients underwent cancer gene panel testing, were registered in C-CAT, and consent for secondary utilization was obtained (C-CAT Ver. 20240219). Of these, 3,114 were IDC (Luminal:1,578(50.7%), Luminal-HER2: 239(7.7%), HER2:152(4.9%), TN:908(29.2%)), and 210 were ILC (Luminal:142 (67.6%), Luminal-HER2:5(2.4%), HER2:3(1.4%), TN:45(21.4%)). RESULTS: Among ILC patients, 53.8% had CDH1 alterations, whereas only 1.9% of IDC patients had CDH1 alterations. CDH1 alterations were significantly more frequent in patients with ILC, as reported previously ($p < 0.0001$). Among ILC patients, 7.1% had ESR1 alterations, while 13.3% of IDC patients had ESR1 alterations ($p = 0.01$). The ratio of patients with high tumor mutational burden was significantly higher in the ILC group than in the IDC group (37/210 (17.6%) vs. 310/3114 (10.0%), $p<0.0001$). According to the alterations in the AKT pathway, 52.4% of ILC patients had PIK3CA alterations, whereas 34.5% of IDC patients had PIK3CA alterations ($p< 0.0001$). However, the AKT1 and PTEN did not differ significantly between the two groups. ARID1A alterations were significantly more common in the ILC group than in the IDC group (21/210 (10.0%) vs. 154/3114 (4.9%), $p =0.003$). MDM4 alterations were more common in the ILC group than in the IDC group (24/210 (11.4%) vs. 208/3114 (6.7%), $p =0.013$). Alterations in TP53, CDK12, GATA3, and FGFR1 were significantly more common in the IDC group than in the ILC group: 59.6% vs. 38.6% for TP53 ($p<0.0001$), 6.6% vs. 1.0% for CDK12 ($p=0.002$), 14.8% vs. 5.7% for GATA3 ($p=0.0004$), and 11.8% vs. 6.7% for FGFR1 ($p=0.03$). In the ILC group, the frequency of peritoneal metastases did not differ between the CDH1 alteration and non-alteration groups (21/113(18.6%) vs. 21/97(21.7%), $p=0.70$). However, ERBB2 non-alteration group were significantly more common peritoneal metastases than ERBB2 alteration group (39/174(22.4%) vs. 1/32(3.1%), $p=0.002$). Furthermore, the relationship between each alterations and overall survival was not significantly different when comparing overall survival with and without CDH1, ERBB2, and PIK3CA in the ILC group (CDH1:110 months vs 97 months, ERBB2:94 months vs 110 months and PIK3CA: 111 months vs 95 month, respectively, log-rank $p=0.821$, 0.183, and 0.672, respectively). Conclusions: This study revealed the genomic landscape of invasive lobular carcinoma in Japanese metastatic breast cancer. It is essential to understand the application of NGS-based genomic testing to support invasive lobular carcinoma.

P3-02-15: Combined Therapy of Progesterone Receptor Antagonist and COX-2 Inhibitor Prevents BRCA1-Deficient Mammary Tumorigenesis in Mice: A Novel Synthetic Lethal Strategy for Breast Cancer Prevention

Oukseub Lee, Priyam Patel, Minhua Wang, Takahiro Tsukioki, Ruohui Chen, Seema Khan

Background: we previously demonstrated that high-dose ulipristal acetate (UPA), a progesterone receptor (PR) antagonist, prevented tumors in a BRCA1-deficient mouse

model. For a clinically relevant translation, this study aimed to test the efficacy of low-dose UPA (5mg) alone and in combination with celecoxib (400mg), a COX-2 inhibitor, in Ad-K8-Cre Brca1f22-24/f22-24; Trp53f2-10/f2-10; R26Y (BPY) mice. This model allows tracing of tumor initiating cells (TICs) which are BRCA1; p53-deficient cells (YFP+) from initiation through premalignant stages and in tumors. We hypothesized that combination therapy enhances low-dose UPA efficacy.
Methods: 2-month-old female BPY mice received intraductal Ad-K8-Cre injections. 10 days later they were randomized into four groups (no-drug control, UPA, celecoxib, and combination; 12 mice/group), and monitored for tumor formation for 21-months. Treatments were incorporated into their diet (Inotiv inc.). Cancer preventive efficacy of drug treatment compared to the control was analyzed using the log-rank test (SAS v9.4) and survival analysis (R package). The coefficient of drug interaction (CDI) is calculated using tumor-free survival % endpoint. Premalignant glands from 1- and 5-month cohorts (3 to 4 mice/group/cohort) were analyzed using fluorescence-activated cell sorting (FACS) and RNA sequencing to identify drug-modulated genes and pathways (P adjusted <0.05).
Results: Combo-therapy (UPA + celecoxib) showed excellent tumor-preventive efficacy whereas monotherapy of each drug failed. At 16 months, tumor incidence was similar among monotherapy and control groups (55-58%), while the combination group showed 8% incidence (p=0.02; HR = 0.12, 95% CI = 0.03-0.55). At 21 months, tumor incidence was lowest in the combination group (33%), followed by UPA (64%), control (73%), and celecoxib (92%) (p=0.03; HR = 0.29, 95% CI = 0.09-0.93). Combo-therapy resulted in a 92% tumor-free survival rate at 500 days, significantly greater than the pure additive effect for monotherapy (36% [UPA] + 42% [celecoxib]), with a CDI of 0.06, indicating strong synergy (CDI <1). FACS analysis revealed that combo- therapy blocked the expansion of TICs (EpCAM+ YFP+), unlike monotherapy. Bulk RNA-seq analysis of TICs from the 1-month cohort showed that combo-therapy significantly increased luminal marker expression (Esr1, Pgr) and suppressed Tnfsf11 (RANKL), basal markers, and EMT genes. Single-cell RNA-seq of the 5-month cohort showed that luminal progenitors become dominant in TICs and combo-therapy upregulated the nonsense-mediated mRNA decay (NMD) pathway across multiple cell types and downregulated cancer-associated pathways (Wnt/β-catenin, TNFα via NF-κB, PI3K/AKT/mTOR, ECM organization) in epithelial cells.
Conclusions: The combo-therapy of UPA and celecoxib showed superior efficacy in preventing cancer in a BRCA1-deficient mouse model, demonstrating strong synergy. These findings provide novel insights into the biology underlying BRCA1-associated tumorigenesis and support the clinical potential of PR antagonists and anti-inflammatory agents as a novel synthetic lethal strategy for breast cancer prevention in high-risk women.

P3-02-17: tRF-1432–a novel target for reversing chemoresistance in breast cancer

Yuhan Dai, Shuhan Zhao, Huilin Chen, Yue Huang, Yiqin Xia, Jinhui Peng, Jiangdong Jin, Yifan Wu, Shui Wang, Yangyang Cui, Hui Xie

Chemoresistance is a significant challenge in the field of oncology and is the leading cause of treatment failure in breast cancer. Cancer cells could adapt to hypoxia microenvironment through metabolic reprogramming, while developing a strong drug resistance phenotype at the same time. However, the mechanism under which is still largely unknown. Efforts need to be done to identify novel targets and treatment modalities to address the complex issue of chemoresistance in breast cancer. In this study, we set our sights on an upregulated tRNA-derived fragment, tRF-1432, while we screened through high-throughput sequencing in breast cancer hypoxia models, especially in drug-resistant breast cancer cells/tissues. tRFs are a new category of small non-coding RNAs that occur when pre-tRNAs or mature tRNAs are selectively sheared by enzymes under certain pressure, and which play crucial roles in tumorigenesis. Further investigation on the biological roles and clinical value of tRF-1432 has been done. Overexpression of tRF-1432 is positively correlated with tumor cell proliferation and anti-apoptosis ability, and significantly increased chemoresistance of breast cancer in vitro and in vivo. Immunoprecipitation experiments confirmed the direct bond between tRF-1432 and RBMS1, knockdown of RBMS1 may deprive the tumor-promoting and chemoresistance properties of tRF-1432. Furthermore, in tRF-1432 overexpression breast cancer cells we observed a significant decrease of CCL3, a gene which could induce the transition in the phenotype of macrophages into a proinflammatory one. As a crucial member of tumor microenvironment (TME), macrophages participate in the mediation of therapeutic responses. Silencing tRF-1432 could facilitate M1 macrophage polarization and enhance the response to doxorubicin chemosensitivity in breast cancer. Mechanismly, tRF-1432 decreased the stability of CCL3-mRNA with the cooperation of RNA binding protein RBMS1, thereby reduced M1 macrophage polarization and promote the progression and chemoresistance breast cancer via CCL3-CCR5 signaling. In conclusion, our study clarified the role of hypoxia-induced tRF-1432 in breast cancer development and chemoresistance, and elucidate the molecular mechanism of which, aiming to provide a novel target for reversing chemoresistance in breast cancer.

P3-02-18: Multi omics reveals silencing of Argininosuccinate synthase and upregulation of nucleotide biosynthesis in tamoxifen resistance invasive lobular carcinoma

Annapurna Gupta, Fouad Choueiry, Jesse Reardon, Nikhil Pramod, Daniel Stover, Eswar Shankar, Steven Sizemore, Jiangjiang Zhu, Bhuvaneswari Ramaswamy, Sarmila Majumder

Background: Invasive Lobular Carcinoma (ILC) constitutes a hormone receptor positive molecular subtype of breast cancer, that are distinct from Invasive Ductal Carcinoma (IDC), primarily due to E-cadherin loss, and slow proliferation rate. Clinical management of ILC patients presents significant challenges due to its advanced stage at diagnosis, resistance to conventional therapies, and late recurrence. Endocrine therapy remains the cornerstone for treating ILC patients; however, the emergence of endocrine resistance resulting in late recurrence poses a substantial clinical obstacle. ILC is an understudied subtype of breast cancer, where therapies tailored for IDCs are used to treat ILC. Understanding endocrine

resistance in ILC is thus of utmost importance as majority of these studies were conducted in IDC.
Objective: To elucidate the mechanisms underlying endocrine resistance in ILC.
Methods: We have developed tamoxifen resistant (TAMR) variants of ILC cell lines (MDA-MB-134-VI and SUM44PE). Both pairs of the parental and TAMR cell lines were subjected to Metabolomics and RNA-sequencing analyses. Growth kinetics was performed by viable cell counting over 120 hours. Gene knockdown was performed using shRNA technology. Promoter methylation was studied by Methylation-Specific PCR. Drug effects were studied using MTT assay. Human breast cancer patient data from TCGA_BRCA (The Cancer Genome Atlas) and the METABRIC Invasive breast Carcinoma cohort was used for survival analysis.
Results: TAMR cells exhibited a two-fold increase in IC50 for tamoxifen compared to the parental cells and significant increase in growth rate and migration. Overlap of metabolomic and RNA seq data revealed deregulation of alanine, arginine, and glutamate (AAG) metabolism, purine metabolism, and arginine and proline metabolism in both MB134-TAMR and SUM44-TAMR cells. Among the 15 commonly dysregulated genes within these pathways, downregulation of Argininosuccinate Synthase 1 (ASS1) significantly correlated with poor overall survival and distant metastasis free survival in ILC patients only if treated with endocrine therapy. Our study showed methylation-mediated silencing of the ASS1 promoter in TAMR cells and in ILC cells grown for long-term in estrogen-deprived media. Treatment of TAMR cells with a demethylating agent, decitabine (5-Aza-2'-Deoxycytidine), restored ASS1 expression. Knock down of ASS1 in parental cells increased IC50 for tamoxifen. Untargeted metabolomics revealed increased nucleotide intermediate levels in TAMR cells. Additionally, TAMR cells exhibited higher expression of several key enzymes in nucleic acid biosynthesis pathways, including PAICS, PRPS1, ADSS2, CAD, and DHODH. Activating phosphorylation of CAD (Ser1859), a key multienzyme protein in pyrimidine biosynthesis pathway was observed in TAMR cells. Pretreatment with decitabine or combined treatment with DHOD inhibitor Farudodstat, increased growth inhibitory effect of tamoxifen in TAMR cells.
Conclusions: Our study unveils ASS1 downregulation as a novel mechanism underlying acquired resistance to tamoxifen and establishes a metabolic link between ASS1 and nucleic acid biosynthesis. Methylation mediated silencing of ASS1 is prompted when estrogen signaling is blocked, diverting one of its substrates, aspartic acid, to nucleic acid biosynthesis and facilitating cell growth.
Significance: These findings offer potential therapeutic strategies to overcome tamoxifen resistance by either ASS1 demethylation or targeting nucleic acid biosynthesis, thereby improving treatment outcomes for ILC patients. Further validation of the combined therapy is warranted in diverse experimental models and patient samples.

P3-02-19: Simultaneous loss of BRCA2 and RB1 results in growth disadvantage but strong CDK4/6i resistance in HR+/HER2- breast cancer

Daniela Haas, Selina Wolf, Urte Stankute, Magdalena Kröll, Philipp Jost, Nadia Dandachi, Marija Balic, Michael Dengler

Background: Genetic instability and dysregulation of the cell cycle are hallmarks of cancer. In advanced HR+/HER2- breast cancer, the standard therapy involves cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) which directly target aberrant growth by inhibiting the CDK4/6-RB1-E2F axis. In combination with endocrine therapy, CDK4/6i substantially extend progression-free survival (PFS), however, therapy resistance is frequently observed in the clinical setting.
Inactivating mutations or loss of the breast cancer susceptibility gene 2 (BRCA2) have been associated with breast cancer for a long time and are observed in 30-40% of sporadic breast cancer cases. Additionally, patients with germline BRCA2 pathogenic variants (gBRCA2 PV) show decreased PFS on CDK4/6i combined with endocrine therapy. However, gBRCA2 PVs may not directly lead to CDK4/6i resistance. Instead, the proximity of the genes BRCA2 and retinoblastoma protein 1 (RB1) on chromosome 13 might result in simultaneous loss of both. Since RB1 is a direct downstream target of CDK4/6, its inactivation leads to significant resistance against CDK4/6 inhibition.
Methods: In the proposed project, we used a lentiviral-based CRISPR/Cas9 system to model the loss of BRCA2 and RB1 alone and in combination in HR+/HER2- breast cancer cell lines and examined the impact on cell proliferation and treatment sensitivity.
Results: The loss of RB1 resulted in increased proliferation, whereas the loss of BRCA2 did not affect growth rates. Interestingly, the combined loss of both genes led to significantly reduced proliferation. However, under therapeutic pressure, loss of RB1 was dominant and led to strong resistance towards the CDK4/6i Palbociclib. Nevertheless, Olaparib, a PARP inhibitor targeting DNA damage repair, remained effective in RB1- and especially in BRCA2-deficient cells where DNA damage repair mechanisms are already compromised.
Discussion: Our results indicate that the loss of RB1 and BRCA2 significantly impacts cell proliferation, with the inactivation of both genes leading to a disadvantage in cell growth. We hypothesize that this is due to the impaired ability to repair DNA double-strand breaks. BRCA2 is crucial for homologous recombination repair, while RB1 is involved in the non-homologous end joining pathway. We believe that the inactivation of both genes increases reliance on other error-prone repair pathways, such as single-strand annealing or microhomology-mediated end joining (MMEJ, also known as alternative end joining). This could also explain the heightened response to Olaparib, which, among other PARP proteins also targets PARP1, a component of the MMEJ repair pathway.
While simultaneous inactivation of both genes leads to growth disadvantage, potentially because of the diminished capacity to repair DNA-double strand breaks, our data suggests that they still retain a strong advantage under treatment pressure and that clones harbouring both mutations evolve during the time of CDK4/6i treatment.

P3-02-20: CDK4/6 inhibitor resistance in patients with ER+ breast cancer: Identification and characterization of resistance mechanisms in thirty-two XPDX models

Delaney Rushing, Alyssa Simonson, Johnnie Flores, Anna Stackpole, Morgan Lynch, Amy Cook, Lisa Gonzales, Jim Lund, Tahmineh Rouzbahani, Eliza Abdul, Kyriakos Papadopoulos,

Gladys Rodriguez, Lorena Mozas, Lorena Gonzalez, Amita Patnaik, Amy Lang, Murali Beeram, Manish Sharma, Emiliano Calvo, Tatiana Hernandez, Michael J. Wick

Background: Resistance to CDK4/6 inhibitors (CDK4/6i) has been well studied with several mechanisms identified, including loss of RB, FAT1, and ERa and altered expression of regulatory genes such as CCND1, CCNE1/2, and CDK2. Additionally, alterations responsible for resistance may be linked to duration of CDK4/6i treatment. Previously (AACR2023), we reported on seventeen ER+ breast XPDX models representing patients who responded to CDK4/6i for up to twelve months (RES12), and greater than one year (RES13+). To better understand if duration of clinical treatment correlates with unique resistance mechanisms, we established and characterized an additional fifteen breast XPDX models from patients post-CDK4/6i and compared molecular profiles and drug sensitivities in the panel of thirty-two models.

Methods: Seventeen breast models were previously established and characterized which included 8xRES12 and 9xRES13+. Fifteen new models were established from thirteen patients: eleven originated from fluid samples of which seven were designated as ductal (ST4137L, ST4322C, ST4322D, ST6023B, STM185, STM188, ST188B) and four as lobular carcinomas (ST4680D, ST6133, STM229F, ST383F); three were established from core biopsies (ST4534B, lymph node; ST5400, breast; STM354, liver), and one from circulating tissue (STM223B), all designated as ductal carcinomas. Of the fifteen new models, six were classified as RES12 and nine as RES13+. These models were passaged and challenged with palbociclib to confirm resistance. Receptor expression was determined by IHC and genomic analyses, including WES and RNAseq, were performed to identify mechanisms of resistance. For in vivo studies, CDK4/6i were dosed via oral gavage, once daily at 50 mg/kg; endpoints included tumor volume (TV) and time from treatment initiation (TTI) with %T/C values and tumor regression reported at study completion; a %T/C of ≤20 versus control was considered sensitive. Tumor regression (%T/C<0) versus Day 0 TV was also reported.

Results: Clinical time to progression (TTP) for RES12 (n=6) was four to twelve months and RES13+ (n=9) from thirteen to thirty-six months. All models, except ST4322C and ST4322D, retained ER expression in evaluated passages with similar histology compared with archival clinical samples. Sequencing identified several variants, including RB1 and/or PTEN loss or deletion, and increased gene expression in CCND1, CCNE1, and the PIK3CA/AKT pathway. PIK3CA mutations were reported in 7/15 models; mutations in RAF1, ESR1, FGFR and other genes were also identified across the panel, some more prevalent based on clinical TTP. Most models were resistant to fulvestrant and insensitive to some or all evaluated CDK4/6i treatments.

Conclusion: We have expanded our platform of breast XPDX from patients post-CDK4/6i treatment to thirty-two models and characterized each based-on duration of clinical treatment, molecular profiles, and drug sensitivities. We have also identified potential mechanisms of resistance based on CDK4/6i therapy and TTP. This platform is a valuable resource for developing novel therapies for CDK4/6i-resistant patients.

P3-02-21: Generation of Sacituzumab Govitecan Resistant Breast Cancer Models

Carson Walker, Julia Altman, Emily Zboril, Rachel Myrick, Nicole Hairr, David Boyd, Bin Hu, Oniya Smith, Mikhail G. Dozmorov, Chuck Harrell

Treating triple-negative breast cancer (TNBC) presents a challenge due to its resistance to several conventional therapies, driven by its lack of expression of estrogen, progesterone, and HER2. Sacituzumab Govitecan (SG), an antibody drug conjugate (ADC) targeting Trop2, has recently been approved for treating TNBC and estrogen receptor positive (ER+) breast cancer after prior systemic treatments. It is largely undefined how cancer cells from different intrinsic subtypes become resistant to SG, therefore these studies focus on the development of model systems to define mechanisms of resistance to this targeted therapy. We hypothesize that SG resistance is driven by variation in the expression of Topoisomerase 1, Trop2, and other proteins involved in SG internalization. To test this hypothesis, we performed a set of studies that incorporated ER+ and TNBC patient-derived xenografts (PDXs). Bulk- and single-cell RNA-sequencing analyses from a set of 15 PDXs and some syngeneic, drug resistant pairs, found that most models had similar Trop2 RNA levels, however TNBCs had significantly higher Trop2 protein expression. Ex vivo dose-response analyses of PDX cells with SG found that TNBCs were more sensitive to SG at lower drug concentrations. In vivo testing of PDX tumors for SG response identified subsets of tumors that were resistant to SG and those that had varying levels of sensitivity. Further studies characterized SG response in several metastatic models, which will serve in identifying truly resistant models and will help to normalize any treatment effects from drugs that could potentially overcome SG resistance. Interestingly, some of the PDXs that were sensitive to SG became resistant after the PDX had acquired carboplatin resistance. Initial bulk RNA sequencing of PDXs with innate or acquired SG resistance have revealed differences in gene expression related to claudin genes, endosome formation, Topoisomerase 1 levels, and Trop2 localization. Ongoing studies are contrasting mechanisms of SG resistance with acquired insensitivity to other therapeutics and defining pharmacological approaches to inhibit SG refractory metastases.

P3-02-22: The role of circular RNAs in triple-negative breast cancer and chemotherapy resistance

Xiyin Wang, Michael J. Emch, Xiaojia Tang, Esther P.B. Rodman, Liewei Wang, Judy C. Boughey, Matthew P. Goetz, Krishna R. Kalari, John R. Hawse

Background: Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer-related death among women worldwide. Triple negative breast cancer (TNBC) represents 15-20% of all incident breast cancers and is a highly aggressive subtype. Neo(adjuvant) chemotherapy (NAC) is standard for early stage TNBC; however, for those with residual breast cancer following NAC, recurrence is common and associated with few effective therapeutic approaches. Thus, identification of novel resistance

mechanisms and alternative treatment strategies remain an unmet clinical need. Circular RNAs (circRNAs) are a newly identified class of largely noncoding RNA molecules with covalently closed circular structures. Recent studies suggest that circRNAs play crucial roles in regulating tumor development, progression and chemoresistance. However, the role of circRNAs in mediating chemotherapy resistance remains unknown.

Methods: As a first step towards identifying circRNAs that participate in the development of chemoresistance, and to determine if targeting such circRNAs may be an efficacious strategy, doxorubicin-resistant (Doxo-R), paclitaxel-resistant (PTX-R), and double-resistant (DP-R) cell lines were generated from MDA-MB-231 cell lines. Human circRNA microarrays were utilized to profile the expression of approximately 14,000 known circRNAs in normal breast tissue, matched TNBC patient-derived xenografts (PDX) generated prior to and following NAC, and TNBC chemosensitive and chemoresistant cell lines. Top hits were validated using RT-PCR. Bioinformatic approaches were employed to identify circRNA-miRNA-mRNA networks regulated by differentially expressed circRNA transcripts. A reverse genetics approach was also employed using CRISPR to interrogate the contributions of over 4000 specific circRNA in driving the development of resistance to doxorubicin and paclitaxel.

Results: circRNA microarray profiling identified 429 and 310 transcripts differentially expressed in doxorubicin and paclitaxel resistant cells, respectively, compared to parental chemosensitive cell lines ($|FC| \geq 1.5$; p value < 0.05). Given that circRNAs can act as microRNA (miRNA) sponges, thereby inhibiting miRNA activity, we computationally identified circRNA-miRNA pairs, and assessed the abundance of mRNA transcripts predicted to be targets of paired miRNAs via RNA-seq. A differentially expressed circRNA-miRNA-mRNA network was further constructed. Dysregulated canonical pathways and gene ontology (GO) enrichment analysis were determined from these networks and revealed multiple GO term included negative regulation of miRNA transcription, miRNA and RNA metabolic process, and endoplasmic reticulum-associated degradation (ERAD) pathway. The CRISPR-Cas13 screen is ongoing at this time but results will be available prior to the meeting.

Conclusions: We have identified cancer specific circRNAs in TNBC cell lines, PDX models and patient tumors in the context of chemotherapy sensitive and chemotherapy resistant disease. Specific biological processes, pathways and signaling cascades have been implicated in the down-stream consequences of dysregulated circRNAs and in the potential development of resistance. Our ongoing studies seek to identify specific circRNAs sufficient to drive resistance to chemotherapy. Outcomes of these studies highlight the potential of specific circRNAs to serve as predictive/prognostic biomarkers and novel therapeutic targets for advanced forms of TNBC.

P3-02-23: Evaluation of ribociclib, abemaciclib and palbociclib resistance in ER+ breast cancer cells reveal novel therapeutic opportunities in ER+/HER2- breast cancers

Srinivasan Madhusudan, Mashael Algethami, Ahmed Shoqafi, Shatha Alqahtani, Jennie N Jeyapalan, Ahmad ALtayyar, Ayat Lashen, Emad A Rakha, Nigel P Mongan

Backgrund: The cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) ribociclib, abemaciclib and palbociclib, have transformed the lives of patients with ER+/HER2− metastatic breast cancer (BC). However, most patients will eventually progress on treatment. The discovery of novel targets and optimization of therapy beyond CDK4/6i is an area of ongoing investigation. We conducted a comprehensive evaluation in CDK4/6i resistant BC cells and aimed to discover novel markers of resistance for therapeutic application.
Methods: The ER+/HER2− BC cell lines, MCF7 and T47D were chronically treated with increasing dose of ribociclib (R), abemaciclib (A) or palbociclib (P) over 8 months (0-600nM). CDK4/6i resistant cell lines (MCF7RR, MCF7RA, MCF7RP, T47DRR, TD7DRA, T47DRP) were isolated. CDK4/6i resistant and sensitive cells were evaluated for spheroid forming ability, cell cycle progression, apoptosis, cross resistance to other CDK4/6i, whole genome RNA sequencing, and cisplatin/volasertib (PLK1 inhibitor)/barasertib (Arora kinase B inhibitor) sensitivity. In addition, immunohistochemical evaluation of PLK1 and Aurora kinase B expression was completed in a clinical cohort of 4000 early-stage BC specimens.
Results: MCF7RR, MCF7RA, MCF7RP, T47DRR, TD7DRA, T47DRP cells manifested aggressive phenotypes with increased spheroid forming ability, progressed through G1/S phase of cell cycle despite CDK4/6i treatment and were resistant to apoptosis. Cross resistance to other CDK4/6is and cisplatin resistance was evident. Whole genome RNA sequencing revealed upregulation of several genes involved in cell cycle regulation, cell signalling, immune regulation, metabolic reprogramming and others across all resistant models compared to controls. Polo-like kinase 1 and Aurora kinase B were consistently overexpressed in MCF7RR, MCF7RA and MCF7RP cells compared to controls. Whereas CDKN4B and TGFβ were upregulated in T47DRR, TD7DRA, T47DRP cells compared to controls. MCF7RR, MCF7RA and MCF7RP cells, whilst resistant to CDK4/6i, remain sensitive to volasertib (PLK1 inhibitor) and barasertib (Aurora Kinase B inhibitor) therapy which was associated with G2/M cell cycle arrest and increased apoptosis. In clinical cohorts, PLK1/CDK4 and PLK1/CDK6 co-expression influence clinical outcomes in BC patients.
Conclusion: In ER+/ HER2− BCs, pathways to resistance to CDK4/6i therapy are complex and diverse. PLK1 or Aurora Kinase B targeting could be an attractive therapeutic strategy in certain CDK4/6i resistant ER+ BCs.

P3-02-24: Quantitative changes in hormone receptor- and Ki67-levels in response to short-term neoadjuvant endocrine therapy in breast cancer

Rehaan K. Machhi, Yunguang Sun, Julie M. Jorns, Yee Chung Cheng, Sailaja Kamaraju, Mary Beth Gonyo, Amanda Kong, Caitlin Patten, Tina Yen, Chandler Cortina, Christopher R. Chitambar, Lubna N. Chaudhary, Hallgeir Rui

Background: A majority of breast cancers (BC) are hormone receptor-positive (HR+), expressing estrogen receptors (ER) and/or progesterone receptors (PR). Patients with HR+ BC benefit significantly from endocrine therapy. However, up to 25% of these patients develop endocrine-resistant disease, which remains a major cause of breast cancer mortality. Neoadjuvant endocrine therapy (NET) offers a valuable opportunity to identify favorable responders and those at risk for endocrine resistance. Quantitative image analysis of multiplex-stained tumors holds the potential for greater insights into these dynamics.
Methods: We conducted multiplex immunohistochemical staining for ER, PR, proliferation marker Ki67, and cytokeratin (CK) on 36 paired tumor specimens from our recently completed interventional clinical trial of short-term neoadjuvant endocrine therapy (NET) in patients with early-stage HR+/HER2- BC (NCT03219476). Optimized immunohistochemistry (IHC) protocols using OPAL reagents (Akoya) were performed on a Leica Bond Rx autostainer. ER, PR, and Ki67 levels in cancer cells within representative tumor regions of interest were quantified using QuPath image analysis software on Akoya PhenoImager scanned images. Pre- and post-NET data were analyzed using paired t-tests. Patient demographics and clinicopathological information have been published. Briefly, 36 patients with cT1-T3, cN0 HR+/HER2- BC were treated with ~4 weeks of NET prior to surgery. Median age was 64yrs (range 42-81), median pre- and post-NET tumor sizes were 1.3 cm (range 0.5-7.7) and 1.2 cm (range 0.09-4 cm), respectively. Six patients had pN1 at surgery, one had pN1mic disease, and one patient achieved a complete pathologic response (pCR).
Results: Post-NET, computed residual cancer cell Ki-67 positivity ≥10% was detected in 11 cases (11/36), indicative of endocrine resistance. Intermediate Ki-67 positivity (2.7–10%) was observed in 7 cases (7/36), while Ki-67 positivity was ≤2.7% in 18 cases (18/36), indicative of complete cell cycle arrest.
The Preoperative Endocrine Prognostic Index (PEPI) score, comprising post-NET tumor size, lymph node status, computed ER, and Ki67 positivity, was employed as a prognostic biomarker. A favorable prognostic PEPI score of 0 was observed for 9 patients, while 23 patients had an intermediate PEPI score of 1-3, and 4 patients had a PEPI score >4. All 9 patients with PEPI score of 0 and 6 patients with PEPI score of 1-3 had > 6.7-fold (85%) reduction in cancer cell %Ki67-positivity after 4 weeks of NET thus identifying a total of 15 patients with highly ER-dependent proliferation. The median reduction in cancer cell Ki67-positivity was 3.1-fold (67%) in the remaining 15 patients with PEPI score 1-3 and 1.7-fold (41%) in the 4 patients with PEPI score >4.
Single-cell analysis of Ki67-positive cancer cells demonstrated a significant reduction in the fraction of ER-positive proliferating cells following NET (median 6.3% post-NET vs. 41.5% pre-NET; $p<0.001$), indicating a shift towards ER-independent proliferation. Multiplex

single-cell metrics could be valuable in further distinguishing patients with tumors that respond to treatment from those at risk of developing endocrine resistance.
Conclusions: Short-term neoadjuvant endocrine therapy is a promising strategy to distinguish between tumors that are responsive to treatment and those with inherent or emerging endocrine resistance. The use of multiplex immunofluorescence and quantitative digital pathology offers the potential for more accurate identification of endocrine resistance. This approach may also help uncover molecular mechanisms that can be targeted by combination treatments, enhancing therapeutic outcomes for patients with hormone receptor-positive BC.

P3-02-25: CRISPR/Cas9 knockout of ALDH1A1 increases radiation response in triple-negative breast cancer

Grace Aijayi, Shirin R. Modarai, Aihui Ma, Lynn M. Opdenaker, Jennifer Sims Mourtada

Currently, there are no targeted therapies for triple-negative breast cancer (TNBC).1 While radiation therapy plays a crucial role in breast cancer treatment, its effectiveness against TNBC is hindered by acquired resistance to radiation over time. This highlights the need for more sensitive and specific therapeutic approaches.2 ALDH1A1 is associated with stemness and poor outcomes in TNBC and is a potential new target for treatment. ALDH1A1 contributes to chemoresistance in TNBC3, and we propose that it also promotes radiation resistance through both its antioxidant properties and regulation of cancer stemness. Previous studies have indicated that the radiation resistance observed in TNBC is linked to increased levels of ALDH1A14, suggesting it plays a protective role against radiation-induced cell death. In this study, we did a CRISPR/Cas9 knock out (KO) of ALDH1A1 in SUM 159 cells and derived single cell clones to screen for the effects of ALDH1A1 KO. Confirmation of ALDH1A1 KO was done at the genomic level by Sanger sequencing and at the protein level by western blotting analysis. The response of ALDH1A1 knockout clonal derived cells to radiation was analyzed using colony forming units (CFU), proliferation assays (Alamar blue), and Annexin V/PI staining. All the ALDH1A1 knockout clones analyzed showed enhanced radiation response with reduced proliferation, and colony formation units post-radiation, as compared to the parental cells. Furthermore, tumor initiation was measured in the parental cells and ALDH1A1 KO clones using the organoid culture system platform. Overall, ALDH1A1 KO clonal derived cells formed fewer tumoroids post-radiation, as measured by cell proliferation assays in a 3D culture system. Together these findings highlight the critical relationship between ALDH1A1 expression and radiation sensitivity, emphasizing the potential of ALDH1A1 as a target for improved treatment of TNBC.

P3-02-26: Sex-biased cancer cells induce endocrine therapy resistance and immune suppression in male breast cancer

Zhishuang Gao, Zehao Wang, Yue Zhou, Xiaoting Chen, Jingyan Xue, Jiong Wu

Sex differences in breast cancer（BC）lead to distinct clinical and molecular characteristics. Sex-associated heterogeneity relies intricately on the oncogenic properties of cancer cells and multicellular interactions in tumor microenvironments. Here we conducted a multiomic analysis encompassing single-cell RNA sequencing, spatial transcriptomics and large-scale histological analysis, combined with genetic and pharmacological perturbations to systematically develop a high-resolution and spatially resolved map of intratumoral expression heterogeneity in male breast cancer（MBC）. Among the malignant cells, we identify 9 consensus meta-programs (MPs, for example, estrogen response and interferon response), each consisting of dozens of genes that are coordinately upregulated in subpopulations of cells within MBC. Of these, MP5 exhibits significant male bias, characterized by aberrant activation of the estrogen receptor α (ERα) signaling pathway, inducing endocrine therapy resistance in MBC. Bidirectional interactions between MP5 malignant cells and immunosuppressive cancer-associated fibroblasts form an immune exclusionary microenvironment mediated by LRBA. Collectively, our study highlights the endocrine therapy resistant and immunosuppressive role of LRBA in MBC, and these findings may provide insights into the molecular features of MBC and facilitate the development of sex-specifical treatment strategies.

P3-02-27: circAXIN1 promotes EMT-mediated metastasis and doxorubicin resistance via Wnt/β-catenin pathway by regulating miR-486-3p/BCL11A axis in TNBC

Yan Liu, Shichao Zhang, Xinyu Liu, Shunan Wang

Circular RNAs (circRNAs) represent a novel type of regulatory RNA characterized by high evolutionary conservation and stability. CircRNAs are expected to be potential diagnostic biomarkers and therapeutic targets for various malignancies. However, the regulatory functions and underlying mechanisms of circRNAs in triple-negative breast cancer (TNBC) are largely unknown.
Using a high-throughput microarray assay, this study identified a novel circRNA, circAXIN1(hsa_circ_0005838), which was upregulated in TNBC tissues and cell lines. We found that circAXIN1 expression was increased in doxorubicin-resistance TNBC tissues and cells. Functionally, we demonstrated that circAXIN1 significantly promoted epithelial-mesenchymal transition(EMT)-mediated cell migration and invasion and enhanced doxorubicin resistance in vitro and in vivo. Mechanistically, RNA pull-down assay, RNA immunoprecipitation, and dual luciferase reporter assay disclosed that circAXIN1 was identified as a miR-486-3p sponge. We also found that BCL11A was a direct target of miR-486-3p, which functioned as an oncogene in breast cancer. Thereby, circAXIN1 upregulated BCL11A protein expression and accelerate TNBC progression. The rescue experiments also revealed that miR-486-3p overexpression or BCL11A knockdown partially reversed the regulatory functions of circAXIN1 on TNBC cell migration, invasion, and doxorubicin resistance. Furthermore, we showed that circAXIN1 promoted BCL11A expression via competitive interaction with miR-486-3p and then activated the Wnt/β-catenin signaling pathway. Additionally, in vitro and in vivo functional experiments demonstrated that circAXIN1/miR-486-3p/BCL11A axis promoted TNBC EMT-mediated metastasis and

doxorubicin resistance via activating the Wnt/β-catenin signaling pathway.
Collectively, our findings clarified a hitherto unexplored mechanism of the circAXIN1/miR-486-3p/BCL11A axis in EMT-mediated tumor metastasis and doxorubicin resistance in TNBC.

P3-02-28: A combination approach to target residual tumors via ferroptosis induction

Zhiming Wang, Hala S. Hassanain, Erin He, Filza Anis, Nancy Azizian, Delaney K. Sullivan, Jenny C. Chang, Mark Pegram, Yulin Li

Background: Selection pressure from chemotherapy can result in small populations of resistant cells, even in tumors with apparent clinical response. These residual tumor cells can tolerate cytotoxic treatments, persist in a reversible, semi-dormant, diapause-like state, and ultimately drive tumor recurrence. Pharmacologically targeting these residual tumor cells has the potential to prevent or significantly delay tumor relapse, but it remains a clinical challenge.
Methods and Results: We report ferroptosis induction as a targeting strategy to eradicate residual tumor cells following chemotherapy. Through focused chemical library screening using an in vitro residual tumor model, we identified ferroptosis inducers that are effective against the residual tumor cells, but not the bulk proliferating tumor cell population. Ferroptosis induction eradicated residual tumor cells generated by treatments with various chemotherapeutic agents and radiation across multiple breast cancer subtypes. The hypersensitivity to ferroptosis induction in residual tumor cells is driven by elevated levels of ferrous irons, the catalyst of ferroptosis. To evaluate the therapeutic potential of ferroptosis induction in vivo, we established residual tumors in triple-negative breast cancer (TNBC) PDX models following treatment with doxorubicin and cyclophosphamide (AC). In TNBC PDX models, we demonstrated that ferroptosis induction with the single agent RSL3, a glutathione peroxidase 4 (GPX4) inhibitor, effectively eliminated the residual tumor cells and significantly delayed tumor recurrence post-chemotherapy. The time from initiation of treatment to recurrence for AC vs. AC+RSL3 groups was: 65.3+/-3.9 vs. 81.6+/-5.4 days, p=4.1E-06, for PDX-3107, and 81.4+/-4.9 vs. 102.9+/-12.3 days, p=1.8E-06, for PDX-3887. Importantly, simultaneous suppression of the two parallel ferroptosis defense mechanisms mediated by GPX4 and ferroptosis suppressor protein-1 (FSP1), through the combined use of RSL3 and iFSP1, further delays tumor recurrence in PDX models. The time to recurrence in AC vs. AC+RSL3/iFSP1 groups was 49.8+/-8.4 vs. 113.1+/-5.8 days, p=5.0E-09, for PDX-3204. Notably, combined treatment with RSL3/iFSP1 led to complete clearance of the residual tumors in 9 out of 11 mice bearing PDX-3887, with no tumor recurrence observed up to four months of follow-up.
Conclusion: Our study demonstrates that ferroptosis induction is an effective strategy for eradicating residual tumors and delaying tumor recurrence in TNBC following cytotoxic chemotherapy.

P3-02-29: The mechanism of acidic microenvironment promotes tumor-associated macrophages secreting glutamine to activate dual signaling pathways of mTORC1 and c-MYC in CDK4/6 inhibitor resistance of ER-positive breast cancer

Fanli Qu, Guanwen Wang, Ningning Zhang, Qing Shao, Xiaohua Zeng

Resistance to CDK4/6 inhibitors in ER-positive breast cancer poses a clinical challenge, and the underlying mechanisms remain unclear. ER serves as a crucial regulator of glycolysis, promoting tumor progression and resistance by inducing microenvironmental acidification. We observed that an acidic microenvironment induces the polarization of tumor-associated macrophage (TAM) toward the M2 phenotype, leading to the secretion of glutamine. This activation of mTOR promotes resistance to CDK4/6 inhibitors in ER-positive breast cancer. Concurrently, glutamine promotes the upregulation of c-MYC in breast cancer cells, inducing lactate production and exacerbating microenvironmental acidification. We propose a scientific hypothesis: the acidic microenvironment drives TAM towards M2 polarization, secreting glutamine. This, in turn, activates both mTOR and c-MYC pathways, promoting resistance to CDK4/6 inhibitors and intensifying tumor microenvironment acidification. Through in vivo and in vitro experiments, we aim to elucidate the role of M2 macrophages in CDK4/6 inhibitor resistance under acidic conditions. We seek to clarify the molecular mechanisms by which M2 macrophages secrete glutamine, mediating CDK4/6 inhibitor resistance in ER-positive breast cancer and worsening microenvironmental acidification. Additionally, we aim to evaluate the sensitizing effects of targeting the acidic microenvironment and glutamine. Successful completion of this study holds the potential to provide a scientific basis for establishing novel approaches to overcome CDK4/6 inhibitor resistance in ER-positive breast cancer.

P3-02-30: PIK3CA hotspot mutations as biomarkers for prognosis and treatment prediction in ER+/HER2- postmenopausal breast cancer patients

Carolin Jönsson, Zeinab Alkashaf, Josefine Sandström, Saira Munir, Annelie Johansson, Magdalena Ríos Romero, Tommy Förnander, Linda Lindström, Olle Stål, Gizeh Perez Tenorio

The PIK3CA gene, encoding the p110α catalytic subunit of phosphatidylinositol 3′-kinase (PI3K), is mutated in over 30% of breast cancers. Most mutations concentrate in the hotspots E542K, E545K, and H1047R, leading to hyperactivation of the PI3K/Akt pathway in vitro. In ER+/HER2- breast cancers, we found more than 40% of these mutations. Although PIK3CA is an oncogene, its mutations are linked to a good prognosis. This study explores the prognostic and predictive role of PIK3CA hotspot mutations in low-risk postmenopausal breast cancer patients randomized to receive tamoxifen or no systemic treatment, followed for over 25 years with extensive clinical records.

Mutation analysis was performed using formalin-fixed paraffin-embedded tumors with digital droplet PCR (ddPCR). PIK3CA mutations were detected in 40% of all patients and 45% of the ER+/HER2- subtype. The most frequent mutation was H1047R (23%), followed by E545K (17%) and E542K (6%). Significant associations were found between all hotspot mutations and low grade, PR positivity, HER2 negativity, and high expression scores of a PIK3CA-mutation-associated gene module. Additionally, all mutations were inversely correlated with multigene modules (IMMUNE1 and IMMUNE2), suggesting an immunosuppressive environment. PIK3CA mutations were often found in patients with ultralow risk of distant recurrences according to the 70-gene signature and lower expression of the proliferation marker Ki67.
PIK3CA mutations were associated with longer distant-recurrence-free intervals (DRFI) in all patients in multivariable analysis after adjusting for tumor size, receptor status (ER, PR, HER2), tumor grade, Ki-67, and tamoxifen (HR (95% CI)=0.53 (0.31-0.92)). The combination of PIK3CA mutations and/or low PTEN status also indicated better prognosis (HR (95% CI)=0.53 (0.30-0.92)).
PIK3CA mutations also indicated a good prognosis for patients with low or high risk of developing distant metastases by the 70-gene signature (HR univariate (95% CI)=0.5 (0.29-0.89)) compared to ultralow risk patients (HR univariate (95% CI)=2.5 (0.48-12.92)). Test for interaction P=0.13.
However, among low proliferating Luminal A subtype, PIK3CA mutations were associated with shorter DRFI after adjusting for size and grade (HR (95% CI)=5.7 (0.95-33.8)), compared to the highly proliferating Luminal A (HR (95% CI)=0.24 (0.06-0.98)). Similar results were found when analyzing the combination variables PIK3CA/PTEN or PIK3CA/pAKT in Luminal A.
PIK3CA mutations per se did not have a clear predictive value regarding tamoxifen response.
In conclusion, PIK3CA mutations predominate within the ER+/HER2- subtype, are associated with good clinical markers, and longer DRFI in all patients, especially among highly proliferative and high-risk tumors, but not within ultralow risk patients. Ongoing investigation aims to decipher other factors associated with PIK3CA mutations in patients with indolent tumors who present long-term relapses and may take advantage of new treatment strategies.

P3-03-01: Awareness of Rare Cancers: Hearing and Engaging Rural Communities (ARCHER-C)

Beau Blass, Hannah Woriax, Rashmi Saincher, Larry Greenblatt, Anh N. Tran, Gayathri R. Devi

Background: Inflammatory breast cancer (IBC), a rare and NIH-designated cancer health disparity, is a highly aggressive form of breast cancer accounting for 7-10% of all breast cancer deaths. Furthermore, the unique presentation of IBC, lacking a solid mass and characterized by diffuse tumor cell spread, often leads to delays in diagnosis and treatment.

Reproductive risk factors and higher incidence rates among younger women and those from minoritized and marginalized populations, underscore the crucial role of primary care providers (PCP)—including physicians, physician assistants, and nurse practitioners. Social drivers of health (SDoH) further limit healthcare access for these communities. Recognizing that primary care practices are the initial contacts for navigating cancer diagnosis and treatment, we postulated that understanding barriers experienced by PCP and members of the public will foster engagement with large academic medical centers and breast clinics for improved diagnosis and management of IBC. In this study, we describe the development of a platform (ARCHER-C), designed to assess PCP and public knowledge, attitudes and health seeking practices related to IBC in the rural setting, as well as rare cancers more broadly.

Methods: Two surveys were developed with guidance from a Community Advisory Board, comprising members from academic institutions, urban and rural practices, topical experts, and patient advocates. PCP were recruited from FQHC and community practice settings within North Carolina. Mixed methods were used to analyze cognitive interview surveys administered to a convenience sample of participants recruited at-large from rural communities via email, social media; and direct recruitment from an urban practice serving primarily low-income, medically complex patients along with another clinic serving distinct rural communities. All responses were summarized using descriptive statistics.

Results: Data from public (n=34) volunteers self-reporting as Black (45%), White (30%), American Indian/Alaskan Native (24%), and residing in households earning under $50,000/yr (40%) along with PCP (n=30) were analyzed. Salient measures of IBC diagnosis, health disparity factors, referral and care coordination practices, COVID-19 impact, and continuing medical education (CME) were identified barriers at the PCP level. Furthermore, seventy-four percent of public participants had not heard of IBC; 38% did not identify being overweight as a risk factor; 38% were not aware of racial disparities; 50% recognized redness or thickening of the skin as symptoms; and even fewer recognized the characteristic “pitted” appearance of the skin. Participants noted worry about what the doctor may find, difficulty or fear talking to a physician, lack of insurance, transportation barriers, and religious reasons as contributing to delays seeking health care. Most importantly, 97% of the participants expressed their enthusiasm in sharing information about IBC and rare cancers with others, specifically family members and friends. In addition, majority expressed that adding visual aids and providing educational materials about IBC at the time of survey would be helpful.

Conclusions: This community-engaged model highlights the need for bidirectional provider- and public-facing research and education to reduce the burden of IBC and associated disparities. Strengthening the connection between primary care and specialized centers is essential for better diagnosis and management of IBC and other rare cancers, ultimately reducing health disparities. Funding in part by Duke Cancer Institute Community Outreach, Engagement, Equity Seed Grant (GRD, ANT) as part P30 CA014236, Duke MERITS Education Grant & Surgery Funds (GRD). Anh Tran and Gayathri Devi; Co-Senior Authors.

P3-03-02: Effects of socioeconomic status on access to next-generation sequencing in patients with metastatic breast cancer

Christine H. Zhang, Conchita Martin de Bustamante, Helen Stephens, Mohammad Khan, Rhea Sudhakaran, Glenda Delgado, Julia Maués, Christine Hodgdon, Rani Bansal, Hannah Chang, Isaac S. Chan

Background: Breast cancer is the most common cancer diagnosis in women. Metastatic breast cancer is difficult to treat and is a major cause of mortality related to breast cancer. Treatment includes therapeutic options that target specific molecular signals and pathways responsible for cancer growth and other malignant features. These advances have necessitated new biomarkers that can identify tumor molecular features to select the right patients who will maximally benefit from these therapies. Focused next-generation sequencing (NGS) on DNA isolated from the tumor tissue or circulating tumor DNA in the blood has quickly become standard of care to create actionable and personalized treatment plans. However, these tests are often expensive, limiting their clinical implementation. We hypothesized that limited access to these therapies increases health disparities in clinical oncology.
Objective: The aim of this study is to examine if neighborhood socioeconomic status (SES), as defined by area of deprivation index (ADI), as well as factors including race, ethnicity, and insurance status influence access to NGS testing in the Dallas area.
Methods: Data from 187 patients with recurrent MBC were obtained from the Dallas Metastatic Breast Cancer Study (DMBCS), a clinical database that was established in 2021 at a single academic medical system to track patient demographics, area deprivation index (ADI), race, ethnicity, treatments, and other variables that are not widely available in other national databases for MBC. Ethnicity was categorized into Hispanic versus non-Hispanic consistent with Office of Management and Budget census standards, and race was separated into White, African American, Asian American and Native Hawaiian/Pacific Islander. Commercial NGS testing was performed on patient tumor tissue or circulating tumor DNA from blood samples by Tempus and FoundationOne between the years 2014 through 2022.
Results and Discussion: Overall, 39% of patients in our dataset received NGS testing. Patients who are not Hispanic or Latino (n=140, OR: 3.99, 95% CI: 1.66-9.61) are about 4 times more likely to receive NGS compared to those who are Hispanic or Latino (n=42). Insurance, whether private (OR: 7.35, 95% CI: 2.29-33.08) or public (OR: 4.90, 95% CI: 1.55-21.81), also significantly increased the likelihood of receiving NGS testing compared to those without insurance. Interestingly, race was not a significant factor amongst White (n =131), African American (n=33), and Asian (n=8). Next, we sought to evaluate whether ADI would correlate with access to NGS testing. ADI measurements include education level, employment, housing quality, and income to rank neighborhoods by SES disadvantage; a higher quartile ADI equates to a greater disadvantage. Our data showed that patients in the lowest quartile ADI are 2.5 times more likely to have NGS testing compared to those in the highest quartile (OR: 2.54, 95% CI 1.07-6.20). These results suggest that NGS testing is disproportionately offered to insured patients with a higher SES, particularly those with insurance. Whether these discrepancies are inherent in clinical practice (e.g. physician

awareness) or from legitimate barriers related to access should be defined in future studies. However, identifying that these disparities in NGS testing exists promotes awareness and encouragement for clinicians to offer NGS more broadly.

P3-03-03: Disparities in Quality of Life Among Breast Cancer Survivors in the All of Us Research Program

Gagandeep Kaur, Jiayuan Wang, An D Truong, Hester Nguyen, Leah Puglisi, Carrie Costantini, Ritesh Parajuli, Hannah Lui Park

Background: Breast cancer is the most common cancer among women. Advancements in breast cancer treatment and early diagnosis have resulted in higher survival rates necessitating the importance of studying quality of life (QOL) among breast cancer survivors. QOL is an important endpoint in clinical trials as it provides insights into the overall well being and long-term outcomes of patients. Understanding QOL is also crucial for guiding treatment decisions, supporting survivorship care, and shaping healthcare policy. Previous studies have shown that racial/ethnic disparities in QOL exist, and factors affecting QOL have been investigated. However, inconsistencies remain regarding specific determinants, and a large-scale study examining disparities in QOL among breast cancer survivors in the U.S. has not been done.
Methods: We analyzed data from 2,022 female breast cancer survivors in the National Institutes of Health's All of Us Research Program database. QOL (scored from 1 to 5) was measured using survey response data in which participants answered the question: “In general, would you say your quality of life is – excellent (5), very good (4), good (3), fair (2), or poor (1).” Univariable and multivariable linear regression analyses were performed to identify demographic, socioeconomic and psychosocial factors associated with QOL. The multivariable analysis consisted of using Bonferroni correction and stepwise regression to adjust the p-values for multiple tests and to select the most statistically relevant variables contributing to QOL, respectively.
Results: The cohort was predominantly non-Hispanic White (84%), with the remaining participants being non-Hispanic Black (5.5%), Hispanic (3.1%), Other/Mixed (2.6%), and non-Hispanic Asian (1.6%). The average age was 70 years old. In the multivariable analyses, non-Hispanic Black (β= -0.33, 95%CI: [−0.49, −0.18], $p < 0.005$) and Hispanic (β= -0.38, 95%CI: [−0.58, −0.18], $p < 0.005$) survivors had lower QOL compared to non-Hispanic white survivors. For each additional year of age, the QOL score slightly increased by 0.01 units (95%CI: [0.009, 0.018], $p < 0.001$). Lower education (high school or lower) (β= -0.28, 95%CI: [-0.42, -0.14], $p < 0.005$) and lower household income levels (annual household income less than $25,000K) (β= -0.66, 95%CI: [-0.84, -0.48], $p < 0.001$) were also significantly associated with lower QOL. Interestingly, lacking confidence in filling out medical forms (β= -0.53, 95%CI: [-0.79, -0.28], $p < 0.005$) and feeling that medical providers were not listening (β= -0.22, 95%CI: [-0.29, -0.15 AZ], $p < 0.001$) were associated with lower QOL. Conversely, having assistance with daily tasks all or most of the time (β= 0.32, 95%CI: [0.19,0.45], $p < 0.001$) was linked to a higher quality of life.

Conclusion: In the national All of Us cohort, quality of life was associated with age, race and ethnicity, age, other socioeconomic factors, and psychosocial factors. Enhancing the availability of daily assistance and improving patient-provider communication can help mitigate some of these disparities. Our findings suggest that recognizing populations at risk and connecting them to resources with social work, support groups, and survivorship clinics will impact survivors' quality of life.\

P3-03-04: "Racial Disparities in Endocrine Response Pathway Activity in ER-Positive Breast Cancer: Insights from a Window of Opportunity Trial"

Diederick Keizer, Yvonne Wesseling-Rozendaal, Catherine Klein, Diana Kantrovich, Anna Weinand, Robert Babkowski, Mehran Habibi

Introduction: Mortality for hormone-receptor positive breast cancer is 19% higher among Black American women compared to White American women, despite having a lower incidence among Black women. Although these differences have been attributed to broader social barriers in accessing high-quality medical care, Jones et al. (Breast Cancer Research and Treatment, 2024 203:125–134) suggested different tumor biology is responsible for this outcome discrepancy. In this study, we utilized a novel technology to measure signal transduction pathway activity in breast tumors, generating new insights into the differences in endocrine response between patients of different races.
Materials and Methods: This single-institution window-of-opportunity study was conducted at Johns Hopkins University, Baltimore, USA. The study included 30 women with IHC-ER positive (>75%) and HER2 negative breast cancer who received neoadjuvant endocrine treatment (NAT) for two weeks. The participants comprised 13 White women and 5 Black women. Primary biopsies were subjected to signal transduction pathway analysis using the OncoSIGNal platform (InnoSIGN), which assessed the activity of four signaling pathways: estrogen receptor (ER), androgen receptor (AR), PI3K, and MAPK. A pathway was deemed active when the measured value, including its confidence interval, exceeded the 95th percentile of a previously established breast tissue reference range.
Results: The primary IHC-ER positive/HER2 negative breast cancer samples from Black women exhibited significantly lower ER pathway activity (43.0 ± 8.4) compared to those from White women (60.4 ± 11.2), with a p-value of 0.002. When these values were related to the breast tissue reference range, 92% of White women showed an active ER pathway, while only 20% of Black women had an activated ER pathway. Additionally, some patients in both racial cohorts displayed higher PI3K activity, with the highest PI3K activity observed in Black patients. There were no observed differences in AR and MAPK pathway activities between the races.
Discussion: This study reveals a significant disparity in ER pathway activity between Black and White women despite the fact all breast cancer samples being strongly ER-IHC staining positive. The lower ER pathway activity in Black women could partly explain their less effective response to endocrine therapy compared to White patients, as endocrine treatments specifically target the ER pathway. Furthermore, pathway analysis indicated

other potentially targetable pathways, such as PI3K, in patients with positive ER-IHC staining but inactive ER pathways.
Conclusion: The findings from this window-of-opportunity study highlight the need for larger cohort analyses to validate these initial observations and further investigate the clinical impact of these racial differences in breast cancer biology and treatment response.

P3-03-05: Impact of Comorbidities on Mortality, Length of Stay, and Hospital Charges in Breast Cancer Patients: A National Inpatient Sample Analysis

Kalaivani Babu, Srinishant Rajarajan, Kriti Dhamija, Vasuki Anandan, Charmi Bhanushali

Background: Breast cancer remains a significant public health challenge, particularly due to its association with high morbidity and mortality rates. Comorbid conditions, as quantified by indices like the Charlson Comorbidity Index (CCI), play a crucial role in influencing clinical outcomes, including mortality, length of hospital stay (LOS), and hospitalization charges. This study utilizes data from the 2021 National Inpatient Sample (NIS) to investigate these outcomes in breast cancer patients, aiming to provide insights for improving patient management and resource allocation.
Methods: We analyzed data from the NIS 2021 database, identifying breast cancer patients using the ICD-10 code C50. The primary outcome of interest was mortality, while secondary outcomes included LOS and total hospitalization charges. The analysis employed survey-weighted methods in Stata software to account for the complex survey design.
Mortality was assessed through overall rates and adjusted odds ratios (ORs) using logistic regression, accounting for variables such as age, sex, race, income quartile, CCI, hospital location, region, teaching status, and bed size. LOS and hospital charges were evaluated through mean calculations and adjusted regressions to identify the impact of demographic and hospital factors.
The Charlson Comorbidity Index was categorized as follows: 0 for no comorbidities, 1 for one comorbidity, 2 for two comorbidities, and ≥3 for three or more comorbidities.
Results: The study included a population size of 140,824.842 breast cancer patients. The overall mortality rate was 5.65% (95% CI: 5.36% - 5.94%).
Key findings from the logistic regression showed that the Charlson Comorbidity Index had a significant impact on mortality with an OR of 1.226 ($p<0.001$), indicating a higher risk of death with increasing comorbidities.
For LOS, the mean was 5.70 days (95% CI: 5.61 - 5.79 days). Significant factors influencing LOS included age (coefficient = 0.015, $p<0.001$), Black race (coefficient = 0.722, $p<0.001$), and the Charlson Index (coefficient = 0.301, $p<0.001$), indicating longer hospital stays with more comorbidities.
The mean total hospitalization charges were $74,939.30 (95% CI: $72,361.40 - $77,517.19). Significant factors affecting charges included Native American race (coefficient = $13,904.88, $p=0.002$) and the Comorbidities. The regression analysis indicated that each additional point in the Charlson Comorbidity Index was associated with an increase in

charges (coefficient = $2,609.05, p<0.001). Hospital characteristics also played a role, with teaching hospitals (coefficient = $8,097.84, p=0.004) and larger bed sizes (coefficient = $18,040.43, p<0.001) being associated with increased charges.
Conclusion: This study underscores the critical role of comorbidities in influencing the outcomes of breast cancer patients. Higher Charlson Comorbidity Index scores are associated with increased mortality, extended hospital stays, and higher hospitalization charges. The findings highlight the need for tailored management strategies to address the burden of comorbidities, aiming to improve patient outcomes and optimize healthcare resource utilization. The variability in LOS and hospital charges across demographic and hospital characteristics suggests potential areas for targeted interventions to enhance healthcare efficiency and patient care.

P3-03-06: Treatment and Survival Outcomes for Transgender and Gender-Diverse Patients with Breast Cancer from 2004–2022 in the National Cancer Database

Kelley Chan, Joseph H Cotler, Alexandra C Istl, Andrew E Petroll, Sailaja Kamaraju, Melinda Stolley, Chandler S Cortina

Introduction: Cancer disparities exist in transgender/gender-diverse (TGD) populations but there are limited data on the association of gender identity with breast cancer (BC) outcomes amongst TGD persons. Using the National Cancer Database (NCDB), we aimed to compare differences between TGD and cisgender patients with BC by examining 1) patient demographics and tumor clinicopathologic variables, 2) treatment characteristics, and 3) five-year overall survival (OS).
Methods: This retrospective cohort study queried the NCDB for TGD and cisgender patients diagnosed with BC from 2004–2022. Self-identified gender identity was abstracted from patient medical records when available. A random unmatched cisgender cohort was selected to explore differences in patient demographics, tumor clinicopathologic variables, and treatment characteristics compared to TGD patients. Next, a matched cisgender cohort was selected, matching on year of BC diagnosis, patient age, sex assigned at birth, race, Hispanic ethnicity, American Joint Committee on Cancer (AJCC) disease stage, and tumor receptor status to compare treatment and OS by gender identity. TGD patients with unknown sex assigned at birth were matched to cisgender female patients for the matched analysis. Chi-squared tests with Bonferroni corrections and multivariable logistic regression models were used to examine associations of variables with gender identity. Kaplan-Meier methods assessed five-year OS by gender.
Results: Of 4,376,089 patients with BC, 4,338,258 (99.1%) were female, 37,579 (0.9%) were male, and 252 (0.006%) were TGD. TGD patients had a median age of 51 years (IQR 42–61), most were non-Hispanic White (65.1%), had no medical comorbidities (78.6%), had health insurance (85.0%), and resided in the West (34.5%) or Northeast (23.8%) United States. Half (55.6%) of TGD persons were assigned female at birth, 20.2% were assigned male sex at birth, and 24.2% had an unknown sex assigned at birth. Of all TGD patients, 52.5% had

hormone-receptor positive (HR+)/HER2- tumors and 55.2% were node-negative.
Compared to a random unmatched cisgender cohort (n=252), TGD patients were younger (median age 51 years (IQR 42–61) vs 64 years (IQR 54–72), p<0.001) and had more persons assigned male sex at birth (20.2% vs 0.4%, p<0.001). While TGD patients more frequently had T2 tumors (24.2% vs 17.5%, p=0.008), there was no difference in disease stage between the TGD and cisgender cohorts (p=0.053). TGD patients with HR+ disease (n=201) received endocrine therapy less often than cisgender patients (58.7% vs 80.2%, p<0.001). On regression analysis, TGD patients were more likely to be diagnosed with BC at age <40 years compared to cisgender patients (OR 3.41; 95% CI 1.63–7.16, p=0.001) and had lower odds of receiving endocrine therapy for HR+ disease (OR 0.27; 95% CI 0.15–0.53, p=0.004).
Compared to a matched cisgender cohort (n=211), TGD patients with HR+ disease received endocrine therapy less often (58.5% vs 67.6%, p=0.04), a finding that remained significant on regression analysis (OR 0.50; 95% CI 0.30–0.82, p=0.032). Five-year OS was lower for the TGD cohort compared to the matched cisgender cohort (84.6% vs 91.7%, p=0.041) and persisted after excluding TGD patients with an unknown sex assigned at birth (n=154, 84.1% vs 93.9%, p=0.026).
Conclusions: Despite similar stage at diagnosis and tumor receptor status, TGD patients with BC were diagnosed at a younger age compared to their unmatched cisgender counterparts, were less likely to receive endocrine therapy for HR+ BC, and had inferior five-year OS compared to their matched cisgender counterparts. Strategic research is needed to elucidate the etiology of these disparities and develop targeted interventions to optimize treatment and outcomes for TGD persons with BC.

P3-03-07: Efficacy of Immunotherapy in Older Patients with Triple-Negative Breast Cancer: A Systematic Review

Marie Liu, Carrie Sha, Diana Lake, Jasmeet Singh, Mark Robson, W. Iris Zhi

Introduction: Immunotherapy (IO) has emerged as a promising treatment option shown to improve outcomes for patients with triple-negative breast cancer (TNBC), however, there exists a notable gap in our understanding of its efficacy within the older patient population. In this systematic review, we examined randomized clinical trials (RCTs) addressing the response to IO in older patients with TNBC.
Methods: We searched Medline ALL (Ovid), Embase (Elsevier), Cochrane Central (Wiley), ClinicalTrials.gov, and the WHO International Clinical Trials Registry Platform. The searches combined terms reflecting (1) the immune checkpoint inhibitors atezolizumab, durvalumab, and pembrolizumab; (2) breast cancer; and (3) RCTs. Results were limited to publications in English from 2013 to September 2023. Only articles that reported efficacy were included. Risk assessment was performed and overall risk of bias was graded. Two independent reviewers rated each study based on graded scales, and conflicts were resolved by a third reviewer.
Results: Our systematic review identified 18 full-text papers on 11 unique RCTs. Only four

RCTs presented results for patients 65 and older: KEYNOTE 355, KEYNOTE 522, IMPASSION 130, and IMPASSION 131. Of the first three RCTs, a total of 530 patients out of 2923 patients (18.1%) were 65 and older. The overall risk of bias was rated low or intermediate in all 11 RCTs.
In the early-stage TNBC setting, 131 of 1174 patients (11.2%) were 65 and older in KEYNOTE 522. The reported primary endpoint pathological complete response (pCR) was significantly improved in patients in the overall intention to treat (ITT) population in the first interim analysis (IO arm n = 401 patients; control arm n = 201 patients) who received pembrolizumab versus placebo (estimated treatment difference 13.6%, 95% CI 5.4 – 21.8%, p<0.001). Of the 602 total patients, 71 patients (11.8%) were 65 and older (IO arm n = 46; control arm n = 25), the treatment difference was 22.3% (95% CI -2.1 – 43.5%, p=N/A). At the fourth interim analysis (IO arm = 784 patients; control arm = 390), the co-primary endpoint event-free survival (EFS) in ITT was 84.5% at 36 months follow up, with hazard ratio (HR) 0.63 (95% CI 0.48 – 0.82, p<0.001). In patients 65 and older, the HR was 0.79 but not statistically significant (95% CI 0.40 – 1.56, p=N/A). In IMPASSION 031, atezolizumab in the early-stage setting was shown to have a significant improvement in the primary endpoint pCR in the ITT population (IO arm n = 165; control arm n = 168; rate difference of 17%, 95% CI 6–27%, one-sided p=0.0044).
In the metastatic setting, KEYNOTE 355 showed that for a total of 323 patients with Combined Positive Score (CPS) ≥ 10, median OS was 23.0 months in the IO arm compared to 16.1 months in the control arm (HR 0.73, 95% CI 0.55 – 0.95; p=0.0185) at median 44.1 months follow-up. In patients 65 and older with CPS ≥10 (n = 66), median OS was 28.3 months in the IO arm (n= 42) and 12.6 months in the control arm (n= 24) (HR 0.51, 95% CI 0.28 – 0.92, p=N/A).
In the metastatic setting, atezolizumab has not been shown to significantly improve OS in the ITT overall population or age-specific groups <65 or ≥65 in the final analysis of IMPASSION130.
Conclusion: There is a significant gap in data from RCTs evaluating the efficacy of IO in older patients with TNBC. The only FDA-approved IO in TNBC, pembrolizumab, was shown in the early-stage setting to improve pCR and EFS in older patients but was not statistically significant. In the metastatic setting, pembrolizumab significantly improved OS in older patients with CPS ≥10. Both studies had a limited number of patients 65 and older. No other studies reported statistically significant outcomes in patients ≥65. These results underscore the need for further research in older patients.

P3-03-08: Clinical Characteristics of Male Breast Cancer by Race and Factors Predicting Survival: An updated analysis

Jayasree Krishnan, Malak Alharbi, Guangwei Yuan, Kristopher Attwood, Arya Mariam Roy

Introduction Male breast cancer (MBC) is extremely rare and represents less than 1% of breast cancer (BC). While racial disparities in outcomes for female BC are well known, limited studies have investigated these disparities among MBC patients (pts). Some studies

indicate that Black race is associated with increased mortality in MBC, whereas conflicting results are observed in other studies. We aim to analyze the clinical characteristics of MBC by race and identify factors predicting survival in MBC pts. Methodology We queried the National Cancer Database for MBC pts diagnosed during 2004-2020. The demographic (age, race, education, income), clinicopathological (tumor stage, grade, nodal status, charlson Deyo comorbidity class (CDCC), hormone receptor status) and treatment characteristics (chemotherapy (CT), radiation(RT), hormone therapy (HT) and surgery (Sx)) were summarized by race. Statistical comparisons between racial groups were made using Kruskal-Wallis and Pearson chi-square tests, as appropriate. The overall survival (OS) by race was summarized using a Kaplan Meier curve. Multivariate analyses were conducted using the cox regression model to identify factors predictive of survival in MBC pts. Results A total of 23,758 MBC pts were identified, of which 80.5% (n=19161) were White (W), 13% (n=3054) Black (B), 3.5% (n=883) Hispanic (H), 1.5% (n=353) Asian (A) and 1.5% other race. The median age at diagnosis for W was higher compared to other races (67 y in W vs 64 y in A, 63 y in B and 60 y in H (P<0.001). Black pts were more likely to have higher comorbidity burden compared to other groups (CDCC 3+ W: 2.1%, B: 3.8%, A: 2.5%, H: 1.9%, all p<0.001). Black pts were also more likely to have stage IV disease (B: 10%, W: 6.5%, A: 5.7%, H: 7.2%, all p<0.001), larger (cT4 B: 8.9%, W: 5.6%, A: 5.7%, H: 6.3%, all p<0.001) and poorly differentiated tumors (W: 30%, B: 33%, A: 30%, H: 33%, all p<0.001) and node positive disease (B: 27%, W: 17%, A: 19% H:21%, all p<0.001). Whites had more estrogen (ER) (W: 89%, B: 85%, A: 84%, H: 85%, all p<0.001) and progesterone receptor (PR) (W: 81%, B: 74%, A: 77%, H:78%, all p<0.001) positive tumors while Black pts had more HER2 positive (W: 7.7%, B: 9.8%, A: 8.8%, H: 7.6%, all p<0.001) compared to other racial groups. Compared to White, other racial subgroups had more triple negative (W: 2.4%, B: 4.3%, A: 4.2%, H: 4.1%, all p<0.001) tumors. White and Hispanic MBC pts received less CT (W: 38%, B: 44%, A: 41%, H: 34%, all p<0.001) compared to Black and Asians. However, White pts received more HT compared to other racial groups (W: 61%, B: 55%, A: 54%, H: 53%, all p<0.001). The OS rates were lower in Black and higher in Asian pts compared to other racial groups (5 y OS: W: 73%, B: 67%, A: 81%, H: 78%). Univariate analysis showed that Black MBC pts had worse OS rates compared to Whites (HR 1.2 95% CI (CI) 1.09-1.24, P<0.01) however after adjusting for other covariates, no racial differences in survival were noted. Multivariate model showed that age (HR 1.04, CI 1.04-1.05, p<0.001), high comorbidity burden (CDCC3+) (HR 2.3 CI 1.88-2.90, P<0.001), TNBC subtype (HR 1.70, CI 1.35-2.14, p<0.001), poorly differentiated tumor (HR 1.35 (1.23-1.49, p<0.001) were associated with worse OS. Receipt of RT (HR 0.52, CI 0.28-0.98, P=0.04), CT (HR 0.73, CI 0.65-0.81, P<0.001) and HT (HR 0.79 CI 0.71-0.88, P<0.001) were associated with improved OS. Interestingly, compared with lumpectomy, pts who had mastectomy (HR 1.22 CI 1.03-1.45 P=0.025) and no surgery (HR 2.53 CI 2.03-3.17, p<0.001) experienced worse OS. Conclusion Greater comorbidity index, higher stage, poor differentiation, and triple negative subtype are associated with worse survival outcomes in MBC. Black MBC pts were observed to have large, node-positive, and aggressive tumors. In our updated analysis, after adjusting for socioeconomic and tumor characteristics, we did not observe any

significant disparities in survival outcomes in MBC based on race. Future research is warranted to develop strategies to improve the survival of MBC pts.

P3-03-09: Evaluating the impact of race, ethnicity, and neighborhood-level socioeconomic factors on invasive lobular carcinoma incidence and survival in the United States

Kathryn Demanelis, Neil Carleton, Margaret Q. Rosenzweig, Julia Foldi, Marija Balic, Stephanie Walker, Megan-Claire Chase, Adrian V. Lee, Steffi Oesterreich

Introduction: Invasive lobular carcinoma (ILC) accounts for ~10% of all female breast cancers (BC) diagnosed and is the most common special type of BC. Disparities related to race/ethnicity, urban-rural residence, and neighborhood-level socio-economic status (SES) influence the entire cancer control continuum from cancer development to diagnosis to survivorship. Presently, the impact of these potential disparity factors on ILC diagnosis and survival have not been extensively reported. The objective our analysis was 1) to evaluate the differences in ILC incidence and survival by these potential disparity factors and 2) to compare with no specific type (NST) BC using data from the Surveillance, Epidemiology, and End Results (SEER) registry.

Methods: We obtained access to the SEER 22 specialized dataset with census tract attributes (November 2022 submission) and included female BCs diagnosed from 2010-2019. Cases were specified as NST and ILC based on ICD-O-3 histologic codes: 8500 and 8520. The following disparity factors were examined race/ethnicity, neighborhood-level SES (quintiles derived from Yost Index), and urban-rural residence (USDA Rural-Urban Commuting Area codes). Age-adjusted incidences were computed, and joinpoint regression analyses evaluated the yearly change in NST and ILC incidence. Multivariable generalized Poisson models were employed to evaluate joint impact of the disparity factors on incidence as well as interaction between histology and each disparity factor. Kaplan-Meier survival curves were used to estimate overall and BC-specific (BCSS) survival. The Fine-Gray competing risk regression model was used to evaluate the impact of these potential disparity factors on BCSS, and models were adjusted for age at diagnosis, race/ethnicity, neighborhood SES, and stage at diagnosis. Stratified analyses were conducted by hormone receptor (HR)/HER2 status and age at diagnosis (<50 or 55+ years).

Results: From 2010-2019, 961,502 BC cases were included in our analysis, and 73.3% (age-adjusted incidence = 92.9 [95% CI: 92.6, 93.1] per 100,000) and 9.5% (incidence = 11.8 [95% CI: 11.7, 11.8]) were NST and ILC, respectively. Within ILC, 87% of cases were HR+/HER2-. ILC incidence increased by 2.3% (95% CI: 1.7, 3.0) per year from 2010-2019 while NST incidence increased by 1.7% (95% CI: 0.8, 2.6). Overall ILC incidence was 29%, 41%, and 53% lower in non-Hispanic (NH)-Black, Hispanic, and NH-Asian women compared to NH-White women, respectively, and these differences were substantially greater than what was observed for NST. ILC and NST incidence decreased by 13% and 6%

per decrease in neighborhood-level SES quintile, respectively. Across all disparity factors overall ILC incidence increased from 2010-2014 to 2015-2019 ($p < 0.001$ for all groups). Poisson modeling uncovered interactions ($p < 0.001$) between NST/ILC and each of these disparity factors, indicating a differential impact of these disparities on the likelihood of ILC diagnosis. For HR+/HER2- BC, 10-year BCSS was lower for ILC compared to NST (83% vs. 87%, $p < 0.001$), and the impact of race/ethnicity and neighborhood SES differed for NST and ILC (pinteraction < 0.05 for both). While HR-/HER2- (i.e., triple negative BC) compromised <2% of ILC cases, 10-year HR-/HER2- BCSS for ILC compared to NST was substantially lower for NH-black (55% vs. 69%) and Hispanic (58% vs. 74%) women as well as women residing in neighborhoods with the lowest SES (55% vs. 69%) and rural areas (51% vs. 73%).

Conclusions: Race/ethnicity and neighborhood-level SES are associated with ILC incidence and survival disparities, and these disparities are greater for ILC compared to NST. While ILC incidence is lower among racial/ethnic minorities, it has been increasing across all racial/ethnic groups, indicating that ILC can affect all women, regardless of race/ethnicity, age, and SES. Our work highlights that additional research and action is needed to address disparities in ILC diagnosis and treatment.

P3-03-10: Leverage GPT-4 and social media to understand health disparity for transgender patients with breast and gynecological cancers.

Kathryn Mishkin

Objectives: This study focuses on the often-understudied experiences of transgender individuals, specifically those assigned female at birth, navigating breast and gynecological cancer care. Leveraging social media and advanced AI (GPT-4), we explored their healthcare journeys, coping mechanisms, challenges, and the broader impact of their diagnoses.
Methods: User-generated discussions from major social media platforms (Reddit, X, YouTube) were collected, spanning 2012 to 2022. A combination of systematic searches, rule-based filters, and AI (GPT-4) was used to extract narratives specific to transgender patients. Pre-established themes were identified through manual analysis and literature review. Two independent researchers coded a subset of the data to ensure reliability, achieving substantial agreement (Cohen's kappa $\kappa = 0.93$). GPT-4 was then utilized to categorize these posts into distinct stages of the patient journey and the pre-established main themes. Emergent subthemes and perspectives identified by GPT-4 were manually validated.
Results: From over 30 million posts on social media, 1,235 were eligible for inclusion. The analyzed posts were distributed across various cancer indications: breast cancer (30.4%), cervical cancer (25.9%), endometrial cancer (34%), and ovarian cancer (9.7%). Three primary themes emerged: lack of awareness, access issues, and clinical challenges. Posts about clinical concerns focused on the burden of disease (87.1%), with emphasis on physical health. A concerning lack of healthcare system and provider awareness of

transgender cancer needs was highlighted in 65.7% of posts, with 16.5% expressing concerns about incorrect pronoun use. Nearly one-third of posts addressed financial issues (health insurance coverage limitations), while 71.9% addressed non-financial access issues, including concerns about trans-competent healthcare providers.
Conclusion: By utilizing social media data and AI, we captured experiences and disparities in breast and gynecological care faced by transgender individuals. Findings underscore the need for increased provider awareness, improved healthcare access, and inclusive clinical practices. Addressing these disparities and advocating for more equitable and empathetic cancer care is crucial, regardless of gender identity.

P3-03-11: Structural Racism and Aggressive Breast Cancer Biology

Neha Goel, Alexandra Hernandez, Susan Kesmodel, Michael Antoni, Steve Cole

Objective: To determine the association between objective (geospatial) and subjective (perceived) measures of structural racism and aggressive breast cancer tumor biology, defined using validated social adversity-associated transcription factor (TF) activity.
Background: Structural racism is associated with shorter breast cancer recurrence-free survival, independent of individual, tumor, and treatment characteristics, suggesting potential unaccounted biological mechanisms by which structural racism influences tumor biology. The field of social genomics offers a mechanistic approach to study the influence of social adversity on tumor biology through validated TFs of social adversity.
Methods: We quantified TF-binding motif prevalence within promoters of differentially expressed genes for 147 tissue samples prospectively collected on protocol. Covariate-adjusted multivariable regression analyzed objective measures of structural racism using the validated Index of Concentration at the Extremes and subjective measures of perceived discrimination using the Expanded Everyday Discrimination Survey with validated TFs of social adversity and aggressive biology—pro-inflammatory activity [nuclear factor-κB (NF-kB) and sympathetic nervous system (SNS) activity [cyclic 3′-5′ adenosine monophosphate response element-binding protein (CREB)], controlling for age, race/ethnicity, BMI, stage, grade, tumor type (TNBC, etc), and neoadjuvant therapy.
Results: Increasing objective structural racism and perceived discrimination were associated with SNS activation (up-regulated CREB) and aggressive tumor biology (up-regulated NF-kB).
Conclusions: To our knowledge, in the largest human social genomics structural racism study, objective measures of structural racism and subjective measures of perceived discrimination were significantly associated with TFs of aggressive biology and SNS activation, implicating SNS activation as one potential mechanism behind structural racism-associated survival disparities. We have previously shown that these TFs correlate with worse clinical outcomes such as shorter survival and higher Oncotype DX scores further reflective of aggressive tumor biology. These findings remain to be validated in a national cohort.

P3-03-12: Social Determinants of Health (SDOH) and Z Code Utilization among Patients with Breast Cancer (BC)

Nehanda Jones, Adam Blair, Elizabeth Lipschultz, Jacob Koskimaki, Brooke Smither, Robert Miller

Background: Previous studies show that SDOH play an important role in BC stage, treatment, and outcomes. Disparities in BC overall survival (OS) by SDOH are well documented. Z codes were introduced into International Classification of Diseases, 10th edition in 2015 to identify reasons for clinical encounters when circumstances other than a disease or injury are recorded as diagnoses, but uptake has been slow. Herein we report Z codes Z55 – Z65, which specifically identify SDOH impacting health care utilization, for BC patients (pts) in CancerLinQ (CLQ). Methods CLQ is a health data platform representing ~7M pts across 100+ US oncology practices and cancer centers. In this retrospective cross-sectional analysis, CLQ pts diagnosed (dx) with BC actively managed in 2021 were identified and pt diagnosis codes (PDC) evaluated. Descriptive statistics and multi-variate logistic regression analysis were performed, estimating statistically significant proportions (%) and adjusted odds ratios with corresponding 95% confidence intervals [aOR (95% CI)] for associations between independent demographic variables and Z code reporting. BC pts with >1 Z code reported were compared to BC pts with no Z codes. Results We evaluated 8,134,071 BC PDC representing 236,115 BC pts actively managed in 2021. BC pts were 77% Non-Hispanic White (NHW), 16% Non-Hispanic Black (NHB), with Asian and Hispanic/Latino BC pts comprising <6%. BC pts dx age <40 were 3%, 12% dx age 40-49, 29% dx age 50-59, 25% dx age 70-79, with 10% dx age ≥ 80. 52% of BC pts were married, 33% divorced/widowed, with 15% single. BC pts were largely female (99%) and urban (86%). Of the BC PDC assessed, 7,069 were Z code PDC representing 7,624 BC pts, 3.2% of CLQ BC pts actively managed in 2021. Among BC pts represented, 50.9% had 1, 13.4% had 2, 6.3% had 3, 14.6% had 4, and 14.7% had 5+ Z codes reported. The 5 most frequently reported Z code groups were: Z63 (35%) - Support group & family circumstances Z59 (27%) - Housing & economic circumstances Z65 (16%) - Other psychological circumstance Z60 (11%) - Social environment Z56 (5%) - Employment NHB, Asian, and Hispanic/Latino BC PDC had greater odds of Z code reporting compared to NHW, with Hispanic/Latino BC PDC having almost 2x greater odds of Z code reporting [1.8 (1.64, 1.94)]. An inverse relationship was observed between dx age and aOR of Z code reporting, with BC PDC of pts dx age <40 having the greatest odds [1.4 (1.24, 1.58)] and BC PDC of pts dx ≥80 having the lowest [0.8 (0.76, 0.92)]. Divorced/widowed PDC [1.7 (1.60, 1.78)] and single PDC [1.6 (1.53, 1.75)] BC PDC had greater odds of Z code reporting compared to married BC PDC. Rural BC PDC [0.9 (0.81, 0.94) had lesser odds of Z code reporting compared to urban BC PDC. Conclusion CLQ BC Z code utilization in 2021 (3.2%) exceeded previously reported disease-agnostic studies (1.3% - 1.9%). Z codes indicative of factors related to socioeconomic status (SES), employment, and social isolation represent 94% of all Z codes reported among BC PDC in this analysis. This finding is consistent with previous studies of SDOH among BC pts. Hispanic/Latino, divorced/widowed, and single BC PDC had the greatest odds of Z code reporting, with rural BC PDC among the lowest odds. The

association of poorer quality care and survival among rural pts is well-known. Similarly, previous studies of women dx age <40 experiencing negative SDOH were more likely to receive chemotherapy, less likely to take endocrine therapy if indicated, and suffered worse OS. Thus, the inverse relationship observed between dx age and Z code reporting as well as low odds of reporting in rural settings should be further studied in future analyses which include BC stage, treatment patterns, and outcomes. Greater Z code reporting by providers could uncover SDOH trends impacting BC diagnosis, healthcare utilization, treatment, and outcomes.

P3-03-13: Ethnic and Geographic Disparities in Mucinous Breast Cancer

Inae Park, Yu Jung Heo, Sungjae Park

Introduction: Mucinous breast cancer (MBC) is a rare subtype of invasive breast cancer which accounts for one to four percent of overall invasive breast cancer in the United States. The clinical features of MBC have not been fully understood due to limited patient data. Here, we report ethnic and geographic disparities in patients with MBC.

Method: Mortality and overall survival rates (OS) were obtained from the Surveillance, Epidemiology, and End Results (SEER) Stat Database 17-registry (2000-2021). The 7th edition of American Joint Committee on Cancer (AJCC) staging was used due to the unavailability of differentiation grade data in the 8th edition of AJCC staging. Patient subgroups were divided into ethnicity (White, Black, Asian American and Pacific islanders; AAPI), household income (>=$75,000 vs <$75,000 per year), age of diagnosis (25-45 vs 45-65 vs 65+ years), and geographics (metropolitan vs nonmetropolitan area). Propensity score matching (PSM) was used to reduce the effect of confounding factors such as surgery, chemotherapy, radiation therapy, stage, grade, hormone receptor status (estrogen receptor; ER and progesterone receptor; PR), and human epidermal growth factor receptor 2 (HER2) status. Univariate and multivariate Cox regression analyses were used to obtain independent prognostic factors. Patients with duplicate record, missing information regarding confounding factors were excluded in the analysis.

Result: Overall, 5,219 patients were included in the final analysis. The independent prognostic factors were age of diagnosis, race, stage, differentiation grade, hormone receptor status (ER and PR), HER2 status, metastases (bone, brain, liver, and lung), surgery, chemotherapy, radiation, income, and marital status. In ethnic subgroups, AAPI showed better OS than in White before and after PSM (before PSM, HR 0.50, 95% CI, 0.41-0.62, p<0.01; after PSM, HR 0.54, 95% CI, 0.42-0.69, p<0.01). White and Black patients did not reveal significant differences in survival. (HR 1.03, 95% CI, 0.88-1.21, p=0.74). After PSM, White patients had an OS benefit than in Black (HR 0.56, 95% CI, 0.44-0.71, p <0.01). In geographic subgroups, patients in the metropolitan areas did not show significant difference compared to patients in the nonmetropolitan areas before PSM (HR 0.87, 95% CI, 0.74-1.02, p=0.09). However, patients in the metropolitan areas exhibited better OS compared to patients in nonmetropolitan areas (HR 0.61, 95% CI, 0.48-0.77, p<0.01) after

PSM. In income subgroups, patients with household income >=$75,000 revealed better OS than those who have income less than $75,000 before PSM (HR 0.82, 95% CI, 0.74-0.91, p<0.01). However, those groups did not show statistical significance in OS after PSM (HR 0.89, 95% CI, 0.80-1.00, p=0<0.01).
Conclusion: Overall, mortality and OS varied among different ethnic groups and regions, though additional studies are warranted for Native Americans or Alaskans with a larger patient dataset. In regards to primary prevention, an early intervention could be especially beneficial for patients in rural areas while MBC is known for its good prognosis. Furthermore, several possible confounding factors such as alcohol or smoking could be further controlled if they are included in the SEER dataset in the future. In addition, the use of AJCC 8th edition with differentiation grade data is warranted in the future.

P3-03-14: Concordance of Self-Reported Demographic and Clinical Variables with Data from the State Cancer Registry among Breast Cancer Survivors of Hispanic Descent

Maria Eduarda de Azevedo Daruge, Eunkyung Lee

Background: Epidemiological research studies and population-based registries use various methods to gather accurate patient data. However, these methods can still be affected by inaccurate reporting. Reliable population-based data is crucial for public health surveillance, representing the source population, and allocating resources to address cancer disparities. This study aimed to compare the information reported in a survey to the data collected by the state cancer registry in order to assess its reliability.
Methods: The Hispanic Breast Cancer Study aimed to enroll Hispanic women with breast cancer using the Florida Cancer Data System (FCDS) patient recruitment process, to examine differences in health-related quality of life through self-reported surveys. After obtaining approval from the Florida Department of Health Institutional Review Board, FCDS provided patient contact information and clinical data for eligible participants. To be eligible, women had to be at least 20 years old, diagnosed with breast cancer at least six months prior, reported to FCDS, not pregnant or lactating, self-identified as Hispanic, and lived in Central Florida. Concordance analysis was carried out to measure the agreement between the self-reported survey data and the information in the cancer registry. This analysis included correlation coefficients for continuous variables such as current age and birthplace, and kappa values for categorical variables like Hispanic origin/ethnicity, race, and laterality.
Results: A total of 364 women completed the surveys. The women's current age showed a strong correlation (r= 0.99, P< 0.001), indicating a high level of agreement between their self-reported age and the age reported by the FCDS. There was a moderate correlation for birthplace (r=0.43, P< 0.001). The agreement for Hispanic origin and race was low (kappa for Hispanic origin= 0.19; κappa for race= 0.05), while the agreement for laterality was deemed acceptable (kappa= 0.52).
Conclusions/Implications: The study's varying concordance levels emphasize the pressing

need for better data collection systems. The low concordance for race and Hispanic origin underscores the significance of this issue. Improving the quality of health data could lessen patient burden during surveys and will be vital in addressing cancer disparities among Hispanic breast cancer survivors.

(This study was supported by the Florida Breast Cancer Foundation Scientific Grant and the University of Central Florida Office of Research to EL.)

P3-03-15: Racial differences in incidence of depression, anxiety, and insomnia among breast cancer patients on endocrine therapy

Shuwen Lin, Cho-Han Chiang, Xiaocao "Haze" Xu, Yu-Cheng Chang, Yu Chang, Cho-Hung Chiang, Daniel Helman

Introduction: Endocrine therapy in breast cancer patients is asscociated with increased risk of developing mood, anxiety, and sleep disorders. Studies have shown that there are lower rates of diagnosis and treatment of mood disorders and anxiety disorders for African Americans and Hispanics than for Caucasians. This study explored whether there are racial differences in incidence of depression, anxiety, and insomnia in breast cancer patients on endocrine therapy.
Methods: We performed a retrospective, propensity score-matched cohort study using the TriNetX Analytics Network database, which includes de-identified electronic health records from over 70 healthcare organizations and 101 million individuals. We included adult female breast cancer patients treated with endocrine therapy from January 2010 to June 2023. We excluded patients with metastatic disease. We also excluded patients with a prior history of depression, anxiety or insomnia. We matched patients on predetermined variables including age, breast cancer-directed therapy, and comorbidities. We compared incidence of diagnosis of depression, anxiety and insomnia among patients in different race/ethnicity subgroups (Hispanic, Black, White, and Asian) either on aromatase inhibitor (AI) or tamoxifen within the first year of initiation of endocrine therapy.
Results: We identified 93,606 and 33,031 patients on AI and tamoxifen, respectively. We matched 23,002 patients in both AI and tamoxifen cohorts. The incidences of depression are 11.65 vs. 12.22 per 1000 patient-years (p=0.64) on AI vs. tamoxifen, respectively; the incidences of anxiety are 17.43 vs. 15.73 per 1000 patient-years (p=0.13) on AI vs. tamoxifen, respectively; the incidences of insomnia are 6.52 vs. 5.26 per 1000 patient-years (p=0.07), on AI vs. tamoxifen respectively. Compared to matched White counterparts, Black patients (n=8946) on AI have a lower risk of depression (HR=0.74, p=0.03), a lower risk of anxiety (HR=0.60, HR<0.01), but no significantly different risk of insomnia. Compared to matched White counterparts, Hispanic patients (n=3472) on AI have a higher risk of insomnia (HR=1.97, p=0.02), but no significantly different risk of depression or anxiety. Compared to matched White counterparts, Asian patients (n=3795) on AI have a lower risk of depression (HR=0.18, p<0.01), a lower risk of anxiety (HR=0.30, p<0.01), but no significant difference in insomnia. Compared to matched White counterparts, Black patients

(n=2675) on tamoxifen have a lower risk of depression (HR=0.74, p=0.05), a lower risk of anxiety (HR=0.68, HR=0.03), but no significant difference in insomnia. Compared to matched White counterparts, Hispanic patients (n=1709) on tamoxifen have no significantly different risk of depression, anxiety or insomnia. Compared to matched White counterparts, Asian patients (n=1884) on tamoxifen have a trend towards lower risk of depression (HR=0.56, p=0.06), a lower risk of anxiety (HR=0.33, p<0.01), but no significant difference in insomnia.
Conclusion: Depression and anxiety are diagnosed at a lower incidence in Black and Asian patients compared to White patients on endocrine therapy. This may reflect lack of access to care, under-recognition, or cultural differences in minority patients, and further studies are needed to identify the causes of these differences.

P3-03-16: Molecular stromal signature to predict Ductal Carcinoma in Situ (DCIS) progression

Niki Prekete, Michael Allen, Eleni Maniati, Louise Janet Jones

Ductal Carcinoma in Situ (DCIS) is a pre-invasive breast carcinoma, where the cancer cells proliferate within the breast duct. Because the ducts are not connected to the circulatory or the lymphatic system, DCIS does not constitute a lethal disease. Due to the implantation of the mammographic screening programme, the percentage of women diagnosed with DCIS is increasing. These women who are diagnosed with DCIS are currently treated as if they were going to progress to invasive cancer, as there is no way to predict the progression of the disease and stratify patient treatment. Analysis of the neoplastic cells of DCIS has not revealed genetic changes linked to the risk of progression, the scientific interest has been turned to the tumour microenvironment.
This study hypothesised that changes that take place in the stromal compartment surrounding DCIS ducts can promote the invasive capacity of the carcinoma and as a result promote the progression from DCIS to invasive disease. The study aimed to discover alterations in the stromal area of normal, pure DCIS and invasive carcinomas that may indicate risk of future progression and create a signature to distinguish the progressive and the non-progressive DCIS.
A cohort of four patients with matched clinicopathological characteristics who were previously diagnosed with invasive breast cancer and did not have neoadjuvant treatment was selected. RNA sequencing was performed on samples from the invasive, DCIS and normal breast areas of these patients (n=12). Although the samples contained the whole tissue, they were selected to represent more the microenvironmental compartment of each disease stage.
The analysis of the RNA sequencing samples led to the identification of 50 genes, that showed a stepwise increase (n=18) or decrease (n=32) in expression from normal, pure DCIS or invasive cases. The majority of the pathways and processes the genes of the signature involved were connected to elements of the microenvironment, such as collagen degradation and crosslinking, avβ3 integrin, and biological processes including T-cell

activation. Interestingly, the RNA sequencing results in these whole tissue samples showed a much higher number of differentially expressed genes between the Invasive Tumour vs DCIS comparison than in the DCIS vs Normal comparison suggesting that the whole tissue DCIS is more similar to the Surround than in the invasive tumour disease stage. Gene targets; FN1, VCAN and MMP11 were validated through Immunohistochemistry or RNAScope in an external sample cohort comprised of normal, pure DCIS and DCIS with invasion cases. Finally, the genes were combined in a signature and an in silico analysis of public datasets that included independent normal, DCIS and invasive cases from patients also validated our polygenic risk score.
This study has managed to identify a panel of genes showing altered expression between normal, pure DCIS and invasive cancer tissues. The results emphasised the importance of the tumour microenvironment in disease progression. The findings were then combined in a multigene signature associated with prognosis and risk of progression on public datasets.

P3-03-17: Genetic Profiles and Precision Medicine in Adolescent and Young Adult Chinese Women with Breast Cancer: A Comprehensive Study

Qing Hao, Fei Pang, Chengyi Wang, Hongrui Zhou, Aodi Wang, Hui Chen

Background: Breast cancer is a major health concern worldwide, especially among Adolescent and Young Adult (AYA) women who face unique biological and clinical challenges. AYA breast cancer patients often present with aggressive subtypes, requiring specific treatment considerations such as fertility preservation and long-term survivorship. This study aims to analyze the genetic characteristics of AYA Chinese women with breast cancer, focusing on genomic alteration profiles and their correlation with clinical outcomes, to provide precise treatment guidance.

Patients and Methods: We analyzed tumor and matched blood samples from 202 young Chinese breast cancer patients (≤39 years) diagnosed between 2014 and 2024. Targeted next-generation sequencing was conducted on formalin-fixed paraffin-embedded (FFPE) or fresh tumors. Personalized ctDNA assays were used for Minimal Residual Disease (MRD) monitoring to detect early recurrence and guide treatment. Experiments were performed in a CAP/CLIA-certified laboratory.

Results: The study cohort had a median age of 35 years (range 18-39). Among them, 48.02% (97/202) were in stages I-II, 42.08% (85/202) in stages III-IV, and 9.9% (20/202) had unclear staging. Molecular subtypes included 28.71% (58/202) HER2+, 32.67% (66/202) ER+/PR+/HER2-, and 28.22% (57/202) triple-negative breast cancer (TNBC). The top 5 mutated genes in TNBC were TP53 (86%,49/57), PIK3CA (14%,8/57), RB1 (14%,8/57), PTEN (10.5%,6/57), and CDKN2A (8.8%,5/57). For HER2+ patients, they were ERBB2 (86%, 50/58), TP53 (64%,37/58), PIK3CA (28%,16/58), CCND1 (10.3%,6/58), and BRAF (5.2%,3/58). ER+/PR+/HER2- patients had TP53 (36%,24/66), PIK3CA (35%,23/66), CCND1 (20%,13/66), PTEN (12.1%,8/66), and AKT1 (7.6%,5/66). Among the 58 HER2+

cases, 49 have ERBB2 somatic gene amplification, while 5 in 49 co-occuring point mutations. Germline testing was performed on 197 patients, with 11.67% (23/197) showing pathogenic/suspected pathogenic mutations in BRCA1/2. A case study of a 34-year-old HER2+ patient demonstrated the value of precision medicine and MRD monitoring. MRD testing detected recurrence two months earlier than imaging. Treatment with the HER2-targeted drug DS-8201 led to complete response, maintained over four consecutives negative MRD tests.

Conclusions: Our findings underscore the diverse molecular subtypes and significant genetic mutations among young Chinese breast cancer patients, highlighting the necessity of personalized treatment strategies. Incorporating precision medicine and MRD monitoring can significantly enhance early recurrence detection and improve overall treatment outcomes. Future research should focus on validating these findings and developing tailored strategies in larger cohorts.

P3-03-18: Hormone receptor status and PD-L1 expression prevalence in breast cancer when assessed with PD-L1 IHC 22C3 pharmDx and Combined Positive Score

Joseph Barreto, Jaret Quiroz, Emily Olander, Donna Kell, Siena Tabuena-Frolli, Camilla Recke, Kelly Martyniuk

Background: Programmed cell death-ligand 1 (PD-L1) is of great interest in breast cancer (BC). PD-L1 IHC 22C3 pharmDx (SK006) is an approved companion diagnostic assay for patients with triple-negative breast cancer (TNBC). Multiple sub-types of BC are identified by the binary expression status (positive/negative) of human epidermal growth factor 2 (HER2) and the hormone receptors (HRs) estrogen receptor (ER) and progesterone receptor (PR). The ability of the assay to reliably identify PD-L1 expression in TNBC (ER-/PR-/HER2-) tissues was previously demonstrated. However, the sensitivity of the assay on HR+/HER2- specimens (including ER+/PR+, ER+/PR-, and ER-/PR+; non-TNBC) is not as well-known. The data presented here demonstrates the ability of the assay to reliably identify the dynamic range of PD-L1 expression on non-TNBC specimens when assessed using the Combined Positive Score (CPS).

Methods: Primary and metastatic BC specimens, sourced from multiple anatomical sites, were prepared and stained according to the assay's Instructions for Use (IFU). The PD-L1 IHC 22C3 pharmDx immunohistochemical assay uses Monoclonal Mouse Anti-PD-L1, Clone 22C3, for detection of PD-L1 protein in formalin-fixed, paraffin-embedded tissues. Stained sections were scored using CPS, which is the number of PD-L1 staining cells (tumor cells, lymphocytes, macrophages) divided by the total number of viable tumor cells, multiplied by 100. CPS totals are displayed as integers with a maximum CPS of 100. Additional cut sections from the same specimens were also prepared and stained using Agilent ER, PR and HER2 reagents, where positivity or status was based upon the IFU for each reagent. Each

specimen was then grouped into non-TNBC or TNBC sub-types. Prevalence was assessed to demonstrate that the assay will detect the target molecule (PD-L1 protein) in BC specimens across the dynamic range of PD-L1 expression (CPS 0–100). For the purposes of this abstract, scores were reported according to the CPS ≥ 1 and CPS ≥ 10 cutoffs.

Results: Prevalence data of Agilent's internal BC tissue bank was evaluated. At the time of the assessment, two categories of BC specimens and their totals were grouped: 149 non-TNBC and 184 TNBC. When examining the CPS ranges for the non-TNBC specimens, 55/149 (36.9%) were found to have a CPS ≥ 1 and 17/149 (11.4%) had a CPS ≥ 10. When examining the CPS for the TNBC specimens, 115/184 (62.5%) were found to have a CPS ≥ 1 and 57/184 (31.0%) had a CPS ≥ 10. For all specimens of each cohort (non-TNBC and TNBC), the assay identified PD-L1 expression across the dynamic range. This analysis indicates that the dynamic range of PD-L1 expression is present across all BC tissues regardless of HR status, though a higher prevalence is noted in TNBC specimens at the CPS ≥ 1 cutoff.

Conclusions: Overall, the assay detected PD-L1 protein across the dynamic expression range (CPS 0–100) for both non-TNBC and TNBC specimens. In this small specimen cohort, retrospective analysis demonstrated that HR status may correlate to a difference in PD-L1 prevalence in HER2- breast cancer specimens. This analysis further demonstrated that PD-L1 IHC 22C3 pharmDx can identify PD-L1 expression in the dynamic range within non-TNBC specimens, specifically. Further studies should be conducted within different combinations of HR status and PD-L1 prevalence to expand on this data, to address gaps in knowledge, and to learn if HR status may inform PD-L1 immune checkpoint inhibitor therapy benefit for BC patients.

P3-03-19: Somatic Mutation Profile of Metastatic Breast cancer in Brazilian Patients using Next Generation Sequencing

Mariana Ferreira, Tatiana Strava Correa, Júlio Antônio P. Araújo, Aline Alves Franzin Vanzo, Ana Maria Ulbricht Gomes, Carlos Henrique dos Anjos, Romualdo Barroso-de Sousa, Débora Gagliato

Background: Advances in next-generation sequencing (NGS) offers multigene mutational profile that provides comprehensive genetic information on breast cancer molecular pathology and increases the likelihood of identifying mutations that may be potentially susceptible to targeted treatments. There are limited data on the molecular epidemiology of metastatic breast cancer in low- and middle-income countries. This study analyzed the clinical-pathological characteristics and mutational profile of the population using NGS tests from two oncologic centers at Brazil, with a focus on actionable mutations that could be targeted and that resulted in a change of cancer treatment. Methods: We conducted a retrospective analysis from 2018 to August 2023 of patients with metastatic breast cancer (MBC) who received NGS in two centers at Brazil. We enrolled patients from São Paulo and Brasilia. Results: In total 78 NGS from patients with MBC were analyzed, including 52 with

luminal phenotype, 07 who were HER- 2 positive, and 19 triple negative breast cancer. The population was predominantly female (97,4%). Median age was 40,5 years. Most of the patients, 88.46% had recurrent disease and 11,54% de novo metastatic breast cancer. The NGS samples were mostly from a metastatic site (67,95%). Liquid biopsy was applied in 8,9% of the cases, while 91,1% were from tissue biopsy most from liver (19,23%), followed by lymph nodes (19,23%), primary breast nodule (14,10%), lungs (12%) and bones (5,3%). A total of 127 gene mutations were found. The clinically relevant mutation found were in TP53 (42,31%), PIK3CA – AKT1- PTEN pathway (41,05%) distributed as 32,05% in PIK3CA, 1% in AKT1 and 8% in PTEN loss, ESR1 (17,95%), ERBB2 mutations (11%), BRCA 1/ 2 mutations (6%) and ATR/ATM/PALB2 (5%). The molecular alterations, such MSI high (1,28%) and TMB (mean value 3 mut/Mb) predictive of response to immunotherapy were rare. For the HR positive tumors mutations at PIK3CA (35,1%), TP53 (28,6%), ESR1 (25%) were the most prevalent. In contrast, the triple negative tumors (24,36%) had a higher incidence of TP53 (76,9%) and a low prevalence of PIK3CA/AKT/PTEN mutation (1,2%). HER 2 population (8,9%) the most prevalent mutations were found in ERBB2 (100%), and TP53 (50%). Of the 78 NGS, 34 had genomic alterations that were targetable by medications approved in FDA, EMA and/or ANVISA (regulatory agency in Brazil). The findings of the NGS resulted in a change of treatment in 17,95%. Nine patients received Alpelisib. Three patients received anti-HER2 therapies, 02 of them were luminal subtype and 01 was HER 2 positive breast cancer. One patient was treated with Olaparib for BRCA 2 somatic mutation, luminal subtype. The median survival of the general population was 218 days. The median survival stratified by change of treatment was 218 days for the group with genomic findings and treatment modification while the median survival was 162 days for the group without genomic findings. But the difference wasn't statistically meaningful (p = 0,35) according to long Rank analyses. Conclusion: The increased accessibility of the NGS may lead to a greater number of potential therapeutic implications. The prevalence of the mutation was different between the intrinsic subtypes of cancer. The mutations in PIK3CA/AKT/PTEN pathway and ESR1 can be targetable after iCDK4/6 inhibitor progression, underlyng the importance and necessity of a NGS in the treatment of HR positive metastatic breast cancer.

P3-03-20: A multicenter retrospective review of clinical-pathological characteristics associated with survival outcomes in a large cohort of metaplastic breast cancer patients.

Naomi Dempsey, Amanda Arnold, Zhuo Li, Siven Chinnah, Ana Sandoval, Lauren Carcas, Manmeet Ahluwalia, Reshma Mahtani, Pooja Advani

Background: Metaplastic breast cancer (MpBC) is a rare and aggressive subtype of breast cancer (BC) that is frequently triple negative (TN) and relatively chemo resistant. MpBC is a heterogeneous group of invasive BC in which cancer cells demonstrate both epithelial and mesenchymal differentiation. Although MpBC is generally treated similarly to invasive ductal carcinoma, these tumors tend to be refractory to chemotherapy (CT) despite the greater incidence of high grade and TN cancers. In this analysis, we examined the clinical

and pathological characteristics associated with worse prognosis in patients with MpBC.
Methods: Patients (pts) treated for MpBC at Miami Cancer Institute (2017-2021; identified by COTA real-world Analytics® platform) and Mayo Clinic (1997-2021; identified by Epic slicer dicer tool) were retrospectively reviewed after IRB approval. Pt demographics, pathologic characteristics, staging, treatment, and outcomes data were collected. Kaplan-Meier method was used to estimate disease-free survival (DFS) and overall survival (OS) at 1, 5, and 10 years (yr) post diagnosis. Univariable and multivariable Cox regression models were used to examine the association between pt/tumor characteristics and outcomes (DFS and OS). All tests were two-sided with p value <0.05 considered statistically significant. The analysis was done using R4.2.2.
Results: We identified 204 pts with MpBC with a median 2.5 yr of follow up from the time of initial diagnosis. Median age at diagnosis was 60.5 yr, and 162 pts (79.4%) were post-menopausal. At presentation 175 (94.6%) had early-stage disease, 160 (84.7%) had tumor size less than 5 cm, and 156 (81.7%) were node negative on imaging. Family history was positive in 48% of pts and 10 (12.2%) had a positive germline mutation. Tumors were ER <1% in 163 (81.5%), ER 1-10% in 17 (8.5%), and HER2 negative in 174 (91.6%). Distant metastatic disease was noted in 21 pts (10.3%). 95 pts (50.8%) had lumpectomy, 90 pts (48.2%), had mastectomy, and 127 (68.3%) had sentinel node biopsy. At surgery, 119 (64.3%) had pT1/T2 tumors and 117 (63.2%) had pN0 tumors and 106 (66.2%) received adjuvant radiation. Spindle cell histology was seen in 43 pts (22.5%), followed by mesenchymal in 51 pts (26.7%) and squamous cell histology in 33 pts (17.3%). Of the total cohort, 57 (28.5%) received neoadjuvant CT and 6 (11.1%) of these pts achieved a pathologic complete response (pCR). pCR did not predict for improved survival outcomes in this group of pts. In the entire cohort, 5-yr DFS was 62.0% (95% confidence interval [CI] 54.2%-70.9%) and 5-yr OS was 79.7% (95% CI 73.0%-86.9%). In multivariate analysis, presence of distant metastatic disease (HR 5.55, 95% CI 1.85-16.69; p=0.002) and spindle cell histology predicted statistically significant worse mortality (hazard ratio [HR] 3.67, 95% CI 1.76-7.67; p<0.001). Increasing stage also predicted statistically significant worse OS (HR 2.17, 95% CI 1.29-3.62; p=0.003).
Conclusion: In this large, predominantly early-stage cohort of pts with MpBC, higher stage at diagnosis, distant metastatic disease, and spindle cell histology predicted worse OS. PCR rates following neoadjuvant CT was low, consistent with the reported literature, confirming the relative chemo resistant nature of MpBC. These results underscore the need for focused research efforts to develop novel therapeutic strategies to improve outcomes, particularly in MpBC with spindle cell histology and pts with distant metastasis.

P3-03-21: EFFECT OF REGULATORY T CELL INFILTRATION ON PATHOLOGICAL COMPLETE RESPONSE RATES WITH NEOADJUVANT THERAPY IN LOCAL AND LOCALLY ADVANCED HER2 POSITIVE BREAST CANCER

Derya Kıvrak Salim, Yasemin Koca, Banu Öztürk, Canan Sadullahoglu

Aim: In our study we aim to reveal the effect of the intratumoral Treg infiltration on the pathological complete response and to find out other clinicpathologic and cellular variables effective on pathologic complete response
Patients and Method: Fifty-five patients were included, aged 18 years and over, who were treated and followed up in the Medical Oncology Department of Antalya Education and Research Hospital between January 2015 and January 2022. Paraffin blocks of biopsy and operation tissues were eavaluated by two different pathologists reviewing immunohistochemical staining with CD4, CD25 and FOXP3. The effect of tumor infiltrating T cell (Tregs and Th cells) quantitiy on pathological complete response is evaluated.
Results: 55 local and locally advanced HER2 positive breast cancer patients were included but 45 patients' data (median age 50) were analyzed. While 34 patients had a pathological complete response (pCR) after neoadjuvant treatment, 11 patients had failed to achieve pCR. Th and Treg infiltration after NACT did not differ between early stage and locally advanced stage diseases. Intratumoral and peritumoral Th infiltration abundancy were observed to be lower in patients with a pCR than in those without a pCR. Similarly, in patients with a pCR, Treg infiltration abundancy in the intratumoral and peritumoral area was found to be lower compared to non pathologic complete responders. There is no TREG or Th cellular abundancy difference between intratumoral and peritumoral microenvironments. But increased intratumoral Treg infiltration increased the risk of non PCR status by 10.8 times.
Discussion and Conclusion: Variety of immune cells in the tumor microenvironment may be related with good or poor cancer outcomes via the activation or inhibition of immune surveillance.
Our study is the first to evaluate Th and TREG cellular abunbancy changes after neoadjuvant chemotherapy (NACT) in Her2+HR negative local or locally advanced breast cancer patients. High Treg infiltration after NACT is also found to be an independent predictor of risk of pCR failure.

P3-03-22: CK2 in breast cancer and associated clinical characteristics

Nicholas Wilson, Isabelle Kreber, Cristian Figueroa

Background: In breast cancer, aberrant casein kinase (CK2) signaling has been linked to invasiveness, metastatic potential, and prognosis. Here we explore how CK2 expression in breast cancer is associated with tumor stage, response to therapy, and prognosis.
Methods: Data analysis was performed with data from The Cancer Genome Atlas (TCGA). R version 4.2.2 was used for analysis. Student's t-test, Welch's t-test, Wilcoxon test, and Pearson and Spearman correlations were used to analyze continuous variables. Bonferroni correction was used to adjust p-values to reduce the risk of type I error for multi-group analysis. Analysis of survival and treatment response was performed using Kaplan-Meier Plotter (https://kmplot.com/) and ROC Plotter (https://rocplot.com/) which draw breast cancer sample data from TCGA, Gene Expression Omnibus (GEO), and other repositories.
Results: Using TCGA data, we examined the relationship between CK2 subunit expression and clinical stage, TMN staging, and hormone receptor positivity for intraductal carcinoma

(IDC). We found that mean expression levels of CSNK2A1, CNSK2A2, and CSNK2B were greater in stage II and stage III IDC than stage I ($p < 0.05$ for all). Looking at the T stage of TNM (tumor size), mean expression levels of CSNK2A1, CNSK2A2, and CSNK2B were greater in T2 than T1 ($p < 0.05$ for both). Mean CSNK2A2 and CSNK2B expression was 43% and 28% greater in ER negative vs ER positive IDC ($p < 0.001$ for both). Mean CSNK2A1, CSNK2A2, and CSNK2B expression was 7%, 36%, and 24% greater in ER negative vs ER positive IDC ($p = 0.012$, $p < 0.001$, and $p < 0.001$). Mean CSNK2A1 and CSNK2A3 expression was significantly greater in HER2 positive cancer than HER2 equivocal or HER2 negative IDC ($p < 0.002$ for all).
KM Plotter was used to explore associations between CK2 subunit expression and overall survival in breast cancer of varying clinical characteristics. In lymph node positive cancer, CSNK2A1 overexpression was associated with worse survival (Hazard Ratio, HR: 1.87, 95% Confidence Interval, CI: 1.14-3.05, $p = 0.011$). CSNK2A3 was also associated with worse survival (HR: 1.93, CI: 1.2-3.1, $p = 0.006$). In lymph node negative cancer, CSNK2A1 and CSNK2A3 overexpression were associated with worse survival (HR: 1.69, CI: 1.13-2.54, $p=0.010$ and HR: 2.38, CI: 1.5-3.76, $p < 0.001$). In ER positive cancer, CSNK2A3 was associated with worse survival (HR: 1.52, CI: 1.07-2.18, $p = 0.020$). In ER negative cancer, CSNK2A1 and CSNK2A3 overexpression were associated with worse survival (HR: 9.66, CI: 1.22-76.31, $p = 0.008$ and HR: 3.51, CI: 0.97-12.77, $p = 0.042$). In HER2 negative cancer, CSNK2A1 and CSNK2A3 overexpression were associated with worse survival (HR: 1.78, CI: 1.27-2.49, $p < 0.001$ and HR: 2.27, CI: 1.59-3.25, $p < 0.001$). In cancer treated with chemotherapy, CSNK2A1, CSNK2A3, and CSNK2B overexpression were associated with worse survival (HR: 3.18, CI: 1.65-6.12, $p < 0.001$, HR: 2.97, CI: 1.54-5.71, $p < 0.001$, and HR: 2, CI: 1.07-3.72, $p = 0.026$).
ROC Plot analysis found that CSNK2A1 was a weak classifier of pathological complete response to FAC (fluorouracil, doxorubicin, and cyclophosphamide) (Area under curve, AUC = 0.651, $p < 0.001$) and FEC (fluorouracil, epirubicin, and cyclophosphamide) (AUC = 0.648, $p < 0.001$).
Lastly, CK2 subunit expression was compared with that of the 21 genes from the Oncotype DX breast cancer assay. CSNK2A2 had significant mild negative correlations with many sex hormone-related genes. CSNK2B had significant mild to moderate positive correlations with many proliferation-related genes, internal control genes, and sex hormone-related genes.
Conclusions: This study demonstrates that CK2 subunit expression associates with a variety of clinical tumor characteristics, response to therapy, and prognosis in patients with breast cancer. CK2 may be useful as a prognostic biomarker and therapeutic target in breast cancer and warrants further exploration.

P3-03-23: Targeting of SEMA7A Signaling Improves Response to Endocrine Therapy in ER+ BC

Rachel Steinmetz, Traci Lyons, Lyndsey Crump

Estrogen receptor-positive (ER+) breast cancer (BC) comprises over 70% of all breast cancers and is the leading cause of BC-related deaths in women worldwide. Despite available therapies against ER+ BC, recurrence inevitably arises, primarily due to therapeutic resistance. Semaphorin 7a (SEMA7A) is a biomarker associated with poor prognosis and endocrine therapy resistance for BC patients. Survival analyses of ER+ BC patients on endocrine therapy confirms very high early recurrence in patients with SEMA7A-high tumors. Thus, our objective is to establish novel treatment strategies to improve outcomes for patients with ER+ SEMA7A-high BC. We are investigating the mechanisms by which SEMA7A promotes resistance to endocrine therapy and its potential as a therapeutic target for ER+ BC. In the normal mammary gland, SEMA7A binds integrins and activates pathways including PI3K/AKT signaling, which promotes tumor cell survival and multi-drug resistance. Using reverse phase protein array we found that SEMA7A-overexpressing (OE) MCF7 cells have increased expression of pAKT and integrins ITGB1 and ITGB4 compared to controls cells. Our mechanistic CoIP studies revealed that SEMA7A binds directly to ITGB1 and ITGB4 on ER+ tumor cells. This novel finding suggests that SEMA7A signals through multiple ECM/integrin mediated pathways that have been associated with treatment resistance (as reviewed by Bissel and colleagues). Further, SEMA7A-integrin binding activates AKT via PI3K stimulation, as well as downstream signaling activated by pAKT. Our preliminary studies in mice show that SEMA7A OE tumors respond poorly to fulvestrant, compared to controls. Therefore, we sought to overcome the promotion of fulvestrant resistance by SEMA7A by inhibiting SEMA7A signaling via PI3K inhibitors (PI3Ki) or our novel anti-SEMA7A monoclonal antibody (SmAb). In vitro, SEMA7A OE cells are sensitive to PI3Ki alpelisib (1uM, Novartis) and GCT-007 (0.5uM, Global Cancer Technolgoy), while control cells are not. Importantly, PI3Ki sensitized SEMA7A-high tumors to endocrine therapy in vivo (n=5/group). Additionally, since SEMA7A has known immunomodulatory roles and we have shown that SmAb restores anti-tumor immunity, we sought to determine the effect of SmAb on tumor growth and fulvestrant resistance in an immune competent ER+ model. Therefore, utilized a novel syngeneic ER+ preclinical model comprised of TC11 murine tumor cells (a generous gift from Linda Schuler), which express SEMA7A, and are derived from FVB/N mice. Our results demonstrate that direct inhibition of SEMA7A via SmAb significantly reduces tumor growth rate in SEMA7A+ tumors. Results were validated in a second syngeneic ER+ model (SSM2 tumors, 129Sv-E mice; a generous gift from Alexander Borowsky). Interestingly, SmAb-treated tumors exhibit increased ER expression, suggesting a potential mechanism by which SmAb could sensitize endocrine-resistant tumors to fulvestrant. Our future studies will investigate therapeutic combinations and dosing regimens of fulvestrant and SmAb to overcome resistance to fulvestrant in SEMA7A+, ER+ tumors. Our studies suggest that patients with ER+SEMA7A+ tumors should be considered candidates for PI3K/SEMA7A-targeted clinical therapies or for direct and/or co-targeting with our novel anti-SEMA7A based therapy.

P3-03-24: Assessment of cell signaling pathway activity and expression of MKI67, ESR1 and ERBB2 as profiling tool for selection of targeted therapy in breast cancer

Yvonne Wesseling-Rozendaal, Dianne van Strijp, Eveline den Biezen, Anke Pierik, Robert Babkowski

Background: Assessment of hormone receptor status and HER2 is important in determining treatment options for breast cancer patients. The current standard of care relies on biomarker testing by immunohistochemistry (IHC) staining and fluorescence in situ hybridization (FISH).
Visual interpretation of staining intensity leads to semi-quantitative scoring and introduces an analytical error due to intra- and inter-observer variability. There is an acknowledged discordance in IHC signal in the low positive ER IHC cases and 1+ HER2 IHC cases. Furthermore, increasing numbers of studies have demonstrated that presence of the receptor on IHC is not always associated with activation of the related signaling pathway. We propose using quantitative and dynamic tumor characterization for ER and HER2 using mRNA expression combined with functional pathway activity profiling.

Methods: While immunohistochemistry measures protein levels of the breast cancer markers, here we measure the RNA of these markers instead. Gene expression levels of MKI67 (coding for the Ki-67 protein; proliferation marker), ESR1 (coding for the estrogen receptor protein), and ERBB2 (coding for the Human Epidermal Growth Factor Receptor 2 protein) were measured for 373 FFPE breast samples (303 tumors and 70 healthy normals). mRNA expression levels are measured using RT-qPCR and normalized to a set of housekeeping genes as part of the OncoSIGNal qPCR pathway test (InnoSIGN) for 7 pathways (ER, AR, PI3K, MAPK, Hh, Notch and TGFβ).

Results: Normalized mRNA expression is interpreted for each marker in relation to selected reference tissue cohorts. The distribution of MKI67 expression levels in primary, untreated breast cancer samples (n=188; 95% confidence interval (CI) [-6.2, -1.3]) was compared to the distribution of normal epithelial breast tissue samples (n=70; 95% CI [-9.6, -3.3]) and, although partially overlapping, were significantly different (p=1.47e-23).
ESR1 expression levels showed a clear separation (p=7.8e-27) between IHC-ER positive (n=89, ≥50% staining; 95% CI [-3.2, 1.8]) and IHC-ER negative (n=69, <1% staining; 95% CI [-10.9, -4.5]) breast cancer samples.
ERBB2 expression levels showed a clear separation (p=2.1e-11) between HER2 positive (IHC3 & FISH positive; n=20; 95% CI [1.9, 6.1]) and HER2 negative (IHC 0 / FISH negative; n=69; 95% CI [-3.5, 1.6]) breast cancer samples. HER2 low positive samples lie in between those clearly defined strongly positive and strongly negative groups: IHC 0/1/2 & FISH positive (n=14) ERBB2 expression 95% CI ranges [-1.5, 1.2]. Similarly, samples with FISH equivocal result (IHC 0/1/2; n=12) have a 95% CI ranging [-1.5, 1.0].

Conclusion: The OncoSIGNal test provides a robust and quantitative method to characterize

low ER and HER2 1+ IHC breast cancer samples. In addition to detecting and quantifying the relevant cell signaling pathways, the mRNA markers can be used to elucidate the results of low ER and HER2 1+ IHC staining, enabling the identification of patients who may benefit from targeted therapy.

P3-03-25: High expression of microRNA-486 levels can be a prognostic biomarker for better survival in ER-positive breast cancer patients

Yoshihisa Tokumaru, Emiri Sugiyama, Makoto Takeuchi, Manabu Futamura]

Background: Preclinical in vitro studies have shown that microRNA-486 (miR-486) functions as a tumor-suppressive miRNA. However, to the best of our knowledge, no study has investigated the clinical relevance of miR-486 in ER-positive breast cancer patients. We hypothesized that miR-486 expression in breast cancer is associated with its immune microenvironment and can be a prognostic biomarker.
Material and Methods: A total of 2042 patients' data were extracted from publicly available databases, The Molecular Taxonomy of Breast Cancer International Consortium (METARBRIC), The Cancer Genome Atlas (TCGA), and GSE57897. The clinicopathological and survival data, as well as transcriptome data, were included in these cohorts. The survival analysis and gene set enrichment analysis (GSEA) was conducted by comparing miR-486 high-expressing and low-expressing tumors, divided by the median cutoff. The association between the miR-486 expression and tumor immune microenvironment was assessed by xCell.
Results: The expression levels of miR-486 were suppressed in human samples. The expression levels of miR-486 were significantly lower in tumor tissues compared with normal breast tissues in both TCGA cohorts and GSE57897. These results were in same line with the notion that it is a tumor-suppressive miRNA ($p<0.001$ and $p=0.003$, respectively). To our surprise, miR-486 expression was not associated with cancer staging in any TCGA cohort subtypes. High miR-486 tumors demonstrated better disease-specific survival (DSS) and overall survival (OS) compared with low expressing in ER+/HER2- breast cancer patients ($p=0.044$, and $p<0.001$), which was not the case for the other subtypes in METABRIC cohort. Interestingly, high miR-486 tumors significantly demonstrated lower expression of MKI67, one of the most commonly used parameters for cell proliferation, correlated with miR-486 expression in ER+/HER2- ($p<0.001$) but not in other subtypes. This was also the case in immune-related gene sets; interferon-alpha response, interferon-gamma response, complement, and complement that enriched to high miR-486 tumors in ER+/HER2- only. Also, in the same line, Immune Score was significantly higher in ER+/HER2- ($p<0.001$). These results implied its association with the tumor immune microenvironment of ER+/HER2- breast cancer. Given these results, we next hypothesized that a high miR-486 tumor would infiltrate many immune cells. As expected, Anti-tumor immune cells, such as M1 macrophages, Dendritic cells, and Natural killer T cells, were all elevated in high miR-486 tumors in the ER+ /HER2- subtype. Given its association with survival outcomes, we cannot help but speculate that the better outcome of ER+/HER2-

breast cancer is associated with a tumor suppressive effect on the tumor immune microenvironment, which leads to improved survival outcomes.
Conclusion: High miR-486 levels in tumors were associated with a tumor immune microenvironment and better survival; thus, it can be a candidate for a prognostic biomarker in ER+/HER2-patients.]

P3-03-26: Long-Read Nanopore Sequencing for the Identification of Gene Fusion-Derived Breast Cancer Neoepitopes

Skylar Henry, Felipe Batalini, Yining Zhang, Eric Wilson, Abhishek Singharoy, Jin Park, Karen Anderson

Neoepitopes, which are unique HLA-binding peptides produced by cancer cells, are potential cancer-specific targets for T cell-based immunotherapies. However, there are ongoing challenges for the selection and prioritization of neoepitopes for therapeutics. First, next generation sequencing (NGS) is primarily used to select the somatic mutations and insertion/deletions that lead to neoepitopes, but this can require extended time periods and centralized equipment and data processing to retrieve results. Second, current HLA prediction algorithms for neoepitope binding rely on sequence-based methods with limited biochemical data for many diverse HLA alleles. To address these issues, we evaluated the use of nanopore long-read sequencing for rapid neoepitope detection. First, we optimized methods for upstream tumor RNA processing and cDNA synthesis to obtain a depth of coverage that provides confidence in sequence calls, given estimated stochastic error rates of 4%. We developed systems for quality control of RNA length and quality that are needed for accurate neoepitope mapping. Using the cell line MDA-MB-231 and six resected breast tumor samples, we demonstrate detection of known chromosomal fusions by nanopore cDNA-PCR sequencing, as well as unique fusions not detected by next-generation RNA-Seq (Illumina). We then developed a custom prediction computational pipeline (NeoTarget) to prioritize the neoepitope repertoire across HLA-class I alleles. This pipeline incorporates HLA-Inception, a deep convolutional neural network for neoepitope prediction based on molecular dynamic modeling of peptide-MHC electrostatic forces. We then demonstrate the detection and prediction of fusion-derived neoepitopes from two organoid PDX models, one pancreatic adenosquamous carcinoma and one cholangiocarcinoma. Overall, these methods can be applied to rapidly identify and prioritize neoantigens for personalized neoantigen-based immune therapies.

P3-03-27: Klotho proteins and small non-coding RNAs as potential prognostic markers and therapeutic targets for human triple-negative breast cancer and canine mammary carcinoma.

Luciana Mayer Kluppel, Klementina Fon Tacer, Fernanda Rosa, Tanja Plavec, Tana Srava, Vladimira Erjavec, Joseph Emmons, Heather Tilman, Alicia K. Olivier, Danijela Herga

Background: In addition to humans, dogs are one of the few animal species that also develop breast cancer, referred to as canine mammary carcinoma (CMC). CMC is the most prevalent tumor detected in intact female dogs. In contrast to laboratory rodents, CMC develops spontaneously and doesn't require genetic engineering or xenograft models. Furthermore, at a cellular level, mammary carcinoma in dogs is very similar to human breast cancer tumors. The high mortality rates of human breast cancer and CMC, along with the limited treatment options for aggressive triple-negative breast cancer (TNBC), highlight the urgent need for early diagnostic markers and new therapeutic targets for these diseases. A family of proteins involved in metabolism and aging, called Klotho, has been found to have an important role in carcinogenesis. αKlotho and βKlotho proteins act like tumor suppressors and are repressed by microRNAs (miRNAs) during oncogenesis. However, the role of γKlotho in cancer remains to be fully elucidated. Our previous studies suggest that γKlotho is activated in TNBC and acts as an oncogene. However, the molecular underpinning of its functions, expression regulation, and expression in CMC is not known. Here we aimed to determine the expression of γKlotho in TNBC and CMC, and its correlation with miRNA signature to understand its function and regulation in both species. Methods: RNA and miRNA were isolated from tumors and benign mammary tissues from female dogs (n=31) and two CMC cell lines (CF41.Mg and CMT U27) and subjected to mRNA and miRNA expression quantification using RT-qPCR, RNA, and microRNA sequencing. Results: Our data suggest that similarly to TNBC, the mRNA expression of γKlotho is significantly upregulated in CMC compared to normal mammary gland ($\mu = 0.007 \pm 0.0007$ AU, min=0, max=0.045) compared to normal tissue ($\mu = 0.0003 \pm 0.0003$ AU, min=0, max=0.0007), suggesting a role of γKlotho in the oncogenesis of both aggressive diseases. Conclusions and future work: γKlotho may represent promising novel therapeutic targets or stratifying markers for aggressive CMC and TNBC. Female dogs may represent a great preclinical model for potential therapeutic interventions of γKlotho-positive tumors, holding the potential to improve the therapeutic alternatives for both human and canine patients. Further analyses are underway to understand the molecular mechanisms of regulation by miRNA and molecular action.

P3-03-28: Integrative Bioinformatics Approach Reveals Potential Liquid Biopsy-based Biomarkers for Breast Cancer Metastasis Monitoring

Hideki Hideki, Cynthia Jinno, HyoYoung Kim, Jina Kim, Sunao Tanaka, Takeo Fujii, Sungyong You, Hideki Furuya

Background: Despite recent advances in screening and therapeutic strategies, breast cancer remains the first leading cause of cancer death among females. The 5-year survival rate is high as 95% at localized stages but drops significantly to 31% once the cancer metastasizes. Therefore, developing predictive tools of metastatic recurrence is an unmet clinical need to design preventive clinical trials. In this study, we explored potential protein-based biomarkers associated with metastatic recurrence in the patients with non-metastatic breast cancer who underwent curative intent local and systemic therapies and further

assessed their functions using publicly available dataset to identify potential biomarker candidates to further develop blood-based protein signatures for a future study.
Methods: This study used a public dataset (GEO ID: GSE102484), which is a microarray dataset that contains primary tumor samples (n = 683) sourced from subjects with (n = 95) and without (n = 582) distant recurrence (metastasis) of breast cancer (met and non-met, respectively). Subjects with stage IV tumor (n = 6) were excluded from this study. Our approach began with two sets of differentially expressed genes (DEGs). The first set of DEGs are from all the samples in the dataset regardless of breast cancer subtypes, while the second set of DEGs are from triple negative breast cancer (TNBC) samples only. To identify subjects with TNBC, basal-like breast cancer samples were selected using PAM50 algorithm with genefu R package. To select potential blood biomarker candidates, we developed an integrative bioinformatics pipeline. Briefly, 1) Differential expression analysis between met and non-met were performed using limma R package. We then selected DEGs with log2 fold change ≥ 0.58 and false discovery rate (FDR) < 0.1, 2) Genes with housekeeping/hematopoietic markers were removed, 3) The genes that can be detectable in human bloods were selected using the human secretome database from the Human Protein Atlas (HPA), and 4) The functional enrichment analysis of gene ontology (GO) and pathways were performed using topGO and pathfindr packages, respectively. This pipeline was applied to the two sets of DEGs separately.
Results: The differential expression analysis of all breast cancer samples identified 134 significantly upregulated genes in met and the selection process with the pipeline resulted in 12 marker candidates including CD93, HPRT1, MMP1, EPHB4, HSPD1, MAP4, CCDC80, MMP11, SAFB2, CALD1, CRISP3, and GAPDH. Subsequent GO enrichment analysis identified functions associated with these markers including angiogenesis, calcium ion binding, and extracellular matrix and structure organizations. Nucleotide metabolism was observed significance in pathway. We then focused on the TNBC samples from the dataset and identified 162 significantly 162 significantly upregulated genes in met from TNBC. The functional enrichment analysis of the 162 genes revealed significant enrichment of GO biological processes in met, including regulation of apoptotic process, angiogenesis, and calcium ion binding. We also found that FoxO signaling pathway, mTOR signaling pathway, and MAPK signaling pathway significantly enriched in met. Out of the 12 marker candidates from the 134 upregulated genes, 8 marker candidates including CALD1, CD93, EPHB4, SAFB2, HSPD1, MAP4, CCDC80, and HPRT1 were also found in TNBC.
Conclusion: Through an integrative computational analysis, we identified 12 markers associated with breast cancer metastasis, of which 8 were specifically linked to metastasis in TNBC. These markers are involved in diverse functions and pathways that contribute to the metastatic process in breast cancer. Future studies will focus on validating these biomarkers using liquid biopsy samples from breast cancer patients, potentially offering a less invasive diagnostic approach.

P3-03-29: Calcification characteristics in women with benign breast disease and the risk of subsequent breast cancer: a case-control study

Merle van Leeuwen, Sandra van den Belt-Dusebout, Jia Ning Zhuchen, Shannon Doyle, Petra Kristel, Lennart Mulder, Jayakrupakar Nallala, Pieter Westenend, Nick Stone, Esther Lips, Ritse Mann, Jelle Wesseling

Background: Benign breast disease (BBD) is commonly detected in women participating in breast cancer screening programs and comprises a diverse group of lesions. The clinical significance of BBD lies in its association with an increased risk of developing breast cancer, which depends on the histological subtype. Calcifications, frequently observed in mammographic screenings, are critical in the detection and diagnosis of both benign and malignant breast conditions. While many calcifications are benign, some patterns are indicative of ductal carcinoma in situ (DCIS) or invasive breast cancer (IBC). Better characterization of breast cancer risk among women with BBD, considering both clinical and molecular findings, can improve surveillance, early diagnosis, and survival. This study aims to identify mammographic and chemical characteristics of calcifications that are associated with subsequent development of DCIS or IBC.
Methods:
A matched case-control study was conducted of women diagnosed with BBD at the Netherlands Cancer Institute and Albert Schweitzer Hospital between 2004 and 2023. Cases (n=65) were women with BBD who developed ipsilateral DCIS or IBC ≥ 6 months after a first BBD diagnosis, whereas controls (n=244) were BBD patients who did not develop subsequent ipsilateral DCIS or IBC during the follow-up (FU) duration of their matching cases. Additionally, controls were matched based on the year and age at the time of BBD diagnosis. Patient characteristics (e.g. age at diagnosis, vital status) and characteristics of both the benign lesions and subsequent malignant lesions were extracted from pathology reports using text searches and Palga codes. Mammographic lesion types (e.g. calcifications, masses, architectural distortion, asymmetries) were extracted from radiology reports. Qualitative mammographic features including calcification morphology and distribution were extracted from mammograms by two researchers and a trained radiologist. Quantitative mammographic features including breast density score and calcification cluster size and number will be extracted using TRANSPARA 2.0, an radiology artificial intelligence decision support system. In a subset of cases (n = 29) and controls (n=59) chemical characteristics were measured using infrared and Raman spectroscopy.
Results : The baseline comparison of mammographic qualitative features comprised 65 cases and 244 matched controls.Median age at BBD diagnosis was 51 years (range 35-80). Median FU from BBD diagnosis to DCIS or IBC was 6 years (range 1-17). Most cases and controls had non-proliferative BBD (89% and 94%) rather than proliferative BBD. Among cases, 19 developed DCIS while 46 developed IBC. While cases and controls showed comparable proportions of mammographic lesions, calcifications were more prevalent among cases (48.0% vs. 34.0%), approaching statistical significance (p = 0.06). Significant differences in calcification morphology were observed (p = 0.009), with cases more likely to display fine pleomorphic calcifications (23 % vs. 8.5%). The distribution of calcifications

was similar between cases and controls (p = 0.49). Multivariate-adjusted conditional regression models showed an odds ratio (OR) of 1.7 (95% CI: 0.9-3.0) for the association between calcification presence and DCIS/IBC development, albeit with considerable uncertainty. Presence of suspicious calcification morphologies (amorphous, fine pleomorphic, linear) suggested an OR of 3.0 (95% CI: 0.9-10.0) compared to benign morphology.
Conclusions: The trends observed in this study suggest potential prognostic value of calcification morphology in women with BBD. Additional results on quantitative mammographic features and chemical characteristics of cases and controls will be presented at the conference.

P3-03-30: Molecular landscape of breast cancer in pre- and postmenopausal women

Sameer Udhane, Pawan Noel, Fadel Alyaqoub, Ariane Kemkes, Cynthia Flannery, Nishitha Therala, Angela Deem, Jean-Paul De La O, Gargi Basu

Background: Breast cancer (BC) in younger women is often more aggressive and diagnosed at a later stage. The choice of endocrine therapy (ET) for women with hormone-receptor positive (HR+) BC varies based on whether she is premenopausal (preM) or postmenopausal (postM): tamoxifen is usually selected for preM women, while postM women receive aromatase inhibitors (AIs). Approximately 20-30% of advanced HR+ BCs will develop ET resistance and progress on first-line therapy. Whether at progression or in the advanced/metastatic setting, comprehensive genomic profiling (CGP) may provide subsequent-line treatment options, including molecularly matched therapies. Evidence suggesting preM women with HR+ tumors have poor persistence with ET underscores the importance of identifying targets for later-line therapy to improve clinical outcomes for these younger patients. This study investigates the difference in biomarker alterations in preM and postM BC.

Methods: A retrospective analysis of BC samples analyzed with the OncoExTra® assay, which identifies somatic mutations and gene fusions by whole exome DNA sequencing and whole transcriptome sequencing, was performed. Because menopausal status was not available, patients were classified as preM or postM based on age: patients aged ≤50 years were considered preM, and those >50 years were considered postM. The frequency of alterations in preM and postM HR+ BC was determined separately for samples collected from primary and metastatic sites. Potential associations between alterations and subgroups were evaluated using Fisher's Exact Test and the Benjamini-Hochberg False Discovery Rate procedure.

Results: We analyzed 2,573 BC samples with non-missing age, including 772 (30.0%) samples from preM women and 1,801 (70.0%) samples from postM women. Most samples were HER+/HER2- (1,721 (66.9%)), with smaller proportions of HER2+ (369 (14.3%)),

triple-negative BC (TNBC; 377 (14.7%)), and not otherwise specified (106 (4.1%)) samples. In HR+/HER2- BC, alterations in several genes were more frequent in preM compared to postM samples, including: BRCA1 (3.4% vs 0.6%), TP53 (28.5% vs 21.1%), IGF1R (5.3% vs 1.5%), MYC (3.6% vs 1.3%), PPM1D (3.8% vs 1.4%), and GATA3 (19.5% vs 12.2%) (P<0.01 for all comparisons). Conversely, alterations in the following genes were significantly higher in postM compared to preM HR+/HER2- BC samples: alterations in PIK3CA that serve as an FDA-approved companion diagnostic biomarker (CDx; 45.0% vs 35.5%) and PIK3CA non-CDx alterations (7.3% vs 4.5%) as well as ESR1 (8.8%% vs 5.1%), MAP3K1 (11.4% vs 7.4%), and CDH1 (18.5% vs 11.3%) alterations (P<0.05 for all comparisons). In HER2+ BC, ESR1 alterations (5.1% vs 0.7%) were more frequent in postM compared to preM BC, while ERBB2 alterations were more frequent in preM compared to postM BC (79.9% vs 69.8%) (P<0.05 for both comparisons). In TNBC, BRCA1 (18.8% vs 3.6%) and KIT (3.9% vs. 0.0%) alterations were significantly higher in preM compared to postM samples (P<0.01 for both comparisons). BRCA1, IGF1R, and PPM1D alterations predominantly occurred in metastatic preM BC samples (P<0.01 for all comparisons). Also, PIK3CA alterations predominantly occurred in primary postM BC, including both CDx (32.0%) and non-CDx (5.5%) alterations. ESR1 alterations, including mutations, fusions, and amplifications, were present in 21.8% of metastatic postM BC tumors, while ESR1 CDx mutations were found in 15.9% of these tumors.

Conclusion: Our analysis uncovered therapeutically relevant differences in biomarker alterations between preM and postM BC. The higher frequency of ESR1 alterations in HR+/HER2- BC samples from postM women may indicate a resistance mechanism to AIs, as postM women with HR+ BC are commonly treated with this class of drugs. Additionally, the frequency of BRCA1 alterations was significantly higher in TNBC as well as HR+/HER2- preM BC. [CR1] [JH2]
I would eliminate this last sentence. This is intuitive and seems self-serving from a CGP-company. [CR1]agree -- at a minimum suggest replacing "increases" with "may have the potential to increase"

P3-04-01: Extracting Chromatin Signatures from Breast Cancer Using Open Chromatin Guided Machine Learning

Sakuntha Gunarathna, Regina Nguyen, Aerica Nagornyuk, Motoki Takaku

Cell-free DNA (cfDNA) is increasingly recognized as a promising non-invasive biomarker that reflects the genetic and epigenetic profiles of originating cells. Cancer cells release cfDNA fragments characterized by distinctive nucleosome positioning patterns, which could be harnessed for cancer prediction. However, a comprehensive understanding of cfDNA's patterns and its application in developing predictive computational models for cancer remains incomplete. To explore this, we isolated cfDNA from plasma samples with the aim of establishing a simple protocol to extract unique genomic signatures enriched in breast cancer patients. Our analysis confirmed the enrichment of cfDNA in regulatory open

chromatin regions, demonstrating tissue-specific attributes. By focusing on open chromatin loci relevant to breast cancer and immune cells, we identified 2,804 genomic regions that exhibited differential enrichment in cfDNA from breast cancer patients compared to healthy individuals. To further confirm the significance of these differentially enriched genomic loci, we conducted an XGBoost machine learning model using publicly available data to test if they are sufficient to distinguish breast cancer cfDNA patterns. The model demonstrated high prediction accuracy, achieving an overall accuracy of 85.29% and a 3-fold cross-validation score of 84.43%, outperforming models trained on randomly selected genomic regions. Furthermore, by extending the analysis of open chromatin regions to include all previously defined ATAC-seq peaks in luminal breast cancer and CD4 positive T cells, our optimized machine learning model demonstrated an even higher accuracy score of 92.06%, with a 3-Fold Cross Validation score of 89.04%. Importantly, the established XGBoost model provides interpretable outputs that enable the extraction of critical genomic regions essential for cancer prediction. Our findings highlight the potential of cfDNA as a non-invasive screening tool for cancer detection. Moreover, our approach demonstrates an effective strategy for identifying specific genomic loci that distinguish cancer patients from healthy individuals, thus paving the way for the development of a promising non-invasive diagnostic tool.

P3-04-02: Advanced Breast Cancer by Region in the Hawaii and Pacific Islands Mammography Registry

Dustin Valdez, Arianna Bunnell, Nusrat Zaman Zemi, John Shepherd

Background: Despite recent advances in early detection and treatment, breast cancer remains a major cause of morbidity and mortality among women in the U.S. Notable racial/ethnic differences in incidence and survival have been described [1]. For example, Native Hawaiian women have the highest breast cancer incidence in Hawaii despite their favorable reproductive patterns. Japanese American women now experience the same breast cancer risk as non-Hispanic White women, although the incidence in Japan is still lower. Further, the percentage of breast cancers that are advanced are considerably higher in Asian American Women in Hawaii and the Pacific compared to the US mainland, 15% versus 9%.

We present the Hawaii and Pacific Islands Mammography Registry (HIPIMR) which contains over 100,000 unique women undergoing breast imaging in the state of Hawaii. Included are demographic, geolocation, risk factor information, and cancer outcomes obtained through linkage with the Hawaii Tumor Registry (HTR) and Hawaii State Department of Health and Vital Records (HSDHVR). In this study, we asked if advanced-stage breast cancer rates differed by region within each island and may be associated with determinants related to access and acceptance of breast health screening.

Methods: Women who participate in mammographic screening in the HIPIMR were grouped into the following regions: Big Island, Maui, Kauai (Molokai, Lanai), 4 divisions of Oahu using zip code groupings (central, Honolulu, leeward, windward) and unknown

region. Chi-squared tests of independence and pairwise comparisons with Bonferroni correction were then performed to identify differences between the regions at a significance level 0.05. Invasive cases were represented as a percent of advanced stage (3 and 4) to all cases.
Results: Currently the HIPIMR contains 124,475 unique women with visits from 2009 to 2024, and of those 5511 women had invasive cancer during this period. Percent advanced stage rates were Big Island 35.71%, Maui 21.8%, Kauai (Molokai, Lanai) 43.86%, 4 divisions of Oahu using zip code groupings (central 31.72%, Honolulu 35.15%, leeward 38.15%, windward 32.13%) and unknown region 40.37%. The pairwise comparisons showed a significant difference ($p<0.05$) between Honolulu and (Big Island, Kauai (Molokai, Lanai), windward and unknown regions. Also, the unknown region was significantly different than (Honolulu, Central, and Leeward). No significant differences were found between other pairs.
Conclusion: Within the HIPIMR, the advanced breast cancer rate is not uniform across Hawaii, with Kauai (Molokai, Lanai) experiencing the highest advanced cancer rate of 43.86% while the lowest rate was Maui at 21.8%. After pairwise comparisons, the advanced cancer rate of Honolulu significantly differed from many of the more rural islands such as Big Island, and Kauai (Molokai, Lanai). Further research must be done to understand the risk factors associated with causing some regions to experience higher advanced cancer rates.

P3-04-03: Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water and Breast Cancer Risk among Women in the Military

Celia Byrne, Michelle S. Mellers, Lynsey L. Lewis, Barbara J. Fuhrman

For several decades, breast cancer rates have increased among younger women under age 50. Previous studies indicated women serving in the U.S. Military had higher incidence of early onset breast cancer than expected based on the U.S. population, but the reasons remain unclear. High levels of Per- and Polyfluoroalkyl Substances (PFAS)), known endocrine disrupting chemicals, have been found in drinking water on a number of US military bases. PFAS are in many industrial and consumer products, but the use of Aqueous Film Forming Foam (AFFF) for firefighting since the 1970's is considered the major source of contamination on military installations. We assessed the association of duration assigned to a military installation reported to have high drinking water PFAS levels with breast cancer rates using data from a nested case-control study among active duty women in the military.
Through the Department of Defense (DoD) Cancer Registry, we identified 832 women diagnosed with (711) invasive breast cancer (BC) or with (121) ductal carcinoma in situ (DCIS), who joined the military since 1990 and were diagnosed between January 1, 2000

and December 31, 2022, while on active duty. We selected 856 matched controls from active duty women who had no reported breast cancer diagnosis at the time of the cases' diagnosis, joined the military in the same year, were born in the same year, and of the same race/ethnicity. In this unique study sample 85% of cases are under the age of 45 and 56% are non-White. In a 2020 report to Congress, the DoD identified 22 military installations where the drinking water PFAS levels were above the 2016 EPA guidelines of 70 ppt. Among the women in this study, 46.8% of the cases and 43.7% of the controls were assigned to one of these 22 installations at some time prior to the cases' year of diagnosis. To estimate the rate ratio for breast cancer associated with time assigned to the identified installations, we calculated the odds ratio (OR) with 95% confidence intervals (CI) using a logistic regression model that controlled for the matching factors.
Compared to women never assigned to any of the identified 22 installations, those assigned for three or more years had an OR = 1.45 (95% CI: 1.09-1.96) for invasive BC or DCIS. The increase in the rate was slightly higher for invasive BC only (OR = 1.52; 95% CI: 1.11-2.07), for those diagnosed with invasive BC before the age of 45 (OR= 1.79; 95% CI:1.27-2.53), and for those diagnosed with invasive BC before 2016, when PFAS contamination was likely higher (OR = 2.02; 95% CI: 1.27-3,21). While assignment to a base with high levels of PFAS in drinking water does not necessarily determine individual exposure levels, these findings might in part provide an explanation for the previously reported higher rates of breast cancer among women serving in the U.S. Military.

P3-04-04: The Butyrate Transporter SLC5A8 Selectively Inhibits Breast Tumor Metastasis

Sonia Batan, Jabunnesa Khanom, Sabarish Ramachandran, Selvakumar Elangovan, Nanditi N. Thangaraju, Subha Sundaram, Snigdha Ganjikunta, Breanna Kennedy, Vadivel Ganapathy, Puttur D. Prasad, Muthusamy Thangaraju

Introduction: The mammary gland is a dynamic organ that undergoes significant developmental changes during pregnancy, lactation, and involution. The process of involution is a highly orchestrated series of molecular and physical events that can be divided into two distinct phases. (Lund et al., 1996). Accumulation of milk in the alveolar lumen (milk stasis) is required to initiate the first phase during which the secretory cells begin to enter apoptosis. Here we provide genetic and molecular biological evidence to shows that the short-chain fatty acid Butyrate (BTR), a significant component in milk, contributes to milk stasis-induced apoptosis in the mammary gland, and SLC5A8, a BTR transporter, is obligatory for this effect. Slc5a8 deletion in mice is associated with delayed mammary gland involution, susceptible forto chemical, xenograft, and syngeneic transplant, and predisposes to early onset of mammary tumorigenesis and accelerated lung metastasis driven by genetically engineered mouse models of breast and lung cancers.

Objective: To establish the functional link between mammary gland remodeling and its relevance to mammary tumor growth (primary) and distant metastasis.
Methods: All animals were housed and handled according to approved protocols established by the Georgia Health SciencesAugusta University (GHSUAU) Animal Care and Use Committee and NIH guidguidelinesance's. For the measurement of HDAC activity, A commercially available HDAC assay kit (BioVisionBio Vision) was used. Statistical analysis was done using one-way ANOVA followed by Bonferroni multiple comparison test. The software used was Graph Pad Prism, version 5.0. A p-value <0.05 was considered statistically significant.
Results: SLC5A8 is a tumor suppressor, and its expression is silenced in many human cancers, including breast cancer (Thangaraju et al., 2006a; Babu et al., 2011). Here we analyzed Slc5a8 expression at various stages of mammary gland development. Slc5a8 expression was evident at mRNA and protein levels in the virgin mammary gland; it was induced marginally during pregnancy and lactation. Slc5a8 was primarily expressed in the lumen-facing apical membrane of the mammary ductal epithelium. deletion of Slc5a8 in mice leads to a delay in mammary gland involution. We also analyzed the expression of involution markers (Stat3, p53, Bax, BMF, survivin, and IGFBP-5) and apoptotic cell death in wild wild-type (Slc5a8-/-) and Slc5a8-knockout (Slc5a8-/-) mice mammary glands at different stages of involution. pStat3 expression was increased dramatically on Inv d1 and d2 in wild- type glands but to a much less extent in Slc5a8 -/- glands. Further, the expression of p53 and Bax (pro-apoptotic genes), BMF (anoikis inducer), and IGFBP-5 (inhibitor of IGF-induced prosurvival signaling) were significantly increased in wild wild-type glands compared to Slc5a8-/- glands. The anti-apoptotic protein survivin was significantly reduced on Inv d1, d2, and d3 in wild wild-type glands, but this reduction was not observed in Slc5a8-/- glands. Slc5a8 transports into cells the HDAC inhibitors butyrate, pyruvate, and propionate into cells the. (Thangaraju et al., 2009). These inhibitors are selective for HDAC1 and HDAC3. Butyrate, a significant component of breast milk, promotes differentiation in normal cells but induces apoptosis in highly proliferative cells and cancer cells. Slc5a8 induces apoptosis in lactating mammary epithelial cells during involution through modulation of HDAC expression and activity. Butyrate, a substrate of Slc5a8, plays a critical role in promoting mammary gland involution through HDAC inhibition and death receptor activation. Administration of exogenous butyrate induces precocious mammary gland involution in mice. Next, we wanted to exploretested whether if the deletion of Slc5a8 plays any a role in mammary tumorigenesis. The biological changes that occur in mammary epithelial cells during pregnancy/lactation and involution are similar in many respects to those associated with tumor development and tumor regression, respectively. Deletion of Slc5a8 in mice is associated with early onset of mammary tumor formation, accelerated lung metastasis, and decreased overall survival. Finally, we wanted to analyze whether if mammary gland-specific overexpression of Slc5a8 SLC5A8 would influence mammary gland involution and mammary tumorigenesis. Mammary gland-specific overexpression of Slc5a8 SLC5A8 induces precocious mammary gland involution and protects from MMTV-Neu-driven mammary tumorigenesis.
Conclusion: Slc5a8 is a tumor suppressor in the mammary gland, and butyrate is essential

for its tumor-suppressive function. Mammary gland-selective overexpression of Slc5a8 SLC5A8 in mice enhances mammary gland involution and protects against breast cancer.

P3-04-05: Expression analysis reveals clues to the molecular mechanisms driving breast cancer risk in women with benign breast disease

Yasminka Jakubek Swartzlander, Hongyu Gao, Jia Ji, Natascia Marino, Rana German, Michele L. Cote

Introduction: A previous diagnosis of benign breast disease (BBD) is associated with an increased risk of breast cancer, although the molecular mechanisms underlying this association remain unclear.
Methods: We conducted a pilot study to investigate differences in expression between breast tissue donated from women with a history of BBD and women without a history of BBD enrolled in the Komen Tissue Bank (KTB). Briefly, the KTB recruits healthy, cancer-free participants to voluntarily donate breast tissue cores collected via needle biopsy. Additionally, detailed risk factor information is collected at the time of donation, and participants are followed for subsequent breast cancers. Of the 186 samples available for analysis, we selected 27 samples from women with BBD at the time of donation (cases) and 27 samples from women without BBD at the time of donation (controls), matched on age, body mass index category (BMI), and menopausal status. Existing transcriptomic data came from a previous study from Marino et al (GEO accession GSE164641) which utilized Illumina's HiSeq4000 to analyze frozen breast tissue cores from healthy, breast-cancer free donors. We utilized the Edge R 4.2.1 software for analysis of raw count data (RNA). In addition to the expression analysis by BBD status, a subset of samples (n = 133) that were NOT included in the differential expression analyses were analyzed to conduct an association analysis between differentially expressed genes identified in the matched subset and Tyrer Cuzick breast cancer 10-year risk scores. These analyses were adjusted for BMI and age with Tyrer Cuzick risk score as the dependent variable.
Results: There was a similar distribution of age, body mass index (BMI), and menopausal status in the case and control groups. We removed 1 control sample (age=52, BMI=34, postmenopausal), because the log10 normalized mean counts was near 0; all other samples had similar distributions of log10 normalized mean counts. A differential expression analysis was conducted and 2 genes (Carboxypeptidase B1; CPB1, and Shieldin Complex Subunit 3; SHLD3) were significantly overexpressed (FDR < 0.05) in breast tissues from women with BBD (log fold-change=2.5 for CPB1 and 0.56 for SHLD3). Additionally, we performed pathway enrichment analyses and observed upregulation of genes involved in the innate and adaptive immune response, cell cycle, as well as Hippo and TGF-beta signaling pathways in women who had BBD. To further investigate the potential utility of CPB1 and SHLD3 gene expression as markers for breast cancer risk, we conducted association analyses between transcripts per kilobase million (TPM) normalized expression of CPB1 and SHLD3 and the 10 year Tyrer Cuzick breast cancer risk score. We observed an association between SHLD3 expression and breast cancer risk score (p=0.007). SHLD3 plays

a critical role in DNA double strand break repair pointing to a potential increase in the rate of DNA damage in breast tissues from women with BBD compared to those without BBD. For CBP1, we did not observe an association between expression and breast cancer risk score (p=0.17).
Conclusions: We identified gene expression differences in healthy breast tissue from women with and without a prior BBD diagnosis. Specifically, SHLD3 may serve as a potential biomarker of breast cancer risk in women with a history of BBD and was also associated with higher Tyrer Cuzick scores in women who did not have BBD. Our results indicate that activation of immune, cell cycle, and signaling pathways known to be involved in cancer initiation and progression are upregulated in healthy breast tissue from women with BBD who have an elevated lifetime risk of developing breast cancer. These findings suggest that tissue-based markers of risk can be identified even in healthy breast tissue years prior to a cancer diagnosis.

P3-04-06: Genomic and transcriptomic profiling of BRCA mutation carrier tissues reveals the landscape of early pathogenesis of BRCA1/2-associated breast cancer

Zuen Ren, Siang Boon Koh, Kai Stewart, Nick Haradhvala, Aylin S. Dedeoglu, Isabella Vianna, Ilze Smidt, Akiko Suzuki, Taisha Joseph, Veerle Bossuyt, Esther Rheinbay, Michael Lawrence, Gad Getz, Leif W. Ellisen

Women who harbor germline heterozygous mutations of BRCA1 or BRCA2 have a high risk of breast cancer. Our previous study showed that patient-derived, ostensibly normal BRCA2mut/+ luminal progenitor (LP) cells are more prone to exhibit sub-chromosomal copy number variations and associated DNA damage relative to non-carriers, potentially reflecting early breast tumorigenesis. Clinically assessable biomarkers for early pathological changes of BRCA1/2 mutation in LP cells remain unknown. Single-cell RNA sequencing (scRNAseq) of LP cells of BRCA1/2mut/+ carriers revealed enrichment of KIT expression (KIT+) and subsequent transcriptional factor activations were observed in LP cells of BRCA1/2mut/+ carriers relative to non-carriers. Moreover, pathway analysis uncovered that KIT+ BRCA-mutated LP cells were enriched in pathways involving DNA binding transcription activator activity and oxidative phosphorylation. These gene signature profiles were recapitulated in bulk RNA-seq of BRCA2 mut/+ carrier LP cells. Collectively, our preliminary data suggest such analyses may identify potential biomarkers for near-term risk prediction that reflect early pathogenesis of BRCA1/2-associated carcinogenesis. Following further validation via tissue microassay analysis and clinical studies, our findings may eventually assist patients and clinicians in decision making regarding the timing and necessity of preventive surgeries for BRCA1/2 mutation carriers.

P3-04-07: Modeling BRCA1 and BRCA2 Mammary Tissues and Estrogen Positive Breast Cancer Using iPSC-Derived Organoid Models

Simon Gayther, Alyssa Okimoto, Subash Dhungana, Kate Lawrenson, Xiaojiang Cui, Nur Yucer

Germline BRCA1 and BRCA2 mutations (BRCA1/2mut) predispose women to all subtypes of breast cancer (BC) - ER positive, ER negative and triple negative disease. The cumulative risks in women by age 80 years for all breast cancer (BC) range from 45-75% in BRCA1mut carriers and 41-70% in BRCA2mut carriers compared to the general population (~13% lifetime risk of BC for women in the USA). Many aspects of the underlying biology of these genes in subtype-specific BC development remain unknown. Specifically, although BRCA1 & BRCA2 interact in the same DNA double-strand break repair pathway and BRCA1mut & BRCA2mut both cause basal, triple negative BC, BRCA2mut are more likely than BRCA1mut to cause luminal like ER positive BC. We hypothesize that exposure of normal mammary tissues to estrogens causes ER positive BC in women with BRCA2mut compared to women with BRCA1mut.

We differentiated induced pluripotent stem cells (iPSCs) from subjects with and without BRCA1/2mut into models of normal mammary tissues using a patient-specific iPSC-derived 3D mammary organoid system and studied the neoplastic phenotypes of organoids with and without estrogen (E2) exposure. The iPSC model system enables self-renewal and differentiation into multiple cell type lineages. Intrinsically, this allows cells to self-organize into different cell partners to study the differential effects of specific genetic and/or environmental risk factors on neoplastic growth. Thus, iPSC-derived, mammary models can reproduce the status of germline genetic mutations associated with the development of breast cancers.

We first developed a protocol to generate iPSC derived mammary models from multiple female subjects with and without BRCA1mut or BRCA2mut. None of the BRCA1/2mut carriers had a history of BC and all had had mastectomy for BC prevention because of their BRCA1/2mut status. Immunofluorescent cytochemical staining (ICC) confirmed that all models stained for lineage specific markers (CK18, mammaglobin, CDH1), confirming their mammary tissue status. iPSC derived mammary organoid models from both BRCA1 and BRCA2 heterozygous mutation carriers conferred a neoplastic phenotype reminiscent of a ductal carcinoma in situ (DCIS), a proposed precursor of BC (i.e., organoid models retained the wildtype copy of BRCA1 or BRCA2) compared to BRCA wildtype (BRCA1/2WT) controls, which retained both copies of both genes (confirmed by whole genome sequencing). This suggests haploinsufficiency contributes to the phenotype in both BRCA1 and BRCA2 carriers.

We will present the data after differentiation of BRCA1mut, BRCA2mut and BRCAWT iPSC derived mammary models and then exposed to 150 picomol E2 treatment. The goal was to evaluate if mammary organoids from BRCA2mut carriers and quantify if they are more sensitive to E2 exposure than BRCA1mut and BRCAWT models. This may suggest that they are more likely to develop into BRCA2mut driven ER positive BC, which would suggest a hormone-dependent neoplastic transformation in BRCA2mut carriers reflecting the ER

positive subtype. These finding could present opportunities for reducing mortality due to ER positive BC by driving BRCA2mut cells to an ER positive BC phenotype: This tumor subtype is know to have improved survival and therapeutic response through hormonal dependent treatments such as Tomoxifen.

P3-04-08: Redefining Bravery: A New Paradigm for Helping Young Women Understand Their Risk for Early Onset Breast Cancer

Ally Moehring, Ginny Kincaid, Nancy O'Reilly, Carolyn Headley, Temeika Fairley

Breast cancer in young women is more likely to be hereditary and is often aggressive and difficult to treat. The Centers for Disease Control and Prevention (CDC)'s Bring Your Brave (BYB) campaign helps young women and health care providers understand risks for breast cancer using the power of testimonials, storytelling, and medical education. Our panel session will discuss how CDC is using audience-centric approaches to share information about breast health and breast cancer with women under the age of 45.

Message Development

The BYB campaign: 1) offers clear, tangible steps to understanding and managing early breast cancer risks; 2) tailors messaging for all communities; and 3) equips women and HCPs with tools to make informed decisions about their health. CDC conducted formative research to develop and assess impact of messages and resources aligned with these goals. We will discuss the process used to develop, disseminate, and test effectiveness of these communication tools.

Entertainment Education

CDC used the power of pop culture and entertainment to deliver messages about breast health and breast cancer to young women.

An analysis of TV storylines (2017-2020) revealed that most depictions of breast cancer featured older white women and end-of-life scenarios, while women of color and positive outcomes were rarely shown in entertainment. Based on these results, CDC partnered with Hollywood, Health, and Society to reach writers and creators in the TV and gaming industries to tell a different story. CDC's efforts have resulted in multiple storyline placements in TV shows and a mobile game integration.

Family Conversations

When young women are the first in their families to learn they have an increased risk for hereditary breast or ovarian cancer (a BRCA1 or BRCA2 gene mutation) they are met with the task of telling other family members about their risk. The process of sharing this information with family members can be difficult while they are coping with their own diagnosis.

CDC partnered with the National Association of Chronic Disease Directors to develop a suite of resources to support family conversations about hereditary breast and ovarian cancer risk. These resources include stories of young previvors or survivors sharing their experiences and discussing risk information with family members. An interactive simulation program was developed to allow users to practice these conversations.

Provider Education
CDC partnered with the American College of Obstetricians and Gynecologists (ACOG) to create a comprehensive, two-part CME course to educate health care providers about early onset breast cancer, including risk factors, signs, and symptoms. Since 2020, there have been 3,670 course registrations, 3,083 course completions, and 20,622 CME/CEUs awarded. Pre/post-test results show a +21% knowledge change for Part I of the course (risk factors), +12% change for Part II (health disparities, genetic counseling and testing, risk reduction, epidemiology, and treatment). 57% of respondents reported an intent to change their practice based on learnings.

P3-04-09: Comprehensive Analysis of Rare Variants Associated with Genetic Predisposition to Non-BRCA Familial Breast Cancer Among Arabs

Ehsan Ullah, Hikmat Abdel-Razeq, Sana Bentebbal, Abdullah Shaar, Nehad Alajez, Mohamad Saad, Julie V. Decock

Background: Familial breast cancer represents 5-10% of breast cancer cases, whereby the prevalence of germline mutations in the breast cancer susceptibility genes BRCA1 and BRCA2 (gBRCAm) varies greatly among ethnic groups. In Jordan, pathogenic gBRCAm have been observed in over 10% of high-risk breast cancer patients tested as per the NCCN (National Comprehensive Cancer Network) guidelines. Almost half of pathogenic/likely pathogenic variants detected are non-BRCA1 or BRCA2 genes. Hence, the underlying genetic factors contributing to familial breast cancer remain unknown.
Methods: This study aims to identify cancer risk variants and assess the performance of existing breast cancer polygenic risk scores (PRS) in a Middle Eastern cohort. We performed whole genome sequencing analyses on germline DNA of 180 patients with familial non-BRCA breast cancer (King Hussein Cancer Center, Jordan), and 6000 healthy subjects from the Qatar Precision Health Institute.
Results: Whole genome analysis identified 88,783 single nucleotide variants that are pathogenic/likely pathogenic or are predicted to have a high impact on protein sequence. Approximately 12% of variants were found in cancer-associated genes, of which 74 were classified as pathogenic/likely pathogenic and high-impact variants. Five variants (in MSH3, XPA, PALB2, TP53, and RAD51) were only observed in patients and not in healthy control subjects, suggesting that they might be associated with cancer risk susceptibility. In addition, we found 37 pathogenic/likely pathogenic and high-impact variants in non-cancer related genes, which were only observed in patient samples and could be of interest for further study as novel genetic variants associated with an increased risk of developing breast cancer. Performance analysis of 120 existing breast cancer PRSs revealed that 84% of scores could discriminate breast cancer patients from controls. The four best-performing PRS (PGS003759, PGS003738, PGS003398, and PGS000510) demonstrated AUCs ranging from 0.664 to 0.702, indicative of a good performance in our cohort.
Conclusions: In-depth genomic analysis of non-BRCA familial breast cancer patients from Jordan identified several rare variants in cancer-related genes as well as in novel non-

cancer-related genes. Four distinct PRSs derived from European ancestry cohorts demonstrated a good performance in our cohort, suggesting an added clinical validity in patients of Arab ancestry. Our findings highlight the need for additional studies across ancestries to identify common and population-specific genetic variants that may predispose women to familial breast cancer.

P3-04-10: Integrated germline and tumor whole genome sequencing to identify novel hereditary breast cancer genes in women with very early onset breast cancer

Lily Owens, Qihong Zhao, Simone McInerny, Maia Zethoven, Theresa Wang, Na Li, Paul James

Background: Early onset breast cancer (EOBC), commonly defined as BC occurring in women < 45 years, accounts for about 7% of all new female BC cases but because of the much worse clinical outcome compared to post-menopausal BC, they account for 15% of BC deaths. Given the very early age at onset and the fact that many of these women have a strong family history of breast and other cancers, it is highly likely a clinically important proportion are driven by high-risk monogenic genetic factors. Despite testing for known hereditary breast cancer (HBC) genes in these women, the causative gene for the majority of EOBC cases is not identified. Consequently, comprehensive germline genetic analysis of women with EOBC is likely to identify novel HBC genes that to date have been elusive when studying women with later onset BC where causes other than high-risk genes will confound the genetic analysis. This study used whole genome sequencing (WGS) to assess the presence of rare pathogenic variants in the germline of women with and extreme phenotype of breast cancer, who had tested negative for known HBC genes.
Methods: Forty-four cases of female BC diagnosed under the age of 35 (32 aged 26-30, 6 diagnosed ≤ 25 years) where both germline and tumour DNA was available for WGS were identified from the Variants in Practice Study. All patients were referred for germline genetic testing and returned a negative result for pathogenic variants in all known HBC genes. WGS was conducted on matched germline and tumor DNA to identify potentially pathogenic germline variants in novel HBC genes as well as assessing for evidence of bi-allelic inactivation in the tumor.

Results: No large deletions or translocation within or in the vicinity of any of the known HBC genes were identified and 8 rare variants identified in known HBC genes were excluded due to the absence of bi-allelic inactivation in the respective tumours. Genome-wide analysis of the WGS data identified 593 rare (<0.001 allele frequency in GnomAD) loss of function (LoF) germline variants across 519 genes. 439 genes were excluded from further analysis based on loss of the LoF allele in at least one tumor leaving 81 variants in 80 genes among 28 individuals where there was loss of the wild-type allele in all the tumours. Few of the 80 candidate genes function in DNA repair or genomic maintenance pathways nor any reported role in cancer predisposition. Only one of the 80

genes, ARFGEF1, had LoF variants identified in two carriers with each of the others only observed in just a single case. ARFGEF1 is a guanine nucleotide exchange factor involved in intracellular protein trafficking and cellular organisation, that is a possible tumour suppressor gene that is somatically mutated in some breast cancer.
Conclusion: Despite selection of BC cases with similar very early onset disease and therefore likely to be due to high-risk monogenic genetic factors, there remained a high degree of genetic heterogeneity similar to previous observations in later onset high risk BC cases. Assuming novel HBC genes conform to a two-hit mechanism, many genes were able to be excluded as candidates because of loss of the LoF variant allele in the tumor. A putative BC predisposition role for ARFGEF1 is supported by the observation of 2/44 case carriers and consistent biallelic inactivation the tumors.
Overall our results identified multiple potential candidate genes of interest, however, despite extreme phenotype of very early onset BC, did not identify a cohesive or recurring underlying genetic cause of BC in this cohort emphasising the extreme genetic heterogeneity that exists in the missing heritability of BC.

P3-04-11: Perceptions, Attitudes, and Education of Oncology Health Care Providers Regarding Genetic Testing and Counseling in a Resource-Restricted Country.

Lulwa El Saket, Allison L. Cirino, Eugene Wong, Sarah Spinette, Perman Gochyev, Bayan Altalla, Sarah Abdel Razeq, Hikmat Abdel Razeq

Access to cancer genetics services in Jordan is limited due to limited genetic counseling workforce, genetic testing options, and absence of formal genetic counseling training programs. As such, non-genetic counseling healthcare providers (NGCHP) are required to fill this gap and are the primary providers of genetic counseling services. Understanding their perspectives and experiences is crucial to bridge the accessibility gap of genetic counseling services in Jordan. This study assessed NGCHP's perceived utility, comfort, and familiarity with genetic testing and counseling as well as their past genetics training and preferences for continuing education regarding genetic counseling/testing.
An online questionnaire was created based on similar studies and input from the study team. Questions included: provider demographics, experience, knowledge, perceptions/attitudes, comfort, education regarding genetic counseling and testing, and hypothetical cancer genetic testing scenarios per National Comprehensive Cancer Network Guidelines. Oncology healthcare providers in Jordan were recruited through the King Hussein Cancer Center, the Jordan Oncology Society, the Jordanian Hematology Association, and LinkedIn. Knowledge was assessed by scoring the responses to questions about hypothetical patient scenarios based on National Comprehensive Cancer Network guidelines. Comparative (linear regression, Pearson, and Spearman correlation) and descriptive analysis were performed using Excel and Stata.
There were 33 participants: 88% were male (n = 29,) and 61 % were physicians (n = 20) with 5 years or more of experience. Majority (n=29, 88%) of participants strongly or

somewhat agreed that genetic testing is relevant to their current practice and 32 (97%) strongly or somewhat agreed that it would be increasingly useful in the future. Most participants were either very or somewhat comfortable with aspects of genetic counseling. However, there was no statistically significant correlation between level of comfortability and either years of experience (Spearman's rho= 0.096) or age (P=0.886). The fewest participants were very comfortable with interpreting test results (n=18, 54%) or choosing the correct test (n=18, 54%). When asked specific questions related to patients' eligibility for germline genetic testing, participants
scored 76% or below in the knowledge section. Breast cancer knowledge scores were lowest for questions related to male breast cancer (40%) and triple-negative disease (60%), emphasizing the need for education and training to improve the identification and counseling of eligible patients for genetic testing. Despite minimal formal training NGCHPs are familiar with aspects of the genetic test process. However, there remains a gap in knowledge and how often they are offering or ordering genetic tests suggesting the need for dedicated genetic counseling services in resource-restricted countries.

P3-04-12: Quantitative evaluation and assessment using the automated volumetric breast density measurement software Volpara Density in Japanese women

Saori Hayashi, Takafumi Morisaki, Yoshiki Otsubo, Yurina Ochiai, Hidenobu Nakagama, Yo Sato, Kimihisa Mizoguchi, Hisaharu Mori, Masafumi Nakamura, Makoto Kubo

Background: Breast cancer screening is being conducted to reduce death from breast cancer, and only mammography screening has been proven to reduce breast cancer mortality. One of the most common causes that reduce the efficacy of mammography screening is a dense breast. The problems with a dense breast are the lower ability to detect breast cancer and the higher incidence of breast cancer. Therefore, evaluating the breast components with objectivity and reproducibility is important. However, in Japan, the composition of the breast is still assessed visually, and this assessment has intra- and inter-observer variability. Although an automated analysis software is widely used to evaluate breast composition in Western countries, there are few studies in Japanese women and limited data are available. Therefore, this study was performed to objectively evaluate the breast density of Japanese women.
Materials and methods: We used the fully automated volumetric analysis software Volpara Density, which performs three-dimensional analysis based on the raw data before imaging. From each set of raw data, the volumetric breast density (VBD), which is the most reliable measure to evaluate dense breasts, was quantified (%) and graded as follows:. a, <3.5% = fatty; b, ≥3.5% and <7.5% = scattered; c, ≥7.5% and <15.5% = heterogeneous ; and d, >15.5% = extremely dense. This study included 23,447 mammograms that were performed at a cooperative research facility between February 2021 and September 2022.
Results: The total number of female participants was 8,350. The median age was 49 years. The most common age group was 40–49 years (36.0%), followed by 50–59 years (33.0%).

The median VBD by age was 21.9% for 30–39 years of age, 19.9% for 40–39 years of age, 15.4% for 50–59 years of age, 13.1% for 60–69 years of age, 11.9% for 70–79 years of age, and 10.5% for 80–89 years of age, and it decreased with age. There was a clear negative correlation between VBD levels and age. We then examined the relationship between breast density and body mass index. We found that the median VBD was 23.9% for women with a body mass index <18.5 kg/m2, 18.6% for ≥18.5 and <25 kg/m2, 9.6% for ≥25 and <30 kg/m2, and 6.1% for >30 kg/m2. This finding indicated that VBD decreased as the body mass index increased. Furthermore, we investigated the effect of the previous childbearing status on VBD. In women aged in their 40s, there was no difference in VBD between those with and those without a history of childbearing. However, in women aged in their 50s and 60s, VBD was significantly lower in those with a previous childbearing history than in those without a history of childbearing.
Conclusion: VBD determined using an automated volumetric analysis appears to be higher in Japanese women than in Western women. Volpara Density software is useful to evaluate breast density in Asians.

P3-04-13: Characterization and Comparison of Breast White Adipose Tissue Inflammation in Nigerian and African American Women with Primary Breast Cancer

Peter Ntiamoah, Tewogbade A Adedeji, Oluwole Odujoko, Oluwatosin Omoyiola, Samson G Ogunleye, Olalekan Olasehinde, Funmilola Wuraola, Marcia Edelweiss, Hannah Kalvin, Noah Peeri, Alexia Iasonos, Avinash Sharma, Israel A Owoade, Rivka Kahn, Bethina Liu, Adeleye Adeomi, Dilip Giri, Olusegun I Alatise, T. Peter Kingham, Neil M Iyengar

Background: Obesity raises breast cancer recurrence risk and mortality in pre-and post-menopausal women. Most obese individuals harbor breast white adipose tissue inflammation (WATi), which is a central driver of obesity-related breast cancers. The prevalence of WATi and its association with obesity varies by race/ethnicity and has not been well characterized in low- and middle-income countries. Here we assess the prevalence of breast WATi and contributing factors, including body mass index (BMI), body composition, clinical characteristics, and blood biomarkers in a cohort of Nigerian women with primary breast cancer. To assess the potential impact of extrinsic factors, we also compared findings in the Nigerian cohort to a cohort of African American (AA) women with breast cancer.
Methods: We collected non-tumorous breast tissue and fasting blood from 97 consecutive Nigerian breast cancer patients and 82 AA women undergoing mastectomy for breast cancer treatment at Obafemi Awolowo University Teaching Hospital (OAUTH), Nigeria, and Memorial Sloan-Kettering, New York, respectively. We identified breast WATi by CD68 immunohistochemistry to highlight macrophages encircling a dysfunctional adipocyte that forms a crown-like structure of the breast (CLS-B). We measured the total adipose area using NIH Image J software to report the severity of inflammation as CLS-B/cm2. In the Nigerian cohort, we measured circulating levels of lipids, insulin, glucose, C-reactive

protein, and adipokines in fasted blood samples. Body composition was measured by bioimpedance analysis. Associations between WATi and clinical variables were analyzed using univariable logistic regression, Wilcoxon rank sum, and Pearson's Chi-squared tests to compare the two cohorts. Among patients with WATi present, the relationship between BMI and the severity of inflammation was assessed using Spearman's rank coefficient rho.
Results: In the Nigerian cohort, 90 women were evaluable (median age 52, interquartile range [IQR] 45-59; median BMI 27, IQR 24-31). Breast WATi was present in 32 (36%) of the Nigerian cohort. Higher BMI (OR: 1.19, 95% CI: 1.07-1.33, p <0.001), increased total body fat (OR: 1.09, 95% CI: 1.04-1.16, p<0.001), increased trunk fat (OR: 1.18, 95% CI: 1.07-1.32, p<0.001), hypertension (OR: 3.20, 95% CI: 1.19-8.88, p = 0.022), higher fasting plasma glucose (OR: 1.16, 95% CI: 1.01-1.39, p = 0.041), and lower circulating adiponectin (OR: 0.03, 95%CI: 0.00-0.56, p = 0.019) were associated with WATi presence on univariate analysis. In the AA cohort, 82 women were evaluable (median age 49, IQR 44-55; median BMI 30, IQR 27-35). Breast WATi was present in 57 (70%) of AA women. Compared to the Nigerian cohort, AA women had higher BMI (p < 0.001) and higher prevalence of breast WATi (p < 0.001).
Conclusion: In this Nigerian cohort, increased adiposity and metabolic syndrome were associated with adipose inflammation – a risk factor for breast cancer recurrence. Compared to AA women with breast cancer, the Nigerian cohort had a lower BMI and a lower rate of inflammation. Further studies are needed to characterize lifestyle differences to inform culturally-specific prevention and intervention strategies.

P3-04-14: Case report of Breast cancer in a transgender PALB2 pathogenic variant carrier taking hormone therapy

Jessica McMillan, Douglas Riegert-Johnson

Background: About one and a half million individuals in the United States identify as transgender or non-binary. Many patients undergoing male to female transition are prescribed gender affirming hormone therapy (HT). Individuals who also carrying pathogenic variants(PVS) in breast cancer susceptibility traits (BRCA1/2, PALB2 and others) likely have their already high risk for breast cancer increased by gender affirming HT. The aim of this study is to report a rare case of breast cancer in a PALB2 PV carrier undergoing gender affirming HT.
Case presentation: A 40 year old patient, assigned male at birth, presented to her primary care providers with a right breast mass. The patient had been taking gender affirming HT for approximately two years (oral estradiol and spironolactone daily). Diagnostic mammogram and targeted ultrasound were completed confirming a large dense lobulated mass in the retroareolar right breast measuring 6 x 6 x 7 cm with prominent right axillary lymph nodes. Pathology of right breast and axillary lymphnodes reported invasive ductal carcinoma (IDC), grade 2, ER-positive (96% staining), PR-weakly positive (4% staining), her 2/Neu-negative (1+ by IHC). Whole body CT was negative for distant metastasis. The patient received 4 cycles of dose dense Adriamycin Cytoxan (AC) as neoadjuvant therapy

followed by right breast skin sparing mastectomy with sentinel node biopsy. Final pathology was grade 3 invasive ductal adenocarcinoma with negative margins and one of two lymph nodes had macrometastases (TMN staging ypT3 (6 cm), ypN1a (1/2 sn). Patient completed adjuvant postmastectomy radiation 5000 cGy in 25 fractions and started tamoxifen.
She was referred to Clinical Genomics for evaluation. Family history is limited as she is estranged from her family. The patient consented to genetic testing and a PALB2 pathogenic variant was found, c.532delG (p.E178Nfs*15) (CancerNext-Expanded® +RNAinsight®Ambry Genetics).
Conclusion: Despite a growing population of gender aware patients, research is limited on genetic counseling for those individuals with a hereditary cancer predisposition syndrome. Clinical guidelines have been developed and adopted for this population in terms of management, but predictive testing for hereditary cancer syndromes is not the standard of care. Our recommendation is that individuals considering gender reassignment surgery and hormonal therapies consider multigene hereditary cancer panel testing to further stratify their risk for cancer prior to initiation.

P3-04-15: Dietary-Advanced Glycation End products and breast cancer risk: Evaluating MYC dependency within the context of AGE-RAGE signaling in cancer associated fibroblasts

Gowtami Aishwarya Panguluri, Bradley A Krisanits, Jackson Lane, David P Turner, and Victoria J Findlay

Breast cancer ranks as the second leading cause of cancer-related mortality among women. The importance of lifestyle factors in cancer prevention is gaining momentum. Advanced Glycation End-products (AGEs) are reactive metabolites formed as a result of a spontaneous non-enzymatic reaction between reactive carbonyl and amine groups, they are irreversible and they accumulate in our bodies as we grow older. Dietary habits including high fat, high sugar and ultra-processed foods, contribute to the increased consumption of AGEs, and our collaborative group have linked the increased consumption of AGEs to the increased incidence of breast cancer and worse outcomes associated with the disease. Unfortunately, the mechanisms linking AGE consumption and breast cancer progression remain inadequately understood. AGEs can bind to and activate the Receptor for AGE (RAGE), prompting inflammatory responses and oxidative stress, potentially contributing to cancer development. We have developed a unique dietary-AGE mouse model to mimic human AGE consumption. In recently published studies, we found that mice fed a high AGE diet during puberty had dysregulation of normal mammary gland development. We also found hyperproliferative lesions in the high AGE fed mice with increased stromal recruitment including fibroblasts and macrophages. Primary fibroblasts isolated from the mouse mammary glands displayed an activated phenotype, similar to that observed in cancer associated fibroblasts, and led to increased epithelial cell migration and invasion in co-culture assays when compared to fibroblasts isolated from regular fed mice. We were able

to recapitulate this phenotype with exogenous AGE treatment ex vivo, and found that the AGE-mediated effect on migration was dependent on RAGE expression in fibroblasts. In new unpublished studies, we found that dietary AGE consumption promotes aggressive breast tumor growth in vivo. However, we are unable to assess the dependency on stromal RAGE in vivo as we found that the Met1 breast tumor cells do not grow in RAGE null mice. To address this, we are performing 1) co-injections studies in RAGE null mice with breast tumor cells and primary fibroblasts isolated from wildtype mice to ask whether fibroblast RAGE is sufficient for tumor initiation and AGE-mediated breast tumor growth; and 2) co-injection studies in wildtype mice with breast tumor cells and primary fibroblasts isolated from RAGE null mice to ask whether fibroblast RAGE is necessary for AGE-mediated tumor growth. Future studies with RAGE flox mice are planned to assess the impact of dietary AGE on tumor growth in mice with fibroblast specific deletion of RAGE. Based on the importance of MYC in breast cancer and its role as a downstream effector of AGE-RAGE signaling, we hypothesized that MYC may be required for the AGE-mediated effects on epithelial cellular migration. Therefore, we inhibited MYC in fibroblasts through transfection of shMYC constructs, lentiviral infection of shMYC virus and pharmacologically with small molecule inhibitors. These fibroblasts were then used in the epithelial migration co-culture assays. We found that inhibition of MYC in fibroblasts negated the AGE-mediated effects on epithelial cell migration similar to that observed with fibroblasts lacking RAGE. We are now assessing whether MYC is required for AGE-mediated fibroblast activation. Our current data support the idea that AGE-RAGE signaling activates a MYC transcriptional program in fibroblasts to promote epithelial cell migration. Taken together, these data support the idea that dietary intervention in young women may reduce breast cancer risk.

P3-04-16: Tumor Tissue Slices from Breast Cancer Patient Derived Xenografts as an Ex Vivo Method for Treatment Response

John Landua, Ping Gong, Lacey Dobrolecki, Christina Sallas, Michael T. Lewis

Introduction: The generation of patient derived xenografts (PDX) by implanting human breast tumors in the epithelium-free mammary fat pad of immunodeficient mice has allowed researchers to overcome the difficulties in consistently obtaining cancer tissue and provides a more biologically accurate model compared to in vitro cell lines. PDXs also allow for the propagation of a cohort of human breast tumors in which to perform preclinical studies to investigate treatment response. However, due to the costs associated with immunodeficient mice, drugs, and labor, these studies can become cost prohibitive. Therefore, we developed a method to generate and maintain thin slices of PDX tumors to provide a cost-effective platform for studying drug interactions while preserving the cellular heterogeneity and microenvironment of the solid tumor. Method: PDXs were harvested from tumor bearing mice, cored, and then sliced with the Alabama R&D Tissue Slicer. Tumor slices were maintained in a high nutrient media in an oxygen permeable plate to support cellular functions and reduce stress throughout multiple cell layers. Results: Cultured slices were compared to the original tumor via immunohistochemical biomarkers

and transcriptional profiling. Using the tissue slice method, we were able to treat PDX models with chemotherapy, inhibitors, and other small molecules ex vivo to recapitulate results shown in vivo.Discussion: The PDX tumor slice platform can offer a cost effective alternative to investigate treatment response and molecular mechanisms before investing in expensive mouse studies.

P3-04-17: 16q is a breast cancer suppressor arm

Sean Egan, Idil Eda Temel, YeJi An, Katelyn Kozma, Amanda Loch, Wei Wang

The loss of chromosome 16q is the single most common genomic event in BC, occurring in over 50% of tumors. Despite this, the literature is focused almost exclusively on the importance of focal mutations that show a maximum frequency of ~35-40%. We have modeled 16q loss by deleted this region in mammary epithelium of genetically modified mice. This event was sufficient to induce mammary tumor formation. This finding establishes for the first time that 16q is a BC-suppressing chromosome arm. We have gone on to identify two genes on 16q that can promote tumor formation when one copy is lost (Cbfb and Ankrd11, each in cooperation with Pik3caHR). We have also identified mutations that cooperate with 16q syntenic sequence loss in spontaneous tumors from our 16q mouse model (c-Met gene amplification and p53 mutation) as well as in a Sleeping Beauty transposon-based screen (identifying mutations that enhance Ras and Rho signaling). Finally, we have used transcriptional profiling and proteomics to compare matching mammary tumors with/without 16q-syntenic sequence loss, which revealed that hemizygous deletion of this region suppressed keratinocyte-like differentiation in mammary tumors.

P3-04-18: An immunological mechanism of resistance to CDK4/6 inhibitors in breast cancer

Claudia Galassi, Giulia Petroni, Lorenzo Galluzzi

Background: Resistance to CDK4/6 inhibitors (CDK4/6is) underlies treatment failure in patients with HR+HER2- breast cancer (BC) (Pandey et al., 2019). Thus, strategies breaking resistance to CDK4/6i+ET in women with HR+ BC are urgently awaited. Recent findings from Dr. Galluzzi in various immunocompetent mouse models of HR+ BC demonstrate that the CDK4/6i palbociclib (P) can be successfully combined with radiotherapy (RT) when delivered according to a precise treatment schedule (Petroni et al., 2021). These data inspired the initiation of a prospective, randomized phase II clinical trial comparing standard-of-care CDK4/6is plus ET vs RT followed by (à) CDK4/6is plus ET in patients with oligometastatic HR+ BC (NCT04563507).
In this context, we set out to dissect the immunological mechanisms underlying sensitivity vs. resistance to treatment in HR+ BC exposed to P+ET vs. RTàP+ET.
Methods: To dissect the impact of these treatments on HR+ BC, we performed scRNAseq on CD45+ cells infiltrating medroxyprogesterone acetate /7,12-Dimethylbenz[a]anthracene

(MPA/DMBA)-driven carcinomas established in immunocompetent mice (a model of luminal B BC), bioinformatic analysis on public patient datasets, functional studies and efficacy studies.
Results: We identified a hypoxia-inhibitable CCL2-depedent pathway recruiting IL17A+ γδ T cells to mouse HR+HER2- BCs after CDK4/6is, which repolarized tumor-associated macrophages (TAMs) towards an immunosuppressive CX3CR1+ phenotype. IL17A or γδ T cell signatures, as well as intratumoral γδ T cell or CX3CR1+ TAM abundance, correlated with tumor grade and reduced survival in two cohorts of HR+HER2- BC patients. Consistent with mouse data, circulating γδ T cells and plasma CCL2 levels negatively correlated with progression-free survival (PFS) in two series of HR+HER2- BC patients receiving CDK4/6is. Moreover, intratumoral γδ T cells were increased in HR+HER2- BC biopsies upon relapse on CDK4/6is compared to paired baseline biopsies. CX3CR1+ TAMs had negative prognostic impact in patients with HR+HER2- BC treated with anti-PD-1 and RT.
Conclusions: Our observations suggest that γδ T cells and CX3CR1+ TAMs may favor resistance to CDK4/6is in patients with HR+HER2- BC, and hence constitute potential targets to delay disease progression.

P3-04-19: Metronomic cyclophosphamide/iodine is proposed as an effective treatment for breast cancer: comparing intraperitoneal and oral administration in a murine model.

Evangelina Delgado-González, Ericka de los Ríos-Arellano, Brenda Anguiano, Carmen Aceves

Metronomic chemotherapy, which consists of the oral administration of conventional drugs in a continuous schedule at minimal effective doses, has shown promising results in metastatic cancer clinical trials. This treatment shows antiangiogenic and immunomodulatory actions with moderated secondary effects. The use of cyclophosphamide in a metronomic manner (mCpp) combined with immunotherapy improves considerably the antineoplastic response, but it is still expensive. Studies from our group show that molecular iodine (I2) reduces the viability of cancer cells and, with chemotherapeutic agents, activates the antitumoral immune response and diminishes side effects. The present work evaluates the adjuvant of oral I2 with mCpp using a murine model of mammary cancer. Female Sprague Dawley rats with 7,12-dimethylbenzantracene-induced tumors received mCpp in two forms: intraperitoneal (50 and 70 mg/kg two times/week, iCpp50 and iCpp70) and oral (50 mg/kg daily, oCpp50). I2 (0.05%, 50 mg/100 mL) and oCpp50 were dispensed in the drinking water for three weeks, during which body weight and tumor growth were registered. iCpp70 was the most efficient antitumoral dose but generated severe body weight loss and inflammation in the bladder epithelium suggesting the installation of hemorrhagic cystitis (HC). I2 prevented body weight loss, exhibited adjuvant actions with all doses of mCpp decreasing tumor growth, and canceled HC. Mechanisms include decreases in vascular endothelial growth factor (VEGF) and Survivin protein expression. oCpp50+I2 diminished angiogenic signals (CD34, vessel-length,

and VEGF content) and proinflammatory cytokines (interleukin-10 and tumor necrosis factor-alpha) and increased cytotoxic (lymphocytic infiltration, CD8+ cells, Tbet and interferon-gamma) and antioxidant markers (nuclear erythroid factor-2 and glutathione peroxidase). In conclusion, I2 enhances the effectiveness of oCpp with minimal side effects, allowing us to propose this binomial as an excellent candidate to scale it to a clinical protocol.

P3-04-20: Anti-cancer Efficacy of Natural Killer Cells in Breast Cancer Cell Lines and Patient-derived Organoids

Ilkyun Lee, Suk Jun Lee, Seungji Lee

Background: Currently, immunotherapy through Adoptive Cell Transfer (ACT) of immune cells, such as T cells or Natural killer cells (NK cell), is being proposed as a new treatment in the treatment of various cancers. NK cell-based therapeutic research has been conducted mainly in blood cancer until recently and is currently being tried in many solid cancers.PurposeThe purpose of the study is to examine the anti-cancer efficacy of natural NK cell-based ACT for breast cancer using breast cancer cell lines and patient-derived breast cancer organoids, which mighty be an alternative model to predict the outcome of developing therapeutics.
Methods: The isolated PBMCs from healthy donors were cultured and expanded following a previously published protocol. Characterization of NK cells was performed by flow cytometry and Enzyme-linked immunosorbent assay (ELISA). Expanded NK cells were evaluated for their anti-cancer efficacy in vitro (breast cancer cells MCF-7 and MDA-MB-453) and in vivo (xenograft breast cancer model using MCF-7 breast cancer cells). Breast cancer organoids using breast cancer cell lines (MCF-7, MDA-MB-231, and MDA-MB-453) and patient tissue were generated. Varying number of NK cells (1x104 – 1x105 cells) were applied to examine the cytotoxic effect of NK cells on the patient-derived organoids. The morphological and size changes of organoids were monitored for any sign of disintegration of the organoids for up to 2 weeks.
Results: In the 2 weeks expanded PBMCs, it was possible to secure a sufficient number of NK cells, and it was confirmed that NK cells had anti-cancer efficacy against breast cancer cell. In the xenograft animal model, the expanded NK cells tended to inhibit tumor growth, but they were not statistically significant.The organoids derived from breast cancer cell lines and breast cancer patients were successfully cultured. In the MCF-7 xenografted tumor mass and organoids made of MCF-7 showed co-localized same ER and PR expression

pattern.
However, in the case of breast cancer-derived organoids, the expression of receptors in the patient's original tumor and organoids was not completely consistent. In addition, no significant anticancer effects of NK cells have been confirmed in organoids derived from breast cancer patients.
Conclusion: NK cell-based treatment was judged to have value as an auxiliary treatment method rather than a main treatment method in the treatment of breast cancer. In the case of organoids derived from breast cancer patients, the expression patterns of receptors in the patient's original tumor and organoids did not completely match, which was thought to reflect the diversity and polymorphism of breast cancer cells. For more accurate characterization and evaluation of effectiveness as an alternative animal model, it will be necessary to conduct phenotypic analysis on a large number of organoids.

P3-04-21: Optimization of lentiviral transduction of a triple-negative breast cancer patient-derived xenograft organoid for modeling tumor cell quiescence and associated treatment resistance

Darien Reed-Perino, Sonali Arora, Alana L Welm, Cyrus M Ghajar, Patrick J Paddison

Triple-negative breast cancer (TNBC, lacking expression of estrogen and progesterone receptors and amplification of HER2) is an aggressive and drug-resistant subtype. Current standard-of-care for early-stage disease with neoadjuvant chemoimmunotherapy results in a pathologic complete response in only ~60% of patients. Proliferative heterogeneity naturally occurs in most tumors, where tumor cells exist in multiple different states with varying proliferative potential—states of active division, long- and short-term quiescence, pre-cell cycle entry, and stress. TNBC tumors exhibit a higher percentage of actively cycling, or Ki-67–positive cells, compared to other molecular subsets of breast cancer, which has been shown to predict higher pathologic complete response rates following neoadjuvant chemotherapy. Unfortunately, despite this, TNBC patients experience worse overall survival rates driven by higher rates of relapse. It has been proposed that a significant portion of noncycling, or Ki-67–negative, cells are in a G0-like, or quiescent, state and predicted therefore to be resistant to cytotoxic chemotherapies that rely on actively dividing cells. The presence of a tumor cell population in a quiescent/G0-like state has been increasingly recognized across many tumor types, including in breast cancer.
Patient-derived tumor organoids have emerged as an appealing model system that retains more cellular heterogeneity from primary tumors compared to widely used two-dimensional cell lines. Organoids show remarkable complexity by single-cell RNA sequencing, representing many more cell states compared to best available two-dimensional cell lines that most closely resemble the mutation, copy number variation, gene expression and protein expression profiles of patient tumors.
A mutant version of p27 containing mutations blocking binding to cyclin/cdk complexes, but retained proteolysis in S/G2/M, combined with an mVenus fluorescent protein (p27-mVenus) has been previously validated as a genetic reporter for steady-state G0 readouts.

We have optimized lentiviral transduction of a triple-negative breast cancer patient-derived xenograft organoid with the p27-mVenus reporter to label quiescent organoid subpopulations. Optimized parameters include method of lentivirus concentration, multiplicity of infection, duration of transduction, presence of protamine, presence of a Matrigel base layer, presence of RetroNectin and use of spinoculation. We will use this p27-mVenus TNBC organoid reporter line to study the response of quiescent cell populations to current standard of care treatments and how they contribute to therapeutic resistance.

P3-04-22: An organoid model derived from a patient with breast angiosarcoma

Xiaoling Liu, Meiyang Huang, Jicheng Li, Aishi Deng, Dong Chen

Background: Breast angiosarcoma (BA) is an extremely rare and highly aggressive breast malignancy, accounting for less than 1% of all breast malignancies and less than 5% of all soft tissue sarcomas. BA is associated with a poor prognosis due to a high risk of postoperative recurrence and future metastases, highlighting the importance of postoperative adjuvant therapy. However, the effectiveness of adjuvant chemotherapy for BA is still unclear, with relevant studies mainly based on case reports and small-scale studies. It is urgent to establish a reliable in vitro preclinical model to explore individualized treatment for BA.
Methods: We reported a case of primary BA in a 36-year-old premenopausal woman who underwent a right-sided mastectomy. In order to investigate the most suitable drugs for this patient, we used the postoperative tumor specimen for digestion and preparation of organoid models. And the BA specimens and organoids were fixed and embedded to make paraffin sections. Both of them were then characterized by H&E and immunofluorescence staining. Subsequently, organoid models were used for screening of sensitive chemotherapy and targeted drugs.
Results: The main clinical presentation of this case is a rapidly growing mass in the upper outer quadrant of the right breast, accompanied by slight purplish skin discoloration. The pathological diagnosis showed primary breast angiosarcoma, with immunohistochemical staining positive for CD34, CD31, ERG, and FLI-1, and a high Ki-67 index (60%). We successfully established an organoid model for BA, which could be passaged continuously and cryopreserved. The BA organoids closely recapitulated the histological features and captured the marker expression in the original tumor, including CD31, CD34, c-Myc, CD117, Ki-67, even after a long-term culture. The dose titration tests of 14 chemotherapeutic and targeted drugs displayed differential drug responses with diverse IC50 values. Among all the drugs, anthracycline, paclitaxel, and tyrosine kinase inhibitors such pazopanib showed excellent anti-tumor effects. Inversely, ifosfamide and endocrine drugs showed no obvious anti-tumor effects.
Conclusion: This study indicate that patient-derived BA organoids may be a novel preclinical model to investigate personalized therapy for patients with BA.

P3-04-23: Utilization of a novel breast microphysiological system to investigate the influence of tumor microenvironment on hormone receptor positive breast cancer

Megan Benz, Jack D. North, Mackenzie L. Hawes, Jack R. Elliott, Delia A. Carlino, Katherine L. Hebert, Van T. Hoang, Bridgette M. Collins-Burow, Frank H. Lau, Matthew E. Burow, Elizabeth C. Martin

Introduction: Hormone receptor positive (HR+) breast cancer accounts for nearly 60% of all breast cancer cases, with roughly 40% of patients experiencing resistance to endocrine treatment. There are known mechanisms of HR heterogeneity in breast cancer cells such as estrogen receptor-a gene (ER) gene mutations, co-activators, enhanced Ki-67 expression and growth factor activated pathways. Despite this, we do not have adequate predictive markers for response to therapy. Currently we have an incomplete understanding of how heterogeneity in the tumor microenvironment (TME) impacts the ER response in breast cancer. It is well established that the TME can modulate cellular proliferation, survival, and resistance to therapy in breast cancer. There is currently a gap in the ability of models to accurately mimic the TME in vitro, thus limiting our understanding of drug resistance and development of novel therapeutics. Here, we have modeled the pre-menopause, obese HR+ breast TME through the incorporation of six pre-menopause, obese human breast tissue (HBT) donors into a novel ex vivo breast tumor model to investigate the influence of the TME on HR+ breast cancer response to endocrine treatment.
Methods: Ex-vivo breast tumors (EVBTs) were created by sandwiching. and then anchoring, healthy human breast tissue seeded with breast cancer cells between two confluent monolayers of breast adipose-derived stromal cells (brASCs). Breast adipose tissue from six different young (<50 years of age), obese (BMI≥28) donors was used to construct the EVBTs which were then seeded with the same representative HR+ breast cancer cell line and treated with vehicle, E2 100ρM, or Fulvestrant 1μM for 48 hours in median environment depleted of exogenous hormones and growth factors. RNA sequencing was used to demonstrate that the breast cancer cell line signatures was retained in the EVBT system and demonstrated ER response through evaluation of ERα and the ER responsive genes (PGR). Additional analysis done with qRT-PCR demonstrated relative gene expression changes in the microenvironment in response to endocrine treatment. To determine the source of transcriptional changes, individual cell populations were evaluated for ER and ECM genes using qRT-PCR following treatment with endocrine therapy.
Results: Results demonstrated the retention of the breast cancer cell line transcriptome in the ex vivo breast tumor for up to 14 days in vitro. In addition, some donors displayed decreased PGR gene expression after treatment with ICI, elevated ERα gene expression, and increased COL6A6 expression. compared to breast tissue not seeded with HR+ breast cancer. Post-endocrine treatment qRT-PCR results showed variable ECM-gene expression changes between the breast tissue donors. To determine the source of the ECM changes, HR+ breast cancer cells and brASCs were evaluated post-endocrine treatment. Results demonstrated that expression of COL6A6 increased in breast ASCs cultured alone following treatment with Fulvestrant. No significant changes were noted in HR breast cancer cells

cultured alone after endocrine treatment.
Conclusion: Given the impact of the TME in breast cancer pathology and therapeutic resistance, it is critical for the contributions of the TME to be included in pre-clinical models of breast cancer. The findings from this study are ongoing, however, data suggest ECM remodeling occurs in response to endocrine therapy which is influenced by the TME. Further studies are needed to better define the interaction of ECM with HR+ breast cancer as well as the impact of endocrine therapies on ECM and TME remodeling.

P3-04-24: Targeting nucleosome synthesis as a therapeutic strategy for triple-negative breast cancer

Joshua Gruber, Harsh Goar, Shreenidhi Rajkumar, Danielle Dixon

The paradigm of modern cytotoxic chemotherapy is to impair DNA replication to prevent cell division. During this process, newly synthesized DNA is wrapped around histones produced de novo to create the fundamental unit of chromatin: nucleosomes. Yet, despite the 50+ approved oncology drugs that target DNA synthesis, there are currently no therapeutic strategies that target nucleosome production. This gap represents a large and untapped opportunity to develop novel, safer and more efficacious anti-cancer therapies. We have focused on histone acetyltransferase 1 (HAT1), an enzyme that acetylates and stabilizes newly synthesized histones in the cytosol to support nucleosome production. Our previously published data demonstrated that HAT1 controls histone production by also binding histone H4 promoters (Gruber et al. Mol. Cell 2019). In the absence of HAT1, cells cannot effectively synthesize nucleosomes and tumor growth is impaired. To further develop rationale for targeting HAT1 for breast cancer we bred the HAT1+/-heterozygous mouse to the MMTV-PyMT model of triple-negative breast cancer. Despite normal development, animals deficient for a single HAT1 allele in the MMTV-PyMT background evinced delayed mammary tumor onset, decreased tumor size and increased survival compared to littermate controls (median survival 172 v. 196 days for WT v. het; log-rank $p < 0.004$). Histologic examination of tumors revealed a strong correlation between Ki-67 and HAT1 protein expression ($R2 = 0.51$, $p < 0.01$). HAT1 expression in heterozygous animals was primarily diminished in normal mammary glandular structures compared to WT controls, but HAT1 levels were high in tumors, which mirrored high expression of HAT1 and related co-factors in a panel of human triple-negative breast cancers. Since HAT1 primarily binds and regulates histone H4 promoters to coordinate nucleosome production further experiments were performed to test the requirement for histone H4 genes for mammary tumorigenesis. Biallelic CRISPR/Cas9 editing of either promoter or coding regions of three separate histone H4 genes in triple-negative breast cancer cell lines demonstrated that all edits diminished tumor growth potential in vivo. In addition, tumor growth could be rescued by re-expressing a single copy of histone H4 into cells bearing H4 gene edits, demonstrating the specificity of these edits. These results establish that the HAT1-histone H4 axis is a critical dependency for triple-negative breast cancer growth. Our lab has recently published the first small molecule HAT1 enzymatic inhibitor, which demonstrated

anti-tumor activity and animal safety in vivo (Gaddameedi et al. J. Med. Chem. 2023). Thus, small molecule strategies to target the HAT1-H4 axis could have therapeutic relevance for triple-negative breast cancer with a goal of improving patient outcomes.

P3-04-25: Investigating Proteostasis in Endocrine Therapy-Resistant Luminal A Breast Cancer

Anthony Peidl, Shaymaa Bahnassy, Henry Vo, Xiaolian Gao, Tasneem Bawa-Khalfe

Proteostasis (or protein homeostasis) maintains a functional proteome through a network of proteins that regulate protein synthesis, folding, modification, trafficking, and degradation. Dysregulation of the proteostasis network drives multiple diseases including neuropathies and cancer. Various components of the proteostasis network, such as the heat-shock protein (HSP) family, are known oncogenes and attractive targets for therapies. Canonical studies establish HSPs, including small HSP HSP27, as chaperones that facilitate proper protein folding and prevent toxic protein aggregation. More contemporary reports highlight the enzymatic properties of HSP27 as a member of the ubiquitin superfamily of proteins. Specifically, HSP27 directs ubiquitin-tags on misfolded/unfolded proteins and targets to the proteasome for degradation. In addition, HSP27 serves as a ligase for ubiquitin-like SUMO modification of select substrates; our recent report highlights the androgen receptor as a novel substrate for HSP27-directed SUMOylation in breast cancer. Specifically, we observe a concurrent induction of SUMO and HSP27 in endocrine-therapy resistant (ET-R) hormone receptor positive (HR+) breast cancer. Yet it is unclear how induction of HSP27 impacts proteostasis and aggregate formation in this highly aggressive cancer type. New data now shows a change in HSP complex formation between endocrine-therapy sensitive (ET-S) and ET-R breast cancer. We show increased protein aggresome formation in ET-R breast cancer, with ongoing drug treatment studies targeting Hsp27 and the SUMOylation machinery being performed to assess changes in aggresome accumulation in these models. Emerging molecular docking studies elucidate a novel binding pocket for targeted drug therapies that could inhibit the SUMO/SUMO-interacting motif (SIM) interactions for Hsp27. Ongoing protein-protein interaction studies analyzing SUMOylation and ubiquitylation of Hsp27 and target substrates as well as computational studies using small molecule and peptide drug screening, molecular docking, and molecular dynamics will help determine how we can target Hsp27 in ET-R breast cancer to restore its chaperone activity.

P3-04-26: DCIS turns fatal: Thrombotic microangiopathy as the cause of death in undiagnosed recurrent metastatic breast cancer

Samantha El Warrak, Naga Vaishnavi Gadela, Jeffrey Nascimento

Introduction: Pulmonary tumor thrombotic microangiopathy (PTTM) is a fatal condition caused by microscopic tumor cells. Very rarely, this can be the only presentation in

recurrent or metastatic solid tumors. It is an underdiagnosed condition with only a few reported cases in the literature because of its challenging diagnosis premortem. We present a fatal case of PTTM in metastatic breast cancer in a patient considered to be in remission.
Case presentation: A 34-year-old female presented to the emergency department with progressively worsening shortness of breath for one week. Her medical history was notable for left hormone-receptor negative breast ductal carcinoma in situ treated with mastectomy 3 years prior to presentation. On presentation to the hospital, she was hypoxic with an oxygen saturation of 86% on room air requiring nasal cannula(NC). Her physical examination was unremarkable. Laboratory findings were significant for D-dimer 2954ng/ml, C-reactive protein 8.24mg/dL, lactate dehydrogenase 1059U/L, ProB-type natriuretic peptide 524pg/ml, and mild transaminitis. CT-angiography of the chest was negative for pulmonary embolism with normal appearing lung parenchyma. CT-abdomen showed multiple hypoechoic liver lesions and sclerotic bone lesions suggesting possible metastasis. Echocardiogram was significant for fibrinous pericarditis, moderate pericardial effusion, normal ejection fraction, no signs of pulmonary hypertension or intra-cardiac shunt. Her hypoxia rapidly progressed within a 72-hour timeframe from 2L NC, high-flow NC, continuous positive airway pressure(CPAP) to mechanical ventilation. She was started empirically on prophylactic anticoagulation, colchicine and ibuprofen for pericarditis, ceftriaxone and doxycycline along with high-dose steroids for possible community acquire pneumonia, tick-borne illnesses and acquired respiratory distress syndrome. Despite efforts to halt this unknown process, she went into cardiac arrest with pulseless electrical activity and died despite aggressive cardiopulmonary resuscitation. An autopsy showed metastatic adenocarcinoma compatible with metastatic breast cancer.
Discussion: PTTM, also called carcinomatosis endarteritis, is a challenging premortem diagnosis and a fatal complication of tumor emboli from metastatic breast cancer. Breast cancer is the second most common cancer associated with PTTM following gastric cancer. Although the pathogenesis is not fully understood, it is attributed to remodeling of vessel walls and interstitial fibrosis leading to pulmonary infarction, alveolar hemorrhage, pulmonary hypertension and subsequent cor pulmonale. It manifests as cancer cells spreading through the intrapulmonary arterial tree, causing occlusion and sudden death. Devastatingly, it can be the only manifestation of recurrent undiagnosed cancer, as seen in our patient. As there are no standard guidelines to diagnose PTTM, physicians should have a high clinical suspicion to appropriately manage this catastrophic condition.
Conclusion: In conclusion, PTTM is an ambiguous clinical manifestation of metastatic breast cancer, especially when the cancer was considered to be in remission. Our case highlights the importance of considering tumor emboli as a cause of acutely worsening unexplained hypoxemia in patients with a history of cancer, regardless of stage.

P3-04-27: Resistance to neratinib in HER2+ breast cancer: Mechanistic insights and treatment approaches

Fu-Tien Liao, Lanfang Qin, Martin J. Shea, Tia Gordon, Sarmistha Nanda, Caroline M. Sabotta, Alekya Raghavan, Chia-Chia Liu, Carolina Gutierrez, Mothaffar F. Rimawi, C. Kent Osborne, Rachel Schiff, Jamunarani Veeraraghavan

Background: Neratinib (Nrb), a potent irreversible pan-HER tyrosine kinase inhibitor (TKI) is approved for use in patients with HER2-positive (+) breast cancer. However, resistance continues to be a key clinical challenge. We previously reported using HER2+ breast cancer cell models that resistance to Nrb is associated with the co-acquisition of HER2 and PIK3CA mutations, which could be overcome by simultaneous blockade of the HER2 and the PI3K pathway. Here, we sought to corroborate the mechanistic underpinnings of Nrb resistance and to extend our studies to the in vivo setting to confirm the efficacy of a promising and potentially less toxic drug combination.
Materials and Methods: Our previously developed HER2+ BT474/AZ cells with acquired resistance to Nrb (NR) or lapatinib (Lap, LR) and their treatment naïve parental (P) cells were used. The Naïve and LR (harboring endogenous HER2 L755S) cells were engineered to ectopically express mutant PIK3CA (mutPIK3CA) using the lentiviral expression system. Upon short-term treatment with small molecule inhibitors targeting HER2 or AKT, either alone or in combination, characterization of relevant cell models, at the signaling level, was performed by Western blot (WB). Changes in cell growth and migration were assessed by methylene blue and Incucyte wound healing assays, respectively. Nude mice bearing GFP/Luc-tagged NR xenografts were treated with vehicle, Nrb, the AKT inhibitor capivasertib (Capi), or Nrb+Capi and monitored for primary tumor growth and metastasis (by bioluminescence imaging). Tumors harvested at the end of experiment were assessed by WB and IHC.
Results: While we previously reported that NR is associated with the co-acquisition of HER2 L755S and a pathogenic PIK3CA mutation (SABCS 2021), the role of PIK3CA mutations, when occurring alone in resistance to Nrb, warranted further investigation. Our new results show that ectopic expression of mutPIK3CA confers resistance to Nrb only when expressed in LR cells that already harbor endogenous HER2 L755S. Interestingly, ectopic expression of mutPIK3CA alone in naïve P cells could confer resistance to tucatinib (Tuca) and Lap but not Nrb. Nrb and Capi only when combined together but not as single agents were effective in overcoming resistance conferred by HER2 and PIK3CA mutations in this ectopic expression system, which agrees with our observation from the acquired NR model. Further, WB analysis of the NR cells showed that Nrb+Capi eliminated the levels of pS6 and induced high levels of the apoptotic marker c-PARP, while single agent Lap, Tuca, and Capi failed to do so. Importantly, our BT474 NR cells not only grow effectively as xenografts in the presence of Nrb but also metastasize to the lung, confirming our in vitro finding that the NR cells are highly migratory compared to P cells. Interestingly, Capi, both alone and in combination with Nrb, was significantly effective in inhibiting the NR tumor growth along with a trend to also inhibit its lung metastatic ability. Evaluating the status of the PI3K/AKT pathway in the available tumors harvested at the end of this experiment, we observed considerably lower

pS6 levels in tumors treated with Nrb+Capi, consistent with our in vitro results. Conclusions: Our data suggest that, in HER2+ BC, the efficacy of Nrb may be reduced by mutations in HER2 together with co-occurring mutations in key downstream mediators such as PIK3CA, which may also confer cross-resistance to other TKIs, especially HER2-selective TKIs such as Tuca. Overcoming this resistance requires the use of small molecule inhibitors co-targeting the mutated HER2 and the downstream component, a strategy that warrants further clinical testing. Our findings thus suggest that the genomic landscape of a HER2+ tumor should guide the treatment decision making in order to ensure the optimal use and sequence of currently available HER2 TKIs.

P3-04-28: Inhibition of FASN and ACC1 as a Potential Treatment for Advanced Endocrine Therapy-Resistant Breast Cancer

Henriette Balinda, Avani Gunuganti, Asmita Sinha, Suryavathi Viswanadhapalli, Gangadhara Sareddy, Ratna Vadlamudi, Andrew Brenner

Introduction: Over the past decade, there have been substantial advancements in improving survival rates for estrogen receptor alpha (ERα) positive breast cancer. Treatments such as selective estrogen receptor down-regulators and modulators (SERMs) like fulvestrant and tamoxifen, mTOR inhibitors like everolimus, aromatase inhibitors (AIs), and cyclin-dependent kinase inhibitors such as palbociclib, ribociclib, and abemaciclib have all contributed to extending the overall survival of breast cancer patients. Unfortunately, resistance to endocrine therapy is a common occurrence and all patients will eventually succumb to their disease. Metabolic rewiring is a biological hallmark of all cancers, yet there are currently no therapies that specifically target cancer metabolism. Fatty acid synthase (FASN) is a key enzyme in lipid metabolism and is overexpressed in more aggressive and therapy-resistant tumors, including breast cancers. FASN inhibitor, TVB-2640, has been evaluated in multiple tumor cell lines and in a phase 1 clinical study, and showed partial responses in 5 patients and multiple patients with prolonged stable disease (≥16 weeks). Acetyl-CoA-carboxylase-1 (ACC1/ACACA) is an enzyme that functions upstream of FASN to provide malonyl-CoA, a rate-limiting step in de novo long-chain fatty acid synthesis and is overexpressed in cancer. Previously, we showed that FASN inhibition in tamoxifen-resistant cells leads to inhibition of proliferation and reduced tumor growth through induction of endoplasmic reticulum stress. We therefore assessed the effects of FASN and ACC1 inhibition in fulvestrant- and palbociclib-resistant breast cancer.

Methods: We generated fulvestrant-resistant MCF7 cells by long term exposure to fulvestrant (MCF7/FR cells), and palbociclib-resistant (MCF7/RB1Crispr and ZR75/RB1Crispr) cells were generated through CRISPR/Cas9 knockout of the retinoblastoma (RB) gene. We assessed the impact of FASN inhibitor, TVB-3166, (and analog of TVB-2640 with slightly lower molecular weight for in vitro use), and ACC1 inhibitor, PF05175157 on proliferation, viability, cell cycle, and apoptosis in these cells, and tumor growth in xenografts. RNA sequencing of fulvestrant-, and palbociclib-resistant cells was performed to investigate gene expression. Unfolded protein response signaling protein

levels were analyzed by western blotting after treatment with TVB and PF05175157. Results: Inhibition of FASN and ACC1 lead to a marked inhibition of proliferation in fulvestrant- and palbociclib-resistant cells compared to the parental cells. However, inhibiting both FASN and ACC1 did not appear to produce an additive effect in these cell lines. TVB increased cells in the G1 phase, whereas PF05175157 increased the number of cells in the S-phase in fulvestrant-resistant cells. Both TVB and PF05175157 increased the number of apoptotic cells in fulvestrant- and palbociclib-resistant cells. RNA sequencing of fulvestrant-resistant and palbociclib-resistant cells showed that treatment with TVB results in alteration in unfolded protein response (UPR) pathway. Additionally, TVB and PF05175157 significantly inhibited tumor growth in mice to untreated controls.

Conclusion: Our preclinical data provide evidence that FASN inhibition by TVB-3166 or ACC1 inhibition by PF057175157 present promising therapeutic strategies for treatment of endocrine-resistant breast cancer. Further clinical development of FASN and ACC1 inhibitors for endocrine resistant breast cancer should be considered.

P3-04-30: Single cell analysis enables tracking the evolution of resistance to CDK4/6 inhibitors in ER+ breast cancer

Yuki Matsunaga, Hima Milan Patel, Emilija Aleksandrovic, Dhyvya R. Sudan, Khushi Ahuja, Dan Ye, Chang-Ching Lin, Lei Guo, Cynthia X. Ma, Siyuan Zhang, Carlos L. Arteaga, Ariella B. Hanker

The combination of CDK4/6 inhibitors (CDK4/6i) with endocrine therapy prolongs survival of patients with ER+/HER2- metastatic breast cancer. Nearly all patients with advanced disease treated with this combination eventually progress, highlighting a need for therapeutic interventions that prevent the emergence of drug resistance. Drug tolerant persister (DTP) cells represent a reservoir of surviving cells from which drug-resistant clones eventually emerge. We hypothesize that targeting the DTP state which emerges under selective pressure from CDK4/6i could prevent the emergence of drug resistance. In vitro treatment of MCF7 and T47D ER+/HER2- breast cancer cells with the CDK4/6i Palbociclib and estrogen deprivation for 4 weeks suppressed cell viability with 2-5% of cells surviving treatment and achieving a DTP state. Cell cycle analysis by PI staining revealed that 95% of the DTP cells were arrested in G0/G1 after 4 weeks of continuous therapy. Upon drug washout, the DTP population resumed proliferation within ~1 week and regained sensitivity to retreatment with CDK4/6i, suggesting epigenetic reprogramming is responsible for the DTP state. Whole exome sequencing did not show enrichment of known genomic alterations associated with CDK4/6i resistance (e.g., RB1, FAT1, PTEN). Bulk RNA sequencing of MCF7 DTP cells revealed transcriptome reprogramming compared to untreated controls, which reverted upon drug washout to that of the treatment naïve state. While cell cycle-related gene signatures such as E2F targets and G2M checkpoint were downregulated, interferon response signatures were upregulated in MCF7 DTP cells relative to untreated controls. MCF7 persisters were characterized by enrichment in senescence and chemotherapy-induced stressed gene signatures, while diapause and MYC

target signatures were downregulated. These same signatures were similarly enriched in ER+/HER2- tumors from patients in the NeoPalAna study treated with neoadjuvant palbociclib and the aromatase inhibitor anastrozole compared to baseline biopsies.
To study evolution of drug resistance, we transduced MCF7 and T47D cells with the LARRY (Lineage and RNA recovery) barcode library to uniquely label and track each persister cells long-term, and identify programs that are causal to the emergence of drug resistant clones. We performed single cell RNA-seq on barcoded cells treated with palbociclib plus estrogen deprivation for 0 h, 72 h, and 4 weeks. Several clones that arrested in G0/G1 initially eventually expanded at 4 weeks, while other clones were eliminated. We are currently investigating which genes/pathways are upregulated in the barcoded clones enriched at the 4-week time point. We will then validate results from these single cell approach in cells surviving neoadjuvant treatment in the NeoPalAna trial.
In summary, a small subset of ER+/HER2- breast cancer cells survive long-term treatment with CDK4/6i plus estrogen deprivation and exhibits reversible transcriptomic features of DTPs. Our ongoing single cell-seq analyses may reveal transcriptional programs that enable the DTP state which, in turn, could be targeted to reduce survival of drug-tolerant cells and prevent the emergence of drug resistance.

P3-05-01: Social Determinants of Health in Patients with Metastatic Breast Cancer in Mexico

Haydee Verduzco-Aguirre, María Fernanda Esparza Orozco, Wendy Alicia Ramos López, Montserrath Alvarado Hernández, Mayte Cruz Zermeño, Lilia Elena Morales Centeno, Anabel Cruz Medina, Daniela Ramírez Maza, Claudia Rodríguez Morales, José Alejandro Adrián Heredia Barreda, Roberto Iván Sánchez Reyes, Enrique Talamantes Gómez, Gregorio Quintero Beuló, Yanin Chávarri Guerra

Background: Breast cancer is the most common cancer in Mexican women, with a significant proportion diagnosed with metastatic breast cancer (mBC) at initial presentation due to access barriers and social disparities. Despite this, the impact of social determinants of health (SDH) on Mexican women with mBC remains understudied. This study aimed to describe SDH among women with mBC in Mexico and their influence on health outcomes.
Methods: A prospective cohort study was conducted across three tertiary public hospitals in Mexico City, enrolling adult patients with mBC undergoing first- or second-line treatment. At baseline, patients completed a standardized SDH screening tool (the American Association of Family Physicians' Social Needs Screening Tool) and questionnaires assessing medication self-efficacy (SEAMS, scale 13-39), quality of life (FACT-G, scale 0-108), and pain control (BPI, scale 0-10). Clinical data were collected from medical records. Personalized recommendations were provided by a patient navigator based on the patients' identified needs across five SDH domains: access to healthcare (transportation), education, economic stability (employment and finances), neighborhood and built environment (housing, food, and utilities), and social and community context (childcare and personal safety). Associations between SDH domains and health outcomes were analyzed.

Results: 329 patients (99.1% female) with a mean age of 58.2±12.7 years (range 24-91) were included. 168 (51.1%) had recurrent disease and 71.4% were under first-line therapy.
284 (86.3%) resided in urban areas. 203 (61.7%) reported a travel time to the hospital of <2 hours and 66.9% used public transportation.
177 (53.8%) had an educational level of less than high school. 73 (22.2%) were employed.
139 (42.2%) had a monthly household income of <415 USD. 137 (41.6%) had social security insurance.
154 (46.8%) were married or had a common-law partner. 269 (81.8%) had at least one child.
At baseline, the mean SEAMS total score was 32.8±6.2, and the mean FACT-G score was 80.8±10.6. 132 (40.1%) reported having pain; pain severity average score was 4.3±2.2, with a mean pain interference score of 4.7±2.9.
314 (95.4%) patients reported at least one SDH need in the following domains: 287 (87.2%) economic stability, 230 (69.9%) neighborhood and built environment, 123 (37.4%) education, 55 (16.7%) access to healthcare, and 46 (13.9%) social and community context. Overall quality of life was significantly different according to the number of SDH needs (p=0.018). The mean FACT-G score was lower among patients with an education need compared to those without it (78.9±10.8 vs 82.0±10.4, p=0.010). Age was significantly negatively correlated with the FACT-G score (r=-0.245, p<0.001). Pain severity and medication self-efficacy scores (p=0.63) were not associated with SDH needs, except for the patients with social and support needs (31.1±6.8 vs 33.1±6.1, p=0.049). Medication self-efficacy scores were also lower among those in second line therapy (31.7±6.6 vs 33.3±6.1, p=0.036).
Conclusion: A great proportion of Mexican patients with mBC exhibit diverse SDH-related needs that can affect treatment adherence and quality of life. Addressing these needs through interventions like patient navigation could potentially improve breast cancer related outcomes, and merits further study.

P3-05-02: The impact of ethnicity on benefit from novel drugs approved for breast cancer treatment: a systematic review and meta-analysis of randomized phase 3 trials of the last decade.

Emma Zattarin, Luca Moscetti, Isabella Sperduti, Elisa D'Agostino, Alberto Bertolotti, Chiara Chiavelli, Federico Piacentini, Laura Cortesi, Massimo Dominici, Angela Toss

Introduction: Asian patients, previously underrepresented in randomized clinical trials (RCTs), lately begun to be more equally enrolled. However, it is still unclear if they derive different benefit from breast cancer (BC) novel anticancer drugs. Thus, we did a systematic review and meta-analysis to evaluate the heterogeneity of treatment efficacy for Asian vs. non-Asian patients enrolled in the major phase III RCTs of the last decade, both in the advanced (aBC) and the early (eBC) setting. Moreover, since the underrepresentation of other ethnicities, especially Black, still limits their evaluation as individual subgroups, we

examined the outcomes of White vs. Non-White patients.
Methods: Novel anticancer therapies approved by FDA between January 2013 and December 2023 for BC treatment were identified. We systematically searched for the eligible RCTs as follows: (a) phase III RCTs with full-text article; (b) enrolling patients with aBC or eBC; (c) comparing the experimental vs. standard drug; (d) available progression free survival (PFS) in the aBC or event free survival (EFS), invasive disease free survival (iDFS) or disease free survival (DFS) in the eBC; (e) reporting the hazard ratio (HR) and 95% confidence intervals (95%CI) for outcomes in Asian and/or non-Asian subgroups or White and/or non-White subgroups. We calculated the pooled HR and 95%CI in ethnic subgroups using a random-effects model, and assessed the heterogeneity between the estimates using an interaction test.
Results: 23 phase III RCTs were identified in the aBC setting, with 1547 (11.1%) patients of Asian ethnicity. Experimental drugs tested included CDK4/6i (palbociclib, ribociclib, abemaciclib), SERD (elacestrant), PI3Ki (alpelisib), PARPi (olaparib, talazoparib), broad variety of anti-HER2 drugs (tucatinib, trastuzumab deruxtecan, pertuzumab, T-DM1, neratinib, margetuximab), anti-PD-1 and anti-PD-L1 drugs (pembrolizumab, atezolizumab) and anti-TROP2 drug (sacituzumab govitecan). 16 RCTs provided HR (95%CI) for PFS in the subgroup of Asians and 17 RCTs for Non-Asians. Overall, the pooled HR for PFS of the experimental arms vs. control arms was 0.58 (95%CI 0.49-0.70) for Asians and 0.61 (95%CI 0.56-0.67) for Non-Asians. 14 RCTs presented the results for the subgroup of White patients and 17 RCTs for non-White patients. The pooled HR for the experimental treatment arms vs. control arms for Whites was 0.64 (95%CI 0.57-0.72), and HR of 0.57 for Non-Whites (95%CI 0.49-0.65). The difference in efficacy in terms of PFS between Asians and non-Asians was not significant (p=0.478), nor between Asians and Whites (p=0.321) nor Whites and non-Whites (p=0.214). For the eBC analysis, we identified 8 phase III RCTs, with a total of 1630 Asian patients (16.4%), but only 4 (experimental drugs abemaciclib, neratinib, T-DM1 and olaparib) reported the outcomes in Asian and non-Asian subgroups. The pooled analysis showed an IDFS advantage for the experimental arms vs. control arms with HR of 0.66 (95%CI 0.50-0.87) for Asians and HR of 0.63 (95%CI 0.53-0.76) for non-Asians, with not significantly different IDFS benefit between Asians and non-Asians (p = 0.808). Pooled HR for IDFS was 0.63 (95%CI 0.52-0.76) for White patients and 0.66 (95%CI 0.52-0.86) for non-White patients. Again, there was no significant difference in the efficacy of experimental treatment arms neither between White and non-White ethnicity (p=0.729), nor between Asians and Whites (p=0.777).
Discussion: The magnitude of benefit from novel anticancer drugs approved for BC treatment in the last decade was not ethnicity dependent. Intrinsic genetic, pharmacogenomic and environmental variability between populations might not be so relevant to determine a different sensitivity to novel anticancer drugs including CDK4/6 inhibitors, ADCs and immune checkpoint inhibitors. This finding is reassuring for the broad applicability of future results of trials conducted with ethnic imbalance.

P3-05-03: Using large-scale, population- or hospital-based data, to identify disparities by race in the use of Oncotype DX: a systematic review

Fabio Girardi, Daniela Iannaccone, Anna Chiara Cattelan, Michel P Coleman, Claudia Allemani, Maria Vittoria Dieci, Valentina Guarneri

Background: In the last decade, genomic tests have been implemented in clinical pratice to gauge the added benefit of adjuvant chemotherapy in reducing the risk of relapse for patients diagnosed with hormone-receptor positive, HER2-negative early breast cancer, eligible for genomic testing based on ASCO guidelines. Several tests are available, but the most widely used is Oncotype DX (ODX). There is evidence for potential disparities in the uptake of ODX by race or other social determinants of health. However, most results derive from clinical trials or studies conducted in academic settings. Data with optimal population coverage are important for unbiased identification of potential barriers in access to care. We aimed to review systematically these large-scale results.
Methods: We considered longitudinal, observational studies of women eligible for ODX testing. Eligible studies had to be population-based or hospital-based, regional or nation-wide, and to include information on the uptake of ODX or treatment decision patterns, by race or ethnicity. The outcomes of interest were the odds of being offered ODX for women who were not non-Hispanic White compared to women who were non-Hispanic White. We searched Embase, PubMed and MEDLINE, using complex search strategies. We selected publications based on the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines.
Results: We retrieved 1,854 publications. After selection by title, abstract and full text, six publications were deemed eligible for inclusion in the systematic review, but only five were unique in terms of calendar time, study population or inclusion criteria. Three studies were based on the National Cancer Data Base (NCDB), a hospital-based dataset covering 70% of the US population, while two were based on the Surveillance, Epidemiology and End Results Program (SEER), a population-based dataset that covers approximately 48% of the US population. NCDB covered breast cancer diagnoses for 2010-2014, while SEER covered a longer calendar period, from 2004 to 2014. Three studies included women with node-negative and node-positive disease, while two were restricted to women with node-negative disease. In SEER, around 70% of the patients receiving ODX were non-Hispanic Whites (NHW), while only 10% or less were non-Hispanic Blacks (NHB) or Hispanics. In 2004, NHB and Hispanics were up to 50% less likely to receive ODX than NHW (odd ratios (OR) around 0.50). By 2014, these disparities had diminished to some extent, but they were still remarkable (OR around 0.70) for patients with node-positive disease. In the SEER data, the odds of receiving chemotherapy did not differ by race, but in the high-recurrence score group, NHB were less likely to receive chemotherapy than NHW (OR 0.76). In NCDB, the proportion of NHW among tested women was even larger than in SEER (around 90%), and racial/ethnic minorities were up to 25% less likely to be tested than NHW, during 2010-2014 (OR 0.76). In NCDB, NHB or Hispanics were more likely to receive chemotherapy than NHW (OR around 1.20), but within a given RS group, chemotherapy was equally used between racial/ethnic groups.

Discussion: This review provides robust evidence for racial disparities in access to ODX. The evidence for disparities in chemotherapy use after testing is less clear. This pattern suggests that barriers to optimal care may arise in referral pathways or in awareness of the relevance of testing among women and oncologists. The disparities slightly subsided over time, but they remain remarkable. Data were only available for women diagnosed up to 2014; further studies are warranted to track progress in reducing such inequities. All the eligible studies were conducted in the US, making it urgent to collect data from other countries where the ethnic makeup is equally diverse.

P3-05-04: Understanding access to HER2-targeted therapy among breast cancer patients treated in a resource-constrained setting: Cross-sectional observational cohort analyses

Mounika M Guru Reddy, M V T Krishna Mohan, Santa A, Pavan Kumar B, Kinjal Shah, Rohan Tewani, Nikhil Pathi, Sanath Kadam, Pallavi Ladda, Suseela Kodandapani, Nisha Hariharan, Senthil J Rajappa

Introduction: Improving access to healthcare in low and middle-income countries is a complex multidimensional challenge. Bio-similar and generic medicines positively impacted access to oncology medications by injecting price competition and helping negotiate reduced prices. Before the availability of biosimilars in India, access to HER-2 targeted therapy was reported for less than 10% of eligible patients. In this retrospective study we aim to understand overall patterns of access to HER-2 targeted therapy in women treated for breast cancer (BC).
Methods: A consecutive series of breast cancer patients diagnosed between, Jan 2023 and Dec 2023 were included in the analyses. The study's primary endpoint was to identify the proportion of patients with access to HER-2 targeted therapy (at least 1 session of targeted therapy) among eligible patients. The secondary endpoint was to describe the source of access and identify the proportion among those with access compliant with total planned targeted therapy (as decided by the treating physician).
Results: In the specified period, 1147 new BC patients were diagnosed, of whom 203 (17.6%) were HER-2 positive. Eleven patients had no further diagnostic workup at our center so were excluded from further analyses. The majority were non-metastatic (NMBC) at diagnosis (76% - 146/192). De novo metastatic BCs in 24% (46/192) and nine patients had recurrent disease. The median age was 52 years (SD 11.0, range 28 - 87). Overall access to HER-2 targeted therapy was 70.3% (135/192) and was similar in MBC (30/46 – 65%) and NMBC cohorts (105/146 – 71.9%). The majority of the patients with access used biosimilar formulations (overall – 87.3%; trastuzumab - 89.7%; ado-trastuzumab-emtansine - 99.4% & no biosimilar available for pertuzumab). In the NMBC cohort, the sources for access to targeted therapy were government-sponsored (37/105 - 37.1%); non-governmental-organization partnership (26/105 - 24.7%); self-pay or out-of-pocket (26/105 - 24.7%); and private medical insurance (14/105 - 13.3%). In the NMBC cohort compliance to planned targeted therapy was for 88.5% of patients (93/105, 20 completed &

73 ongoing therapy). The mean number of targeted therapy cycles in NMBC was 9.8 (SD 4.3, range 2 – 17). The major reason for incomplete therapy among those with access remains non-compliance related to social concerns (travel, leave for the caretaker, etc.) rather than resource limitations.
Conclusions: Availability of bio-similar drugs improved access to HER2-targeted therapy. Fostering partnerships between public and private sectors, including pharmaceutical companies, to support cancer therapy and better patient education can improve access further to HER2-targeted therapy in BC.

P3-05-05: A Comprehensive Study of Breast Cancer Mortality and DALY Trends considering Smoking as a Risk Factor from 1991-2021 in the USA and exploring the State-level disparities

Vaibhavi Mukhtiar, Charmi Bhanushali, Ronit Juthani, Raj Shah, Mansi Mehta, Devang Namjoshi, Navya Perkit Reddy

Introduction: Breast cancer is the second leading cause of cancer death in women. Smoking has been considered an important risk factor. Over the past 25 years, intensive screening strategies have been implemented to detect breast cancer early. Numerous legislative acts have also been passed to prohibit smoking and public tobacco use. In this study we highlight the trends in breast cancer mortality and disability adjusted life years (DALY) using tobacco as a risk factor with a focus on sex and state wise disparities.

Method: Data on Age-standardized death rates and Disability-Adjusted Life Years (DALY) for breast cancer with smoking as a risk factor were extracted from Global Burden of Disease database. Information about males and females across all U.S. states from 1991 to 2021 were studied. To evaluate performance, the percentage decline in mortality and DALY for every state was computed from 1991 to 2021 and compared to the overall trend in the US. Joinpoint regression analysis was used to examine gender and temporal trends in the US.

Results: Mortality rates in the US decreased by 55.1% from 1991 to 2021. Within the States, the largest reduction was seen in the state of Massachusetts (71.05%) and least decrease was observed in Mississippi (31.89%). On sub-group analysis based on sex, mortality decreased by 51.4% for females and 46.2% for males in the US. Within the States, Massachusetts had the most significant decrease in breast cancer mortality associated with smoking tobacco in females (70.7%) Mississippi had the lowest reduction for both at 30.25% for females and 22.3% in males.
In the US, DALY rates decreased by 57.42% overall, with a more significant decrease in females (56.79%) than in males (46.03%). On state-specific trends, some of the notable decrease were seen in Massachusetts (73.61%), California (65.06%) , New York (66.7%), Maryland (62.06%) and Connecticut (64.96%) from 1991 to 2021. In terms of sex specific data, Massachusetts has shown the greatest reduction in DALY among females (73.4%) and

males (61.45%). Lowest reduction in DALY was seen in West Virginia (30.8%) in females and Mississippi (19.53%) in males.
Conclusions: The results indicate a notable decrease in mortality and DALY related to tobacco-associated breast cancer. This is likely due to improved screening strategies and treatment options. These findings also underscore the advances in the breast cancer landscape. However, substantial state-level disparities remain, emphasizing the need for further epidemiological studies to identify and address the underlying factors.

P3-05-06: The Development of a Hispanic/Latinx Breast Cancer Clinic

Claudia Tellez, Jorge Heneche, Marie Harris Fuentes, Michelle Nava, Anayency Maslat, Jackie Renteria, Laurie Ann Llaguno, Maeve Alexander, Michel Balbotin, William Gradishar

Background: Breast cancer is the leading cause of death for Hispanic women. Even though Hispanic women are 30% less likely to develop breast cancer than non-Hispanic whites, studies have reported a higher risk of breast cancer mortality for Hispanic women compared to non-Hispanic white women. Many factors influence the disparate diagnosis and mortality, including genetic, environmental (estrogen -related,) and socio-economic. Important social factors include the lower rates of mammography screening, longer times to diagnosis after the abnormal test or palpable abnormality. Increased mortality may also be related to tumor specific factors, including increased incidence of triple negative as well as HER2 -positive breast cancer, both subtypes associated with a worse prognosis. Stage at diagnosis is another important factor as Hispanic patients are less likely to have localized stages I and II and higher likelihood to have stages III or IV cancer, which are associated with a much worse prognosis.Once diagnosed with cancer, Hispanic patients are less likely to receive evidence -based treatments, including surgery, chemotherapy, radiation, endocrine and targeted therapy treatments. Similarly, adherence and compliance to adjuvant endocrine therapy is frequently not optimal. Finally, Hispanic patients represent a very small percentage of patients participating in breast cancer clinical trials.

Methods: To address some of the factors related to disparate health outcomes, Northwestern Medicine established The Hispanic Breast Cancer Clinic in September 2023. The clinic's aims are to elevate the care being offered to Hispanic breast cancer patients in their native language. The clinic is doing so by connecting the patient to resources and addressing social determinant of health that could prevent prompt initiation of therapy. By offering evidence-based guideline concordant recommendations for surgery, radiation, and systemic therapy and for appropriate patients, connecting them to clinical trials. The clinic consists of a Spanish-speaking breast cancer oncologist, nurse, medical assistant, administrative assistant, research coordinator and social worker. ResultsThe clinic has served 110 patients, enrolled 7 patients in therapeutic clinical trials, initiated four collaborative research projects, including a study evaluating meditation (29 pts), a phone app to provide breast cancer education in Spanish (60 pts), a questionnaire to determine social determinants of care factors (15 patients) and a program helping patients to cope with anxiety (22 patients).Two additional projects are in development including a survey

regarding clinical trial barriers, as well as a second questionnaire regarding patient reported outcomes related to the Hispanic clinic. We have a submitted grant applications and received a recent grant to fund a collaboration between Northwestern Medicine and the local county hospital (Stroger)to transfer 2 to 4 patients per week for education, consultation, and discussion regarding diagnosis, prognosis, treatment, and clinical trial options.All patients are evaluated by our social worker and are connected to a variety of resources for additional support.

Conclusion: There are many factors that have resulted in worse mortality for Hispanic patients with breast cancer. The factors may be social, genetic or tumor-related. The aim of the Hispanic clinic is to elevate the care and ultimate the outcome of Hispanic patients, once diangosed with Breast cancer by addressing their specific needs. The clinic serves as both a vital resource for patients and a research hub, fostering collaboration with faculty to address pressing questions about breast cancer care, and trust among Hispanic women. This initiative marks an important step towards achieving health equity and advancing tailored healthcare solutions. We will update the numbers of patients participating in the clinic as well as the collaborative projects that are currently ongoing.

P3-05-07: Early Pilot Results From the Navigator-Assisted Hypofractionation (NAVAH) Program to Aid African-American Breast Cancer Patients

Shearwood McClelland III, Ursula J Burnette, Louisa Onyewadume, Chesley W Cheatham, Maya J Stephens, Tamika K Smith, Corey W Speers, Janice A Lyons

Purpose/Objective(s): In the United States, African-Americans have the highest overall cancer death rate and shortest survival time of any racial or ethnic group. By far the most commonly diagnosed cancer in African-American women is breast cancer. Consequently, breast cancer provides an excellent opportunity to address barriers impeding equal access to optimal treatment, for which radiation therapy (RT) has been established as essential by Level 1 evidence. Disparities in access to RT, mortality rates, and treatment outcomes among African-American breast cancer patients compared to other populations highlight the urgent need for targeted interventions. The Navigator-Assisted Hypofractionation (NAVAH) program, with its innovative patient navigation approach and culturally sensitive survey, aims to better identify the specific barriers faced by this population. This study is an early report of our experience piloting a culturally sensitive survey in an ongoing NAVAH program clinical trial involving African-American breast cancer patients (ClinicalTrials.gov# NCT05978232).

Materials/Methods: Following IRB approval, African-American breast cancer patients having been referred for RT in multidisciplinary tumor board, seen by Radiation Oncology, and consented to receive RT were approached to participate in trial participation. Surveys were conducted in person or by telephone prior to RT onset. Survey information was

assessed by topic category and survey responses were amalgamated into a representative score for each category (outstanding, excellent, good, average, below average). Survey categories involved availability (access to a medical center, coordinating care, and overall quality of care), accessibility (transportation, distance to care, and healthcare literacy), affordability (financial considerations, employment, and level of education), accommodation (access to internet, navigating transportation), and acceptability (comfort and prejudice among interactions with the system).

Results: Trial enrollment rate thus far has been 67%, with a total of 14 patients having completed the survey; 6 in person and 8 by telephone. Median survey completion time was 27.5 minutes (range=10-45 minutes). Median distance from RT treatment was 5.3 miles (range=3.7-11.4 miles). The mean response noted outstanding availability, excellent accessibility, good affordability, excellent accommodation, and good acceptability. Although satisfaction and trust in interactions with doctors and nurses scored well, responses in the acceptability category highlighted a high perception of disparities in the medical system, including high prevalence of racial prejudice, and high prevalence of treatment differences between high-income and low-income patients in clinical settings. Less than 10% of patients reported using alternative/complementary medicine for their cancer prior to being evaluated for treatment.

Conclusion: Our early NAVAH program findings indicate that this survey design is feasible in the African-American breast cancer population, with early findings revealing optimal availability of care and excellent accessibility to and accommodation for care, with almost no patient using alternative/complementary medicine for their cancer. These findings are tempered by concerns regarding prejudice by patient race and socioeconomic status. Further implementation as this trial accrues will provide more definitive and comprehensive answers regarding these and additional other categories in the survey, including cancer screening, financial toxicity, and perception of treatment during cancer care. Additional investigation involving patients actively receiving breast cancer RT remains ongoing.

P3-05-08: Examining Racial Disparities in the Association between Food Swamps, Liquor Store Density, and Postmenopausal Breast Cancer Mortality among Georgia Cancer Center Patients

Malcolm S. Bevel, April Parham, Aashka Sheth, Meng-Han Tsai, Sydney Elizabeth Andrzejak, Samantha R. Jones, Justin X. Moore

Purpose: Breast cancer (BRCA) is the 4th leading cause of cancer death in the United States (U.S.) and is one of 13 obesity-related cancers. Healthy food consumption (i.e. eating fresh fruits and vegetables, whole grains, less processed foods) is a protective factor shown to decrease obesity risk and postmenopausal BRCA death, but racial and ethnic disparities regarding postmenopausal BRCA continues to persist. Also, residing in geographical areas

with no access to healthy food options and more unhealthy food options (i.e. food swamps) reduces access to healthy foods and has been severely understudied. The influx of liquor stores in the South, or businesses that advertise and sell unhealthy food products including processed foods and alcohol, may contribute to elevated postmenopausal BRCA death. We assessed the relationship between residing in food swamps and liquor store density with risk of postmenopausal BRCA death among a subsample of Georgia Cancer Center patients.
Methods: We conducted a retrospective cohort analysis utilizing 2012, 2014, 2015, 2017, and 2020 data from the U.S. Department of Agriculture Food Environment Atlas and linked them via county FIPS codes with 2016 – 2022 postmenopausal BRCA death (restricted to 45+ years old) patient data from the Georgia Cancer Center's electronic medical record database. Food swamp score (FS) was calculated as the ratio of fast-food and convenience stores to grocery stores and farmer's markets. Liquor store density was calculated as the proportion of beer, wine, and liquor stores to Georgia county populations per 100,000. We categorized FS and liquor store density to low versus high; higher scores indicated patients residing in counties with poorer healthy food resources or greater access to liquor stores. Multilevel Cox proportional hazard models were used to estimate the association between FS and postmenopausal BRCA death.
Results: Out of 282 Georgia Cancer Center patients, the majority of NH-Black and Other patients and married patients resided in high FS and liquor store dense scored counties, respectively (p – value < 0.0001). Overall, patients at the high level of FS counties had an increased risk of postmenopausal BRCA death (adjusted hazard ratio (aHR) = 4.00, 95% CI = 1.06 – 15.1). In our fully adjusted models, NH-Black and Other patients residing in high FS scored counties had a non-significantly higher risk of postmenopausal BRCA death (adjusted hazard ratio (aHR) = 2.27, 95% CI = 0.37 – 14.0) compared to NH-Whites living in low FS scored counties.
Conclusions: Our subsample of cancer patients living in the worst food environments had increased risk of postmenopausal BRCA death. Local and state policymakers should make a concerted effort to partner with community stakeholders and farmers to employ sustainable approaches at combating obesity and BRCA by increasing healthier accessible food sources (e.g. community gardens, indoor hydroponic vertical gardens).

P3-05-09: Invasive Lobular Carcinoma Has Aggressive Molecular Subtypes in African American Women

Genevra Magliocco, Roy Khalife, Anthony Magliocco

Introduction: Breast cancer is a heterogeneous disease with many biological subtypes. Invasive lobular carcinoma (ILC) is a rarer subtype of increasing clinical importance, with distinct clinical pathological and molecular features that are not fully understood. The incidence of ILC is increasing compared to ductal carcinoma in the US. While the incidence of breast cancer is lower in African American/Black (AA/B) women compared to White women (W), mortality rates are disproportionately higher. The reasons for this disparity are unclear. The aim of this study is to better characterize the molecular features of lobular breast cancer and determine if differences exist between AA/B women compared to W women.

Methods: The Cancer Genome Atlas firehose data set was analyzed in cBioPortal, comparing AA/B (n=16) and W (n=166) women with lobular breast cancer. Statistical tests including linear cox regression, Fisher's exact test, and chi square analysis were performed using R (version 4.4.1, 2024). Variables included race, stage, age, and hormone receptor status. Analysis compared differences in overall and disease-free survival and interpreted molecular differences between the two groups. ClinVar was used to determine frequency of germline mutations in the general population.

Results: There were no differences for distribution of age or stage between racial subgroups. Proportions for stage were 18.7% AA and 15.7% W for stage 1, 62.5% AA and 50.3% W for stage 2, and 18.8% AA and 33.9% W for stage 3. The median age was 59.3 for AA/B and 62.0 for W.

Overall survival at 36 months was worse (76.7%) in AA/B compared to (94.6%) in W women with ILC (p=0.056). In this cohort, age and stage were not associated with differences in overall survival.

Estrogen receptor (ER) negative status was more prevalent in AA/B subgroup with ILC (22%) compared to W women with ILC (2%). Overall survival at 36 months for patients with ER negative ILC was shortened compared to ER positive ILC (50% vs 98% respectively, p=0.0001). However, when separated by racial subgroup, ER status was not associated with differences in overall survival for AA/B vs. W. Patients with ER negative ILC were 14.29 times more likely to have a TP53 alteration compared to ER positive ILC (p= 0.002).

TP53 mutation was more prevalent in AA/B (37.6%, n=6) compared to W (3.6%, n=6) in lobular cancer. Within the AA subgroup, disease free survival at 36 months for patients with TP53 alterations was 25% (n=5) compared to 100% for patients with unaltered TP53 (n=11) (p=0.0004). Within the W subgroup, patients with TP53 alterations were less common and associated with longer disease-free survival at 3 months (100%, n=6 for altered) compared to unaltered TP53 (89.5%, n=160) (p=0.50). Among the 6 AA/B patients with TP53 alterations, four had allele frequencies of 0.4-0.7, possibly suggestive of germline mutation. A search of ClinVar revealed two out of the four TP53 mutations were previously seen in Li Fraumeni syndrome (R248W, L255 del).

Conclusion: Overall survival for ILC was worse in AA/B women compared to their W

counterparts, consistent with existing literature. Differences in hormone status and inherited and somatic gene mutations were identified between racial subgroups. Among ILC there is an aggressive subtype characterized by ER negativity and TP53 mutations. This subtype may be more common in AA/B. These results suggest that some TP53 mutations in AA/B may be inherited; this could have implications for future targeted TP53 therapy in AA/B. However, analysis is limited by small sample size for AA/B women with ILC, and absence of detailed sociodemographic, treatment and outcome data. Future studies should include a larger size of AA/B, and control for sociodemographic and treatment variables.

P3-05-10: Racial Disparities in Clinical Trials of PARP Inhibitors for Breast Cancer - A Comprehensive Review

Elizabeth John, Simran Sekhon, Parnian Kheirkhah Rahimabad, Noufil Adnan, Arindham Bagchi

Breast cancer is the most common cancer worldwide. When it comes to African American women (AAW), their mortality rate is 40% higher compared to other ethnic groups in the US. AA patients are younger in age at diagnosis, have a higher incidence of triple-negative breast cancer (TNBC), and AA males have higher incidence of breast cancer. These suggest that genetic predisposition plays an important role in the disparate outcomes based on race. An unbiased analysis of TNBC cases has shown that the prevalence of pathogenic germline BRCA1 and 2 mutations is approximately twice as high as in breast cancer overall. Additionally, there is limited data on the enrollment of racial and ethnic minorities in the pivotal trials for PARP inhibitors, which have shown effectiveness in treating metastatic breast cancer associated with germline BRCA1 or BRCA2 mutations.
We conducted a systematic review of phase II/III clinical trials of PARP inhibitors in BRCA 1 and 2 mutated breast cancer. Our review examined the demographic data reported in these trials from 2016 to 2023. To highlight the disparities in the enrollment of minority groups, we calculated the enrollment fractions of various racial groups in these trials. We gathered studies from PubMed, Embase, Scopus, CENTRAL, Clinicaltrials.gov, and Cochrane.
Out of 56 full-text studies identified, 14 met the inclusion criteria, totaling 5,067 patients. Five trials were excluded due to missing racial data. Our review included 2845 White pts, 136 African American (AA) pts, 83 Hispanic pts, 662 Asian pts, and 247 pts from other racial backgrounds. Among the enrollees, 71.6% were White, 16.7% were Asian, 6.2% were in the "other" category, 3.4% were AA, and 2.1% were Hispanic.
We compared the racial demographics of trial participants to breast cancer incidence rates using SEER*Stat software. We applied time series analysis (ARIMA models) to estimate the incidence rates for 2021 to 2023. White, African American, Asian, and Hispanic racial groups were consistently represented in the clinical trials and the SEER dataset. We calculated the Enrollment Fraction (EF) by comparing the number of trial enrollees to the estimated number of cancer cases for each racial subgroup and logistic regression to determine the odds ratio (OR) of clinical trial enrollment across racial groups, considering a P value of < 0.05 as statistically significant.

Compared to the White pts as the reference group, the enrollment OR was 0.28 for AA, 0.14 for Hispanic, and 2.13 for Asian. All these differences were statistically significant (P < .0001). The EF was highest for Asians (0.95%), then White (0.45%), AA (0.13%), and Hispanic (0.06%). Although Asians had higher EF and OR compared to the White group, this estimate does not reflect the enrollment of this population from the US. The Asian trial enrollees were primarily from Asian countries rather than from the Asian population in the US. Therefore, comparing Asian trial enrollees to the Asian cancer incidence cases in the SEER dataset may lead to invalid estimations due to the differing populations. However, other racial minorities were primarily recruited from within the US. To address this issue, we ran an analysis excluding Asians to assess their influence on the estimates of the remaining racial groups. When excluding Asians, the proportion of trial enrollment was even higher for Whites (92.9%), followed by AA (4.4%) and Hispanics (2.7%). Excluding Asians, the EF of other categories remained the same. The OR of enrollment for AA and Hispanics remained the same and statistically significant after excluding Asians.
Racial minorities are consistently underrepresented in pivotal PARP inhibitor trials, contributing to the race-based disparities in breast cancer. These disparities result in a lack of representative data, limiting the generalizability and efficacy of PARP inhibitors.

P3-05-11: Patient Experience and Perceptions Related to Breast Health, Mammography and Artificial Intelligence in Healthcare

Nancy Brinker

The Promise Fund and Hologic Inc. have partnered to expand access to AI-supported breast cancer screening exams in a medically underserved population. As part of this initiative, patient focus groups and patient navigator interviews were conducted to explore patient experiences and perceptions related to breast health, mammography, and artificial intelligence (AI) in healthcare. These interviews were held, virtually, between February and March 2024, and focus groups were held, in-person, on April 9-10, 2024, with participants at FoundCare and the Community Health Center. FoundCare, a federally qualified health center (FQHC), and Community Health Center, a free clinic, both collaborate with the Promise Fund in promoting access to women's breast and cervical health screenings, diagnostic follow up and cancer care services.
The in-person sessions, attended by twenty patients, and the virtual interviews, attended by six patient navigators, were designed to represent diverse linguistic, racial, and cultural backgrounds, including multiple Spanish-speaking communities from Mexico, Dominican Republic, Guatemala, Chile, and Venezuela. All patient navigators were adult women from various free clinics and FQHCs. Patient participants were adult females, all at or below 200% of the Federal Poverty Guidelines.
Key themes from the discussions included:
1. Health Information Sources: Patients primarily relied on the internet, community health centers, medical visits, family, and cultural community communications for health information. Some patients expressed difficulty in keeping up with health information and

emphasized the importance of direct medical consultations with providers and preventive care. Patient navigators were a critical source of information once the patient could access and be connected to that resource. Clinical health and more upstream social services, such as transportation to health appointments and family food security, were also critical needs that patient navigators were key in facilitating.

2. Mammogram Experiences: Experiences with mammograms varied, with some patients reporting pain and discomfort, particularly those with implants. Regular screenings, family history of breast cancer, and personal vigilance were common motivators for mammograms. Financial barriers, insurance issues, and the need for patient advocacy were frequently highlighted.

3. AI in Healthcare: Patients had mixed levels of awareness and understanding of AI. Many associated AI with advanced diagnostics and potential improvements in early disease detection and surgical precision. Concerns included the potential loss of personal interactions with healthcare providers, privacy issues, and the fear of job displacement. However, patients had key opinions on AI that were more favorable than anticipated. There was optimism about AI's ability to enhance diagnostic accuracy, patient experience, provider trustworthiness, and treatment outcomes. Additionally, both patients and patient navigators preferred that physicians and AI work together. Patient navigators were even more familiar with AI. Given the critical role patient navigators hold, their knowledge may play an integral role in improving patient education and access to new technologies in the future.

4. Whole Health Experience: Patients expressed a desire for a more comfortable and supportive mammography process, greater access to care, enhanced trust between patients and providers, and comprehensive information sharing across healthcare providers. Education on breast cancer, early detection, and AI in healthcare was identified as a critical need.

Conclusion

The findings underscore the importance of trustworthy, patient-centered approaches in healthcare, particularly in the integration of AI technologies. Enhancing patient education and provider transparency, improving access to preventive services, and maintaining the human element in healthcare are essential for optimizing patient outcomes and satisfaction.

P3-05-12: The Prognostic Impact of Stress, High Levels of Tumor Infiltrating Lymphocytes and Race in Women Diagnosed with Triple Negative Breast Cancer

Himaja Gaddipati, Hadeel Altameemi, Nagla Salem, Carrie Dul, Susan Spuznar

Introduction: Tumor infiltrating lymphocytes (TILS) are the all-encompassing category of lymphocytes within the tumor microenvironment. High levels of TILS in triple negative breast cancer (TNBC) are associated with better response to chemoimmunotherapy and serve as a valuable prognostic marker. In particular, CD8+ T cells have been shown to mediate neoplastic progression. Many of these same immune players, however, are also

recruited during stress. The CD8+ exhausted phenotype has been documented as a downstream effect of stress, ultimately compromising cancer immunosurveillance. Chronic stress has been noted to directly inhibit the antitumor function of TILS. Furthermore, black women have been observed to have more robust immune systems with overall poorer outcomes. In this pilot study, we looked at the interplay of psychosocial distress scores, high levels of TILS, and race.
Methods: This is a historical cohort study of patients with TNBC from two metro Detroit community hospitals. We studied patients collected from December 31st, 2015 through January 1st, 2019. We assessed progression free survival at 3 years (PFS3), 5 years (PFS5) and overall survival at 5 years (OS5). We obtained stress scores via the National Comprehensive Cancer Network (NCCN) distress thermometer. We collaborated with the pathology department to delineate specimens with high TILS, defined as >50%.
Results: We included 27 patients in total. Twenty identified as white, six identified as black, and one did not disclose race. The mean age was 55.7 ± 13.8 (sd) years. The mean distress score was 5.0 ± 3.5 out of 10. High TILS was found in 32% of the group. Though not statistically significant, our data showed the following trends:

Patients with high TILS had higher distress scores (mean distress score 6.4 ± 2.8 vs 3.7± 3.2, p=0.05)
Patients with higher distress scores had worse outcomes. Mean distress scores for patients that did not reach PFS3, PFS5 and/or OS5 were higher. (PFS3 6.6 ± 3.6 vs 3.7 ± 3.1, p=0.6; PFS5 5.4 ± 3.9 vs 3.9 ± 2.8, p=0.3; OS5 5.8 ± 3.8 vs 3.6 ± 2.8, p=0.1)
Patients with high TILS were less likely to achieve PFS3 (28.6% vs 70.6%, p=0.06), PFS5 (28.6% vs 57.1%, p=0.2), and were more likely to die by five years (71.4% vs 35.7%, p=0.1).
Black women were less likely to achieve PFS3 than white women (50.0% vs 57.9%, p=0.7), PFS5 (25.0% vs 47.1%, p=0.4) and were more likely to die by five years (75% vs 47.1%, p=0.3).

Conclusion/Future Directions: Consistent with existing literature, we demonstrated that black women had poorer outcomes overall. Higher distress scores were also associated with poorer outcomes. Interestingly, we showed that patients with high TILS had worse PFS and OS, which is in opposition to current literature. Multivariable analysis was not indicated as only one variable was statistically significant. We postulate that with a larger population, we may see meaningful and statistically significant stratification among distress scores, race and high TILS.

P3-05-13: Determinants for concordance of ASCO quality of care measures in women with breast cancer in a Brazilian cohort

Anne Dominique Nascimento Lima, Suzana Sales de Aguiar, Anke Bergmann, José Bines, Luiz Claudio Santos Thuler

Introduction: Breast cancer is the main cause of cancer death among women in Brazil, accounting for 1 in every 6 deaths. ASCO has developed quality measures on the administration of adjuvant endocrine therapy, radiotherapy and chemotherapy to improve the quality and accessibility of cancer care. We applied these measures to describe the quality of care offered to women with breast cancer in a public hospital in order to identify its determining factors.
Methods: Retrospective cohort study of patients diagnosed with breast cancer at the National Cancer Institute (HC III/INCA). Patients treated from April, 2016 to October, 2018, with stages I to III were included. Statistical analyzes were carried out in the Software Statistical Package for the Social Sciences (SPSS®) environment. The association between independent variables and outcome was performed using the crude odds ratio (OR). The variables that presented $p<20$ in the univariate analysis were included in the multiple logistic regression model using the forward stepwise method, and those with $p<0.05$ remained in the final model. This study and the respective amendment were approved by the Research Ethics Committee (CEP) of the National Cancer Institute (n°. 1,400,320 and 6,224,883), in accordance with the ethical principles established by the National Health Council.
Results: Of the 1556 eligible patients, 590 were excluded. 322 (44.8%) initiated endocrine therapy within 365 days of diagnosis with a median time to initiation of 379 (IQR 278.8-445.5) days. 78 (35.3%) began radiotherapy after breast conserving surgery within 365 days of diagnosis with time mean to start this treatment of 430 (SD ±140.4) days. Regarding women with hormone receptor-negative breast cancer, 9 (100%) received chemotherapy after 120 days from diagnosis. After adjustment, age >60 (OR 1.49; IC95% 1.6-2.9; $p<0.001$ and OR 2.74; IC95% 1.42 - 5.28; $p<0.003$) and locally advanced staging (OR 4.03; IC95% 2.89 - 5.62; $p<0.001$ and OR 13.47; IC95% 3.05 - 59.44; $p<0.001$) were predictors non-concordance with endocrine therapy and radiotherapy, respectively. On the other hand, Luminal A-like tumors had a greater chance of agreement with the start of hormone therapy and radiotherapy before 365 days after diagnosis (OR 0.40; IC95% 0.27-058; $p<0.021$ and OR 0.22; IC95% 0.11-0.46; $p<0.03$). Patients who underwent adjuvant radiotherapy had a greater chance of not starting treatment with hormone therapy within 365 days. (OR 1.69; IC95% 1.14-2.50; $p<0.009$).
Conclusion: We described breast cancer care in a major Brazilian institution underperforming the quality measurements suggested by ASCO. Age over 60, advanced staging and adjuvant radiotherapy were predictors of non-agreement while Luminal A-like tumors increased the chance of measurement agreement. The measures were informative about the quality of public care, making it possible to identify determining factors that interfere with the provision of high-quality care.

P3-05-14: Male Breast Cancer Disparities & Demographics: A National Inpatient Sample Database Analysis & Literature Review

Akshit Chitkara, Rushin Patel, Fnu Anamika, Mrunal Patel, Zalak Patel, Sohiel Deshpande, Darshil Patel, Atulya Aman Khosla, Akshee Batra, Karan Jatwani, Rohit Singh, AnaMaria Lopez

Background: Male breast cancer (MBC) disparities exist due to variations in MBC diagnosis and management. We aim to study the literature on MBC disparities and understand the demographic characteristics and utilization patterns of healthcare among MBC patients using a large-scale population-based sample.
Methods: We conducted a staged literature search on databases using relevant MeSH keywords following PRISMA guidelines. After full-text analysis, only relevant articles on MBC disparities were included. For the database study, we used inpatient hospitalization data from the National Inpatient Sample (NIS) between January 1, 2016, and December 31, 2019. We obtained data of male patients with primary or secondary discharge diagnoses of primary breast cancer (ICD10-CM codes C50 & D05) to analyze demographics, inpatient cost, and length of stay.
Results: Nine studies were gathered using the MeSH framework, with six deemed relevant. The American Cancer Society in 2022 reported the highest incidence of MBC in white men (2,650 cases), followed by black/African American men (510 cases). MBC exhibited a slightly higher mortality (530 deaths) compared to female breast cancer, attributed to delayed diagnosis and later-stage detection.
Our NIS database analysis of 1803 hospitalizations supported the demographic findings above, with predominantly White (70.83%), followed by Black (17.72%) and Hispanic (6.61%) patients. The mean age was 67.8 years, with Medicare as the primary insurance coverage (65.02%). Most cases exhibited Charlson Comorbidity index scores of 3 or more (84.80%), with mainly non-elective admissions (77.75%). Hospitalizations were widespread across census divisions, predominantly in urban teaching hospitals (72.77%) and large facilities (48.75%). The mortality rate among hospitalizations for primary MBC was 4.9% (88/1803), with a mean length of stay of 5.2 days & mean hospital charges of $58,279.
The literature shows that non-modifiable and modifiable risk factors contribute to these racial disparities. Men diagnosed with breast cancer often face unique challenges, including delayed diagnosis, limited awareness, and a lack of tailored treatment options. Addressing MBC disparities requires multifaceted approaches involving raising awareness, increasing education, expanding research efforts, and providing comprehensive support services. Collaboration among healthcare professionals, advocacy organizations, researchers, and policymakers is crucial for reducing disparities and improving outcomes.
Conclusions: Our database analysis indicates primary MBC predominates among the elderly, whites, and Medicare beneficiaries, and we need a multifaceted approach to address these disparities. Males should also be educated to recognize breast cancer signs and seek timely medical care, as early detection enhances outcomes significantly.

P3-05-15: Race, Stress, and Breast Cancer: A Scoping Review

Noon Eltoum, Faris Alamin, Keyonsis Hildreth, Sara Abdelrahim, Ritu Aneja, Katherine Reeder-Hayer, Abby R. Rosenberg, Kathryn Kaiser, Gabrielle Rocque

Background: Various physiological and biological pathways triggered by toxic stress may influence breast cancer risk and progression, and these impacts may be differential based on socially constructed racial categories, but the underlying mechanisms are complex and poorly understood. To explore this relationship, we systematically reviewed the literature on the relationships among race, stress (psychological and biological), and breast cancer (BC).
Methods: We searched PubMed (prior to August 2023), Embase, Web of Science, PsycINFO, and Scopus (prior November 2023) to identify relevant peer-reviewed studies. We included studies investigating various measures of stress in women with breast cancer across different racial/ethnic groups. We excluded abstracts, posters, gray literature, non-US studies, non-English publications, studies on other cancers, studies on breast cancer risk without diagnosis, and studies focused on quality of life, physical concerns, symptoms, distress, or burden. Two independent reviewers screened titles and abstracts, and subsequently, independently reviewed full text with disagreements resolved by discussion or a third reviewer. Data extraction using a standardized form and thematic synthesis were also conducted by two independent reviewers with discrepancies resolved through consensus discussions.
Results: Our review identified 30 articles examining the association between race, stress, and breast cancer; 21 were original observational cross-sectional (n=12) or longitudinal studies (n=9) that utilized data from population-based registries, clinical registries, clinic settings, and cancer registries. Nine other articles identified were narrative or systematic reviews. Primary studies explored biological markers including measures of allostatic load (AL), epigenetic changes, and social determinants of health. Studies suggested Black women with breast cancer exhibited higher AL and shorter telomeres compared to White women, suggesting that racial differences exist in objective measures of physiologic stress among patients with breast cancer. Epigenetic modifications were also noted to be associated with social determinants of health, including socioeconomic status potentially influencing breast cancer risk and aggressiveness. Studies highlighted the significant association between neighborhood disadvantage, social support, and psychosocial stress among women of color with breast cancer. These findings emphasize the complex interplay between individual, neighborhood, and societal factors and suggest disparate social conditions may be a driver of higher stress among breast cancer patients of color.
Conclusion: This review provides a landscape view of the current limited evidence on the complex interplay between social stressors, biological responses, and racial and ethnic disparities in breast cancer outcomes. The findings highlight the significant, yet often overlooked, role of chronic psychosocial stress in the disproportionate burden of breast cancer faced by marginalized racial and ethnic groups. This study highlights the need for further mechanistic exploration and evaluation of multilevel, targeted interventions including individual-level stress management techniques, neighborhood-level

improvements to resources, and societal-level policies addressing discrimination and limited access to healthcare. Additionally, identification of biomarkers and pathways that capture the intricate interplay between social stressors and biological responses are crucial for informing more effective and equitable approaches to breast cancer prevention, early detection, and management.

P3-05-16: Extreme ESR1 polyclonality, mutational dynamics and effects on treatment outcomes in patients with ER+ metastatic breast cancer

Tess O'Meara, Emily Podany, Marla Lipsyc-Sharf, Annika Putur, Shannon McLaughlin, Teresa T. Ho, Maxwell R. Lloyd, Arielle J. Medford, Joyce A. O'Shaughnessy, Aditya Bardia, Cynthia X. Ma, Hyo Han, Seth A. Wander

Background: Mutations in ESR1 are commonly acquired on endocrine therapy (ET) and confer variable resistance to estrogen-directed treatments. The impact of polyclonality, including the dynamics of ESR1-mutant clones, interactions with co-occurring mutations, and associations with treatment outcomes have not been fully explored. In this case series, we investigate the course of 6 patients (pts) treated for ER+ metastatic breast cancer (MBC) who demonstrate extreme ESR1 polyclonality.
Methods: We conducted a retrospective case review by querying clinical databases across 3 academic cancer centers. We selected all pts with >= 10 concurrent ESR1 variants on any circulating tumor DNA (ctDNA) Guardant 360 test in MBC, defined as extreme ESR1 polyclonality. We explored prior lines of therapy, sites of metastases, frequency of ESR1 variants, commonly occurring co-mutations, and clonal changes in ESR1 in response to treatments.
Results: In our preliminary cohort (n=6), 5/6 pts were post-menopausal at primary diagnosis (median age 53.3y; 59.5y at first metastatic recurrence). 5/6 pts were ER+/PR+/HER2-; 1pt was ER+/PR-/HER2-. 4/6 pts received adjuvant chemotherapy (3/4 ddACT, 1/4 TC); 4/6 received adjuvant AI for >= 4 years (1 pt declined therapy; 1 pt found to have de novo metastasis). All 6 pts had bone metastasis at first metastatic diagnosis; 2/6 pts also had lymph node and adrenal involvement.
Pts had serial ctDNA testing (range 1-4). On initial ctDNA test, there was a range of 0-31 ESR1 clones with a median of 5.5. Pts received a median of 1 line of ET in the metastatic setting prior to first ctDNA test. The most frequent ESR1 clone was Y537N, followed by Y537S, L327R. Capecitabine use was associated with a decline in polyclonality from 10, 16 and 20 variants to 4, 8 and 9, respectively. In 1 pt, eribulin and abraxane did not have the same effect; ESR1 polyclonality was maintained. One pt with 1 ESR1 clone after 2.5 years of fulvestrant+palbociclib developed 15 additional clones after 1.5 years of an experimental SERD+everolimus. Another pt with 1 ESR1 clone after anastrozole+palbociclib developed 9 additional ESR1 clones after 10 months of AKT inhibition+anastrozole. This same pt had a reduction to 4 ESR1 clones on capecitabine with an expansion to 8 clones on a subsequent experimental ADC.
The most frequent co-alterations were in FGFR1 and CCND1, both occurring in 3/6 pts. In 1

pt with 12 ESR1 variants, only TP53 was co-mutated; another pt with 16 ESR1 variants had only AKT1 co-mutated. 1/6 pts carried PIK3CA mutations; this pt had 31 ESR1 variants on initial ctDNA test with 3 PIK3CA clones. Tumor mutational burden will be reported at the conference.
Conclusions: This is the first investigation of dynamic changes in
extreme ESR1 polyclonality in association with treatment outcomes in pts with ER+ MBC. Capecitabine was associated with a decrease in detectable ESR1-mutant clones, while increased polyclonality was found at progression on SERD+everolimus, AKT-inhibitor+AI, and an ADC. Although extreme ESR1 polyclonality is rare, understanding mutational dynamics will improve our understanding of polyclonality more broadly and its impact on treatment resistance. Additional analyses of these and additional pts will be presented at the conference.

P3-05-17: Identifying immune-related predictive factors for post-eribulin therapy in patients with HER2-negative advanced breast cancer - A multicenter retrospective study

Junichiro Watanabe, Yoshiya Horimoto, Yasuo Miyoshi

Background: In the EMBRACE study, eribulin (ERI) monotherapy improved the overall survival (OS) of patients with HER2-negative advanced breast cancer (HER2-ABC) [Cortes, 2011, Lancet Oncol]. A post hoc analysis of the EMBRACE study identified the baseline absolute lymphocyte count (ALC) as a predictive marker in the ERI arm [Miyoshi, 2017, Breast Cancer]. However, there is no report regarding predictive factors of post-ERI OS so far.
Patients and methods: We retrospectively reviewed the medical records of HER2-ABC patients who received ERI therapy from July 2011 to March 2018 in two institutions. Clinical data were extracted from medical records, including ALC, neutrophil-to-lymphocyte rate (NLR), and other clinically significant factors (age, visceral lesion, estrogen receptor, nuclear grade, anthracycline history, taxane history). Statistical analyses were performed using the Kaplan-Meier method, log-rank test, Wilcoxon's test, and Cox hazard model. OS was defined as follows; OS1, survival from the initiation of ERI to death of any cause; OS2, survival from the initiation of post-ERI therapy and OS3, survival from the termination of post-ERI therapy, respectively.
Results: We identified 218 HER2-negative ABC patients who underwent ERI therapy, and 210 out of 218 patients were eligible for analyses. Of 210 patients, 153 patients (72.9%) had recurrent disease, 164 (78.1%) patients revealed hormone-receptor-positive, 180 (87.6%) patients had a history of anthracycline and/or taxane treatment, and 126 (60.0%) had the visceral disease at the initiation of ERI therapy. The median treatment line for ABC of ERI was 2 (ranged 1–9). The median OS (range) was; OS1, 540.0 (41-2700) days; OS2, 337.5 (0-2267) days, OS3, 175.5 (0-1974) days, respectively. According to the multivariate analyses, factors significantly associated with OSs were for; OS1, Time to discontinuation (TTD) of ERI therapy as ≥120 days (hazard ratio [HR], 0.286; 95% confidence interval

[95%CI], 0.193-0.426; P <0.0001), ALC ≥1,500 at the initiation of ERI therapy (HR, 0.610; 95%CI, 0.374 -0.995; P = 0.0479); OS2, ALC ≥1,000 at the initiation of post-ERI therapy (HR, 0.610; 95%CI, 0.416-0.895; P = 0.0115), TTD of ERI therapy (HR, 0.710; 95%CI, 0.525-0.960; P = 0.0262); OS3, TTD of ERI therapy (HR, 0.682; 95%CI, 0.501-0.928; P = 0.0150). Meanwhile, there was a correlation between the TTD of ERI therapy and ALC at the initiation of post-ERI therapy (HR, 0.741; 95%CI, 0.551-0.997; P = 0.0480). Looking at factors affecting the TTD of ERI therapy were anthracycline-based regimen (HR, 1.788; 95%CI, 1.175-2.720; P = 0.0067) and high nuclear grade (HR, 1.526; 95%CI, 1.034-2.254; P = 0.0335), however, no independent factor related to TTD of post-ERI therapy was identified. Conclusion: According to our real-world study we found that 1) a maintained ALC at the initiation of ERI therapy was significantly associated with better outcomes, i.e., both OS1 and OS2 of HER2-ABC patients, 2) ERI therapy responders, i.e., TTD of ERI therapy ≥120days, had been maintained their ALC subsequently, and 3) patients with longer TTD of ERI therapy had been maintained both OS2 and OS3. Those findings support the significance of maintained ALC and patent survival in late-phase ABC [Jimbo, 2022, Breast Cancer Res Treat; Horimoto, 2024, BMJ Support Palliat Care], furthermore, those prompt the use of ERI in HER2-ABC patients who have a maintained ALC. Funding: not applicable.

P3-05-18: Prognostic value of ctDNA dynamics and protein biomarkers in patients treated with alpelisib (ALP) and endocrine therapy (ET) for HR+/HER2- PIK3CA-mutated advanced breast cancer (ABC) in all 3 cohorts of the phase II BYLieve study

Dejan Juric, Yoon-Sim Yap, Stephen Chia, Sherene Loi, Fabrice André, Nicholas Turner, Patrick Neven, Eva M. Ciruelos, Sara M. Tolaney, Jessica Makofske, Mukta Joshi, Estelle Roux, Murat Akdere, Hope S. Rugo

Background: The BYLieve study demonstrated efficacy and safety of ALP (PI3K-α inhibitor and degrader) + ET in patients (pts) with PIK3CA-mutated HR+/HER2− ABC post-progression of treatments including cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). We assessed the prognostic role of ctDNA dynamics and protein biomarkers in pts from this study.
Methods: Pts on prior immediate treatment of CDK4/6i + aromatase inhibitor (AI, Cohort A, n=101), and AI followed by chemotherapy/ET (Cohort C, n=98) receiving ALP + fulvestrant and prior immediate treatment of CDK4/6i + fulvestrant receiving ALP + letrozole (Cohort B, n=97) were included for biomarker analysis. ctDNA fraction levels for samples collected at baseline (BL; Cycle 1, Day 1 [C1D1]) and at end-of-treatment (EOT) were analyzed using cfDNA 2.0 assay for all 3 Cohorts and samples collected at C2D1 (only for Cohort A & B) were analyzed using cfDNA 2.1 assay, both utilizing PanCancer analysis panel that covered coding exons of 579 genes. Genomic landscape alterations in Pi3K/AKT pathway and potential CDK4/6i resistance markers were assessed across those time points. Circulating proteins from a selection of matched patient/timepoint samples (Cohorts A, B and C, n=578) were assessed via SomaScan, an exploratory proteomics platform profiling 7,596

proteins from a single plasma blood sample. The association between ctDNA fraction and protein markers (SOMAmers) was assessed for all matched samples and the prognostic value of identified enriched SOMAmers was investigated at BL (all cohorts, n=292). Results: Among pts who had matched samples at C1D1 and C2D1, 15 of 82 in Cohort A and 11 of 80 in Cohort B had ctDNA fraction=0 at BL. In pts with ctDNA fraction >0 at C1D1, ALP treatment led to a rapid decrease in median ctDNA fraction at C2D1 in Cohort A (C1D1, 0.1; C2D1, 0.055; P=0.023) and Cohort B (C1D1, 0.126; C2D1, 0.079; P=0.044). No significant differences were observed in gene mutation frequencies (including ESR1 and TP53 mutations) across timepoints, in both cohorts, except the Pi3K/AKT pathway-related genes (AKT1,2,3, PIK3R1, PTEN) that revealed an increased number of alterations at EOT. The alterations in genes implicated in CDK4/6i resistance (CDKN2A, CDKN2B, RB1, PIK3R1, ERBB2, FAT1, NF1, CHD4) were consistent in both pt cohorts, but caution needed to interpret this due to limited sample size. Pts in Cohort A, with ctDNA fraction >0 at C1D1 and C2D1 had shorter PFS vs pts with undetectable ctDNA at C2D1 (P<0.0001). Correlation analysis between circulating proteins and ctDNA fraction at BL from matched samples revealed significant enrichment for SOMAmers positively (n=858) and negatively (n=316) correlating with ctDNA fraction. The top enriched SOMAmers for positive correlation with ctDNA fraction exhibited significant predictive value for poor PFS (P<0.0001), while the top enriched SOMAmers for negative correlation showed significant predictive value for favorable PFS (P<0.0001); both with comparable predictive value to ctDNA fraction. The combination of ctDNA fraction and protein signal at BL provided better prediction of PFS compared to either measurement independently. Identified SOMAmers also show evidence of further discrimination of PFS response in pts with ctDNA fraction=0. Conclusions: ctDNA fraction reduction at early timepoints demonstrates rapid and early response of ALP treatment in PIK3CA-mutated HR+/HER2– ABC. With the exception of Pi3K/AKT pathway-related genes, we observed consistency in alterations, especially in genes implicated in CDK4/6i resistance across timepoints suggesting that ALP does not alter overall tumor biology. Notably, an increase in alterations within Pi3K/AKT pathway genes at EOT may indicate a potential resistance mechanism and provide guidance on next lines of therapy The SomaScan analysis highlights independent value of circulating protein markers and their complementarity with ctDNA fraction, suggesting their prognostic value.

P3-05-19: High Prevalence of HER2-Low and Increased TIL Levels in ILC Patients with Residual Disease Following Neoadjuvant Therapy Provides a Rational for use of HER2-Antibody-Drug Conjugates or Immunotherapy Approaches

Melinda Sanders, Guadalupe Garcia, Paula I. Gonzalez-Ericsson, Laura Kennedy, Tina Chai

Background: Invasive lobular carcinoma (ILC) accounts for 5-15% of breast cancer (BC). Most ILCs are hormone receptor positive (HR+), HER-negative (HER2-) and lack associated tumor infiltrating lymphocytes (TILs), a state referred to as “immune desert”. The benefit of chemotherapy in reducing ILC recurrence is unclear, while endocrine therapy (ET) plays a

key role for patients with ILC. For patients with locally advanced disease, neoadjuvant ET or chemotherapy may be warranted to downstage ILC and permit breast conservation. However, pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) or neoadjuvant endocrine therapy (NET) in patients with ILC is significantly lower than that observed in no special type (ductal) carcinomas. Although tumor-infiltrating lymphocytes (TILs) predict response to neoadjuvant therapies in HER2-positive BC, their role in HER2-Low ILC is unknown. However, TIL counts > 5% in ILC have been previously correlated with decreased survival. HER2-Low BC are defined by an immunohistochemical score of 1+ or 2+ with a negative HER2 FISH test. The prevalence and implications of HER2-Low in ILC are currently poorly characterized.
Methods: Patients with ILC treated from 2018 to 2022 at our institution were identified from a breast cancer database. HER2-Low status was correlated with clinicopathologic features including TILs and treatment response among patients with HR+/HER2- ILC treated with neoadjuvant therapy (NAT) at our institution. Stromal TILs were quantified as < 5%, 5 to 10%, >10%.
Results: Between 2018 and 2022, a total of 196 women with ILC were treated at our institution. Median age at diagnosis was 63 years old (range 25–90 years). The majority of ILC tumors were HR positive (98%), intermediate to low grade combined histologic grade (92%) and 52% were HER-low. Of these, 37 women with ILC received NAT. Thirteen received neoadjuvant chemotherapy (NAC) and 24 received neoadjuvant endocrine therapy (NET). Median age at diagnosis was 59 years (25–82). Twenty-three (62%) were HER2-Low. None were ER-low positive. The majority (81%) were intermediate or high combined histologic grade and 7 (19%) had an intermediate or high proliferative rate. Collectively, most were cT2/cT3 (84%), multifocal (76%) and lymph node positive (76%). 54% had > 5% stromal TILs, 35% had associated tertiary lymphoid structures (TLS), and 24 (65%) had both. HER2-Low tumors were associated with higher TILs and presence of tertiary lymphoid structures (TLS) (65% vs 35% showed > 5% stromal TILs; 78% vs 24% had > 5% TILs and/or TLS, Fisher's test p= 0.0395). No other differences among clinicopathological characteristics were observed between HER2-Low and HER2-0 tumors. No patients achieved pCR and 95% were RCB II/III. Among patients with RCB II/III, 60% of those who received NAT and 77% of those who received NET were HER2-Low.
Conclusion: HER2-low status is common in ILC patients who receive NAT and is associated with higher TIL levels than HER2-0 tumors. The high prevalence of residual disease after NAT in HER2-low ILC suggests treatment resistance, and alternative treatment approaches are warranted. These could include antibody drug conjugates (ADCs) and/or immunotherapy-based approaches.

P3-05-20: Novel liquid biopsy technology reveals cancer-specific isoforms for breast cancer diagnosis and therapy

Richard I. Kuo, Yuanyuan Cheng, Björn Geigle, Amy Robinson, Jillian VanOrsouw, Juan Carlos Entizne, Katrina Morris, Mark Barnett, Arran Turnbull, Rick Hockett, J Michael Dixon

Background: Developing new technologies for breast cancer diagnosis and therapy is crucial to improving patient outcomes and survival rates. Advanced molecular profiling enables earlier and more accurate detection of breast cancer, and can identify new targets for targeted therapies and personalized medicine. The most promising new technologies include detecting circulating tumor DNA (ctDNA) and RNA (ctRNA). Although ctDNA methods have shown promising diagnostic potential, in breast cancer ctDNA concentrations are extremely low. Current RNA approaches have focused on shorter RNAs, but these lack the resolution and complexity to provide more clinically relevant information for cancer detection and treatment.

Methods: Wobble Genomics have developed a novel liquid biopsy assay that utilizes full-length RNA sequencing from whole blood to create comprehensive transcriptome profiles. Combining Level-Up, our biochemical cDNA normalization technology, and TAMA, our full-length RNA annotation software, our platform maximizes efficiency of detection for ctRNA and enables accurate characterization of cancer-specific isoforms.

Patients: 200 patients with early breast cancer and matching controls with benign disease or no cancer on imaging have had 7.5 mL of blood collected. 2.5 mL of the blood is analyzed for transcriptome profiling. Sequential samples pre and post surgery are also being collected.

Results: From the first 130 cancers and controls analyzed, we have built an extensive breast cancer RNA database comprising 569K breast cancer specific transcripts with an average length of 1376 ± 793 bp. Of these, 11K, 146K, and 15K are unique to DCIS, stage 1, and stage 2 breast cancer, respectively, providing biomarker candidates with the potential of high diagnostic precision and higher informative value. While 36K of these cancer-specific RNA signals originate from protein-coding genes, the majority are characterized as novel long non-coding RNAs, which are not detectable by other platforms. RNA splicing patterns unique to cancer patients have been identified, uncovering previously overlooked identifiers for breast cancer.

Furthermore, based on the cancer-specific RNA discovered, we have constructed a therapeutically relevant protein-coding transcript database consisting of 2,184 isoforms that contain putative protein regions found only in cancer patients. Among 1,292 genes encoding these isoforms, 132 are established cancer genes, 30 of which are known oncogenes and 77 are tumor suppressor genes. These predicted cancer-associated protein sequences are primarily resulted from novel RNA splicing sites or new combinations of known splicing sites, and therefore constitute more pronounced amino acid changes from their normal protein counterparts that differ from single point mutations. This database provides a source of potential new targets for developing new cancer treatments, including mRNA vaccines and antibody-drug conjugates.

Conclusions: This completely novel platform can detect and characterize full-length breast

cancer specific RNA transcripts. This could allow earlier cancer detection and provide new insights into cancer behavior, biomarker discovery, and identification of new targets for drug development.

P3-05-21:Multicenter retrospective cohort study of the sequential use of antibody drug conjugates trastuzumab deruxtecan & sacituzumab govitecan in patients with HER2 low metastatic breast cancer: a subgroup analysis of next generation sequencing results.

Reshma L. Mahtani, Laura Huppert, Mehmet Murat Zerey, Karthik Giridhar, Samantha Fisch, Dame Idossa, Ruta Rao, Sarah Premji, Ana Sandoval Leon, Lauren Carcas, Naomi Dempsey, Joseph Panoff, Manmeeet Ahluwalia, Hope Rugo

Background: Trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan (SG) are both approved antibody-drug conjugates (ADCs) for patients (pts) with HER2 low metastatic breast cancer (MBC). Biomarkers that predict response and/or resistance to sequential use of these therapies are needed.
Methods: In this cohort of patients (pts) with HER2 low MBC treated with both ADCs (in either sequence), we previously reported real-world efficacy and subgroup analyses by age, sites of disease, and use of intervening therapies. Here, we provide a descriptive analysis of next generation sequencing (NGS) results in a subset of pts (N=66) who underwent liquid and/or tissue NGS testing at any of the following time points: prior to ADC1, prior to ADC2, or after receipt of both ADCs. Genomic information captured included specific genomic mutations, microsatellite instability status (MSI), and tumor mutation burden (TMB). Commercial testing per routine clinical practice was performed by Guardant Health, Foundation Medicine, Tempus, Caris, and/or UCSF CLIA-approved testing. We performed Cox proportional hazard analysis to evaluate the relationship between patient and treatment characteristics and genomic expression with real-world overall survival (rwOS) from the start of ADC1.
Results: The study cohort included 74 pts from 4 sites, with 66/74 (89%) with available NGS data from at least one-time point [47 (71%) HR+/HER2 low and 19 (29%) HR-/HER2 low]. The median number of tissue NGS was 1 for both the HR+ (range: 0-4) and HR - (range: 0-3) cohorts. The median number of liquid NGS was 1 (range 0-3) and 0 (range 0-4) for the HR+ and HR- cohorts, respectively. The median total number of NGS (any combination of liquid/tissue) was 2 (range 1-5) and 1 (range 1-5) for the HR+ and HR- cohorts, respectively. Types of NGS testing and timepoints were as follows: Prior to ADC1 liquid 9, tissue 31, both 10, no NGS16; Prior to ADC2 liquid 9, tissue 13, both 1, no NGS 43; after both ADCs liquid 16, tissue 4, both 1, no NGS 45.
In the entire cohort, 39 pts (59.1%) had a TP53 mutation; 29 pts (43.9%) had a PIK3CA mutation, and 13 pts (19.7%) had an ESR1 mutation. In the HR+ cohort, the most frequently detected mutations were PIK3CA in 26 (55.3%), TP53 in 24 (51.1%), and ESR1 in 13 (27.7%). In the HR- cohort, the most frequently detected mutations were TP53 in 15

(78.9%), PIK3CA and NF1 in 3 (15.8%). MSI testing demonstrated microsatellite stability (MSS) in all 66 patients. Median TMB was 4.70 (range: 1-14) for HR+ pts and 3.85 (range: 0.78-17.37) in HR- pts.
In multivariate analysis evaluating the impact of HR status, age, time since MBC diagnosis, ADC order, de novo MBC, visceral disease, CNS disease, PIK3CA status, and TP53 status on rwOS from the start of ADC1, shorter time since MBC diagnosis [HR 0.96 (0.96-1.0, p=0.010] was the only factor associated with longer rwOS in a Cox proportional hazard analysis. Of note, the presence of TP53 mutations or PIK3CA mutations did not impact rwOS [HR 0.70 (0.36-1.36), p=0.293 and HR 1.74 (0.81-3.74), p=0.156, respectively].
Conclusion: In this cohort of pts with HER2low MBC who received sequential ADCs, most pts underwent NGS testing, and the genomic landscape of mutations was consistent with incidence in the reported literature. The presence of TP53 or PIK3CA mutations did not impact rwOS from the start of ADC1. Given the heterogeneity in the type of NGS testing and the timing related to ADC administration, correlations with outcomes are limited. This study highlights the need for prospective evaluation of NGS information to clarify mechanisms of response and resistance to ADCs.

P3-05-22: Prognostic Significance of Tumor-informed Personalised Circulating Tumor DNA Monitoring in Breast Cancer Patients Undergoing Neoadjuvant Therapy

Yunjiang Liu, Yubin Wang, Xiangmei Zhang, Chao Shi, Xiaofei Ren, Meizhen Hu, Fei Pang, Kai Wang

Background: Minimal residual disease (MRD) in the peripheral blood of breast cancer (BC) patients undergoing neoadjuvant therapy (NAT) and surgery is associated with an increased risk of recurrence. Circulating tumour DNA (ctDNA) and its kinetics are often used to assess the presence of MRD in operable BC. There is currently no gold standard for evaluating MRD in BC patients treated with NAT. Therefore, we applied a sensitive tumour-informed personalised assay called OriMIRACLE™S-MRD explore associations between detectable ctDNA and prognostic value.
Methods: Clonal mutations in tumour tissue were identified by whole-exome sequencing. Then a personalised panel was designed to monitor ctDNA changes in patients' plasma at baseline of NAT, during NAT, after NAT and after surgery. CtDNA assay was performed using OriMIRACLE™S-MRD by Origimed (Shanghai, China).
Results: A total of 28 female patients with stage II-III breast cancer were enrolled, including 7 with triple-negative breast cancer and 21 with HER2-positive disease. The median age of the patients was 52 years (range: 28-64). Whole-exome sequencing analysis identified 93% (9096/9747) variants of uncertain significance (VUS), and approximately 63% of variants were copy number variants and fusions/arrangements, which are challenging to detect via liquid biopsy. Among all the genes involved in single nucleotide variants, 91% of the genes were detected in a single sample only. A personalised panel was successfully designed for each patient. Twenty-six individuals underwent single-sample testing at baseline. Twenty-

seven individuals collected 1-7 samples during NAT. Twenty-three individuals collected 1-2 samples after NAT, and 9 individuals collected 10 post-operative samples. In cases where more than one sample was collected during a given phase, the ctDNA status of that phase was defined as positive if any one of the samples tested positive. A given stage is defined as negative for ctDNA only if all samples within that stage are negative. The positivity rate of ctDNA at baseline was 92% (24/26). CtDNA concentration at baseline was found to be proportional to the postoperative grey and white matter hard zone volume ($R^2 = 0.64$). The ctDNA positivity rate decreased to 22% (6/27), 17% (4/23) and 11% (1/9) during NAT, after NAT and after surgery, respectively. None of the patients with positive ctDNA after NAT achieved pathological complete response (chi-square test, $p = 0.01$). A HER2+ patient with baseline ctDNA positivity who had multiple interruptions of NAT due to intolerance of the initial treatment regimen maintained a positive ctDNA at cycle 5 of NAT. After modification of the treatment regimen, the ctDNA became negative at cycle 7 of NAT and remained ctDNA negative after NAT with a pathological complete response. This patient has been followed up for 629 days with no signs of recurrence or metastasis. In one triple-negative BC patient, ctDNA was negative during NAT, but became positive on day 6 after NAT. Imaging progression and another ctDNA positivity were observed simultaneously on day 23 after NAT. The patient underwent radical resection three days later. Despite negative ctDNA at 3 months postoperatively, the patient experienced metastasis at 349 days postoperatively.
Conclusion: Stage II-III breast cancer suffers from a high proportion (93%) of VUS and a high degree of genetic heterogeneity (91% of unique single nucleotide variant-associated genes). These factors predict a significant advantage of tumor-informed personalised panels for dynamic monitoring of MRD in BC patients undergoing NAT. Positive ctDNA after NAT was significantly associated with efficacy of non-pathological complete response. Individual case analyses suggest that personalised MRD testing can predict treatment efficacy and recurrence in advance, offering valuable insights for clinical decision-making.

P3-05-23: Single nucleus chromatin accessibility and transcriptome analyses reveal aberrant inter-cellular communication in inflammatory breast cancer

Harikrishna Nakshatri, Poornima Bhat-Nakshatri, Cihat Erdogan, Hongyu Gao, Yunlong Liu

International efforts focused on discovery of biological targets in inflammatory breast cancer (IBC) have suggested that aberrant inter-cellular relationship instead of genomic aberrations is the key driver of IBC. To identify such IBC-specific aberrations, we generated single nucleus chromatin accessibility and transcriptome atlas of IBCs (9,628 nuclei from three donors) and compared IBC atlas with a similar atlas of the healthy breast (81,735 nuclei from 92 donors). We recently reported single nucleus atlas of breast tissues of healthy women of diverse genetic ancestry (Nature Medicine in press). In that report, we described markers that identify three major epithelial cell subtypes [Basal-myoepithelial (BM), luminal adaptive secretory precursor (LASP), luminal hormone sensing (LHS)], two

endothelial cell subtypes, two adipocyte subtypes, fibroblasts, macrophages, and T cells of the healthy breast. We also showed that LHS cells are the likely cells-of-origin of Luminal A, Luminal B and HER2+ breast cancers. Unlike these breast cancer subtypes, IBC does not appear to have a cell-of-origin, as epithelial cells in IBCs shared gene expression pattern across BM, LASP and LHS cells. Similar results were obtained when comparison was restricted to ancestry-specific healthy breast atlas. However, individual gene level expression differences affecting specific signaling pathways were observed in epithelial cells of IBCs. LASP, and LHS cells of IBCs overexpressed GPR137C, a positive regulator of mTORC1 signaling, and HS6ST3, an enzyme required for heparan sulfate synthesis. LASP and LHS cells of IBCs displayed activation of mitotic and matrix metalloproteinase signaling, respectively. Endothelial cells of IBCs, which showed significant gene expression differences compared to endothelial cells of the healthy breast, displayed enhanced integrin cell surface interaction but loss of cell junction organization. Most critically, BM, LASP, LHS, and endothelial cells of IBCs compared to their counterparts in the healthy breast showed downregulation of TEX14, an inter-cellular bridge forming factor in germ cells and a regulator of mitosis. Downregulation of TEX14 expression in these cells was accompanied with changes in the chromatin accessibility patterns of this gene. These results reinforce the notion that defective inter-cellular communication is a hallmark of IBC and TEX14 expression levels may serve as a biomarker of this defect. We suggest that greater attention to vascular biology and vascular-epithelial cell communication has to be given for better understanding of IBC biology and therapeutic targeting.

P3-05-24: Mapping the Genomic Landscape: Comprehensive Profiling of Diverse Histological Types of Breast Cancer

Taro Yamanaka, Tatsunori Shimoi, Mai Onishi, Rui Kitadai, Mai Hoshino, Munehiro Ito, Ayumi Saito, Shosuke Kita, Asuka Kawachi, Hitomi Sumiyoshi-Okuma, Aiko Maejima, Yuki Kojima, Kazuki Sudo, Emi Noguchi, Yasuhiro Fujiwara, Takafumi Koyama, Kan Yonemori

Introduction: Breast Cancer (BC) is a highly heterogeneous tumor consisting of various histological types. Data on genomic alterations (GAs) in special types of breast cancer, which account for about 10% of all breast cancers, remain limited. We aimed to clarify genomic profiles of BC, especially focusing on breast cancer of special type.
Methods: We retrospectively reviewed data on female patients with unserectable / metastatic BC who underwent comprehensive genomic profiling (CGP) tests and were registered for the Center for Cancer Genomics and Advanced Therapeutics in Japan from June 2019 to June 2024. CGP tests were conducted by NCC Oncopanel System, FoundationOne CDx (F1CDx), or GenMineTOP. We examined somatic GAs, microsatellite instability (MSI) status, and tumor mutation burden (TMB) of BC. TMB-high was defined as ≥10 mutations/Mb. Actionable GAs were counted if they were classified as "pathogenic/oncogenic" or "likely pathogenic/likely oncogenic variants". Druggable GAs were defined as actionable GAs that are the targets of drugs approved for BC or other types of cancer, or that have been shown to be effective in clinical trials for BC or other types of

cancer.
Results: 3763 patients were identified, of which cases in which detailed histology could not be determined or non-epithelioid tumors were excluded, and finally 2915 patients were included in the analysis. The most used CGP test showed F1CDx (89.7%). Histological types included invasive ductal carcinoma (IDC), invasive breast cancer of no special type (IBC-NST), invasive lobular carcinoma (ILC), metaplastic carcinoma (MpBC), mucinous carcinoma (MuBC), solid papillary carcinoma, adenoid cystic carcinoma (ACC), inflammatory breast cancer (IBC), secretory carcinoma (SBC). The number of each histological subtypes were 2212, 410, 169, 81, 22, 7, 6, 6 and 2, respectively. There were statistically significant differences regarding the PI3K/AKT/mTOR pathway (IDC vs ILC: 57.8% vs 72.8%; p = 0.0045, IBC-NST vs ILC: 55.4% vs 72.8%; p = 0.0031) and BRCA1/2 alterations (IDC vs ILC: 8.7% vs 4.1%; p = 0.039). The frequency of ESR1 alterations was the highest in mucinous carcinoma (36.4%), and the lowest in ACC, MpBC, IBC, and SBC (all of them: 0%), but did not show statistically significant differences by histological type. The proportions of MSI-high and TMB-high were the highest in ILC (1.2% and 18.3%, respectively), but the differences were not statistically significant by histological type. The frequency of druggable GAs was the highest in SBC (100% for NTRK fusion), and the lowest in ACC (33.3%), but did not show statistically significant differences.
Conclusions: Despite the limited number of cases in some histological types, this study revealed genomic characterizations among many histological types of BC. This information will provide an important basis for considering genome-based precision medicine in the future.

P3-05-25: Dynamic increases in T cell repertoire diversity determine palbociclib efficacy and improved antitumor immune response

Sara Cabrero de las Heras, Eva Riveira-Muñoz, Eudald Felip, Federico Fondelli, Alfonso Saera-Vila, Aintzane Rueda Martínez, Javier Perez Venero, Edurne Garcia-Vidal, Joan Climent, Ricard Mesía, Bonaventura Clotet, Anna Martínez-Cardú, Mireia Margeli, Ester Ballana

Background: Inhibitors of cyclin dependent kinase 4 and 6 (CDK4/6i) are the current treatment of choice in hormone-receptor positive breast cancer patients. In addition to their well-described role in cell-cycle regulation, it is now clear that they also impact T-cell immunity. Single cell transcriptomic profiling of circulating immune cells enables high sensitivity detection of rare cells and may identify T cell antigen receptors (TCR) involved in the anti-tumor response, potentially leading to a non-invasive mean of monitoring treatment-induced immune activity. In our study, we perform TCR single-cell sequencing in advanced breast cancer patients undergoing palbociclib treatment to explore changes in T-cell repertoire and monitor antitumor immune responses.
Methods: Longitudinal blood samples of 9 advanced breast cancer (ABC) patients treated with palbociclib were collected and peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll-Hypaque density gradient centrifugation. To characterize T cell

response, profiling of peripheral CD3+ T cells was performed using 10x Genomics VDJ single-cell sequencing. The study cohort consisted of 9 patients diagnosed with HR+HER2- advanced breast cancer, with metastatic lesions present only in bone and treated with palbociclib in combination with hormonal therapy as first-line treatment. Blood samples,were collected at three different time-points, pre-treatment initiation, after 3-6 months while on response (On-treatment) and at progression or last follow-up (LFUP), after 24 months of sustained clinical response. Patients were clinically stratified in good (n=4) or bad (n=5) efficacy based on our own algorithm, that takes into account clinical and survival data according to data from pivotal studies.
Results: Eleven T cell subpopulations, including naïve and memory CD4+ and CD8+ T cells, activated CD4+ and CD8+ T effector cells, activated CD4+ T regulatory cells, were characterized in all samples from the nine enrolled patients based on their transcriptomic profiles, at baseline and longitudinal timepoints. T cell subpopulation distribution was similar in pre-, post- treatment and progression/last-follow up samples in all nine patients. Similarly, no significant differences in TCR diversity and clonality were observed in basal samples from good and bad efficacy patients, albeit TCR repertoire evolved during palbociclib. Indeed, there was a significant increase in the diversity of TCR repertoire in post-treatment samples of patients from the good efficacy group (32% mean increase), compared to pre-treatment samples. On the contrary, TCR repertoire diversity decreased in samples from the bad efficacy group (25% mean decrease) when compared to baseline. At progression/LFUP, TCR diversity decreased in all cases, although it was less pronounced in the good efficacy group, who presented higher TCR diversity index in all time-points studied. Importantly, tracking over time the expanded T cell clonotypes reveals growth of pre-existing effector populations in all patients, but the emergence of novel expanded clones was more frequent in the good efficacy patients, suggesting that Palbociclib treatment increases the antitumor T cell memory pool, resulting in a more effective response and prolonged progression free survival.
Conclusions: Overall, our results indicate that efficacy of Palbociclib treatment is associated with increased TCR diversity and enhanced T cell clonal expansion, both characteristic of improved antitumor immune response. These data are consistent with the model that T cells play a key role in palbociclib-mediated tumor control, and warrant further investigation in a larger sample population.

P3-05-26: Efficacy of first-line CDK4/6 inhibitors stratified by ER, PR, HER2 expression levels and Ki-67 in hormone receptor-positive, HER2 negative metastatic breast cancer: Real-world outcomes

Maya Gogtay, Olivia L. Makos, Lina Elsayed, Robin R. High, Meghana Kesireddy

Introduction: Cyclin-Dependent kinase 4 and 6 (CDK4/6) inhibitors (palbociclib/ abemaciclib/ ribociclib) combined with endocrine therapy (ET) as first-line treatment has significantly improved progression-free survival (PFS) in hormone receptor-positive (HR+), HER2 negative (HER2-) metastatic breast cancer, with ribociclib also showing statistically

significant improvement in overall survival (OS) in phase III studies. However, these phase III studies have not assessed efficacy differences based on estrogen receptor (ER), progesterone receptor (PR), HER2 receptor, or Ki-67 levels. Our study aims to evaluate the impact of ER, PR, HER-2, and Ki-67 on PFS and OS in metastatic HR+, HER2- breast cancer treated with CDK4/6 inhibitor and ET in their first line.

Methods: We conducted a retrospective study of 146 patients with metastatic HR+ HER2- breast cancer treated with first-line CDK4/6 inhibitor and ET at our institution. We have recorded ER, PR, HER2, and Ki-67 expression levels from their first metastatic site biopsy, along with age, gender, ethnicity, menopausal status, location of metastatic sites, date of initiation of CDK 4/6 inhibitor, and date of progression or death. The primary endpoints were PFS and OS stratified by ER (≤50% vs >50%), PR (≤50% vs>50%), HER2 (0 or 1+ vs 2+ on IHC) and Ki67 (≤20% vs >20%) levels. Survival distributions were estimated using the Kaplan-Meier method, and independent group t-tests were used to compare the difference in median between two groups. We also calculated OS and PFS using restricted mean survival time (RMST) which is the area under the survival curve upto a specific time. Results: The ≤ 50% ER group had a median time for PFS of 15.5 months, RMST for PFS of 29 months, median OS of 47 months, RMST for OS of 48.3 months; whereas the > 50% group had significantly longer median PFS of 49 months, RMST for PFS of 47.3 months, median OS of 80.3 months, RMST for OS of 64 months (p=0.002, 0.016, 0.006, 0.05 respectively).

The ≤ 50% PR group had a median PFS of 27.3 months, RMST for PFS of 60.5 months, median OS of 63.7 months, RMST for OS of 93.2 months; while the >50% PR group had significantly longer median PFS of 77.3 months, RMST for PFS of 99.4 months, median OS of 116.7 months, RMST for OS of 133.9 months (p= 0.013, 0.024, 0.014, 0.039 respectively).

The 0 or 1+ HER2 IHC group had a median PFS of 45.4 months, RMST for PFS of 53.9 months, median OS of 71 months, RMST for OS of 69.9 months; while the 2+ HER2 IHC group had a median PFS of 49 months, RMST for PFS of 48.4 months, median OS of 77 months, RMST for OS of 71.4 months (p=0.25, 0.50, 0.74, 0.86 respectively).

The ≤ 20% Ki-67 group had a median PFS of 75.9 months, RMST for PFS of 96.3 months, median OS of 225.3 months, RMST for OS of 140.9 months, while the >20% Ki-67 group had a significantly shorter median PFS of 37.3 months, RMST for PFS of 56.4 months, median OS of 68.8 months, RMST for OS of 82.6 months (p=0.005, 0.006, 0.006, <0.001 respectively).

Conclusion: Higher ER and PR levels were linked to significantly longer PFS and OS, while higher Ki-67 levels were associated with significantly shorter PFS and OS. HER2 IHC levels had no significant impact on PFS and OS. Our study highlights ER, PR and Ki-67 levels as predictive factors for HR+ HER2- metastatic breast cancer patients on CDK4/6 inhibitors. Larger studies are warranted to confirm the utility of these markers as predictive factors for CDK4/6 inhibitor therapy across different treatment lines.

P3-05-27: Real-world evidence on the use of the 21-gene assay in prognostically intermediate luminal breast cancer (BC): experience from a French multicenter cohort (N=1,126)

Natacha Joyon, Caroline Charles, Nadine Dohollou, Loic De Poncheville, Barbara Pistilli, Magali Lacroix-Triki, Elie El-Rassy, Joana Ribeiro Mourato, Chayma Bousrih, Alessandro Viansone, Bruno Cutuli

Background: Real-world data on the use of Oncotype DX® testing (RS) and its impact on treatment choices in early-stage ER+/HER2– breast cancer (BC) pN0/1 patients are limited in settings where broad access for all is not available.
Methods: We conducted a comprehensive retrospective observational study of the use and impact of RS in 4 French public/private practice comprehensive cancer care centers where RS was proposed according to National guidelines.
Results: 1,126 pts underwent RS testing, including 577 across 3 private clinics (Apr 2014 – June 2024) and 549 at Gustave Roussy Cancer Campus (Nov 2020 – June 2024).
Pt characteristics were as follows: age distribution at diagnosis, ≤50y 32.7%, 51–70y 59.4%, >70y, 7.9%; menopausal status, 64.0% postmenopausal, 35.2% premenopausal; male 0.8% (n=9).
Pts received breast-conserving surgery or underwent a mastectomy in 79.8% and 20.2% of cases, respectively. Sentinel lymph node biopsy and axillary dissection were performed in 84.0% and 19.3% of cases.
Clinicopathological features were as follows: main histological subtypes, invasive ductal carcinoma (IDC) 76.6%, invasive lobular carcinoma (ILC) 13.5%, mixed IDC/ILC 5.9%, other 4.0%; pathological tumor size, pT1a 0.4%, pT1b, 7.8%, pT1c 56.9%, pT2 33.4%, pT3 1.5%; tumor grade, grade 1 9.9%, grade 2 73.6%, grade 3 16.4%; mitotic count: 1 46.8%, 2 42.2%, 3 11.0%; multifocality, unifocal 78.0%, bifocal 11.1%, multifocal (≥3 lesions) 10.9%; Ki67 <20% 37.8%, 20–30 47.4%, >30% 14.8%; node status, pN0 63.7%, pN1mi 11.3%, pN1 25.0%.
Retrospective analysis showed that the primary reason for testing was decision uncertainty due to discordant/intermediate histoprognostic factors (69.1%). Other reasons included the need to confirm CET or endocrine therapy (ET) only indication (20.9% and 8.3%, respectively).
RS testing led to major changes in therapeutic choices, with a 68.9% reduction in the indications of chemotherapy (CT) in our cohort. In pN0, pN1mi and pN1 pts, CT indication was reduced by 62.6%, 67.9% and 83.9%, respectively.
In specific patient subgroups (all with a p<0.001), RS impact (% decrease in CT indication) was as follows (CET de-escalation):
- Age groups: ≤ 50y / 51–70y / > 70y, 55.4%/76.5%/64.3%
- Menopausal status: Premenopausal/Postmenopausal/Men, 56.3%/75.1%/88.9%
- Hormone receptors: ER≥90 PR≥10 / ER<90 PR≥10 / ER≥90 PR<10 / ER<90 PR<10, 75.1%/54.6%/51.3%/36.0%
- Histological subtype: IDC/ILC/Mixed/Other, 66.4%/81.6%/64.7%/79.1%
- Grade: 1/2/3, 84.9%/72.0%/49.2%

- Ki-67: <20%/20–29%/>30%, 84.8%/62.3%/56.0%

Excluding men (small sample size), the highest de-escalation rates were seen in:

- Grade 1 tumors in postmenopausal pts: 96.1%
- Grade 1 pN1 tumors: 96.1%
- pN1 tumors with Ki-67 <20%: 95.2%
- Ki-67 <20% tumors in postmenopausal pts: 93.3%
- pN1 ILCs: 92.3%

RS result (continuous variable) was strongly correlated with histological grade (Kruskal-Wallis and ANOVA, $p < 0.001$). RS (continuous variable) was also correlated with Ki-67, with a linear distribution across Ki-67 index ranges (Pearson correlation, $r=0.375$; $p<0.001$). Similar trends were observed for ER and PR (≥90 vs <90 and ≥10 vs <10, respectively), with RS being inversely correlated with staining (% tumor cells) ($p=0.005$ and $p<0.001$, respectively [t-test]).

Conclusions: RS In this real-life, purpose-selected population, RS decreased the indications of CT by a mean of 68.9%. These results confirm the test's utility in refining management strategies and avoiding overtreatment in our daily practice according to ongoing guidelines of use.

The distribution of RS and its impact on adjuvant CT decisions will be detailed during the presentation, which will showcase this updated data on over 2,000 cases from 8 centers and present a multiparametric model.

P3-05-28: A clinical risk prediction model for subsequent invasive breast cancer after ductal carcinoma in situ

Charlotta Mulder, Will Harley, Petra Kristel, Lennart Mulder, Sten Cornelissen, Renee Menezes, Michael Schaapveld, Marjanka K. Schmidt, Jelle Wesseling, Esther H. Lips

Upon the inception of population-based screening programs, the incidence of ductal carcinoma in situ (DCIS) increased 6-fold. DCIS is a non-obligate precursor lesion of invasive breast cancer (IBC), of which the majority does not progress. This implies that women with non-progressive DCIS are overtreated. Within the Cancer Grand Challenge PRECISION project, we identified prognostic markers, including immunohistochemical, morphological markers, and an RNA-seq classifier holding promise in distinguishing progressive from non-progressive DCIS. We now aim to validate these externally and build a clinical prediction model.

We conducted a case-cohort study nested in a Dutch population-based cohort of 8987 patients with DCIS treated with breast-conserving surgery (BCS) between 2005 and 2015. Women who subsequently developed ipsilateral IBC were considered cases and controls were those who did not.

Our study population consisted of a random sample of 10.7% of the full cohort as our subcohort, and all other additional cases, totaling 1237 women (cases n=308; controls n=929). Tissue blocks were requested for all women, of which 940 were received and eligible for immunohistochemical analysis of ER, HER2, COX-2, Ki67 and P16 1. A new H&E

slide was cut for the measurement of adipocyte size 2, level of periductal fibrosis 3 and a ductal morphometric analysis 4. RNA-sequencing was carried out on a selection of BCS-only patients (cases n = 100; controls n = 100). To assess the association of each marker and iIBC risk, prentice-weighted Cox proportional hazards models, with age as the underlying time variable, were implemented. Multivariable models were also implemented and adjusted for treatment, margins status, DCIS grade and size. To account for multiple comparisons, a false discovery rate (FDR) < 0.05 was used to define statistical significance.
The median follow-up time for the case-cohort was 7.2 years (interquartile range (IQR): 5.2-10.1). The age at primary DCIS diagnosis was similar for breast cancer cases and controls (58.0, IQR: 51.0-64.0 vs 58.0, IQR: 51.0-66.0), as was the size of the tumor (p = 0.06). After final surgery, 10.4% of cases and 6.7% of controls had involved margins of <2mm (p = 0.06). Cases were treated more frequently with radiotherapy than controls (76.0% vs 68.4%, p = 0.01) and were more often high grade DCIS (46.4% vs 38.0%, p = 0.04).
In December, we will present the validation of immunohistochemical, morphological markers, and an RNA-seq classifier for predicting subsequent ipsilateral IBC after DCIS and the benefit of using these markers in a clinical prediction model. Ultimately, this will aid individual risk stratification of women with primary DCIS, and can be used to diminish the current overtreatment of harmless, low-risk DCIS.

P3-05-29: Seven in Absentia Homolog (SIAH) expression and clinicopathological correlates in early-stage triple-negative breast cancer (TNBC)

Roberto Leon-Ferre, Sarah K Reed, Michael Keeney, David M Zahrieh, David Hillman, Judy C Boughey, Krishna Kalari, Peter C Lucas, Fergus J Couch, James N Ingle, Harry D Bear, Amy Tang, Matthew P Goetz

Background: TNBC is an aggressive breast cancer subtype with higher rates of disease recurrence and mortality. Clinically and biologically distinct TNBC subtypes have been described, offering the potential of personalized, targeted therapy in subsets expressing

targetable biomarkers. SIAH is an E3 ligase involved in ubiquitination and proteasome-mediated degradation of specific proteins. Elevated SIAH expression has been associated with poor prognosis in early-stage TNBC and is indicative of persistent EGFR-K-RAS-SIAH pathway activation. We evaluated the association of SIAH expression with TNBC clinicopathologic characteristics in early-stage TNBC.
Methods: We measured SIAH protein expression using immunohistochemistry (IHC) in tumors from 280 patients who underwent upfront surgery for early-stage TNBC. SIAH expression was quantified according to staining intensity (none, weak, moderate, or strong) and to the percent of nuclear staining (0-100%). SIAH expression was dichotomized as high (moderate to strong staining in >25% of nuclei) or low/negative (low: weak staining in any % nuclei or moderate/strong staining in ≤25% of nuclei, negative: no staining in any nuclei). We evaluated the association of SIAH expression with clinicopathologic characteristics of interest.
Results: Among 280 patients with upfront resected TNBC, 212 (76%) tumors exhibited moderate to strong SIAH staining in >25% of nuclei (SIAH-high). Most patients (76%) were younger than 65 years old and 57% were postmenopausal. On pathologic staging, most tumors were > 2 cm (54%) and N0 (60%). Compared to SIAH low /negative, SIAH-high TNBC tumors occurred more often in women < 65 years old (80% vs 63%, p=0.006) and were more often > 2 cm (58% vs 40%, p=0.008), node-positive (43% vs 29%, p=0.044), grade 3 (97% vs 85%, p<0.001), with high (>15%) Ki-67 proliferative index (89% vs 55%, p <0.001), and PD-L1 positive (54% vs 36%, p=0.022). Co-expression of high levels of the androgen receptor (AR) was less common in SIAH-high TNBC (IHC <10% in 76% vs 63%, p=0.053). Consistently, molecular subtyping revealed that SIAH-high TNBC was more commonly of a non-luminal androgen receptor (LAR) phenotype (89% vs 73%, p=0.063, assessed via RNA-seq). We observed no differences in menopausal status or stromal tumor-infiltrating lymphocytes (sTILs) between SIAH high vs. low/negative tumors. Associations of SIAH expression with survival outcomes will be presented at the meeting.
Conclusions: High levels of SIAH expression in early-stage TNBC were associated with younger age, larger tumors, higher frequency of nodal involvement, and more aggressive pathologic features (e.g. higher grade and proliferative index). Furthermore, SIAH expression was inversely associated with AR expression and correlated with a non-LAR molecular subtype. Further evaluation of this biomarker and its potential interaction with AR signaling in larger cohorts of TNBC are warranted.

P3-05-30: Clinically Advanced Neuroendocrine Carcinoma of the Breast (CANEBC): A Genomic Landscape Study

Melissa Taylor, Dean Pavlick, Ethan S. Sokol, Julia C. F. Quintanilla, Mia A Levy, Jeffrey S. Ross, Neal A Fischbach, Lajos Pusztai, Maryam Lustberg

Background: CANEBC is a rare form of breast cancer that exhibits neuroendocrine features on histology. The genomic features of CANEBC are currently not well described.
Methods: A series of 86 predominantly Stage IV CANEBC and 1138 CA non-neuroendocrine

ductal breast carcinomas (CAIDC) underwent comprehensive genomic profiling (CGP) to assess all classes of genomic alterations (GA). Microsatellite (MSI)-high status, tumor mutation burden (TMB), homologous recombination deficiency signature (HRDsig), genomic ancestry, and single base substitution genomic signatures were all determined by hybrid capture-based sequencing of extracted DNA from FFPE tissues. ER, PR and HER2 expression were determined by immunohistochemistry (IHC) with HER2 Low defined as either 1+ or 2+/FISH- staining. Results were compared using the Fisher exact method with the false discovery rate (FDR) corrected using Benjamini/Hochberg adjustment.
Results: By design, synaptophysin IHC expression was positive in all (100%) CANEBC. Comparing CANEBC vs CAIDC, the median age (57.5 v 57.0 yrs) and frequencies of EUR ancestry (77.9% vs 68.1%) and APOBEC signature (3.5% vs 4.9%) were similar. The frequencies of ER+ status (60.2% vs 63.3%) and PR+ status (39.8% vs 45.5%) were similar. On IHC, CANEBC were more frequently HER2 negative (0+) (65.0% vs 34.1%; p<.0001), less frequently HER2 Low (1+) (20.0% vs 32.6%; p<.0001) and less frequently HER2 positive 3+ IHC and gene amplified (0% vs 12.9%; p<.0001). Using the CGP data, ERBB2 was less frequently amplified in the CANEBC group (0% vs 14.1%; p=.005). The CCND1/FG3,4,19 amplicon was more frequently amplified in the CANEBC group (25.6% vs 14.6%; p=.037) as were GA in FGFR1 (29.1% vs 13.8%; p=.005) and RB1 (31.4% vs 8.7%; p<.0001). GA in PIK3CA were less frequent in the CANEBC (19.8% vs 34.8%; p=.023). GA in ESR1 and PTEN were similar in both groups. Biomarkers for immune-oncology (IO) drug response including MSI-high and TMB≥10 mut/Mb status were similar in both groups.
Conclusions: CANEBC is an uncommon form of breast cancer that shares features with classic non-neuroendocrine CAIDC with similar frequencies for the endocrine and immunotherapy biomarkers but with lower frequencies of targeted therapy indications for drugs targeting ERBB2 and PIK3CA.

P3-06-01: Occupational exposure to ionizing radiation in female physicians and risk of breast cancer: a systematic review and meta-analysis

Milena Martello Cristófalo, Yedda Nunes Reis, Jonathan Yugo Maesaka, Bruna Salani Mota, José Maria Soares-Jr, Edmund Chada Baracat, Michail Ignatiadis

Background: Recent advancements in health technologies have enabled minimally invasive procedures with the increasing use of ionizing radiation for radioscopy and fluoroscopy by orthopedic surgeons, radiologists, urologists, cardiologists, vascular surgeons, and plastic surgeons. Concurrently, there appears to be an increased incidence of breast cancer among these professionals. In addition to various other risk factors to which they are exposed, it is likely that ionizing radiation also plays a role in carcinogenesis. This study is a systematic review and meta-analysis conducted to evaluate the prevalence of breast cancer in female physicians exposed to ionizing radiation in the workplace.
Methods: This systematic review was conducted following the PRISMA protocol and was registered in PROSPERO (ID: CRD42024553635). PubMed, Embase, and LILACS databases

were searched. Also, reference lists from other articles were searched. Mesh terms used were: breast neoplasms, physicians and prevalence. Articles that described the prevalence of breast cancer among female physicians exposed to ionizing radiation in the workplace were included. We restricted the publication languages to English, Spanish, or Portuguese. Article screening was performed independently by two evaluators (MM and YR) using the Rayyan platform. Methodological quality assessment and biases of included studies were assesed using the Newcastle-Ottawa Scale (NOS) for cohort studies. All statistical analyses were performed using the Review Manager (RevMan) Web v. 8.0.0 (The Cochrane Collaboration).
Results: As of January 2024, 2597 studies were retrieved, with seven studies meeting the inclusion criteria. One study was excluded due to duplicate data. Six cohort studies were included, evaluating a total of 34,744 female participants, including 8,103 female physicians exposed to ionizing radiation, and 26,641 participants in the control group, with a minimum follow-up of 10 years (ranging from 10 to 30 years). According to the NOS instrument, five studies were rated as good and one as fair. Meta-analysis assessment revealed an increased risk among female physicians exposed to ionizing radiation in the workplace, with an odds ratio (OR) of 1.84 (95% CI 1.11 to 3.06; p = 0.02; I^2 = 71%; six studies; 34,744 participants). A sensitivity analysis excluding the study rated as fair showed that the risk of breast cancer in the exposed group still increased, with an OR of 1.42 (95% CI 1.06 to 1.89; p = 0.02; I^2 = 0%; five studies; 23,854 participants).
Conclusions: Female physicians exposed to ionizing radiation during procedures such as radioscopy or fluoroscopy, appear to have an increased risk for breast cancer compared to female physicians not exposed to radiation. However, currently, there are no mandatory regulations for measuring radiation exposure, recommendations for the use of protective equipment according to the physician's body type, or specific screening policies for these professionals. Therefore, the assessment of this exposure and the associated increased risk of breast cancer should be further investigated to enhance worker safety measures and to guide specific screening strategies.

P3-06-02: Prenatal diethylstilbestrol (DES) exposure and risk of benign breast disease

Paloma R. Mitra, Kimberly A. Bertrand, Ruth M. Pfeiffer, Julie R. Palmer, Soumya Ramireddy, Marianne Hyer, William C. Strohsnitter, Kjersti Aagaard, Dezheng Huo, Elizabeth E. Hatch, Linda Titus, Rebecca Troisi, Gretchen L. Gierach

Introduction/Background: Diethylstilbestrol (DES), a synthetic estrogen and potent endocrine disruptor, was prescribed between the 1940s and 1970s to reduce risk of pregnancy complications and loss. DES was later found to be associated with increased risk of vaginal and other cancers among those who were prenatally exposed and is thus no longer prescribed during pregnancy. Whether in utero DES exposure is also associated with subsequent risk of developing benign breast disease (BBD), a risk factor for breast cancer, is unknown, and evaluating the impact of DES may serve as a model of potential

intergenerational chemical toxicity. We assessed the risk of developing BBD, overall and by histologic BBD subtype, associated with prenatal DES exposure.
Methods: From the National Cancer Institute Combined DES Cohorts Follow-Up Study, we examined associations of prenatal DES exposure with BBD risk among 4208 DES-exposed and 1830 unexposed women born between 1933 and 1976. Prenatal DES exposure status was abstracted from medical records or physician notes, and cumulative high or low DES dose was assigned in cohorts with recorded regional prescribing patterns. BBD diagnoses were self-reported on questionnaires from 1990 to 2017. Pathology-confirmation of BBD was available for 600 out of 1086 self-reported BBD cases. Cox proportional hazards models with age as the time scale were used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for the association of DES exposure (DES unexposed, exposed) with BBD risk. Follow-up started at birth and ended at the earliest of a diagnosis of BBD or breast cancer, death, or loss to follow up; the baseline hazard was stratified by year of birth (1933-1951, 1952-1953, 1954-1957, 1958-1976) and cohort, and further adjusted for baseline questionnaire year (1994, 1997 or 2001) and number of questionnaires a woman had answered in a time-varying fashion. We estimated cumulative incidence of BBD by DES exposure status. In additional analyses, we censored women with a BBD diagnosis only obtained by self-report at the age of BBD, and considered risk by histologic BBD subtype (nonproliferative, proliferative without atypia, proliferative with atypia) separately. To test for heterogeneity of associations of DES exposure by histologic BBD subtype, we used case-only polytomous logistic regression models adjusted for follow-up time and year of reported BBD.
Results: 6038 women contributed a total of 333,455 person-years with a median follow-up of 43.0 (range: 13.8-74.0) years for cases (n=1086) and 59.9 (range: 19.7-80.3) years for non-cases (n=4952). BBD diagnoses were confirmed by pathology among 225/350 (64%) unexposed women and 375/736 (51%) DES-exposed women. For the 600 BBD cases with pathologic confirmation, histology did not vary meaningfully by DES exposure: 54.7% nonproliferative, 32.1% proliferative without atypia, and 9.5% proliferative with atypia. Comparing women who were prenatally exposed to DES to unexposed women, we found no evidence of an association between DES exposure and risk of BBD (aHR: 0.98; 95%CI: 0.85, 1.12). There was no evidence of a dose-response relationship or difference in cumulative incidence by exposure status. The aHRs for nonproliferative BBD, proliferative BBD without atypia, and proliferative BBD with atypia were 0.83 (95%CI: 0.64, 1.07), 0.94 (95%CI: 0.67, 1.32), and 0.60 (95%CI: 0.33, 1.09), respectively, with no evidence of statistical heterogeneity by BBD subtype (p-heterogeneity: 0.86).
Conclusions: The risk of BBD was not elevated among women who were exposed to DES in utero, suggesting that previously observed increases in breast cancer risk associated with DES are not likely meditated through this pathological mechanism.

P3-06-03: Multi-drug adherence and breast cancer recurrence: A nationwide study of US veteran women with breast cancer and depression

Maya Aboumrad, Kala Visvanathan

Background: In a prior study, we demonstrated a strong relationship between major depressive disorder (MDD) and recurrence in veteran women diagnosed with breast cancer (BC). We now hypothesize that low adherence to both endocrine therapy (ET) and antidepressants may contribute to disease progression in this population.

Objective: To investigate whether adherence to either antidepressants or ET modifies the association between pre-diagnostic MDD and BC recurrence.

Methods: We used the Veterans Health Administration's electronic medical record database to evaluate treatment adherence in a retrospective cohort of women (age ≥ 18 years) with surgically resected early-stage invasive estrogen receptor positive BC diagnosed between 2010 and 2019 with follow-up through 2022. Our primary outcome of interest was BC recurrence. Using dispensed prescription records, we evaluated adherence to antidepressants during the two-years prior to BC diagnosis and adherence to ET at two-years following ET initiation. Women who had a BC recurrence or death during the two-year treatment period were excluded. Treatment adherence was calculated based on the Proportion of Days Covered (PDC): (number of days covered by a drug / two-year treatment period) x 100%. Multiple PDC thresholds were evaluated to identify an adherence threshold which we defined as the adherence level that was associated with the lowest risk of recurrence for either antidepressants or ET independently. Multivariable proportional hazards regression was used to examine associations between pre-diagnostic MDD and treatment adherence, accounting for interactions and adjusting for demographic, socioeconomic, clinical, and prognostic factors. Wald's test was used to evaluate significance of interactions.

Results: Our cohort was comprised of 4,757 women with estrogen receptor positive BC, of whom 1,359 (29%) had a pre-diagnostic MDD diagnosis. Based on a threshold for antidepressant adherence of 90%, women with MDD who were non-adherent to antidepressants had a 76% (HR=1.76; 95% CI: 1.44, 2.14) higher risk of recurrence compared to women with BC alone, whereas those with MDD who were adherent to antidepressants had a much lower increase in recurrence risk at 25% (HR=1.25; 95% CI: 1.02, 1.54), p-interaction<0.001. Based on a threshold for ET adherence of 80%, women with MDD who were non-adherent to ET had a 58% (HR=1.58; 95% CI: 1.01, 2.45) higher risk of recurrence compared to women with BC alone who were adherent to ET, whereas those with MDD who were adherent to ET had a lower increase in recurrence risk at 28% (HR=1.28; 95% CI: 0.93, 1.74), p-interaction<0.001. In secondary analyses, we examined the impact of adherence to both treatments on recurrence using the same adherence thresholds. Among the subgroup of women who were adherent to ET, women with MDD

who were non-adherent to antidepressants had two times (HR=2.00; 95% CI: 1.45, 2.77; p-interaction<0.001) the risk of recurrence compared to women with BC alone. Among the subgroup of women who were adherent to antidepressants, women with MDD who were non-adherent to ET had a 78% (HR=1.74; 95% CI: 0.95, 3.35; p-interaction<0.001) higher risk of recurrence compared to women with BC alone.

Conclusion: Our findings highlight the need for providers and patients to optimize adherence to both antidepressants and ET in women with MDD and estrogen receptor positive BC to maximize reduction in BC recurrence. Integrated care strategies could help support treatment adherence in this population.

P3-06-04: The effect of socioeconomic status on late-stage breast cancer by race and estrogen receptor status: Insights from the Carolina Breast Cancer Study

Joel Begay, Matthew R. Dunn, Brittney A. Gedeon, Melissa A. Troester, Marc A. Emerson

Background: Late-stage breast cancer (LSBC), defined as stage 3 or 4, significantly contributes to breast cancer (BC) mortality, underscoring the importance of pre-diagnostic care and screening. Understanding the factors contributing to LSBC, overall and by race and estrogen receptor (ER) status, could lead to strategies for timely diagnosis. OBJECTIVE: To evaluate the association between individual demographic and socioeconomic status (SES) characteristics and LSBC, overall and by race and ER status.

Methods: Using data from the Carolina BC Study, a population-based cohort of women diagnosed with invasive BC from 2008-13, we assessed the frequency of LSBC (n=545) compared to stage 1 diagnoses (n=1,225) using individual-level, self-reported demographic and SES data (marital status, education, poverty status, health insurance, pre-diagnostic care, screening history, and a multivariable SES latent class variable). Stage at diagnosis and ER status were abstracted from medical records. Age-adjusted relative frequency differences (RFDs) and 95% confidence intervals (CIs) were estimated separately for Black (n=835, 47.2%) and non-Black (n=935, 52.8%) women, and further stratified by ER status (negative vs positive). Results: Black women had more frequent LSBC diagnoses compared to non-Black women (38.7% vs 23.7%) and were more likely to be diagnosed with ER negative BC (32.7% vs 19.4%). Black women also lacked pre-diagnostic care (17.4% vs 7.4%) and were more frequently under-screened (25.6% vs 21.1%). Overall, marital status, education, poverty status, health insurance, pre-diagnostic care, screening history, and the multivariable SES latent class variable were significantly associated with higher LSBC frequency. Most associations persisted by race[JB1] , but lower screening history had a greater age-adjusted effect on LSBC frequency among Black women (RFD: 28.2, 95% CI: 20.0, 36.3) compared to non-Black women (RFD: 14.7, 95% CI: 7.1, 22.3). Among Black women, marital status and the multivariable SES latent class variable were significantly associated with LSBC frequency, but these associations were not observed among non-Black

women. ER-stratified analyses showed that marital status, poverty status, pre-diagnostic care, and screening history remained statistically significant for both ER positive and ER negative BCs, with greater effects of marital status and screening history among ER negative BCs. Health insurance was significantly associated with LSBC frequency among women with ER negative but not ER positive BC. Among ER positive BCs, poverty, pre-diagnostic care, and screening history were significantly associated with LSBC frequency in both Black and non-Black women, with a greater effect of under-screening among Black women. Among women with ER negative BC, pre-diagnostic care and screening history were significantly associated with LSBC frequency among Black women only.

Conclusion: Access to both pre-diagnostic care and screening services is crucial in reducing LSBC frequency, especially for Black women with ER negative BC where the effects were more pronounced. Further investigation is needed into the factors that protect non-Black women with lower SES and into the specific combinations of SES factors that delay diagnosis among Black women. Addressing SES-related disparities in preventive care is essential for achieving health equity.

P3-06-05: Real-world impact of remote symptom monitoring program on hospitalizations and emergency room visits in women with breast cancer

Gabrielle Rocque, Jeffrey A. Franks, Luqin Deng, Nicole E. Caston, Andres Azuero, Bradford E. Jackson, Nicole L. Henderson, D'Ambra Dent, Stacey Ingram, Noon Eltoum, Indya Starks, Joud El Dick, Nusrat Jahan, Erica Stringer-Reasor, Katia Khoury, Angela M. Stover, Ethan Basch, Jennifer Young Pierce, Courtney P. Williams

Background: Clinical trials have shown remote symptom monitoring (RSM) using electronic patient-reported outcomes (ePROs) reduces healthcare utilization among patients with different cancer types. However, the impact of RSM is not well understood in real-world, standard-of-care patients diagnosed with early stage or advanced breast cancer.
Methods: This analysis of a hybrid, type 2 implementation-effectiveness trial evaluated the impact of RSM on healthcare utilization (hospitalizations & emergency room [ER] visits) among patients with breast cancer receiving chemotherapy, immunotherapy, or targeted therapy at the University of Alabama at Birmingham. We compared patients receiving RSM with historical controls who met RSM eligibility criteria yet received care prior to RSM implementation. Healthcare utilization was assessed 3 and 6 months post-RSM enrollment or date of first RSM qualifying treatment for controls. Unadjusted analyses included crosstabulations and estimation of effect sizes using Cramer's V (V: 0.10~small, 0.30~ medium, and 0.50~large effect size). We estimated risk ratios (RR) and 95% confidence intervals (CI) of healthcare utilization between patients receiving RSM and controls using modified Poisson regression with robust standard errors. Penalized logistic regression was used in subgroup analysis by stage (early [I-III] vs. metastatic [de novo or recurrent]) to estimate odds ratios (OR) and CIs of healthcare utilization for RSM-enrolled patients compared to controls. Models controlled for age at RSM enrollment, race, sex, cancer stage (Poisson models only), insurance status, prior treatment, number of comorbidities, rurality

of residence, area deprivation index, and an indicator for follow-up time during COVID-19 pandemic (April 2020-July 2021).
Results: From May 2021 to February 2024, 328 patients with breast cancer were enrolled in RSM; 30% were Black, 13% resided in a rural area, and 24% lived in a highly disadvantaged neighborhood. Patients receiving RSM were similar to controls treated from January 2017 to January 2021 (n=494) in terms of race and residence (28% Black, 18% rural residence, 27% lived in a highly disadvantaged neighborhood). However, patients receiving RSM more often had metastatic disease at diagnosis compared to controls (25% vs. 11%). Compared to controls, patients receiving RSM were less often hospitalized at 3 months (10% vs. 13%; V=0.02) and 6 months (19% vs. 26%; V=0.07) post-enrollment. Patients receiving RSM visited the ER less often compared to control patients (3 months: 15% vs 16%; V=0.02; 6 months: 21% vs. 25%; V=0.04). In adjusted models, 6-month risk of hospitalizations and ER visits were 30% and 31% lower, respectively, for patients receiving RSM compared to controls (RR 0.70, CI 0.52-0.93; RR 0.69, CI 0.53-0.90). Though not statistically significant, the 3-month risk of hospitalizations and ER visits were also 21% and 24% lower, respectively, for patients receiving RSM compared to controls (RR 0.79, 95% CI 0.52-1.21; RR 0.76, 95% CI 0.55-1.06). In subgroup analyses, 6-month odds of hospitalizations and ER visits were 37% and 39% lower for early-stage patients receiving RSM compared to controls (OR 0.63, 95% CI 0.41-0.96; OR, 0.61, 95% CI 0.39-0.94, respectively). Though not statistically significant, 6-month odds of hospitalizations or ER visits also trended lower for metastatic breast cancer patients receiving RSM compared to controls (OR 0.49, 95% CI 0.18-1.33; OR 0.49, 95% CI 0.18-1.30, respectively).
Conclusions: The use of ePRO-captured RSM reduced the risk of hospitalizations and ER visits for breast cancer patients in real-world settings, with the greatest impact seen for patients with longer engagement in RSM. Further work to expand this intervention nationally is needed.

P3-06-06: Associations between social drivers of health and breast cancer stage at diagnosis among US Black women

Mollie Barnard, Bo Qin, Marc A. Emerson, Etienne X. Holder, Elisa V. Bandera, Christine B. Ambrosone, Julie R. Palmer, Melissa A. Troester, Terry Hyslop, on behalf of the Breast Cancer Research Foundation's Health Equity Initiative

Introduction: In the US, Black women who are diagnosed with breast cancer experience disproportionately high disease-specific mortality. This is, in part, because US Black women are more likely to be diagnosed with advanced-stage breast cancer. We sought to understand how social drivers of health (SDOH) relate to breast cancer diagnostic stage among US Black women.
Methods: This analysis included self-identified Black or African American women diagnosed with breast cancer who were participants in the Black Women's Health Study (BWHS; n=1,777), the Women's Circle of Health Study (WCHS; n=1,725), or the Carolina Breast Cancer Study Phase 3 (CBCS; n=1,493). SDOH were self-reported at enrollment in WCHS

and CBCS, and on pre-diagnosis questionnaires in the BWHS. Data on stage at diagnosis and tumor characteristics were abstracted from medical records and state cancer registry records. We used polytomous logistic regression adjusted for age at diagnosis, insurance status, and household income below the federal poverty line to estimate odds ratios (OR) and 95% confidence intervals (CI) for stage at diagnosis in association with each categorical SDOH exposure. Two categories of advanced stage (stage 2; stage 3 or 4) were compared to stage 1. Stages 3 and 4 were combined due to small numbers of stage 4 participants (BWHS n=75, WCHS n=50, CBCS n=109). Study-specific ORs were combined using fixed effects meta-analysis.
Results: Higher odds of late stage (3 or 4) versus stage 1 cancer were significantly associated with underutilization of mammographic screening (OR=2.97, 95% CI 1.85-4.77) and household income below the federal poverty line (OR=1.90, 95% CI 1.17-3.11). ORs were above 1.0 for lack of health insurance (OR=1.48, 95% CI 0.82-2.67) and lower educational status (i.e., did not graduate from high school; OR=1.24, 95% CI 0.76-2.03) but were not statistically significant. Marital status was not associated with late stage.
Discussion: SDOH that reflect economic instability and lower access to preventive healthcare were associated with later stage at diagnosis among US Black women with breast cancer. Interventions to increase screening utilization must contend with financial and insurance barriers to reduce late-stage diagnoses in this historically underserved population.

P3-06-07: Plant-based Diets and Risk of Breast Cancer: A Pooled Analysis of 21 Cohorts

Emily Riseberg, Stephanie A. Smith-Warner, on behalf of the investigators of the cohorts

Background: Investigating relationships between dietary patterns and molecular subtypes of breast cancer may lead to a greater understanding of their pathogenesis. In the Nurses' Health Studies, the healthy plant-based diet index (hPDI), which considers the quantity and quality of the plant foods consumed, was associated with lower breast cancer risk, particularly estrogen receptor negative (ER-) tumors. These associations need to be studied in larger and more diverse cohorts.
Objective: We investigated relationships between the hPDI and unhealthy PDI (uPDI) and breast cancer risk overall and for subtypes defined by ER, progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) status in a pooled analysis of participant-level data in the Pooling Project of Prospective Studies of Diet and Cancer.
Methods. These analyses included 21 cohorts (N=1,446,309 women) that assessed usual diet at baseline using validated food frequency questionnaires or diet histories. Data on ER/PR status were provided by all studies; 10 studies provided HER2 status. Three overarching food categories each including ≥5 food groups were included in each index: healthful plant foods (e.g., vegetables, nuts), unhealthful plant foods (e.g., fruit juices,

refined grains), and animal foods (e.g., meat, eggs). For the hPDI, healthful plant foods received a positive score, and unhealthful plant foods received a negative score. For the uPDI, unhealthful plant foods received a positive score, and healthful plant foods received a negative score. In both scores, animal foods received a negative score. Indices (score range=18-90) were modeled using study-specific quintiles. Multivariable Cox proportional hazards models were used to calculate study-specific hazard ratios (HR) and 95% confidence intervals (95%CI). Models were adjusted for breast cancer risk factors and potential confounders (e.g., parity, body mass index). The random-effects meta-analysis method was used to pool log-HR estimates.
Results: During a median follow-up ranging from 8 to 28 years across cohorts, 70,099 breast cancers [9,305 ER-; 15,694 ER+ and/or PR+/HER2- (luminal A-like); 2,512 ER+ and/or PR+/HER2+ (luminal B-like); 971 ER-/PR-/HER2+ (HER2-enriched); and 2,092 ER-/PR-/HER2- (triple-negative)] were documented. Comparing the highest vs. lowest quintile, the hPDI was significantly associated with lower risk of overall (HR=0.94; 95%CI=0.92, 0.97), ER+ (HR=0.96; 95%CI=0.93, 0.99), ER- (HR=0.84; 95%CI=0.78, 0.91; p-heterogeneity with ER+=0.003), and triple-negative (HR=0.80; 95%CI=0.69, 0.94) tumors. The uPDI was significantly associated with higher risk of overall (highest vs. lowest quintile HR=1.04; 95%CI=1.01, 1.07), ER- (HR=1.19; 95%CI=1.10, 1.28; p-heterogeneity with ER+=0.001), and triple-negative (HR=1.21; 95%CI=1.04, 1.42) tumors. Weaker and nonsignificant results were observed for the remaining subtypes.
Conclusion: Healthful plant-based diets were associated with a slightly lower risk of breast cancer overall, with stronger inverse associations observed for ER- and triple-negative tumors. Unhealthful plant-based diets were associated with higher risks of the same subtypes. Following a healthy plant-based diet may aid in preventing breast cancer subtypes with fewer treatment options and poor survival.

P3-06-08: Chemotherapy decision making and physical and psychological symptoms in young breast cancer survivors

Krystal Wright, Yue Zheng, Kate Dibble, Greg Kirkner, Shoshana M Rosenberg, Karen Sepucha, Kathryn J Ruddy, Jeffrey Peppercorn, Lidia Schapira, Steven E Come, Virginia F Borges, Ann Partridge

Background: When young women are diagnosed with breast cancer, they often present with more advanced and/or aggressive forms of the disease. Given the use of chemotherapy is the recommended for women with triple-negative and HER2-positive subtypes of breast cancer (BC), as well as for locally advanced and genomically higher risk ER+, HER2- disease, most young women receive chemotherapy for early breast cancer. Despite clinician recommendations, patients may not have confidence in the decision to be treated with chemotherapy. Understanding different facets pertaining to this and its potential impact on physical and psychological symptoms is essential to improve patient care.
Methods: Using data from the Young Women BC Study (YWS), a prospective cohort of 1,302 women who were ≤40 and diagnosed with BC from 2006-2016. We evaluated the

association between confidence in chemotherapy decision (as assessed on the 6-month survey, rated by participants on a 10-point Likert scale) for women with stage I to III BC treated with chemotherapy, and physical symptom burden at 1-year survey (SF-36 and CARES), fear of recurrence at 1-year (Lasry Fear of Recurrence index), and anxiety and depression at 1-year (HADS). Logistic regression models used cut-offs chosen apriori with ratings of 7-10 grouped as 'high' confidence and ratings of 0-6 grouped as 'low to moderate' confidence. Ratings of ≥11 for both HADS subscales (depression and anxiety) was used, and indicates a significant number of symptoms that likely correspond with a clinical diagnosis. This analysis controlled for tumour subtype, stage, education, and hormonal therapy treatment.
Results: A total of 681 women were analysed due to eligibility and completeness of the data. The majority were non-Hispanic white (n = 602, 88.4%); 3% were non-Hispanic Black (n = 18) and 5% Hispanic (n= 33). The median age at the 6-month survey was 37 years (Range = 18-42). Most respondents (n=452, 66.4%) expressed a high level of confidence (rating it 10 out of 10), while smaller percentages had lower confidence ratings, ranging from 0 to 9. Individuals with less confidence in chemotherapy reported worse outcomes on the general health ($t(680) = 2.34$, $p = .012$) and mental health ($t(680) = 3.03$, $p = .003$) SF-36 subscales at one year, as well as the CARES psychological ($t(680) = 3.45$, $p < .001$) and medical domain subscales ($t(680) = 5.91$, $p < .001$). Individuals who reported less confidence in chemotherapy at six months reported greater anxiety ($t(680) = 2.78$, $p = 0.006$) and depression ($t(680= 3.53$, $p < .001$) at one year. No significant associations were found for fear of recurrence. In the logistic regression model, grouping by high confidence (indicating 7-10 on the Likert scale, n=637, 93.5%) and low to moderate confidence (indicating 0-6, n=44, 6.5%), participants with low to moderate confidence had higher odds of depression at one year compared to those in the high confidence group (OR 3.83, 95% CI 1.57 - 9.34) ($p = .003$). Confidence was not significantly associated with anxiety (OR 1.20, 95% CI 0.60 – 2.41) ($p = .603$) or fear of cancer recurrence (OR 1.20, 95% CI 0.57 – 2.51) ($p = .629$) in the multivariable models.
Conclusion: In this analysis of young breast cancer survivors who received chemotherapy, we found that most indicate high confidence in their chemotherapy decision. Our finding of an association between lower confidence in the chemotherapy decision and depressive symptoms at 1 year suggests this group may need targeted intervention to improve psychosocial outcomes.

P3-06-09: Effect of a 6-Month Tailored Exercise Program According to Cancer Trajectories in Patients with Breast Cancer: Preliminary Results of a Randomized Controlled Trial

Su Jin Yeon, Justin Y. Jeon, Seho Park, Jiwon Kang, Rosa Park, Susanna Jun

Purpose: This randomized controlled trial (RCT) aims to explore the short-term effects of a tailored home-based exercise program for breast cancer patients, individualized according to the phase of treatment and patient-specific conditions. The study seeks to assess the

impact of this intervention on physiological outcomes, including fasting insulin levels and shoulder function, during the first 6 months of the 12-month intervention period. These preliminary findings contribute to understanding how phase-specific exercise interventions influence recovery and overall health in breast cancer patients.

Methods: 96 patients with stage 1–3 breast cancer were planned to be enrolled in this 12-month RCT. Participants were randomized into either a tailored exercise group or a usual care group. The exercise program was home-based and tailored to the patient's treatment phase. In Phase 1 (post-surgery), the focus was on improving shoulder strength and range of motion (ROM). In Phase 2 (during chemoradiation therapy), the focus shifted to maintaining physical function and preserving muscle mass. This interim analysis presents preliminary data from 49 patients who completed the 6-month follow-up. The primary outcome was fasting insulin levels, with secondary outcomes including shoulder strength and ROM.

Results: Among the 49 participants analyzed (mean age 53.02 ± 7.46 years), fasting insulin levels in the exercise group showed a downward trend from baseline (8.80 ± 5.54) to 6 months post-intervention (6.05 ± 4.55), though this reduction did not reach statistical significance ($p = 0.149$). In the usual care group, fasting insulin levels exhibited a slight increase over the same period (7.49 ± 5.20 to 8.53 ± 8.47), but this change was also not statistically significant ($p = 0.896$). While the impact on insulin levels was inconclusive, improvements in shoulder strength were more pronounced. Shoulder strength recovery, analyzed through separate movements (flexion, abduction, extension), was significantly better in the exercise group (93.41 ± 27.2) compared to the usual care group (74.19 ± 16.55) at 1-month post-surgery ($p = 0.013$). Additionally, 33.33% of participants in the exercise group achieved full shoulder strength recovery by 1-month post-surgery, compared to none in the usual care group.

Conclusion: Preliminary findings suggest that early, tailored exercise interventions can significantly improve shoulder function in breast cancer patients. While changes in fasting insulin levels were not statistically significant at this stage, the improvements in shoulder strength highlight the potential benefits of integrating individualized exercise programs into clinical care. Further analyses of long-term outcomes, including cardiopulmonary fitness and insulin resistance, will provide additional insights into the efficacy of tailored exercise regimens throughout the cancer treatment trajectory.

*The protocol for this study has been registered with the Korean Clinical Trials Registry (KCT0007853); DOI: https://doi.org/10.1186/s12885-023-10664-1

P3-06-10: Triple Negative Breast Cancer: The standpoint of Mexican population

A. Michelle Barboza-Portillo, Marianela Madrazo-Morales, Alder E. Perales-Mendoza, Ricardo Cerda-Flores, Diana C. Pérez-Ibave, Fernando J. Peña-González, Miranda N. Cardona-Serrato, Marlene A. Luna-Rubio, David Hernández-Barajas, Oscar Vidal-Gutiérrez

Introduction: Breast cancer is the malignant neoplasm with the highest incidence and mortality rate among Mexican women, accounting for 28% of cancer cases and 16 deaths per 100,000 women over 20 years of age. Triple-negative breast cancer (TNBC) is a subtype of breast cancer that does not express estrogen and progesterone receptors, nor human epidermal growth factor receptor 2 (HER-2). Conventionally it presents with a poor prognosis compared to other subtypes and usually relapses within the first 3 years after diagnosis.
Objective: The aim of this study was to describe sociodemographic, epidemiologic, clinical, histopathological and prognostic characteristics of TNBC in a northeast Mexican-based cohort.
Methods: Original, retrospective, descriptive and analytical data were analyzed.The study was approved by the Research and Bioethics Committee, 18-year-old patients and older with TNBC diagnosis were included, treated at our University Hospital "Dr. José Eleuterio González" between 2014-2019. Sociodemographic, epidemiologic, histologic, biochemic, diagnosis, treatment and prognosis data were obtained from clinical records.
Results: One-hundred thirty-five patients were enrolled. The mean age at diagnosis was 48 ±12.9 years and the most common histological type was invasive ductal adenocarcinoma in 80.7% of cases. Regarding clinical stage, 24.4% were classified as stage IIA, followed by stage IIIA in 21.5% of the patients. Stage IV accounted for 11.9% of the patients. Thirty-four percent of the tumors had a Ki67 index of more than 20% and 11.4% presented BRCA mutations, with BRCA1 being the most prevalent. Platinum based chemotherapy was prescribed in 20.8% of patients. Surgical treatment was performed in 92.4% of patients and 84.9% received radiotherapy. Sixty-two patients reached clinical surveillance and 13 had disease recurrence.
Discussion: TNBC represents 23.1 % of breast tumors in México in comparison to USA reports with approximately 15% cases. In our study we observed that the age of diagnosis with a predominance above 40 years was greater than reported in developed countries where TNBC is more commonly diagnosed in premenopausal women; this is probably associated with poor health access and lack of public health education in secondary prevention of breast cancer. Twenty-nine (21.48%) patients had a history of menarche under 12 years. Age of diagnosis, histologic subtype and risk factors tendencies correlate to literature worldwide reports.
BRCA mutations in México are estimated at approximately 23% of cases and the incidence of TNBC has been reported substantially in patients with BRCA1 mutations. Reproductive risk factors including early menarche and non-parity regardless of its general relation with breast cancer independently of histologic subtype were frequent among our patients. Unhealthy lifestyles such as sedentarism, overweight, high carbohydrate intake, alcohol

consumption and tobacco have been strongly related to breast cancer development and were the predicted lifestyles of our cohort patients. Outlining the epidemiologic and sociodemographic characteristics of patients with TNBC in our population and its influence in the prognosis highlights the importance of reinforcing screening policies and implementing programs that promote healthy lifestyles.
Conclusion: The incidence of TNBC in Mexico exceeds the statistics reported in the United States by approximately 8%, with an 8-year greater mean age of diagnosis in comparison to American women. This is due to poor access to healthcare services and the lack of education regarding breast cancer screening, leading to a diagnosis at later stages and, consequently, to a worse prognosis and fatal outcomes. The BRCA prevalence mutations reported in our study was almost 12% lower than reported worldwide, probably due to lack of resources to obtain genetic testing and poor medical follow-up.

P3-06-11: Efficacy of a Structured Educational Program in Enhancing Breast Cancer Knowledge Among Caregivers in Egypt: A Quasi-Experimental Pilot Study

Emad Shash, Fatma Bektash, Maram Montaser, Sarah Ghobrial, Jackline Safwat, Kholoud Reda, Nourhan Mahran, Reem Eid

Background: In low- and middle-income countries, breast cancer (BC) awareness and education are often hindered by misinformation, cultural barriers, and low literacy rates. Effective patient education is essential for improving health outcomes, yet structured interventions remain limited. This study assesses the impact of a comprehensive educational program designed to enhance BC knowledge among caregivers at Cairo University's National Cancer Institute (NCI).
Methods: A quasi-experimental design was employed in this pilot study involving 59 participants. The intervention consisted of a three-hour educational session focused on BC awareness, treatment options, misconception correction, and psychological health. Pre- and 30 days post-intervention knowledge assessments were conducted using a structured questionnaire. The statistical significance of the knowledge gains was evaluated through paired sample t-tests.
Results: Participants demonstrated significant improvements in key knowledge areas. Post-intervention scores showed marked increases in understanding BC symptoms (mean score: 1.1 ± 0.7 pre-test vs. 1.9 ± 0.3 post-test; $p < 0.001$), risk factors (2.7 ± 1.6 vs. 5.7 ± 1.4; $p < 0.001$), nutrition misconceptions (0.6 ± 0.6 vs. 1.6 ± 0.7; $p < 0.001$), and breast self-examination techniques (1.3 ± 0.87 vs. 2.2 ± 1; $p < 0.001$).
Discussion: The educational program effectively addressed gaps in BC knowledge, reflecting the urgent need for structured patient education in similar settings. Cultural and educational backgrounds were considered, with tailored content ensuring relevance and accessibility. The program also highlighted the importance of patient advocate groups and the role of healthcare professionals in ongoing education.
Conclusion

This study underscores the potential of structured educational interventions to significantly improve BC knowledge among caregivers in low- and middle-income countries. By correcting misconceptions and enhancing understanding, such programs contribute to better health knowledge. Future research should explore scaling these interventions to larger populations and diverse settings.

P3-06-12: Breast Cancer and Mortality Rates: An Analysis Using the NIS 2021 Database

Kalaivani Babu, Srinishant Rajarajan, Kriti Dhamija, Vasuki Anandan

Background: Breast cancer remains a significant public health concern worldwide, with numerous factors influencing patient outcomes. This study aims to evaluate the mortality rates among breast cancer patients in the United States, utilizing data from the National Inpatient Sample (NIS) 2021 database. The analysis focuses on demographic, socioeconomic, and healthcare-related variables to understand their impact on mortality rates.
Methods: Data was extracted from the NIS 2021 database, and interpreted using STATA software. Inclusion criteria were set for adult patients (aged ≥18) diagnosed with breast cancer, identified by ICD-10 code C50. Variables studied included age, sex, race, Charlson Comorbidity Index (CCI), income quartile, insurance status, hospital bed size, teaching status of the hospital, and geographic location of the hospital. The Charlson Comorbidity Index was categorized as 0 (CCI=0), 1 (CCI=1), 2 (CCI=2), and 3 (CCI≥3). Survey-weighted analysis was conducted to generate totals and proportions, and linear regression was applied to assess the association between variables and outcomes.
Results: Among the 6,666,752 observations, 140,855 breast cancer patients met the inclusion criteria. The majority were female (98.66%) with an average age of 66.1 years (SE = 0.144). Racial distribution indicated 67.82% were White, 17% Black, 9.11% Hispanic, 3.13% Asian/Pacific Islander, 0.43% Native American, and 2.51% of other races. Socioeconomic status, represented by the median household income quartile, was evenly distributed among the patients.
The majority of patients (83.77%) had a Charlson Comorbidity Index of 3 or more. Insurance coverage showed 60.17% had medicare, 11.78% were medicaid, and 26.7% had private insurance. Hospital characteristics revealed that 51.6% of patients were treated in large hospitals, 76.27% in teaching hospitals, and 92.98% in urban settings.
The overall mortality rate among breast cancer patients was 5.65% (SE = 0.00147). The survey-weighted total estimate of deaths was 7,949.98 (SE = 234.21), with a 95% confidence interval of 7,490.80 to 8,409.16.
Conclusion: This analysis provides a comprehensive overview of the mortality rates and demographic factors among breast cancer patients in the U.S. hospital setting using the NIS 2021 database. These insights could provide additional information to identify vulnerable populations and guide healthcare policies and targeted interventions to improve outcomes for breast cancer patients.

P3-06-13: Prevalence and Effect of Comorbidities on Survival of Breast Cancer Patients by age

Bombi Park, So-Youn Jung, Young Ae Kim, Danbi Lee, Eun-Gyeong Lee, Seeyoun Lee, Jai Hong Han

Purpose: More than 30% of breast cancer patients have comorbidities unrelated to cancer before and after diagnosis, and there is a lack of research on the impact of this on the survival rate of breast cancer patients. This study aimed to examine the impact of comorbidities on the survival rate of breast cancer focusing on variation according to age.

Method: This study utilized data from the Cancer Public Library Database (CPLD), part of the Korean Clinical Data Utilization for Research Excellence project (K-CURE), to analyze breast cancer patients' treatments and comorbid conditions. Female patients diagnosed with breast cancer (ICD-10 code C50) between 2014 and 2019 were included. We estimated survival according to Age-adjusted Charlson Comorbidity Index (ACCI) and survival was determined by univariate and multivariate Cox proportional hazard regression analysis.

Results: A total of 128711 patients were included in this study. The mean ACCI for patients under 40 and in their 40s before and after diagnosis increased from 1.2 to 1.6 and from 2.3 to 2.7, respectively, and the most common comorbidities in both age groups were COPD (under 40 7.5%, 40s 6.9%, respectively) before diagnosis and liver disease (under 40 20.8%, 40s 23.1%, respectively) and gastric ulcer (under 40 18.2%, 40s 15.0%, respectively) after diagnosis. The mean ACCI for patients in their 50s increased from 3.7 to 4.0, with high blood pressure (21.7%) and liver disease (10.4%) being the most common before diagnosis and the same after diagnosis (25.5%, 25.9%, respectively). The mean ACCI for patients in their 60s increased from 5.3 to 5.6, and the most common cases were high blood pressure (55.1%) and diabetes (21.8%) before diagnosis, and high blood pressure (48.5%), liver disease (27.0%) after diagnosis. The mean ACCI for patients over 70 increased from 7.0 to 7.2, and the most common diseases were diabetes (35.5%) and hypertension (28.4%) before diagnosis, but hypertension (72.8%) and diabetes (37.7%) after diagnosis. The diseases that significantly increased breast cancer-related deaths were heart failure (aHR 1.5, 95% CI 1.2-1.8), dementia (aHR 1.6, 95% CI 1.0-2.2), paralysis (aHR 1.5, 95% CI 1.0-2.1), and kidney disease (aHR 1.5, 95% CI 1.1-1.8). The comorbidities with the highest proportion of untreated patients were dementia and paralysis, and these increased the risk of death the most across all age groups (HR 6.9, 95% CI 5.8-8.1, HR 6.4, 95% CI 5.4-7.4, respectively). Excluding dementia and paralysis, the diseases that most significantly increased mortality by age were cardiovascular disease and kidney disease in those under 40 and in their 50s, myocardial infarction and kidney disease in those in their 40s, and kidney disease and heart failure in those over 60s.

Conclusion: As age increased, the rate of age-related comorbidities increased. Dementia and paralysis have most significantly increased the mortality rate among the elderly so management at the national level is needed to ensure that these patients receive

appropriate treatment. Although there were differences by age group, kidney disease and heart failure also showed a significant increase in mortality, making appropriate management necessary.

P3-06-14: Evaluating “Spinning Science” A Patient-Led Health Literacy Educational Program for People Living with Metastatic Breast Cancer

Mya Roberson, Brianna D. Taffe, Amy Beumer, Lesley Glenn, Maryam Lustberg

Background: There are currently over 150,000 people living with metastatic breast cancer (MBC) in the United States, a number projected to increase to over 169,000 people living with MBC by 2025. MBC treatment requires patients to digest an overwhelming amount of technical medical information to understand and participate fully in shared decision-making regarding testing and treatment. There have been limited efforts to increase MBC patient health literacy to improve self-efficacy systematically. This study aimed to evaluate “Spinning Science,” an MBC patient-led and delivered educational intervention designed to improve MBC-specific health literacy amongst people living with MBC.
Methods: Spinning Science was developed by an MBC patient advocate with doctoral training in biology, and the objectives were reviewed by other patient advocates, an oncologist, and a researcher. It consists of five online sessions covering basic scientific and technical topics related to MBC treatment and survivorship, such as breast cancer subtyping, genetic and genomic testing, clinical trials, ctDNA, information literacy, and more. The workshops were intentionally kept small (>20 people). Small group work, chat monitoring, time for questions throughout, and polling were used to encourage participation and deeper engagement with the material. The program was offered twice, in the Fall of 2023 and Spring of 2024, to members of Project Life, a virtual wellness community for people living with MBC and their loved ones. Participants in the program were asked to complete pre- and post-program surveys to gain an understanding of their change in knowledge as a result of the program, as well as the most salient aspects of the program. Paired 2-sample T-Tests were conducted to assess change in mean scores in the pre- and post-program surveys. Thematic qualitative analysis was conducted on free text responses in the post-program surveys.
Results: 54 people living with MBC participated in the Spinning Science program from Fall 2023-Spring 2024. 14 of the 17 Fall 2023 participants and 32 of the 37 Spring 2024 participants responded to both the pre- and post-program surveys, for a total of 46 complete survey respondents. In the pre-test 43% (n=23) of participants reported that they agreed or strongly agreed with the statement “I don’t know enough to make my own medical decisions” compared to only 13% (n=6) reporting agreeing with that statement in the post-test ($p<0.05$), demonstrating significantly improved self-efficacy. Qualitative analysis of free-text responses revealed that Spinning Science was responsive to participant feedback from the Fall 2023 to the Spring 2024 program. Specifically, the updated program addressed participants’ desire to learn more about clinical trials included a stand-alone workshop on how to read and understand academic posters, abstracts, and literature. The

Spring program also provided more MBC-specific content and addressed participant concerns about program pacing, workshop duration, and accessibility of program materials both during and after the program has finished.
Conclusion: Overall, Spinning Science improved participating MBC patients' health literacy and self-efficacy and responded to the feedback and needs of the Project Life community by addressing areas for improvement from one iteration to the next. Future Spinning Science iterations should implement validated survey-based evaluation metrics and focus on recruiting Project Life members with lower baseline health literacy and self-efficacy to evaluate the program's impact on MBC patients fully.

P3-06-15: Trajectories of Daily Step Counts in Breast Cancer Survivors in the Breast Cancer Weight Loss (BWEL) Trial

Chao Cao, Karla V. Ballman, Linda McCall, Thomas A. Wadden, Catherine M. Alfano, Xiaolan Feng, Linda M. Delahanty, Elizabeth Frank, Olwen Hahn, Dawn L. Hershman, Judith O. Hopkins, Melinda Irwin, Erica L. Mayer, Lori Minasian, Linda Nebeling, Marian L. Neuhouser, Electra D. Paskett, Patricia A. Spears, Vered Stearns, Cynthia A. Thomson, Anna Weiss, Julia White, Pamela J. Goodwin, Clifford Hudis, Eric P. Winer, Ann H. Partridge, Lisa A. Carey, Jennifer A. Ligibel

Background: Step count is one of the most accessible and widely used device-measured metrics for monitoring physical activity levels. Step counts are associated with hospitalizations during cancer treatment and with other health outcomes in cancer patients (pts). The BWEL (Alliance for Clinical Trials in Oncology A011401; NCT02750826) trial is a phase 3 randomized trial testing the impact of a supervised weight loss intervention (WLI) on invasive disease-free survival in 3180 women with stage II-III breast cancer (BC) and a body mass index (BMI) ≥27 kg/m2. This secondary BWEL analysis describes 2-year (yr) trajectories of daily step counts in the BWEL WLI group.
Methods: Eligible pts were within 16 months (mos) of diagnosis of stage II-III HER2-negative BC, had completed chemotherapy and radiation, and were randomized 1:1 to a telephone-based WLI plus health education (HE) or an HE alone control group. WLI pts were assigned a trained coach at the BWEL call center and were provided 42 phone calls over the 2- yr intervention period. Calls were delivered weekly for the first 12 weeks (wks), biweekly for the remainder of the 1st yr, and monthly in the 2nd yr. The WLI focused on caloric restriction and exercise, with an activity goal of 150 minutes (min) of moderate to vigorous-intensity exercise per wk in the first 6 mos of WLI, increasing to 225 min/wk in mos 6-24. WLI pts were provided with a Fitbit for motivation and assessment of activity. Valid daily step counts (defined as ≥ 100 steps/day) were extracted from the BWEL portal and averaged (avg) weekly to capture habitual patterns. Linear mixed-effect models accounting for individual variances and Joinpoint regression were used to evaluate trajectories of daily step counts over the 104-wk WLI. Univariable and multivariable (including baseline age, race/ethnicity, and BMI) mixed-effect regression models were used to examine difference in daily step counts over 104 wks by pt factors.

Results: Of the 1591 WLI pts, 1240 provided Fitbit data with 466,400 records of daily step counts. Pts with Fitbit data had mean baseline BMI of 34.4 (±5.6) kg/m2 and mean age of 53.2 (±10.3) yrs; 10.8% self-identified as African American (AA) and 6.1% as Hispanic. A higher proportion of individuals without Fitbit data identified as AA (19.1%) or Hispanic (10.5%) compared to those with Fitbit data (P<.001). Trajectory analysis indicated that step counts increased from 4864 (95% CI: 4631-5096) to 5663 (95% CI: 5444-5882) avg steps/day from wk 1 to wk 12 (P for trend <.001) and to 6647 (95% CI: 6476-6818) avg steps/day between wks 26 and 52 (both P for trend <.001). Step counts decreased to 6058 (95% CI: 5782-6334) avg steps/day at wk 104 (P for trend <.001) but remained significantly higher than baseline (P<0.001). Patients aged ≥65 yrs had significantly lower avg daily step counts (5402 [95% CI: 5033-5772]) than those aged <65 (6389 [95% CI: 6225-6552]). Avg daily step counts were also significantly lower in pts with BMI ≥35 (5503 [95% CI: 5267-5739]) vs those with BMI <35 (6691 [95% CI: 6502-6879]). AA pts had lower avg daily step counts (5793 [95% CI: 5334-6252]) than pts who did not identify as AA or Hispanic (6297 [95% CI: 6128-6466]). Each 1-yr increase in age was associated with an avg 30 (95% CI: 16-44) fewer steps/day over the WLI period in a multivariable model. Similarly, each 1-unit increase in BMI was associated with 117 (95% CI: 91-143) fewer avg steps/day.
Conclusions: Daily step counts significantly increased in early BC survivors during a telephone-based WLI. Further follow-up of the BWEL trial will evaluate relationships between daily step trajectories and disease and pt-reported outcomes.

P3-06-16: Heterogeneity of Tertiary Lymphoid Structures Predicts the Response to Neoadjuvant Therapy and Immune Microenvironment Characteristics in Triple-Negative Breast Cancer

Qing Wang, Yushuai Yu, Chenxi Wang, Zirong Jiang, Jialu Li, Xiaofen Li, Xiewei Huang, Ying Song, Zhenhui Li, Shicong Tang, Chuangui Song

Background: Tertiary lymphoid structures (TLS), as functional microenvironments for immune responses, are closely associated with the prognosis of various cancers. In the treatment of triple-negative breast cancer (TNBC), neoadjuvant therapy (NAT) is a primary strategy. However, the role of TLS in the immune status of TNBC and its interaction with NAT remains insufficiently understood.
Methods: This study utilized single-cell RNA sequencing (scRNA-seq), multiplex immunofluorescence staining (mIF), and radiomic techniques to comprehensively assess TLS and the tumor microenvironment (TME) in paired samples from TNBC patients before and after NAT.
Results: In TNBC, the presence of TLS was associated with B-cell maturation and T-cell activation. Tumors with high TLS expression exhibited stronger cytotoxic expression of immunoglobulin family genes (IGHM and IGHG1) in B-cells and neoantigen-specific CD8+ T-

cells (neoTCR8) compared to tumors with low TLS expression. Furthermore, mIF assessments revealed significant heterogeneity between TLS and TME in TNBC. Interestingly, total CD8+ T-cell levels were not effective predictors of NAT response. Instead, the maturity of TLS correlated significantly with NAT response and improved prognosis ($P<0.05$). Finally, we developed an imaging biomarker scoring system to predict TLS status and the efficacy of NAT.
Conclusion: Our findings reveal changes in TLS and TME in TNBC patients post-NAT, confirming the predictive capability of mature TLS. Additionally, the study elucidates the immunomodulatory effects of NAT, enabling personalized immunotherapy based on immune characteristics of post-chemotherapy samples, ultimately improving clinical outcomes for breast cancer patients.

P3-06-17: IAPP mediated anti-breast cancer function of CD8+T cells via targeting cuproptosis

Zhijian Huang, Xiaoting Qiu, Cuifeng Zheng, Yi Zeng

Abstract: Objective: Breast cancer (BRCA) is the most common cancer worldwide, characterized by high heterogeneity and recurrence rates. It has been found that the biological behavior of tumors can be regulated by immunity and cuprotosis. Therefore, exploring potential targets or prognostic biomarkers to mediate immunity and cuprotosis is urgent for the therapy of BRCA.
Methods: By mining the TCGA database, we identified immune-related genes and immune-cuprotosis-related differentially expressed genes (ICR-DEGs). Prognostic analysis, differential expression analysis, univariate and lasso regression analyses were used to determine independent prognostic values for ICR-DEGs. Then, the role of the tumor immune microenvironment (TIME) in breast cancer was explored. To evaluate the relation between ICR-DEGs and immune scores, we constructed a prognostic risk model to evaluate immune checkpoints. Mitochondrial morphology was examined via electron microscopy. T cell functionality was assessed through flow cytometry and ELISA, and the anti-tumor effect of T cells was evaluated in a subcutaneous tumor model via RNA-seq analysis of related signaling pathways.
Results: 16-gene prognostic signature was constructed. The high-risk group had lower prognosis than the low-risk group. The AUC for the 1-, 3-, and 5-year risk scores were 0.733, 0.709, and 0.704, separately. The levels of CD8+T cell immune cell infiltration of high-risk group was lower than that of low-risk group, and the high-risk patients had lower Stromal Score, Immune Score, and ESTIMATE Score than the low-risk patients. In addition, prognostic features were significantly associated with immune checkpoint inhibitor (ICI)-associated genes. Downregulation of IAPP reduced cuprotosis of CD8+T or Her2-CAR-T cells while promoting cytokine release, thereby enhancing in vitro and vivo anti-BRCA functionality. IAPP mediated copper promotion of CD8+T viability and function through the NF-κB pathway
Conclusion: This study has provided novel insights into the role of ICRSig in the

development and progression of BRCA, laying a foundation for the identification of new markers and therapeutic targets for breast cancer. Furthermore, our research had clarified the function and mechanism of IAPP in T cells, providing new ideas for improving the diagnosis and treatment of BRCA.

P3-06-18: Novel regulators of PDGF-BB secretion in breast cancer

Jesse Reardon, Steven S. Sizemore, Gina M. Sizemore

Platelet-derived growth factor-B (PDGFB) is necessary for normal cell growth and development, with major roles in angiogenesis, differentiation, and migration. PDGFB is the preferred ligand for the receptor tyrosine kinase platelet-derived growth factor receptor-beta (PDGFRß) and is a known oncogene that our lab has reported to mediate breast cancer (BC) primary tumor growth and metastatic spread to the brain. As the mortality rate of metastatic BC patients, especially those with BC-associated brain metastasis, is extremely high, our current research focuses on identifying and targeting mechanisms that direct differential tumor-specific PDGFB overexpression and secretion. In normal physiology, PDGFB is expressed by epithelial and endothelial cells, and via paracrine signaling, activates PDGFRß on neighboring mesenchymal cells. While these interactions are well known, both the secretory cascade and extracellular regulation of PDGF-BB is grossly understudied in BC. In particular, it is known that PDGF-BB is associated with positively charged heparin sulfate proteoglycans on the cell surface. This cell-associated form can undergo proteolytic processing, where C-terminal cleavage releases the mature PDGF-BB dimer. Yet, the enzyme responsible for this cleavage is unknown. Here, we hypothesized that the endoglycosidase, heparanase (HPSE), was capable of cleaving extracellular heparan sulfate proteoglycan chains, thereby releasing PDGF-BB bound to heparan sulfate. We show that silencing HPSE in PDGF-BB secreting BC cell lines diminishes its secretion by ~40%. We are currently investigating other candidate regulators of PDGF-BB secretion through protease inhibitor screening and have identified the serine protease superfamily and MMPs as crucial regulators of PDGF-BB secretion, perhaps by direct cleavage of the C-terminus. Ongoing studies aim to delineate the precise roles of the superfamily members and study the in vivo roles of HPSE, serine proteases, and MMPs in PDGF-BB secretion. Importantly, PDGFB and HPSE expression are synergistically prognostic in patients. Together these findings suggest a crucial need to understand PDGF-BB secretion in BC.

P3-06-19: Spatial mulitomic assay for assessing immune cell phenotype and function in the tumor microenvironment

Anushka Dikshit, Debia Wakhloo, Julia Yu, Paul Liu, Sonali Deshpande

Tumormicroenvironment (TME) is a complex milieu of multiple cell types mainly including tumor cells, immune cells, endothelial cells and stromal cells. Immune cell profile within the TME can determine success of immunotherapies, indicate therapeutic efficacy and determine any potential therapeutic toxicity in various malignancies including breast

cancer. Spatially interrogating these immune cells is crucial in studying immune-immune and immune-tumor interactions. Characterizing immune cells require assessing cell marker expression using protein detection and activation markers using RNA detection. To address this, we have developed a high throughput RNAscope™ assay on the BOND RX to spatially visualize RNA and protein markers on the same slide.
We utilized the new RNAscope™ Multiomic LS assay that can detect up to 6 RNA and protein targets in breast cancer FFPE tissue. The TSA-based amplification strategy offers signal boost for both RNA and protein targets. To optimize protein detection, the workflow is completely protease-free there by preserving antigen integrity and tissue morphology. The assay can be customized to include any target RNA and proteins of interest. Here, we demonstrate the use of our pre-conjugated antibody panel which includes CD8, CD4, FoxP3 and PanCK to visualize tumor infiltrating lymphocytes (TILs). We also utilized unconjugated primary antibodies for CD68 and CD163 to detect tumor macrophages in multiple tumor tissues.
Infiltrating Cytotoxic T cell lymphocytes were detected using CD8, GZMB and IFNG co-expression. Regulatory T cells were detected using CD4, FOXP3 co-expression. PanCK was used as a tumor marker to delineate tumor from stroma. Similarly, tumor associated macrophages were detected using CD163, CD68 , IL10 and IL-1B expression. We also identified distinct M1 and M2 macrophage populations in the breast tumor sample.

P3-06-20: Lean adipocyte-secreted oxylipin, 9S-HODE, triggers ferroptosis and protects against obesity-accelerated breast cancer

Meghan Curtin, Guoying Wang, John Maschek, David Lum, James Cox, Keren Hilgendorf

Approximately 1 in 8 women will develop breast cancer in their lifetime, and over 40,000 women in the United States die from breast cancer every year. Post-menopausal breast cancer risk and mortality rates are exacerbated by those who are classified as obese, such that a 5-unit increase in body mass index is linked to a 12% increase in risk. The rising rates of obesity make understanding the link between obesity and the incidence, progression, and mortality of breast cancer of high priority. Obesity is marked by an expansion of white adipose tissue, which accounts for 90% of the breast cancer microenvironment. While several studies have identified paracrine factors secreted by obese adipose tissue that promote tumorigenesis, the role that lean adipose tissue plays in breast cancer progression remains underexplored.
In this study, I screened the secretome of primary adipocytes isolated from multiple fat pads from both lean and obese mice for the ability to modulate the growth of breast cancer cell lines across multiple different subtypes. I discovered a potent role of lean mammary adipocytes in selectively inhibiting breast cancer cells in vivo and in vitro. This inhibitory function is specific to lean mammary adipocytes, as the secretomes of obese mammary adipocytes or adipocytes isolated from visceral fat depots do not inhibit breast cancer cell growth. Further, I discovered that the lean mammary adipocytes, but not obese adipocytes, secrete an oxylipin called 9S-HODE, an oxidized metabolite derived from the essential fatty

acid linoleic acid. I show that lean adipocytes and 9S-HODE inhibit breast cancer cell growth by triggering ferroptosis. However, normal breast epithelial cells are protected from 9(S)-HODE-induced ferroptosis by transiently growth-arresting and rapidly forming lipid droplets. We propose that lean adipocytes actively inhibit the growth of breast cancer cells by secreting the ferroptosis inducer 9(S)-HODE, and that in patients with obesity, breast cancer is accelerated, at least in part, due to the loss of 9(S)-HODE-mediated tumor suppression.

P3-06-21: Needle Biopsy Accelerates Pro-Metastatic Changes and Systemic Dissemination in ER+ Breast Cancer: Implications for Mortality by Surgery Delay

Takemi Tanaka

Breast cancer is the most commonly diagnosed malignancy in the U.S. and over two-thirds of invasive breast cancer cases are diagnosed early stage. However, 15-year survival rates for early-stage breast cancer remain in the range of 70-77%. Mounting evidence showed an increased risk of disease progression and mortality among early-stage breast cancer patients whose surgery was delayed over 60 days after the diagnostic biopsy. Yet, the mechanism(s) underlying the rapidly increased mortality due to delay of surgery after diagnosis remains unknown.
Our cohort analyses of early-stage breast cancer patients reveal the emergence of a significantly rising mortality risk when the biopsy-to-surgery interval was extended beyond 53 days. Additionally, histology of post-biopsy tumors shows prolonged retention of a metastasis-permissive wound stroma dominated by M2-like macrophages capable of promoting cancer cell epithelial-to-mesenchymal transition and angiogenesis by secretion of transforming growth factor beta 1 (TGF-β1) and vascular endothelial growth factor (VEGF). We show that needle biopsy promotes systemic dissemination of cancer cells through a mechanism of sustained activation of the cyclooxygenase-2 (COX-2)/prostaglandin E2 (PGE2) cascade, which favors M2-polarization and its associated pro-metastatic changes, but are abrogated by oral treatment with COX-2 inhibitors in estrogen receptor-positive (ER+) syngeneic mouse tumor models.
Therefore, we conclude that needle biopsy of ER+ breast cancer provokes progressive pro-metastatic changes, which may explain the mortality risk posed by surgery delay after diagnosis. Also, our data may provide a rationale for a pharmacologic strategy to inhibit the COX-2/PGE2 cascade in cases when delay of surgery is unavoidable.

P3-06-23: Determining organotropic drivers of metastasis in a new genetically engineered mouse model

Eran Andrechek

The majority of transgenic and knockout / knock-in mouse models that develop mammary tumors also develop pulmonary metastasis. However, human breast cancer metastasizes to a variety of distal sites other than the lungs. It is unclear why mouse models are limited in this regard and there is a clear need for models that better reflect the human disease. Using a bioinformatic approach, we have predicted that the E2F transcription factor family is critical in mediating metastasis, with a particular role noted for E2F5. Testing an E2F5 gene signature, we noted that alterations to E2F5 were associated with lymph node metastasis in human breast cancer. In order to investigate the role of E2F5 in breast cancer, we proposed to interbreed the tumor strains with knockouts of E2F5. However, the E2F5 knockouts suffer from early lethality and we thus generated an E2F5 conditional knockout using MMTV-Cre to ablate E2F5 in the mammary epithelium.
The E2F5 conditional knockout mice have developmental abnormalities, including pubertal development delays and pregnancy proliferation delays. However, after a long latency these mice also develop mammary tumors with no other initiating oncogenic events. Indeed, we were surprised that loss of E2F5 alone in the mammary epithelium was sufficient to induce tumor formation. The tumors that developed in these mice were also highly metastatic to the lungs and importantly in other tissues, including the lymph nodes and livers of mice at endpoint. Given the long latency of the strain, all tumors and metastases were viably frozen. Reimplanting these tumors into syngeneic hosts allowed us to examine the tumors that metastasized to lymph node and liver. Repeated rounds of transplantation of metastases back to the mammary gland resulted in tumors that were enriched for their ability to metastasize to specific distal sites.
The role of particular genetic programs in these distal metastases was assessed through whole genome sequencing and through RNAseq analysis. Initially we noted differences in key pathways including cyclin D1 in these tumors. Studies into the role of specific pathways for the various organotropic lines are ongoing.

P3-06-24: Characterization of a Living Biobank of Patient-Derived Invasive Lobular Carcinoma Organoids that Retain Tumor Heterogeneity in 3D Culture and Tumorigenicity In Vivo.

Minakshi Gandhi, Melissa Kramer, Jill Habel, Zihua Wang, Raditya Utama, Suzanne Russo, Payal Naik, Karen Kostroff, David L Spector

Breast cancer (BC) is one of the primary causes of cancer related deaths among women worldwide. According to Cancer Statistics, over 310,720 new breast cancer diagnoses are expected in the United States in 2024 with an estimate of over 42,250 expected BC related deaths. Invasive Lobular Carcinoma (ILC) accounts for the 2nd most frequently diagnosed histological subtype of BC, constituting 10%-15% of all reported cases. ILC is hormonally driven (estrogen and progesterone receptors) with a hallmark characteristic of ILC being lack of E-cadherin (CDH1) and with mutations in the CDH1 gene reported in over 90% of cases. Mutations in the CDH1 gene have also been associated with 39%–52% increased lifetime risk of developing breast cancer in women. Patient-derived organoid (PDO) models

have been shown to offer significant advantages in terms of better recapitulating the tumor/microenvironment niche, however such models have not been available to study ILC.
With a vision to develop 3D models to better understand ILC and develop specific therapeutic targets, here, we describe the establishment and comprehensive characterization of a diverse biobank of ILC PDOs. We have performed in-depth genomic, transcriptomic and histologic profiling of the established ILC PDOs and validated the models to be true representatives of ILC tumors. Comprehensive genomic profiling of ILC PDOs using a custom 143 cancer driver gene panel (targeted exome sequencing) identified ILC specific mutations in CDH1, PIK3CA, TBX3, RUNX, etc. in PDOs. Short Multiply Aggregated Sequence Homologies (SMASH) identified widely reported copy number gains and losses (gains on Chr1q and losses on Chr16q and Chr17p among others) in established ILC PDOs. Transcriptomic profiling performed on matched tumor-normal pairs revealed the upregulation of ESR1 signalling-related pathways known to drive ILC carcinogenesis. Multiplexed single-cell RNA sequencing revealed that the established PDOs retained their cellular complexity and heterogeneity even after multiple passages and contained hormone responsive, hormone secretory, basal, fibroblasts, and proliferating populations of cells representing major cell types in ILC tumors. Lastly, we also show that the established ILC PDOs when xenografted (either in mammary glands or intra-ductally) in NOD-SCID gamma mice retain their tumorigenicity in vivo and the single file growth pattern, a characteristic of invasiveness in ILC tumors. In summary, we have established a living biobank of ILC PDOs often with matched normals (adjacent and/or distal) that are representative of different subtypes of ILC (classic, pleomorphic, tubule-lobular, mixed, etc.). Overall, this study has optimized a pipeline for establishment, culturing and validation of ILC PDOs as robust models available for studying ILC biology with a focus on basic, translational, and personalized medicine.

P3-06-25: Humanized patient-derived xenograft models of triple-negative breast cancer for analyzing the safety and effectiveness of mRNA lipid nanoparticle cancer vaccines

Maria F. Chervo, Wei Qian, Karina A. Ortega-Martinez, Jianying Zhou, Raghav Shroff, Chiara Mancino, Liliana Guzman-Rojas, Francesca Taraballi, John P. Cooke, Jimmy D. Gollihar, Jenny C. Chang

Background. Triple-negative breast cancer (TNBC) has the highest rates of recurrence and relapse compared with other breast cancer subtypes. Chemotherapy alone, or in combination with immune checkpoint blockade is the current standard of care. However, many patients still do not benefit from these treatments. While T-cell targeting of tumor neoantigens through mRNA lipid nanoparticle (mRNA-LNP) cancer vaccines has become a truly personalized tool to elicit effective antitumor activity, more predictive preclinical models are needed to drive the rational design of cancer vaccine candidates and minimize failures in future clinical trials. Here we established a humanized patient-derived xenograft

(hu-PDX) mouse model of TNBC that recapitulates interactions between human immune cells and tumors to investigate the effectiveness and safety profile of mRNA-LNP cancer vaccines in vivo.
Methods. Tumor neoantigens were identified in the TNBC PDX model MC1 using a proprietary algorithm that prioritizes vaccine candidates on their likelihood to induce neoantigen-specific T-cell responses. mRNA encoding 20 selected HLA-A2-restricted neoantigens (Neo20 cancer vaccine) was synthesized and encapsulated into LNPs for in vivo administration. To assess the Neo20 cancer vaccine in vivo, we developed a hu-PDX mouse model of TNBC expressing human leukocyte antigen (HLA) class I. Briefly, human immunity was reconstituted in female HLA-A2 transgenic NSG mice through I.V. transplantation of human CD34+ hematopoietic stem cells from HLA-A2+ cord blood donors. Mice showing efficient human CD45+ (hCD45+) cell engraftment were implanted with MC1 tumors into the mammary fat pad. Once the tumors were established, MC1-hu-PDX mice received Neo20 mRNA-LNPs (10 μg mRNA/mouse) or empty LNPs as a control by intramuscular injection. Animals were treated every three days for one week and evaluated for vaccine immunogenicity and tumor growth. To analyze neoantigen-specific T cell responses, splenocytes were harvested 7 days after the last dose and pulsed with vaccine peptides for human interferon (IFN)-γ ELISpot assay. To examine the side effects of the Neo20 vaccine, major organs were collected for histopathological analysis and colorimetric detection kits were used to quantitatively measure biochemical markers [alanine aminotransferase (ALT), aspartate aminotransferase (AST) and blood urea nitrogen (BUN)] in serum samples.
Results. Flow cytometry analysis of hCD45+ subpopulations of cells confirmed human reconstitution with T-cells, B-cells, myeloid cells/macrophages, and NK cells in blood, spleen, and bone marrow collected from MC1-hu-PDX mice. Two out of five mice treated with Neo20 vaccine generated functional human T-cell subsets with HLA-A2-restricted immune responses against multiple vaccine peptides as measured by ex vivo IFN-γ production. We observed a small but not significant change in tumor size between the Neo20 vaccine and control group after one week of treatment, suggesting that our treatment protocol should be further optimized to improve neoantigen-specific T cells and associated anti-tumor responses. Hematoxylin and eosin staining of tissue sections showed no histological differences between controls and Neo20 mRNA-LNP-treated mice, indicating no notable toxicity. ALT/AST and BUN levels were calculated to evaluate liver function and kidney activity, respectively. We found no obvious changes in these parameters in serum from mice after treatment with the Neo20 mRNA-LNPs, confirming negligible side effects.
Conclusions. This study provides evidence associated with mRNA-LNP cancer vaccines against TNBC supporting the use of hu-PDX mice as a model to preclinically validate early vaccine candidates, mRNA doses, and treatment schedules.

P3-06-26: p53 Haploinsufficiency Epistatically Masks A3B Tumor Phenotype in vivo

Joshua Proehl, Cameron Durfee, Yuan Zhao, Nuri Alpay Temiz, Reuben Harris

The single-stranded DNA cytosine deaminase enzyme, APOBEC3B (A3B), has been implicated as a mutational driver in multiple human cancers1,2. Breast cancer in particular shows high levels of A3B expression and positive associations with poor clinical outcomes3. Recent studies have also demonstrated that human A3B expression in mice is carcinogenic with significantly shortened life expectancies4. The only genetic factor in breast cancer thus far associated with A3B expression and APOBEC signature single base substitutions is p53 mutation5.
Therefore, here we test the hypothesis in vivo that human A3B expression will show pathlogical synergy in the form of accelerated mammary tumor penetrance upon combination with p53 haploinsufficiency due to a heterozygous deletion mutation spanning exons 2-10. Custom and commercially available animals were subjected to standard breeding practices to generate experimental (A3B, p53Delta exons 2-10/+) and control groups (p53Deltanexons 2-10/+). Surprisingly, in contrast to A3B-accelerated tumor development on a wildtype genetic background, A3B had no effect on the rates of tumor development in p53 heterozygous animals (median 13.5 months). The observed genetic epistasis was not due to a lack of A3B expression or activity, as evidenced by strong IHC positivity and a clear acculumlation of APOBEC signature single base substitution mutation in tumors. We conclude that A3B-accelerated tumor development requires full p53 function, and that a haploinsufficiency in p53 enables tumor cells (or their precursors) to better tolerate DNA damage lesions induced by A3B.

P3-06-27: Immunotherapy and PI3K/mTOR inhibition combination to mediate metastasis and immunotherapy resistance in triple-negative breast cancer

John Friend, Michelle Melino, Wen Juan Tu, Taniya Ahuja, John Vandermeide, Martina Proctor, Amanda Bain, Gahyathiri Nallan, Helle Bielefeldt-Ohmann, Sudha Rao

Background: Triple negative breast cancer (TNBC) tends to be highly aggressive, and almost 50% of patients develop distant metastasis to the brain, liver, and/or lung, at which point the median survival time is only 8-13 months. The average time to relapse in TNBC patients

is 19-40 months and the mortality rate within 3 months after recurrence is 75%. Although the addition of immunotherapy to neoadjuvant chemotherapy has improved the survival of patients with stage II–III TNBC, drug resistance remains a problem. Hence there is an urgent need to develop new therapy regimens and targets.
Methods: Extensive preclinical program initially starting with in vitro breast cancer cell lines (MDA-MB-231 and MCF-7) to evaluate various PI3K and PI3K-mTOR inhibitors using WST-1 cell proliferation assays, cell migration assays, qRT-PCR and immunofluorescence analysis.
In vivo studies utilised the highly aggressive, immunotherapy resistant, TNBC mouse model, 4T1. Briefly, six-to-eight-week-old female BALB/c mice were inoculated with 1 x 105 4T1 cells administered into the mammary fat pad. Once tumours reached ~50-100 mm3, the PI3K-mTOR inhibitor, Paxalisib, was administered daily by oral gavage in combination with either anti-PD-1 (pembrolizumab) treatment or PARP inhibitor (olaparib). Extensive pathology, nanostring and CODEX spatial analysis was used to evaluate primary tumour burden, metastases and inflammation.
Results: Dual targeting of the PI3K-mTOR pathway but not PI3K alone inhibited cancer cell proliferation and migration and promoted a favorable mesenchymal-to-epithelial phenotype. In vitro, the PI3K-mTOR inhibitor, Paxalisib, reduced metastasis-initiating cell signatures including the highly aggressive CD44high/CD24low CSC phenotype, persister cancer cell phenotype (p65, FOXQ1, NRF2, NNMT), and drug resistance markers (ABCB5, SNAIL, ALDH1). PI3K-mTOR blockade also reduced NFκB p50 and the pro-inflammatory downstream target IL-6 whilst inducing viral mimicry genes, making cancer cells more immune visible. Dose de-escalation of paxalisib in the highly aggressive 4T1 TNBC mouse model substantially reduced primary tumor burden, lung metastases, and liver inflammation in combination with immunotherapy +/- chemotherapy whilst overcoming toxicity complications and resistance associated with standard-of-care treatment. Paxalisib in combination with the PARP inhibitor olaparib also reduced primary tumor burden and metastases compared with olaparib monotherapy. NanoString analysis of paxalisib +/- immunotherapy-treated tumors showed a marked reduction in “pro-tumorigenic” immune populations whilst CODEX spatial analysis revealed an increase in the infiltrating adaptive immune arm following paxalisib + anti-PD-1 treatment.
Conclusions: The addition of paxalisib to immunotherapy in the 4T1 TNBC mouse model reduced primary tumor burden, lung metastases, and liver inflammation whilst overcoming toxicity complications and resistance associated with standard-of-care immunochemotherapy. Paxalisib in combination with the PARP inhibitor olaparib, but not monotherapy alone, also reduced primary tumor burden and metastases. Moving forward, work is ongoing to elucidate the PI3K-mTOR mechanism of overcoming metastasis and drug resistance as well as the translation of the data into a clinical development program for patients with TNBC and advanced breast cancer.

P3-06-28: Neo-adjuvant administration of MDNA11, a long-acting IL-2 Superkine, prevents metastasis, protects against tumor rechallenges and provides long-term survival in an orthotopic model of breast cancer

Abdalla Sheikh, Nina Merchant, Aanchal Sharma, Fahar Merchant, Minh D. To

Background: MDNA11 is an albumin-fused 'beta-enhanced not-alpha' IL-2 superkine that preferentially expands and activates immune effector cells over immune suppressive Tregs. MDNA11 effectively inhibited subcutaneously implanted syngeneic tumors with complete tumor regression and a potent memory response. Mice treated with MDNA11 demonstrated increased tumor infiltration of CD8+ T and NK cells and elevated circulating memory and antigen-specific CD8+ T cells. Given these results, we hypothesize that preconditioning of immune cells against cancer cells by MDNA11 prior to tumor resection can prevent metastasis and prolong survival. This study compared the efficacy of MDNA11 in neo-adjuvant and adjuvant settings in an aggressive orthotopic breast cancer model prone to distant metastasis following tumor removal.
Method: Female Balb/c mice with 4T1.2 tumors implanted in mammary fat pads were treated with a single dose of MDNA11 prior to or following tumor resection and survival was monitored. Excised tumors are being analyzed for immune cell infiltration. Surviving mice underwent re-challenges by subcutaneous implanting 4T1.2 cells without any additional treatment. Necropsy was performed to identify gross metastasis.
Results: All control mice that had tumors resected but received no treatment died by study day 54 with gross metastasis in multiple organs. In the adjuvant group where mice received a single dose of MDNA11 following tumor resection, 3 of 8 (37.5%) survived to study end (study day 134). Of the 5 mice in the adjuvant group that died while on study, 4 had distant metastasis. In contrast, of the 8 mice that were administered a single dose of MDNA11 prior to tumor resection, 7 (87.5%) survived to study day 134 with no observable clinical symptoms. The single mouse that was found dead had no metastasis. Remaining mice in the neo-adjuvant (n = 7) and adjuvant (n = 3) were re-challenged at day 65 by implanting 4T1.2 cells subcutaneously in their flanks. A second re-challenge was performed on study day 98. Mice did not receive any additional treatment and on both re-challenge occasions there was no tumor growth or metastasis whereas control naïve mice that were also implanted with 4T1.2 cancer cells showed robust tumor growth at the implanted site.
Conclusion: A single dose of MDNA11 in a neo-adjuvant setting confers immediate and long-term protection from metastatic disease in the 4T1.2 orthotopic breast cancer model.

P3-06-29: Circulating tumor cell expansion from frozen PBMCs enables drug screening against metastatic tumor cells

Shian-Jiun Shih, Yi-chun Han, David Hsieh

Background: Despite metastasis representing the foremost cause of mortality in cancer patients, current oncology drug development primarily relies on cell lines or primary tumor-derived models, which may not fully represent the complexities of metastatic

disease. We aim to develop a drug screening platform to enable the identification of drug candidates capable of targeting metastatic tumors.
Materials and Methods: Using a patented cell culture system from AcroCyte (Taiwan), we selectively cultivate circulating tumor cells from the peripheral blood of cancer patients with solid tumors. This process employs either 5 milliliters of fresh whole blood or equivalent frozen PBMCs, obtained from commercial sources or collaborations with patient consent. The cultured patient samples demonstrate formation of circulating tumor cell colonies, which often grow as three-dimensional organoid-like spheres within several weeks. These colonies can be subsequently expanded for drug screening, banked as frozen cells for future use, and have been employed to evaluate drug efficacy by assessing cytotoxicity over the course of 7 days. Drug concentrations used in assessing cytotoxicity were selected based on available human pharmacokinetic Cmax data; in the absence of such data, we relied on prior findings from cell line screening and/or in vivo studies. These colonies undergo comprehensive multi-omics analysis, including immunostaining and transcriptome profiling, to further characterize their properties before and after drug treatment.
Results: We have successfully established colonies from circulating tumor cells (CTCs) derived from frozen peripheral blood mononuclear cells (PBMCs) of patients with breast cancer, as well as other solid tumors, including lung, colon, prostate, and melanoma. These colonies exhibit expression of EpCAM and cytokeratin, confirming their identity as CTCs. Notably, CTC colonies from breast cancer patients generally exhibit slower growth compared to those from other solid tumors, often forming only cell clusters rather than three-dimensional organoids. Additionally, we have cultivated primary cancer colonies from dissociated tumor cells for comparative molecular characterization and drug sensitivity analysis. Our findings indicate that both CTC and primary tumor colonies display diverse sensitivities to standard-of-care chemotherapy drugs, as demonstrated by alterations in cell viability and morphology following drug exposure.
Conclusions: We demonstrate a robust drug screening platform against metastatic tumors using circulating tumor cell-derived colonies for solid tumors. The ability to bank these colonies and perform drug sensitivity characterization and multi-omics analysis suggests its potential for identifying effective therapies for the treatment of metastatic cancer. Our results affirm the potential of CTC colonies in understanding tumor biology of metastatic cancer and their role in personalized cancer therapy, particularly for breast cancer.

P3-06-30: Novel Humanized LIV-1 Antibody Based ADCs Conjugated with Topoisomerase I Inhibitor Payloads Displayed Significantly Higher Anti-tumor Activities than MMAE based ADCs in TNBC Tumor Models

Fei Teng, Huanhuan Guo, Hongjun Li, Lizhi Qin, Hanjing Mao, Sonny Yao, Xiaoli Zi, Lisa Zheng, Yi Gu, Xueming Qian

LIV-1 is a member of the zinc transporter family and an estrogen-regulated gene in metastatic breast cancer. While normal tissue expression is limited, LIV-1 was found to be

overexpressed in a high prevalence in breast cancer (93%), as well as in melanoma (82%), prostate (72%), ovarian (48%) and uterine (30%) cancers. LIV-1 is considered as one of the attractive cell surface targets for developing ADC therapeutics. To develop next generation LIV1 targeting ADC, we generated 48D6, a proprietary novel humanized anti-LIV-1 mAb with high affinity, specificity, internalization ability, unique epitope and improved pharmacokinetics profile in mice. In vitro studies indicated that breast tumor cells, such as MDA-MB-468 and MCF-7, are more sensitive to Topo I inhibitor than MMAE. Therefore, we generated two Topo I inhibitor-based ADCs (ADC-1 and ADC-2) using glycotransferase mediated site-specific conjugation. Both ADC-1 and ADC-2 have a drug-to-antibody ratio (DAR) of 4 but with different payload: a modified Topo I inhibitor for ADC-1 and Exatecan for ADC-2. A MMAE based ADC (ADC-3) with the same site-specific conjugation and DAR4 was also synthesized as the control. ADC-1 and ADC-2 displayed similar and specific cytotoxic activities against human LIV-1-expressing tumor cells in vitro, as compared to SGN-LIV1A analog (DAR8) or ADC-3. In the human LIV-1 transfected MDA-MB-468, a triple-negative breast cancer (TNBC) tumor model, ADC-1 or ADC-2 demonstrated dose-dependent anti-tumor activities and inhibited tumor growth more potently than the SGN-LIV1A analog or ADC-3. At 3 mg/kg the tumor growth inhibition (TGI)% are: ADC-1 92.4%, ADC-2 94.7%, ADC-3 68.5% and SGN-LIV1A analog 57.0% on Day 30; At 3 mg/kg, the overall response rate (ORR, 50% reduction of tumor volume from baseline) of SGN-LIV1A analog or ADC-3 was 0%, while ORRs of ADC-1 and ADC-2 were 40% and 70%, respectively. At 6 mg/kg, ADC-1 and ADC-2 had ORR of 100% and CR rate of 90% and100% on Day 29 respectively. And the body weight of mice didn't change significantly at either 3 or 6 mg/kg for ADC-1 or ADC-2. The enhanced anti-tumor activities of ADC-1 and ADC-2 are likely contributed by the high affinity binding of 48D6 to LIV-1 and high cytotoxicity of Topo I inhibitor in breast tumor cells. These data warrant further investigation of the lead LIV-1 targeting ADC (ADC-1 and ADC-2) as potential next-generation therapeutic agent in LIV-1 positive breast cancer and other solid tumors.

P3-07-01: Comparative effectiveness and safety of initial operation in inoperable locally advanced breast cancer—a real-world retrospective cohort study in China

Yan Lin, Bowen Liu, Ying Xu, Xin Huang, Yidong Zhou, Qiang Sun, Yu Song

Purpose: There are sparse data on the effect of initial operation for patients with locally advanced breast cancer (LABC), and even fewer data for inoperable LABC. This real-world cohort study aimed to present long-term outcomes of initial operation in women with inoperable LABC in China.
Methods: This is a retrospective cohort study of patients with LABC (stage III) who were treated from January 2017 to December 2018. Among them, inoperable patients (stage III, excepting T3N1M0) with limited locoregional involvement were included into our comparative survival analysis. All enrolled inoperable LABC were then divided into upfront surgery group and upfront chemotherapy group. Upfront surgery patients were matched

(2:1) to upfront chemotherapy patients with similar subtypes, nodal status, tumor status, age, and chemotherapy regimens. The primary objective was disease free survival (DFS) and overall survival (OS) in each group. Pathologic complete response (PCR) was secondary objective. Subgroup analyses included DFS and OS according to age, tumor status, nodal status and subtypes.

Results: Between Jan 1, 2017, and Dec 31, 2018, of the 3843 patients with breast cancer who were newly treated, 565(14.7%) patients presented with LABC. From them, 168 inoperable LABC patients were included into final analysis (112 for surgery-first group and 56 for neoadjuvant group). At data cut-off of Dec 1, 2023, median follow-up was 60.9 months (range, 40.0-85.1 months). No difference in OS was observed between surgery-first group and neoadjuvant group (hazard ratio [HR]=0.47; 95% CI, 0.19 to 1.17, P=0.11) and so do in DFS (HR=0.78; 95% CI, 0.42 to 1.45, P=0.43). The corresponding 5-year OS was 89.6% in the surgery-first group and 81.9% in the neoadjuvant group. The 5-year DFS was 73.0 % for surgery-first group and 67.1% for neoadjuvant group. Similarly, no significant difference in locoregional (7.9% versus 11.9%) and distant (22.1% versus 21.6%) recurrence were observed between patients who received primary surgery and their matched group. Multivariate analysis showed that patients with stage IIIA (HR, 0.22; CI, 0.06 to 0.86) and younger than 60 years old (HR, 0.32; CI, 0.11 to 0.96) had increased overall survival from initial surgery.
Conclusion: Initial operation was feasible in inoperable LABC with limited locoregional involvement and gave satisfactory long-term survival. However, this report acknowledges the limitations inherent in experience of management of LABC from a single center.

P3-07-02: Sentinel node biopsy alone versus sentinel node biopsy plus axillary dissection in cT2 cN0/1 breast cancer patients after neoadjuvant chemotherapy: 15 year results of a prospective interventional trial

Gabriele Martelli, Rosalba Miceli, Francesco Barretta, Carlo Muzi, Chiara Listorti, Ilaria Maugeri, Federica Pilotta, Chiara Osio, Deborah Bonfili, Secondo Folli, Gianfranco Scaperrotta, Claudio Vernieri, Giulia Bianchi, Giancarlo Pruneri, Cristina Ferraris

Background: There is no consensus on axillary management after neoadjuvant chemotherapy (NAC) in patients with clinically node positive breast cancer downstaged to pN0 after NAC. We investigated whether sentinel node biopsy (SNB) alone is adequate axillary treatment if the sentinel nodes (SNs) are clear (pN0) in cN0/N1 breast cancer patients given SNB after NAC.
Methods: From January 2007 to December 2023 we recruited 486 cT2 cN0/N1 breast cancer patients, median age 48 years (IQR 42-57), scheduled for NAC, to a prospective interventional study (NCT04436809). If the SNs were pN0 after NAC, patients usually received no further axillary treatment (SNB only); if the SNs were pN1, axillary dissection (AD) was usually performed. Primary outcomes were overall (OS) and disease-free survival (DFS) in SNB only versus SNB + AD patients, assessed by weighted Kaplan-Meier and log-

rank test, after estimating propensity scores to account for bias due to non-random assignment to SNB versus SNB + AD.
Results: Median follow-up was 102 months (IQR 59-162 months) in the SNB only group and 200 months (IQR 168-213 months) in the SNB + AD group. OS and DFS did not differ significantly between the groups by propensity score weighted comparison: 15-year OS: 89.4% (95% CI: 81797.8%) in SNB only patients versus 77.8% (95%CI: 66.6-91.0%) in SNB + AD patients (p=0.241); 15-year DFS: 75.1% (95% CI: 65.3-86.5) versus 67.6% (95% CI: 55.0-83.0%; p=0.604), respectively. Of 177 patients cN1 downstaged to SN pN0, 132 had SNB only. None of the 132 SNB-only patients developed axillary relapse after a median follow up of 100 months (IQR 56-166 months).
Conclusion: This prospective interventional study shows that, in cT2 CN0/1 breast cancer patients whose SNs are pN0 after primary chemotherapy, SNB can be offered with no further axillary treatment given if the SNs are negative, irrespective of axillary status beforehand, without affecting OS or DFS.

P3-07-03: Real-world comparison of safety and effectiveness of dose dense (2-weekly) versus weekly paclitaxel given with trastuzumab as neoadjuvant treatment in HER2-positive early stage breast cancer.

Yael Berner-Wygoda, Eitan Amir, Chloe Perlon, Diego Malon, Michelle B. Nadler, Jacqueline Savill, Meredith Li, Massimo Di Iorio, Neha Pathak

Background: Traditionally, trastuzumab-based chemotherapy combinations used in HER2-positive early-stage breast cancer are delivered as 21-day cycles, either comprising weekly paclitaxel or 3-weekly docetaxel). In Ontario, Canada, an alternative dose-dense protocol allows the administration of 4 cycles of doxorubicin and cyclophosphamide (AC) followed by 2-weekly paclitaxel concurrently with trastuzumab over 4 cycles. Little is known about the effectiveness or safety of this schedule.

Methods: A single institution, retrospective chart review of patients with HER2-positive early-stage breast cancer treated with neoadjuvant AC-Paclitaxel chemotherapy between the years 2015-2019 was performed. Comparative effectiveness of AC followed by 2-weekly (dose dense) or weekly paclitaxel regimens was assessed as the proportion of patients achieving pathologic complete response (pCR). Safety was assessed as the proportion of patients completing the course of treatment and of patients with cardiac toxicity defined by the ESC guidelines. Differences between regimens were evaluated as the test of 2 proportions (Z-test). Statistical significance was defined as $p<0.05$.

Results: The initial analysis comprised 70 patients; 45 treated with 4 doses of paclitaxel 175mg/m2 every 2 weeks and 25 treated with 12 doses of paclitaxel 80mg/m2 weekly. Trastuzumab was given as an 8mg/kg loading dose and 6mg/kg maintenance dose, the latter either every 2 weeks or every 3 weeks based on paclitaxel schedule. The median age in the 2-weeks regimen was 54 years (30-77) and 55 years (35-71) in the weekly treatment.

The 2-weekly regimen demonstrated a pCR proportion of 68% (31/45), while for weekly treatment, pCR was observed in 40% (10/25). This difference was statistically significant (p=0.023). Treatment completion rates were 100% (45/45) for the 2-weekly group and 64% (16/25) for the weekly group (p<0.001). There were no differences in the cardiotoxicity profiles between the protocols (p=0.68). The 2-weekly regimen resulted in cardiotoxicity in 6% (3/45) of patients, moderate cardiotoxicity in 2% (1/45), and no cases of severe cardiotoxicity. The weekly regimen reported mild cardiotoxicity in 4% (1/25) of patients, no moderate cardiotoxicity, and severe cardiotoxicity in 8% (2/25).

Conclusion: In this retrospective study, both completion rates and pathologic complete response (pCR) rates were more favourable when AC was followed by 2-weekly paclitaxel/trastuzumab regimen compared to weekly paclitaxel/3-weekly trastuzumab. There was no difference between cardiac toxicity between the two schedules. An expanded dataset as well as an analysis of healthcare delivery costs, will be reported at the meeting.

P3-07-04: Postoperative upper Limb Edema & Dysfunction Generated by axillary nodes Excision w/ or w/out axillary vein branches reservation in breast cancer patients (PLEDGE-Surgery):a prospective,multiple-center,double-blinded, randomized controlled study

Xiangyun Zong, Yang Yu, Hongjian Yang, Xue Peng, Fen Tang, Wei Zhang, Ziwei Sun, Junhong Zhou, Fang Cheng, Kewei Sun, Qi Shao, Weiyun Pan, Yurong Zheng, Jiejie Hu, Chengdong Qin, Qianrui Xu

Background: Breast cancer-related lymphedema (BCRL) is a common complication after breast cancer treatment. The purpose of the study is to compare the effects of axillary lymph node dissection with or without axillary vein branches reservation on the incidence of postoperative upper limb edema and dysfunction in breast cancer patients.

Methods: The study was designed as a multicenter, prospective, double-blind, randomized, controlled clinical study, which was carried out in the following institutions: Shanghai Sixth People's Hospital, Shanghai Fengxian Central Hospital, and Zhejiang Cancer Hospital in China. Patients aged 18-69 years with breast cancer who were confirmed by histopathology and required axillary lymph node dissections before surgery were enrolled. Eligible patients were assigned to two groups to receive radical breast cancer surgery including axillary dissection by central stratified block randomization. The randomization table was generated by an independent statistician, and the random number was printed by the center. The allocation ratio was set at 1:2 in the study group and the control group. Participants, data collectors and data analysts were blinded, while surgeons will not be blinded in this study. In the control group, the axillary vein branches were routinely cut off during axillary dissection, while in the study group, they were preserved as much as possible. The primary endpoint of the clinical trial was the incidence of short-term(1-

month, 6-month and 12-month) upper limb lymphedema and dysfunction on the affected side after surgery. The secondary end points were tumor-free survival and the incidence of upper limb lymphedema and dysfunction at 5 years postoperatively. Data collection and initial analysis were conducted 6 months after all cases were enrolled and underwent planned surgical treatment. All intent-to-treat patients were included in the final follow-up and analysis. The trial was registered at ClinicalTrials.gov(NCT05120180) on January 3, 2022, closed to new participants on April 1, 2024.

Findings: From January 3rd, 2022 to April 1st, 2024, a total of 316 female breast cancer patients were recruited, 22 of whom were excluded because they did not meet the inclusion conditions. The remaining 294 patients received randomization, of which 36 patients voluntarily withdrew or did not continue to participate in the study plan due to meeting exclusion criteria. Finally, 258 patients completed randomization and received all planned treatments, including 87 in the intervention group and 171 in the control group. The average age of the patients was 52.81 ± 10.063 years, with a median age of 53 (47, 59) years. The physical state scores are all 0-1. One month after surgery, the incidence of upper limb edema in the intervention group and control group was 1/85 (1.18%) and 2/144 (1.39%), respectively, with no significant statistical difference(ARR 0.21%, Fisher's exact test, P>0.05, OR 0.845, 95% CI [0.075, 9.463]). The RR of upper limb edema in the intervention group was 0.897(95% CI [0.179, 4.483]), while the RR in the control group was 1.061(95% CI [0.474, 2.377]). Six months after surgery, the incidence of upper limb edema in the intervention group was significantly lower than that in the control group(0/59 (0%) vs. 11/102 (10.78%), ARR 10.78%, Fisher's exact, P=0.007, OR was not available). The RR of upper limb edema in the control group was 1.648(95% CI [1.449, 1.875]). At 12 months after surgery, the incidence of upper limb edema in the intervention group was significantly lower than that in the control group(1/42 (2.38%) vs. 11/68 (16.18%), ARR 13.8%, Fisher's exact, P=0.028, OR 0.126, 95% CI [0.016, 1.018]). The RR of upper limb edema in the intervention group was 0.199(95% CI [0.030, 1.320]); The RR in the control group was 1.576(95% CI [1.241, 2.002]). There were significant differences in upper limb dysfunction reported by patients and scored by researchers between the intervention group and the control group (DASH scores at 1, 6, and 12 months were 8.02 ± 2.983, 3.56± 2.611, 1.65± 1.881 in intervention group and 10.67 ± 3.756, 6.02± 3.422, 2.98± 2.439 in control group, respectively, analyzed using a general linear model). The DASH scores of each group decreased over time (Greenhouse Geisser, F=334.133， P=0.000) with similar trends(Greenhouse Geisser, F=0.954， P=0.371); The mean DASH scores of the intervention group were significantly lower than that of the control group (F=10.167, P=0.002). Both groups of patients did not experience any serious complications or deaths related to surgery. There were significant differences in the proportion of postoperative arm circumference changes between the intervention group and the control group (using a general linear model analysis, the proportion of arm circumference changes in the intervention group at 1, 6, and 12 months were 0.02 ± 0.022, 0.02 ± 0.019, and 0.02 ± 0.036, respectively, while the control group was 0.02 ± 0.028, 0.04 ± 0.041, and 0.04 ± 0.044). The

proportion of arm circumference increase in each group changed over time (Greenhouse Geisser, F=4.386, P=0.029) and the trend of change was different (Greenhouse Geisser, F=5.698, P=0.012）；The average increase in arm circumference in the intervention group was significantly lower than that in the control group (F=7.101, P=0.009).During the follow-up process, there were 2 deaths (2.30%) in the intervention group, who died from severe bone marrow suppression after chemotherapy (1/87, 1.15%) and fulminant hepatitis (1/87, 1.15%), respectively.

Interpretation: Lymphectomy with preservation of axillary vein branches is beneficial to reduce the short-term incidence of postoperative upper limb edema and upper limb dysfunction, which is worth promoting in breast cancer patients who need axillary lymph node dissection.

P3-07-05: An Application of the Air Inflation Adjustment Technique in Reverseâ€‘Sequence Endoscopic Nippleâ€‘Sparing Mastectomy with immediate breast reconstruction : A prospective cohort study

Kawun Chung, Zhongjian Zhu, Mengxue Qiu, Yanyan Xie, Faqing Liang, Qing Zhang, Hui Dai, Tianyuan Li, Xiaoman Cao

Background: One of the leading causes of suboptimal aesthetic outcomes following breast implant reconstruction is implant malposition, which is mainly caused by improper placement and fixation of the implant, pectoralis major muscle contraction after surgery, and the distribution of the skin and nipple-areola complex is not aligned with the position of the implant. Secondary or multiple surgeries are often required to correct the appearance of defects. Our center developed the air inflation adjustment technique (AIAT) by inflating air into the implant envelope with the patient in an upright position postoperatively to make the implant naturally align with the contralateral breast under gravitational influence, enhancing aesthetic outcomes. This prospective study aimed to evaluate the efficacy and safety of AIAT by comparing complications and aesthetic outcomes between patients who underwent AIAT or not (N-AIAT) after reverse-sequence endoscopic nipple-sparing mastectomy (R-E-NSM) with immediate breast reconstruction (IBR).
Methods: In this prospective, single-center, non-randomized study, we consecutively recruited women aged 18 years or older who underwent R-E-NSM with IBR at the Breast Center, West China Hospital, Sichuan University, between September 2020 and June 2023. Patients were divided into the N-AIAT and AIAT groups and were comprehensively

compared to surgical complications and early cosmetic outcomes. We conducted a prespecified risk-factor analysis using mixed-effect regression to investigate the relationship between surgery type and incidence of complication.
Results: A total of 323 patients were prospectively enrolled in the study, with 168 (52.0%) in the N-AIAT group and 155 (48.0%) in the AIAT group. Compared to the N-AIAT group, patients in the AIAT group demonstrated a shorter hospital stay, reduced costs, more significant breast ptosis, and a shorter median follow-up period ($P < 0.05$). After adjusting for clinical covariates, the AIAT group exhibited a significantly lower rate of deterioration in Ueda scores at 1 month (0.235 [95% CI, 0.067-0.831]; $P = 0.025$) and at 12 months (0.414 [95% CI, 0.222-0.772]; $P = 0.006$) post-surgery, compared to the N-AIAT group. Meanwhile, in both univariate and multivariate analyses, no significant differences were observed in the incidence of complications over three periods: 12 months postoperatively, within the first month, and between one and twelve months. Subgroup multivariate analysis further indicated that AIAT is more suitable for patients undergoing prepectoral implant-based breast reconstruction, unilateral implant reconstruction, and those requiring chemotherapy and radiotherapy.
Conclusion: AIAT is a safe, effective, straightforward, and easily applicable non-surgical technique that can significantly enhance postoperative aesthetic outcomes and effectively reduce the need for secondary surgery due to implant malposition, especially suitable for patients undergoing prepectoral implant-based breast reconstruction, unilateral implant reconstruction, and those requiring chemotherapy and radiotherapy.

P3-07-06: Axillary Lymph Node Dissection or Not Among Women with Breast Cancer and Sentinel Lymph Node (SLN) Metastasis in Upfront Surgery: A Meta-Analysis of Randomized Trials

André Mattar, Marcelo antonini, Francisco Pimentel Cavalcante, Felipe Zerwes, Eduardo de Camargo Millen, Fabrício Palermo Brenelli, Antonio Luis Frasson, Patrícia Baruel, Lucas Okamura, Luiz Henrique Gebrim

Background: In women with early breast cancer, axillary lymph node dissection (ALND), axillary radiotherapy (AR), and sentinel lymph node biopsy (SLNB) yield similar survival rates. In 2024, with the publication of a new clinical trial and updated data from previously published studies, an opportunity arises to update and pool the results on overall survival (OS), disease-free survival (DFS), and axillary recurrence (AxR). We conducted a systematic review (SR) and meta-analysis to compare and update the summarized effects of ALND versus AR and SLNB alone in upfront surgery.
Methods: This systematic review, registered with PROSPERO (CRD42024585305) and adhering to PRISMA guidelines, was driven by the following research question: In randomized controlled trials (RCTs), what are the outcomes of OS, DFS, AxR, and lymphedema when comparing SLNB alone with ALND or AR in women with cN0 early-stage breast cancer and 1-2 positive SLNs? A comprehensive search of Medline, Embase, and the Cochrane Central Register, covering 2010 to July 2024, was conducted using indexed terms

such as 'breast cancer,' 'RCT,' 'axillary radiotherapy,' and 'SLNB,' without language restrictions. Articles were retrieved, and data were extracted by two independent reviewers and validated by three experienced breast surgeons. Random-effects meta-analyses were performed using the DerSimonian and Laird method to calculate pooled risk ratios (RR) with 95% confidence intervals (CI) for all outcomes. Heterogeneity was assessed using I^2 values.
Results: A total of 2,462 papers were initially identified. After thorough review, 14 articles from 7 RCTs were included in the final analysis, representing 7,338 women with a mean age of 57 years, enrolled between 1999 and 2020, with follow-up periods ranging from 2.8 to 10 years. The 10-year OS did not differ significantly across RCTs, with a pooled RR of 1.02 (95% CI 0.98 to 1.06). Similarly, the 10-year DFS was comparable between the SLNB and ALND groups (RR = 1.0, 95% CI 0.95 to 1.06), as was regional recurrence (RR = 2.18, 95% CI 0.98 to 4.84). Lymphedema was significantly less frequent in the SLNB arm compared to the ALND arm (RR = 0.35, 95% CI 0.2 to 0.6).
Conclusions: This systematic review, including updated RCT data, demonstrates that SLNB, AR, and ALND provide comparable efficacy in reginal recurrence and survival outcomes. However, SLNB or AR is associated with a 65% lower risk of lymphedema compared to ALND, indicating that a more conservative approach could improve quality of life without compromising long-term survival or DFS in women with early breast cancer.

P3-07-07: 10-Year Local Recurrence Rates Following Selective Omission of Re-excision for Patients with Ductal Carcinoma in Situ and Margins

Cecily Stockley, Shiva Bahmanyar, Yuan Xu, Jeffrey Cao, May Lynn Quan, Alison Laws

Background: Current guidelines recommend ≥2mm margins for ductal carcinoma in situ (DCIS) with or without microinvasion to optimize local control following breast conserving surgery (BCS). There is some evidence to suggest it is acceptable to omit re-excision for "close" margins (i.e. not on-ink but <2mm), particularly when radiation therapy (RT) is planned. This study evaluates 10-year local recurrence (LR) rates following selective omission of re-excision in patients with DCIS and margins <2mm.

Methods: We conducted a retrospective population-based cohort study on patients undergoing BCS for DCIS with or without microinvasion from 2010-2014 in the province of Alberta. Final margin status was categorized as on-ink, <1mm, 1-1.9mm and ≥2mm. Given small sample size with on-ink margins, these were included with the <1mm group for analysis. As per provincial guidelines, use of RT boost was recommended for margins <2mm. The primary outcome was local recurrence of in situ or invasive disease in the ipsilateral breast. We generated Kaplan Meier curves and performed Cox proportional hazards analysis to evaluate the effect of margin status on LR. We used an interaction test to determine if the effect of margin status differed by RT use.
Results: 468 patients underwent BCS for DCIS with a median age of 59 years (IQR: 50.5-66). The majority were unifocal (n=409, 87.4%) with pure DCIS without microinvasion (n=424,

90.6%), and 51.5% (n=241) had grade 3 disease. Hormone receptor testing was not routine, but among tested patients, 88.9% were estrogen receptor (ER)-positive. The re-excision rate was 23.9% (n=112). Final margin status was on-ink in 13 (2.8%) patients, <1mm in 39 (8.3%), 1-1.9mm in 37 (7.9%) and ≥2mm in 379 (81.0%). Among those 89 patients with margins <2mm, most (94.4%) had only a single margin location <2mm. In 36 (40.4%) patients, the only margin that was <2mm was in the anterior or posterior location, and thus re-excision may not have been feasible. The majority (n=390, 83.3%) had adjuvant RT, whereas adjuvant endocrine therapy (ET) use was infrequent (n=43, 9.2%).

The only clinical characteristic that differed for patients with <2mm vs. ≥2mm margins was proportion of multifocality (20.2 vs. 10.8%, p=0.02). Otherwise, there was no significant differences in age, grade, pure DCIS vs. microinvasion, ER status, RT use (82.9% vs. 83.8%) or ET use (all p>0.05), including when those with only anterior/posterior margins <2mm were excluded from the <2mm group.

Median follow-up was 10.9 years (IQR: 9.8-12.3). 10-year rates of LR by final margin width were as follows: 23.0% (95%CI: 13.1-38.6) for <1mm, 8.8% (95%CI: 2.9-24.9%) for 1-1.9mm and 5.9% (95%CI: 3.9-8.9%) for ≥2mm (log-rank p<0.001). In Cox proportional hazards analysis, margins <1mm were associated with significantly higher risk of LR compared to margins ≥2mm (HR 4.22, p<0.001), while margins 1-1.9mm were not (HR 1.35, p=0.62). Results were unchanged when adjusting for multifocality (adjusted HR for <1mm margins = 4.16, p<0.001; adjusted HR for 1-1.9mm margins = 1.25, p=0.72), and also when those with only anterior/posterior margins <2mm were excluded from the <2mm groups.

There was no statistically significant interaction between margin status and RT use (p=0.52), though absolute LR rates were numerically higher in patients without RT: 18.9% (RT) vs. 46.4% (no RT) for <1mm, 6.7% (RT) vs. 25.0% (no RT) for 1-1.9mm and 6.0% (RT) vs. 5.5% (no RT) for ≥2mm.

Conclusion: For patients undergoing BCS for DCIS with or without microinvasion, our findings support that re-excision can be selectively omitted for limited volume 1-1.9mm margins, as the 10-year LR rates are comparable to margins ≥2mm when followed by adjuvant RT. However, we advise caution against omission of re-excision for margins <1mm given significantly higher rates of LR regardless of RT use.

P3-07-08: Breast-Conserving Surgery in US Young Women With Early-Stage, HR-Positive/HER2-Negative Breast Cancer: National Trends and Oncologic Outcomes after Neoadjuvant Systemic Therapy

Jincong Freeman, Jared H. Hara, Ted O. Akhiwu, Shreyas Kalantri, Adam W. Scott, Heather J. Hoffman

Background: In the United States, the incidence of breast cancer for young women has been rising in recent years. Neoadjuvant chemotherapy (NACT) or neoadjuvant endocrine therapy (NET) is often used to downstage tumors allowing for breast-conserving surgery

(BCS) among patients with early-stage, HR-positive/HER-negative breast cancer clinically. However, there is a paucity of data on BCS trends and associated treatment response and long-term survival as compared to mastectomy in the young patient population nationally.
Methods: We analyzed real-world data from the 2010-2020 National Cancer Database. This retrospective study was restricted to female patients aged <40 years with stage I-III, HR-positive/HER-negative breast cancer and included 2 treatment cohorts: NACT and NET. Surgery type was classified as mastectomy and BCS. Pathologic complete response (pCR) was defined as ypT0/Tis ypN0. We fit log-binomial regression models to assess trends in BCS and percent change per year (95% CI). Overall survival was event or censored at the time of death from all causes or last known patient contact. Estimated 5-year and 10-year probabilities of overall survival with 95% CIs were generated and compared using the Kaplan-Meier method and the log-rank test stratified by surgery type for both treatment cohorts.
Results: Of 4,561 patients treated with NACT, 35.0% underwent BCS, with a significant increasing trend from 31.0% in 2010 to 41.7% in 2020 (P for trend < 0.001; percent increase per year 2.6 [95% CI: 1.3-4.0]). Of 956 patients treated with NET, 33.7% underwent BCS and there was a significant increasing trend from 28.1% in 2010 to 44.1% in 2020 (P for trend = 0.001; percent increase per year 6.0 [95% CI: 2.6-9.5]). Young patients who achieved a pCR after NACT were more likely to have undergone BCS than those who did not (42.7% vs 33.9%; P < 0.001). Similarly, young patients who achieved a pCR after NET also had a greater likelihood of having undergone BCS than those who did not (46.9% vs 32.7%; P = 0.021). In the NACT cohort, compared to patients who underwent a mastectomy, those who underwent BCS had longer 5-year overall survival (89.9% [95% CI: 87.7-91.6%] vs 82.8% [95% CI: 81.1-84.5%]) and 10-year overall survival (80.1% [95% CI: 75.5-83.8%] vs 65.9% [95% CI: 62.1-69.5%]) (P < 0.001). In the NET cohort, patients who underwent BCS also had longer 5-year overall survival (93.3% [95% CI: 87.7-96.4%] vs 85.3% [95% CI: 80.9-88.8%]) and 10-year overall survival (91.0% [95% CI: 84.2-94.9%] vs 71.5% [95% CI: 62.6-78.6%]) than those who underwent a mastectomy (P = 0.002).
Conclusions: In this US national sample of young women with early-stage, HR-positive/HER-negative breast cancer, BCS rates increased significantly from 2010 to 2020, and achieving a pCR was associated with higher rates of BCS in both NACT and NET cohorts. Regardless of neoadjuvant treatment modality, young patients who underwent BCS had better long-term overall survival than those who underwent a mastectomy. Our findings highlight the benefit of neoadjuvant systemic therapy for BCS eligibility in young patients who achieve a pCR and improved survival among those who underwent BCS, which suggests the need for strategies to address disparities in treatment response and mortality. Etiologies of these disparities in the young patient population also require further investigation.

P3-07-09: Cost Differences of Hospital Admission vs. Home Recovery following Mastectomy

Leah Kim, Miranda Moore, Rachel Greenup, Donald Lannin, Tristen Park

Introduction: Home recovery (HR) after mastectomy promotes faster recovery and may improve patient experience. We examined the cost differences after mastectomy, comparing same day mastectomy discharge to inpatient admission amoung commercially insured women.
Methods: Merative MarketScan Commercial and Medicare Databases (2017-2019) were used to identify women ≥18 years old who underwent mastectomy. Mastectomy encounters were classified as home recovery (stays spanning a single calendar date) or inpatient stay (stays >1 calendar day) based on the length of the visit. Total payments (from both patients and insurers) for the mastectomy encounter were calculated by summing all paid claims falling within the start and end dates of the encounter. Payments were also summed separately for professional versus facility claims, and by patient versus insurer payments. Median costs were calculated stratified by home recovery status, and calculated by various encounter characteristics, such as patient region and occurrence of simultaneous breast reconstruction. Medians were compared between home recovery groups using rank-sum tests.
Results: Of 11,508 patients undergoing mastectomy, 4,683 (40.7%) were HR patients while 6,825 (59.3%) underwent hospital admission. Mean age of HR patients was 53.6 yo while admission patients was 51.8 yo ($p<0.001$). The mean length of stay for the inpatient group was 2.3 days. Overall, median total costs were significantly lower among women who underwent HR when compared to hospital admission ($23,173 vs $33,901, $p<0.001$); facility costs also differed ($16,721 vs $23,539, $p<0.001$) as well as professional surgical cost ($6,441 vs $7,962, $p<0.001$). The median cost difference was also present with simultaneous non-autologous reconstruction ($35,739 vs $41,028, $p<0.001$). Geographical location also affected median surgical costs: Northeast ($29,327 vs $41,233, $p<0.001$), North Central ($18,739 vs $28,455, $p<0.001$), South ($11,911 vs $32,819, $p<0.001$), and West ($23,912 vs $36,790, $p<0.001$). HR after mastectomy remained less costly than hospital admission regardless of Medicare ($7,322 vs $18,072, $p<0.001$) vs commercial insurance ($26,269 vs $34,691, $p<0.001$). The median 1-year all healthcare cost is less in the outpatient mastectomy group compared to admission group ($34,748 vs $38,410, $p<0.001$).
Conclusion: Following mastectomy, Home Recovery is associated with significantly lower costs when compared to hospital admission regardless of geographical region, simultaneous reconstruction, and insurance coverage. With fewer costs, faster recovery, and improved patient satisfaction, home recovery after mastectomy is a clinically and financially non-inferior alternative to conventional inpatient admission for the appropriate patient population.

P3-07-10: Omitting axillary dissection in Triple-negative and HER2-overexpressed cancers After neoadjuvant Chemotherapy: OTHER-NAC Study

Neslihan Cabioglu, Hasan Karanlik, Atakan Sezer, Abdullah Igci, Onur Dulgeroglu, Guldeniz Karadeniz Cakmak, Gunay Gurleyik, Mustafa Tukenmez, Suleyman Bademler, Mahmut

Muslumanoglu, Enver Ozkurt, Nilufer Yildirim, Umit Ugurlu, Selman Emiroglu, Cihan Uras, Vahit Ozmen, Bahadır Gulluoglu

Even though there is an increasing evidence of published reports that omitting axillary lymph node dissection (ALND) following sentinel lymph node biopsy (SLNB) in patients with clinically node positive breast cancer could be oncologically safe in selected patients, those especially with a good response to neoadjuvant chemotherapy, more data is needed for those patients with an agressive tumor biology with high recurrence risk. We therefore investigated the outcome in patients with triple negative or HER2-neu positive node positive breast cancer who were treated with SLNB alone without axillary dissection.
Material and Methods: Clinically node positive patients (cT1-4N1-3M0) with triple negative or HER2-positive breast cancer were included into the study from 9 centers. All patients were treated with SLNB alone without ALND after neoadjuvant chemoterapy (NAC) followed by regional nodal irradiation. The primary end points were the axillary, locoregional and systemic recurrence rates, and 5-year disease free (DFS) and disease specific survival (DSS) rates.
Results: Between 2010 and 2021, 259 patients underwent SLNB without ALND after NAC. The median age was 46 (range, 38-55). The majority of the cohort presented with cT1-2 (76.2%) and cN1 (81.5%) disease. Of those, 63.7% underwent breast-conserving therapy (BCT). The median lymph node number retrieved was 4 (IQR, 2-5). The pathologic complete response rate was 47.1%, whereas breast and axillary pCR rates were 49.8% and 78.4%, respectively. Of 56 ypN-positive patients, the lymph node metastases were macrometastases in 24 (42.9%), micrometastases in 21 (37.5%), and isolated tumor cells in 11 (19.6%). Of 259 cases, 88 (34%) had triple-negative breast cancer (TNBC), 106 (40.9%) had luminal HER2-positive, and 65 (25.1%) had non-luminal HER2-positive cancer. The median Ki67-level was 40 (IQR, 23-66). Patients with TNBC were more likely to have younger age <50 (68.2% vs 55%, p=0.04), BCT (72.7% vs 59.1, p=0.03), ypN0-disease (85.2% vs 74.9%, p=0.055), and increased Ki67 scores (median; TNBC: 60, IQR, 40-80, vs HER2+: 35, IQR, 20-55, p<0.001) compared to patients with HER2-positive tumors. As expected, patients with non-luminal cancers were more likely to have higher Ki67 scores (median; non-luminal: 50, IQR, 30-75, vs luminal: 30, IQR, 20-50, p<0.001), higher pCR (52.9 vs 38.7, p=0.024), and axillary pCR (86.3% vs 67.0%, p<0.001) rates compared to those with luminal tumors.
At a median follow-up time of 46 months (IQR, 34-63), the axillary, locoregional, and systemic recurrence rates were 0.8% (n=2), 2.7% (n=7), and 7.7% (n=20), respectively. Since the present cohort consisted of selected patients who had a clinically excellent axillary response to chemotherapy, the advanced cT-stage (cT3-4) was the only significant factor associated with decreased DFS and DSS (DFS: cT1-2, 92.1% vs cT3-4, 75.3%, p=0.002).
Conclusion: Omission of axillary dissection could be safely considered in clinically node-positive patients with an aggressive tumor pathology with low locoregional recurrence rates as long as a good response to neoadjuvant chemotherapy has been achieved and effective local therapies including adjuvant radiotherapy in addition to the systemic therapies have been provided.

P3-07-11: Avoidance of axillary lymph node dissection in patients with 1-2 pre-operative positive lymph nodes undergoing upfront surgery: 'Primary targeted axillary dissection' early outcomes

Radhika A Merh, Jennifer Rusby, Marios Konstantinos Tasoulis, Katherine Krupa, Rachel O'Connell, Gerald Gui, William Allum, Victoria Sinnett, Julie Scudder, Peter Barry

Introduction: NCCN guidelines support safe omission of axillary lymph node dissection (ALND) in clinically node negative (cN0) patients with 1-2 positive sentinel lymph nodes (SLNs) if they meet the eligibility criteria of ACOSOG Z0011 and AMAROS trials. For patients undergoing neoadjuvant systemic anti-cancer therapy (SACT), targeted axillary dissection (TAD) is recognised as a highly accurate technique to spare patients ALND whose cN+ status converts to ypN0.
However, there is no consensus on the optimal management of patients with low volume cN+ disease undergoing upfront surgery with ASCO guidelines recommending ALND and NCCN guidelines supporting primary TAD. In this context, 'primary TAD' combines these principles to de-escalate axillary surgery in patients with ultrasound-detected abnormal or biopsy-proven 1-2 positive lymph nodes (cN1) that are clipped for removal in combination with SLN biopsy to optimise further axillary surgical decisions. This method evolved after biopsy-proven involved nodes were missed during planned ALND.
Aims
To evaluate the early outcomes of primary TAD in a single high volume tertiary cancer unit in the United Kingdom (UK).
Methods
A prospective database of the first 126 patients ≥ 18 years with cT1-2cN1 undergoing primary breast surgery either as breast conserving surgery or mastectomy with primary TAD between 30/08/2018 and 12/03/2024 at the Royal Marsden NHS Foundation Trust was evaluated. We define primary TAD as removal of 1-2 marked axillary nodes using Magseed, either biopsy-proven or suspicious on axillary ultrasound scan but indeterminate biopsy, combined with SLN mapping with the use of Tc99m / SPIO / Patent Blue V. The clipped node(s) were sent to histopathology (as already known to contain disease), and additional SLNs underwent intra-operative assessment using one step nucleic acid (OSNA). If a total of 3 positive nodes (including marked nodes + those with macrometastasis on OSNA) were confirmed, the patient underwent completion ALND in the same operative sitting. If only 1-2 nodes, total from marked nodes and OSNA, contained macrometastatic disease, the patient was spared ALND and offered regional nodal irradiation (RNI). Patient demographics, tumor characteristics, treatment details and outcomes including breast and/or axillary recurrence, distant recurrence and overall survival were assessed. Descriptive statistics were used to report results.
Results
A total of 125 women and 1 man underwent primary TAD. The median age at surgery was 60.5 years. The majority of tumors (109/126) were hormone positive (HR+) and HER2 negative (86.5%), with 78/126 of the luminal A subtype (61.9%) and cT2 with a median tumor size of 24mm (IQR 17-34.8). Pre-operatively, 24/126 (19%) had suspicious nodes

unproven on biopsy, 1 abnormal and proven axillary metastatic node was detected in 74/126 (58.7%), and 2 abnormal with 1 biopsy-proven node in 28/126 (22.3%). Clipped node(s) were successfully removed in 125 patients. A median of 3 non-Magseed SLNs were excised for OSNA, of which median 0 (IQR 0-1) were positive. Of 126 patients, 121 (96%) had axillary metastatic Magseed node(s), 97 (77%) avoided ALND, 27 (21.4%) underwent immediate ALND, 2 (1.6%) underwent delayed ALND post SACT. Out of 126, 65 (51.6%) patients underwent RNI. Median follow-up was 21.2 months (IQR 11.2- 35.8); 1 patient developed axillary recurrence requiring further axillary surgery, no patients developed breast recurrence, and 3 patients developed and died of distant metastasis.
Conclusion
Primary TAD is feasible with reassuring early oncological outcomes but long-term follow-up is required. This method can be utilised to optimise axillary surgery in suitable patients to safely facilitate omission of routine ALND.

P3-07-12: Breast-conserving surgery versus mastectomy in patients with locally advanced breast cancer.

Alexander Petrovsky, Viktoria Amosova, Oxana Trofimova, Mona Frolova, Alexey Rumyantsev, Elena Artamonova

Objective: Contemporary treatment strategies for locally advanced breast cancer (LABC) involve a multimodal approach that combines systemic and local treatments. However, the role of breast-conserving surgery (BCS) in locally advanced breast cancer following NAT remains uncertain.
Materials and methods: This study was a retrospective cohort study of 874 consecutive patients with LABC who received NAC and underwent BCS or mastectomy from Jan 2000 to Dec 2020in N.N. Blokhin National Cancer Research Center. Of these, 179 patients (21%) underwent BCS, while 695 patients (79%) underwent mastectomy. Outcomes examined included overall survival(OS), disease-free survival (DFS), and loco-regional recurrence rates (LRRs). The variables were compared using log-rank statistics and Cox regression model.
Results: The 3-years DFS was 92,2% in the BCS group and 90,7% in the mastectomy group (p = 0,41). In univariate analysis age of patients, size of tumor, clinical T stage, tumor grade, pCR, triple-negative subtype were significant variables related to DFS and were included in the multivariable analysis, type of breast surgery was also included in the multivariable analysis as a candidate factor. Multivariable Cox regression analysis showed that pCR (OR 0,523; 95% Cl: 0,382-0,715; p<0,001), triple-negative disease (OR 2,299; 95% Cl: 1,543-3,427; p<0,001), clinical T stage (OR 0,987; 95% Cl: 0,962-1,009; p=0,004) were independent predictors of DFS, but type of breast surgery was not independent predictors (p = 0,391).
LRR rate was 5.8% (10/179) for BCS and 10.2% (71/695) for mastectomy (p=0,061, OR 0,567; 95% CI: 0,292-1,099). Univariate analysis showed that triple-negative subtype was associated with a worse LRR-prognosis (p=0,011). Multivariate analysis also showed an

independent negative effect of triple-negative subtype (OR 2,367; 95% CI: 1,154-5,134; p=0,023) and tumor grade (OR 1,32; 95% CI: 0,963-1,809; p=0,085).
The 5-years OS was 94,8% in the BCS group and 92,8% in the mastectomy group (p = 0.667). Univariate analysis showed that OS was related to age of patients, tumor grade, PR and ER status, clinical T stage, ki-67, molecular subtypes and pCR. Type of breast surgery was non-significant variables in univariate analysis, but also included in the multivariable analysis as a candidate factor. Multivariable Cox regression analysis showed that triple-negative disease (OR 3,581, 95% CI: 2,017-6,354; p<0,001) and pCR (HR 0,387, 95% CI: 0,253-0,593; p<0,001), but type of breast surgery was not independent predictors.
Propensity-score analysis was performed for 179 BCS and 358 mastectomy patients. In univariate analysis 3-year local relapse free survival was 97,3% (95% CI 95,7-99,1%) for BCS group and 98,8% (95% CI 97,2-100,0%) for mastectomy group. 3-year OS for BCS group was 97,2% (95% CI 95,5-98,9%) and 97,2 (95% CI 94,8-99,7%) for mastectomy group (p = 0,834).
Conclusion: Our findings suggest that BCS is oncologically safe in LABC patients. The recurrence and survival outcomes are comparable with BCS and mastectomy. BCS can be performed in selected patients with small tumor size and good response to NAT.

P3-07-13: Preoperative Predictors of Nodal pCR for Potential De-escalation of Axillary Surgery in Inflammatory Breast Cancer

Jennifer Chen, Salyna Meas, Becky S. Slack Tidwell, Vanessa N. Sarli, Joshua Upshaw, MDACC Inflammatory Breast Cancer Team, Savitri Krishnamurthy, Vicente Valero, Rachel M. Layman, Azadeh Nasrazadani, Susie X. Sun, Bora Lim, Wendy A. Woodword, Anthony Lucci

Background: Despite successful de-escalation of aggressive surgical management for invasive breast cancer, similar efforts in inflammatory breast cancer (IBC) have been unsuccessful thus far. We sought to identify predictors of nodal pCR in IBC patients for whom future clinical trials of de-escalation of surgery might be considered.
Methods: This was a retrospective analysis of stage III IBC patients enrolled in a prospective registry from 2007-2023 at University of Texas MD Anderson Cancer Center. All patients underwent mastectomy and axillary lymph node dissection. pCR was defined as no invasive residual carcinoma in the resected breast specimen and all sampled regional lymph nodes (ypT0/Tis ypN0 per AJCC staging). ER- and PR-positivity was defined by staining of ≥ 1% of tumor nuclei by immunohistochemical staining. Student's t-test and chi-squared test were used to compare group differences. Univariate logistic regression was performed to identify predictors of pCR and multivariate logistic classification and regression tree (CART) was performed to investigate joint effects on pCR status and determine optimal cut-off points for predictors.
Results: Of the 290 patients included, median age was 52.0 years (IQR 44-61) and BMI was 31.0 kg/m2 (IQR 26.7-34.8). Patients were predominantly White (227, 78.3%), followed by Hispanic (36, 12.4%), and Black (17, 5.9%). The majority of patients were postmenopausal (175, 60.3%) with node-positive (275, 94.8%), ductal (259, 89.9%), and high grade (197,

67.9%) disease. Receptor subtypes were 39.3% (114) HR+/HER2-, 24.8% (72) triple negative, 19.7% (57) HR-/HER2+, and 16.2% (47) HR+/HER2+. Distribution of HR expression consisted of 52.1% ER+ (52.1%, 151) with 9.3% (27) ER-low (1-10%) and 36.2% (105) PR+ with 10% (29) PR-low (1-10%). The majority of patients had Ki-67 ≥ 20% (177, 92.2%), with a median of 50.0% (IQR 30.0-75.0). Almost all patients received trimodality therapy – neoadjuvant systemic therapy (289, 99.7%), modified radical mastectomy (271, 93.4%), and adjuvant radiotherapy (283, 97.6%). Patients were more likely to achieve pCR if they were ER- (pCR 50% vs. 23%, $p < 0.0001$) with lower ER% (median 0% vs. 30%, $p < 0.0001$), PR- (pCR 46% vs. 19%, $p < 0.0001$) with lower PR% (median 0% vs. 0.5%, $p < 0.0001$), HER2+ (pCR 48% vs. 28%, $p = 0.001$), or had higher Ki-67 (median 60% vs 45%, $p = 0.003$). Four iterations of CART analysis were performed, the first two using ten predictor variables – BMI, race, menopause status, AJCC stage, nodal status, ER and PR (status or %), HER2 status, grade, and tumor histology, the third using Ki-67 alone, and the fourth using Ki-67 with ER and PR %. When HR status was considered as a dichotomous variable, ER- status was the strongest predictor of pCR, followed by non-White race, PR-, and HER2+ status. Patients who were ER- and non-White had the highest pCR rate of 73.5% while those who were both ER+/PR+ had the lowest pCR rate (16.0%). Repeat CART analysis including HR status as a continuous variable identified a cutoff point of ER < 41% as predictive of pCR (48.8% vs. 15.2% when ER ≥ 41%). Additional CART analysis of Ki-67 alone identified a cutoff point of ≥ 35.7% as predictive of pCR (43.0% vs. 16.4% when Ki-67 < 35.7%).
Conclusion: We identified six potential predictors of nodal pCR in stage III IBC using CART analysis – ER negative, PR negative, and HER2-positive status, ER < 41%, non-White race, and Ki-67 ≥ 35.7%. These factors could be used to select appropriate patients for future trials of de-escalation of axillary surgery in patients with IBC.

P3-07-14: Omitting axillary dissection in Triple-negative and HER2-overexpressed breast cancers with positive sentinel Lymph nOdes during upfront surgery: OTHELLO Study

Neslihan Cabioglu, Hasan Karanlık, Vahit Ozmen, Mustafa Tukenmez, Abdullah Igci, Yusuf Emre Aytin, Hande Koksal, Halime Mutlu, Selman Emiroglu, Mahmut Muslumanoglu, Cihan Uras, Enver Ozkurt, Nilufer Yildirim, Suleyman Bademler, Onur Dulgeroglu, Atakan Sezer, Guldeniz Karadeniz Çakmak, İsmail Zihni, Bahadır Mahmut Gulluoglu

Background: Prospective trials including ACOSOG Z011 or SENOMAC have shown no survival benefit of completion axillary dissection in patients with clinically node negative early breast cancer in the presence of 1 or 2 positive sentinel lymph nodes (SLNs). However, these studies mostly included patients with hormone receptor-positive breast cancer, but limited number of patients with aggresive tumor biology. Therefore, we investigated the oncological safety of omitting axillary dissection in selected patients with HER2-positive or triple-negative breast cancer (TNBC).

Method: The present retrospective cohort study included patients with clinically node-negative breast cancer who were treated with sentinel lymph node biopsy (SLNB) alone in the presence of 1 or 2 positive nodes and triple-negative or HER2-positive breast cancer. Patients with clinically node-positive breast cancer, receiving neoadjuvant chemotherapy, with axillary dissection or a lymph node pathology without any metastasis, any systemic metastasis were excluded from the study. All patients received regional nodal irradiation.The primary end points were axillary and locoregional metastases and disease free (DFS) and disease specific survival (DSS).
Results: Between 2015 to 2020, 118 patients with triple negative- or HER2-positive breast cancer were included into the study from 8 centers. Median age was 53 (34-73). Of those, patients with cT1, cT2, or cT3 were 37.3% (n=44), 57.6% (n=68) and 5.1% (n=6), and 72% (n=85) underwent underwent breast conserving surgery. The majority of the patients had invasive ductal cancer (n=109, 92.4%), and grade 3 tumors (n=85, 72%). The pathological subgroups were triple-negative in 33% (n=39), and luminal HER2-positive in 51.7% (n=61), and non-luminal HER2-positive in 15.3% (n=18). The majority of the patients (n=98, 83.1%) had 1 metastatic lymph node in SLNB. The lymph node metastases were macrometastasis in 50% (n=59), micrometastasis in 36.4% (n=43), and isolated tumor cells in 13.6% (n=16). At a median follow-up of 53 months (34-73), the locoregional recurrence rate was 2.5% (n=3), and the systemic recurrence rate was 11.9% (n=14) without any axillary recurrence. The 5-year disease free and disease specific survival rates were 86.4% and 88.0%. In cox regression analysis, factors associated with increased hazard ratio (HR) for DFS were cT2-3 (HR=7.77,1.01-59.54), and TNBC (HR=3.87, 1.01-14.81). Similarly, presence of TNBC was the only significant factor associated with increased HR for DSS (HR=9.61, 95% CI, 1.11-83.24).
Conclusion: Patients with cN0 HER2-positive and TNBC disease treated with upfront SLNB-alone with 1-2 lymph node metastases have shown a favorable outcome with excellent local control with omitting ALND as long as regional nodal irradiation is provided.

P3-07-15: VARIATION IN PRACTICE AND PROVISION OF CONTRALATERAL SYMMETRISING MASTECTOMY AFTER UNILATERAL MASTECTOMY FOR BREAST CANCER: A UK NATIONAL PRACTICE SURVEY

Katherine Fairhurst, Cora Griffin, Sam Brunsden, Shelley Potter

Background: Up to 40% of the 56,000 women diagnosed each year in the UK undergo mastectomy and NICE recommend that breast reconstruction is routinely offered to restore symmetry. While not all women want or are suitable for reconstruction, most desire symmetry. For these women, a contralateral mastectomy to achieve 'flat symmetry' is a good option. While breast reconstruction is routinely offered, however, contralateral symmetrising mastectomy (CSM) is not and lack of equity in service provision has been raised as a concern.
We aimed to survey current UK practice and provision of CSM as an alternative to breast reconstruction for women undergoing unilateral mastectomy for breast cancer as the first

step to improving equity of access for this group.
Methods: An online survey was co-developed with patient advocates based on the literature and expert opinion. The survey explored the existence and components of current pathways for women seeking CSM, any local policies regarding the offer of and funding for CSM, professionals involved in the process and the information/support provided. It was circulated between July 2023 and May 2024 via social media and UK professional breast surgery associations with one survey completed per unit. Simple descriptive statistics were used to summarise results and content analysis for free text.
Results: 51 units completed the survey, including both small and large volume units (median number of cancers treated per year 401-600) with good geographical spread across the UK. Most units (n=45, 88.2%) reported experience managing women requesting CSM and commonly (n=33, 64.7%) estimated receiving 10 or fewer CSM requests per year. Less than 10% (n=4) units reported routinely discussing CSM as an option with patients and most units (n=36, 70.6%) only discussed symmetrising mastectomy if it was specifically raised by the patient. Funding for CSM was routinely available in most units (n=39, 76.5%). Just over a quarter of responding units (n=14, 27.5%) reported having a formalised pathway for the management of women seeking CSM. These varied widely in their requirements and included a combination of discussion at multidisciplinary team meetings (n=12, 85.7%), referral to psychology services (n=7, 50%) and/or plastic surgery (n=10, 71.4%) and/or inclusion of a cooling off period (n=7, 50%), but most had been developed exclusively by breast surgeons with little multidisciplinary involvement. None had involved patients. Units without pathways reported managing patients on a case-by-case basis. These units often still reported having a 'cooling off' period of between 6-12 months after completion of active treatment. Very few units (5.9%, n=3) said they would perform CSM at the time of the index mastectomy. Information and support for women seeking CSM was also variable. Respondents expressed concerns about decisional regret, a reliance on psychologist input, variation of practice, and a desire for standardised guidance to improve equity of access to CSM.
Conclusions: There is significant variation in the practice and provision of CSM in the UK resulting in a lack of equity in access to care which urgently needs to be addressed. This is as a UK research priority. The UK FLAME study (Co-development of an evidence-based pathway to improve access and outcomes for women seeking FLat symmetry and an Alternative to breast reconstruction after Mastectomy for brEast cancer) aims to use qualitative interviews with patients and professionals to explore experiences, concerns, and attitudes to CSM including timing of surgery, support required and views on potential pathways of care. This work will underpin development of consensus-based guidelines co-developed with patients to support professionals to equitably offer CSM as a valid alternative to breast reconstruction.

P3-07-16: Validation of a Novel Prognostic Staging System for De Novo Metastatic Breast Cancer: A Real-World Experience

Ibrahim Khamees, Himil Mahadevia, Kensey Gosch, Parth Sharma, Simran Chandra, Shelby Davis, Kelly Gast, Timothy Pluard, Whitney L Hensing

Background: De novo metastatic breast cancer (dnMBC) comprises 6–10% of new breast cancer diagnoses and 30% of metastatic breast cancers (MBC), with varying survival rates. The latest AJCC staging system integrates anatomic factors, including the tumor size, nodal status, and metastasis sites, and non-anatomic factors, such as biomarker status and tumor grade, to assign the prognostic stage. Based on this staging system, all patients with MBC are assigned to stage IV. Plichta et al. utilized a statistical approach from large population data sets to a novel staging system for dnMBC, stratifying patients with dnMBC into four prognostic stages (IVA-D) based on relevant clinical and pathologic variables, such as HER2 status and sites of metastasis at diagnosis. In this study, we presented an updated analysis aiming to validate this new staging system in an independent real-world population of patients with dnMBC.

Methods: This study utilized data from a retrospective cohort of patients with dn[GKL1] MBC who received treatment at the Koontz Center for Advanced Breast Cancer Center (KCABC) at St. Luke's Cancer Institute. The KCABC is one of few centers dedicated solely to caring for patients with MBC. These patients were grouped into prognostic stage IVA, IVB, IVC, and IVD according to the system designed by Plichta et al., JCO 2023. Overall survival (OS) was compared between groups using Kaplan-Meier analysis and the log-rank test. Given the association between age and survival, we performed a stratified analysis based on age <60 versus ≥60 years.

Results:131 patients with dnMBC were included in the analytic cohort. The mean age at diagnosis was 56.1 years, and most patients identified as either white (74.0%) or black (21.4%). 12 patients were assigned stage IVA (9.2%), 50 stage IVB (38.2%), 52 stage IVC (39.7%) and 17 stage IVD (13%). Most stage IVA dnMBCs were hormone receptor-positive (HR+), HER2-positive (triple-positive) (66.7%), most stage IVD dnMBCs were triple-negative (70.6%), and the majority of stage IVB-C were HR+, HER2-negative (74.5%). OS differed significantly between the four stage groups, both in the overall population (log-rank $p<0.0001$) and when patients were stratified by age at diagnosis (≥60 or <60) (both log-rank $p<0.05$). The overall population's overall 5-year survival rates were 88.9%, 68.4%, 49.5%, and 8.6% for patients with dnMBC stages IVA, IVB, IVC, and IVD, respectively.

Conclusions: The novel prognostic staging system that integrates subtype, grade, T stage, and sites of metastasis was able to stratify our real-world cohort of patients with dnMBC into four prognostic groups. These findings demonstrate the utility of this staging system in determining prognosis for patients with dnMBC.

P3-07-17: Adjuvant Therapy in Patients with Positive Lymph Nodes Post-Neoadjuvant Chemotherapy With and Without Axillary Lymph Node Dissection

Anthony Baez, Caitlin Marsh, Acacia Sharma, Alyssa Marmer, Lindsay Chevlin, Charles Dimaggio, Deborah Axelrod, Amber Guth, Freya Schnabel, Mary Gemignani

Introduction: The current standard of care for breast cancer patients with pathologic lymph node positivity (pN+) after neoadjuvant chemotherapy (NAC) is completion axillary lymph node dissection (ALND). However, recent data suggests a shift in patterns of care to less than standard surgical therapy. The aim of our study is to compare adjuvant treatment of patients with pN+ disease after NAC who underwent completion ALND with those who had sentinel lymph node biopsy (SLN) alone.
Methods: Retrospective review of IRB-approved prospective database was performed to identify patients with invasive breast cancer treated with neoadjuvant chemotherapy from 1/2010 to 12/31/2023. Clinical, pathologic and treatment data was collected and the Chi-square test was used to compare patients with pN+ disease undergoing ALND vs SLN only.
Results: Our study group consisted of 374 patients who received NAC and 148 (39.6%) had pN+ disease. There were no significant differences in age (p=0.379), gender (p=1.000), or histologic subtype (p=0.270) between patients with pN+ disease and those with no nodal disease (pN-). Patients with pN+ disease had larger tumors at diagnosis compared to pN- patients (2.60 cm (SD 2.20) vs 1.89 cm (SD 1.84), p=0.002). Treatment data was available for 138 patients with pN+ disease. Among these, 8 (5.8%) had SLN surgery only, while the remaining underwent ALND.
Patients with pN+ undergoing ALND, had higher rates of mastectomy compared to those who had SLN-only (76.1% vs 25%, p=0.002) resulting in a statistically significant difference in the rates of PMRT and WBRT between these groups (p=0.006). However, the rates of regional nodal irradiation were similar (SLN-only, 87.5% vs ALND, 84.6%, p=0.716). In addition, the SLN-only group had a mean of 1.4 (SD 0.5) positive nodes compared to a mean of 4.4 (SD 4.2) positive nodes in the ALND group, likely representing a larger burden of residual disease.
Conclusion: In our study group, we noted that most patients with positive nodes after NAC were treated with ALND. In the small subset of patients who had SLN only, no difference in adjuvant regional nodal irradiation was noted. Data regarding the equipoise in treatment of radiation (RT) only vs ALND/RT is forthcoming and warranted.

P3-07-18: Sacituzumab Govitecan in Metastatic Breast Cancer: Impact of Age and BRCA Mutational Status in a Real-World Cohort

Laurys Boudin, Anthony Gonçalves, Frederic Viret, Louis Tassy, Lucas Usclade, François Bertucci, Alexandre de Nonneville

Background: Sacituzumab Govitecan (SG) is an antibody-drug conjugate targeting Trop-2, showing efficacy in HER2-negative metastatic breast cancer. We assessed the real-world efficacy of SG, focusing on the impacts of age and BRCA mutation status on survival outcomes.
Methods: This retrospective cohort study included 97 female patients treated with SG at the Paoli-Calmettes Institute French Comprehensive Cancer Center from May 2021 to October 2023. Patient demographics, BRCA mutation status, hormone receptor (HR) status, HER2 expression, metastatic sites, treatment lines, and dose reductions were recorded. Progression-free survival (PFS) and overall survival (OS) were analyzed using univariate and multivariate analyses to identify significant predictors of treatment outcomes.
Results: The cohort had a median age of 60 years, with 24% aged 70 or older. TNBC was predominant (65%), and 11.3% had BRCA mutations. The median number of previous lines received in the metastatic setting was 3 (range 0 to 12). The median PFS was 2.8 months, and the median OS was 8.1 months. SG dose reductions were more frequent in patients ≥ 70y than in patients < 70 years (52.2% vs. 23%; p=0.008), but no age-related difference was observed in survival analyses with mPFS of 2.8 months in patients ≥70y vs. 2.7 months (p=0.072, log-rank test), and mOS of 7.8 months in patients ≥70y vs. 8.3 months (p=0.579). No difference in grade 3-4 toxicity prevalence was observed according to age (26.1% in ≥70y vs. 14.9%; p=0.216). mPFS and mOS for patients with and without BRCA mutations were 2.2 vs. 2.8 months (p=0.157), and 3.9 vs. 8.3 months (p=0.026), respectively. In multivariate analyses including HR and BRCA statutes, age was not associated with PFS or OS. While BRCA mutation did not independently affect PFS, it did have a significant negative impact on OS (HR 2.48 [95CI 1.01-6.11; p=0.047]).
Conclusions: SG demonstrates similar relative efficacy across different age groups of heavily pretreated patient without increased toxicity in the elderly population. This study highlights the need for further research into BRCA mutation-related cross-resistance mechanisms, which could inform future treatment strategies for BRCA-mutated metastatic breast cancer. These real-world data support SG's use in patients aged 70 or over.

P3-07-19: Survival Outcomes in Breast Cancer with Brain Metastasis Based on Prior Lines of Systemic Therapy for Metastatic Disease

Harkarandeep Singh, Myla Strawderman, Ruth M. O'Regan, Nimish A. Mohile, Carey K. Anders, Sarah Sammons, Allison Magnuson, Anna Weiss, Ajay Dhakal

Background: Breast cancer brain metastases (BCBM) are often associated with short survival. However, specific prognostic factors for patients with BCBM are poorly understood. This single institution retrospective study compares Overall Survival (OS) in

patients with BCBM based on number of lines of prior systemic therapy (ST) for metastatic (M) BC at the time of their BCBM diagnosis.
Methods: This study included patients with BCBM, diagnosed from Jan 2010 to June 2021. Patients were classified into Early BM [BCBM that developed either de-novo (at the time of MBC diagnosis) or during 1st line of ST] and Late BM (BCBM that developed during or after 2nd lines of ST for MBC). Baseline characteristics were compared using Fisher's Exact & Wilcoxon Rank-sum tests. OS was estimated using Kaplan Meier methods and compared using Log Rank test. Important covariates were adjusted for using Cox-regression model.
Results: 123 BCBM patients were identified and divided into Early BM (n=83) and Late BM (n=40) groups.30% of Early BM were HR+/HER2- vs 60% of Late BM (p=0.005). 47% of Early BM had visceral metastasis vs 75% of Late BM (p=0.0004). Other baseline variables were not significantly different between the groups. Median OS (years, 95% CI) for Early BM was 2.8 (1.6-4.6) vs. 0.5 (0.4-1.5) for Late BM (p=<0.0001). In a Cox regression model, Late BM was associated with significantly higher risk of death vs Early BM [Hazard Ratio (95% CI) 2.246 (1.311-3.850)]. Older age, triple negative subtype (vs HR+/HER2- or HER2+) and worse performance status were also significantly associated with shorter OS. A reduced cox model for all factors significantly associated wtih OS obtained using a backward elimination procedure showed similar HR estimates.
Conclusion: This single institution study showed that OS in BCBM patients was significantly associated with number of prior line of systemic therapy for MBC at the time of diagnosis of BM. If validated, these results could provide important prognostic information for BC patients with BM.

P3-07-20: New Wine in Old Bottles - The Therapeutic Promise of the PARP Inhibitor Rucaparib as an N-WASP Inhibitor for Breast Cancer Metastasis

Rhiannon Yannan Yu, Q Ping Dou, Elyas Khan, Wen G. Jiang, Tracey A. Martin

Background: Rucaparib is an established PARP inhibitor known for its efficacy in treating BRCA-mutated cancers. Recent studies suggest its potential utility in targeting additional pathways involved in oncogenesis and metastasis, such as those mediated by the N-WASP proteins, which are essential in cell motility and invasiveness. This study investigates Rucaparib's capability to act beyond PARP inhibition by targeting N-WASP proteins, offering a novel approach to curb cancer metastasis.
Methods: Utilizing two breast cancer cell lines, MDA-MB-231 and MCF-7, along with HECV, an endothelial cell line, comprehensive in vitro biological assays included cytotoxicity tests, cell growth assay, Electric Cell-substrate Impedance Sensing (ECIS), wound scratch assay, immunofluorescence, qPCR and western blotting were conducted, to discerning Rucaparib's effects on cell proliferation, adhesion, motility, and its specific impact on N-WASP protein expression at both mRNA and protein levels. Chemical-target protein docking was carried out by computer-assisted modelling.
Results: The impact of Rucaparib on cellular dynamics was profound across the studied cell lines. Growth assays showed a statistically significant decrease in cell growth (P=0.0054,

P=0.0034, P<0.0001). Rucaparib effectively impaired the ability of cancer cells to adhere and migrate (P<0.0001, P=0.0214, P=0.0003). Rucaparib markedly decreased the RNA and protein levels of N-WASP (P=0.0019, P<0.0001, P<0.0001), indicating a potent inhibitory effect on this metastasis-related protein. These results not only reinforce Rucaparib's inhibitory role in essential cellular processes but also highlight the potential to disrupt mechanisms underlying metastatic progression, especially N-WASP, a key regulator of cytoskeletal reorganization. Finally, compound docking revealed that Rucaparib had an excellent binding profile with multiple amino acids of key domains of N-WASP protein. Conclusion: The study validates Rucaparib's potential as a multifaceted inhibitor, demonstrating substantial efficacy in inhibiting N-WASP protein expression, thereby reducing tumour cell proliferation, adhesion, and migration. It highlights Rucaparib's prospective role as a dual-action therapeutic in the management of metastatic breast cancer, presenting a promising avenue for further clinical exploration.

P3-07-21: Transcriptomic analysis of the tumor immune microenvironment (TIME) in patients with breast cancer with liver metastasis (BCLM)

Jiayi Tan, Weihua Guo, Bryan Chan, Cynthia Mark, Jin Sun Bitar, Shikha Bose, Vivek Pujara, Moray Campbell, Stephen Lawrence Shiao, Yuan Yuan

Background: Breast cancer with liver metastasis (BCLM) is a significant predictor of worse prognosis and poor overall survival. Liver specific homing of breast cancer is not well understood, and the tumor immune microenvironment (TIME) likely plays a critical role in the process of forming BCLM. This retrospective study was conducted to determine the clinical risk factors and transcriptomic biomarkers associated with BCLM.
Methods: A retrospective single institute chart review was conducted. Patient, disease characteristics and treatment variables were reviewed. Liver metastasis specific survival (defined by overall survival time from the diagnosis of liver metastasis) were compared across three breast subtypes (i.e., ER+/HER2-, HER2+, and triple-negative (TN) breast cancer) using Kaplan-Meier curves. Next generation sequencing (NGS) via commercial platforms were then used to obtain transcriptomic data. Transcriptomic analysis including differential gene expression analysis, gene set enrichment analysis (GSEA), as well as gene deconvolution analysis with TIMER2.0 were conducted for comparison of transcriptomic profiles and immune compositions across the three breast cancer subtypes.
Results: 176 patients with BCLM and available liver metastasis biopsy were identified through retrospective chart review. Liver metastasis specific survival was compared, HER2+ BCLM patients (n = 17) had the best outcome and TN BCLM patients (n = 46) had the worst outcome with ER+ BCLM patients (n = 112) in the middle ($p < 0.0001$, ER+ vs TNBC $p < 0.0001$, ER+ vs HER2+ $p = 0.038$, HER2+ vs TNBC $p = 0.00011$). Principle component analysis on the transcriptomic data of 30 liver metastatic samples revealed different expression profiles between ER+ (n = 20) and TN (n = 7) BCLM, while HER2+ (n = 3) BCLM did not show statistical differences with either group. B cell mediated immunity was

upregulated in TN BCLM compared to ER+HER2- BCLM by GSEA (normalized enrichment score = 2.35, adjusted P-value = 0.19). Consistently, plasma cells were relatively enriched in TN BCLM compared to ER+ and HER2+ BCLM (p = 0.037) based on CIBERSORT estimation. In contrast, monocytes and neutrophils were enriched in ER+ BCLM (p = 0.0093 & 0.018) based on TIMER2.0 estimation. Additional NGS analysis is currently underway for increased sample size.
Conclusions: BCLM in TNBC was associated with significantly worse overall survival. TIME in TN BCLM enriched for genes associated with B cell mediated immunity while ER+ BCLM had more monocyte/neutrophil mediated immunity.

P3-07-22: A miRNA expression profiling of breast cancer to develop a metastases predictor model and identify new molecular players of metastatic outgrowth.

Andrea Fontana, Raffaela Barbano, Barbara Pasculli, Tommaso Mazza, Orazio Palumbo, Elena Binda, Tommaso Biagini, Michelina Rendina, Antonio lo Mele, Giuseppina Prencipe, Sara Bravaccini, Roberto Murgo, Luigi Ciuffreda, Maria Morritti, Vanna Maria Valori, Francesca Sofia Di Lisa, Patrizia Vici, Marina Castelvetere, Massimo Carella, Paolo Graziano, Evaristo Maiello, Massimiliano Copetti, Paola Parrella

Background: Metastasis is the leading cause of breast cancer-related mortality. Current classification is based mainly on immunohistochemical markers and fails to reliably predict metastatic potentials. In recent decades, microRNAs (miRNAs) have emerged as promising clinical biomarkers due to their capacity to regulate key molecules involved in cancer progression and metastatic spread.
Methods: To identify novel miRNA-based biomarkers, we analyzed three retrospective cohorts. A miRNA Affymetrix Gene Chip 4.0 array was used to identify relevant miRNAs in the discovery cohort (n=40). Next, RT-qPCR analysis was performed to evaluate the accuracy of selected miRNAs in identifying patients who developed distant metastases in the extended cohort (n=223). A stepwise logistic regression model was used to construct a prognostic tool for metastases, including miRNA levels and clinicopathological features. The effects that both miRNAs may exert on tumor cell phenotype was preliminary assessed in a panel of breast cancer cell lines in terms of cell viability. Following ectopic modulation of candidate miRNAs by miRVANA miRNA mimics, cell viability was measured by PrestoBlue viability reagent.
Results: Global expression analysis of the discovery cohort identified eight miRNAs with differential expression between metastatic and non metastatic tumors. In the extended cohort, miR-3916 and miR-3613-5p were the best miRNAs for identifying patients who developed distant metastases. Increased expression levels of miR-3916 were associated with a reduced risk of developing distant metastases (OR=0.42, 95% CI: 0.23-0.70, p=0.002), while increased expression levels of miR-3613-5p were associated with an elevated risk (OR=2.06, 95% CI: 1.27-3.50, p=0.005). Importantly, by including the expression levels of miR-3916 and miR-3613-5p in a model with clinicopathological

covariates, the discriminatory power reached an AUC of 0.85 (95% CI: 0.79-0.91), outperforming a model with clinicopathological covariates only (AUC=0.76, 95% CI: 0.68-0.84) (delta-AUC p=0.001). As expected, the evaluation of the effects of miR-3613-5p and miR-3916 transfection in vitro showed that both miRNAs were able to impair cell viability in breast cancer cell lines.
Conclusions: In this study, we identified miR-3613-5p and miR-3916 as putative metastases associated miRNAs. A logistic regression model including both miRNAs and clinicopathological characteristics were able to predict the risk of metastases development supporting their potential utility in the clinical setting. Moreover, our initial in vitro studies suggest both miRNAs may affect tumor cell phenotype. Further in vitro and in vivo are currently ongoing to characterize miR-3613-5p and miR-3916 role in the mechanisms underlying metastases development in breast cancer.

P3-07-23: Incidence, Risk Factors, and Survival Outcomes of Brain Metastases in Breast Cancer Patients: Insights from a Tertiary Care Center

Abdullah Almutairi, Alhanouf Mansour AlMansour, Nada Ibrahim Alrufayyiq, Ghaida Abdulrahman Alkhorayef, Norah Khalid Alobaid, Husam I Ardah, Mohammad Alkaiyat, Nafisa Abdelhafiez

Introduction: Breast cancer is one of the most prevalent cancers. Despite awareness efforts, many patients are diagnosed at an advanced stage. Some of these patients present with brain metastases, while others develop brain metastases throughout the disease trajectory.

Methods: This retrospective observational cohort study was conducted at King Abdullah Specialized Children's Hospital (KASCH), in Riyadh, including all female breast cancer patients diagnosed and treated between 2016-2022. The study aims to measure the incidence of brain metastases among breast cancer patients and its association with molecular subtypes, and their overall survival in comparison to those without brain metastases. Additionally, the study provides insights about the association of BM with other factors such as age, tumor grade, and disease stage.

Results: A total number of 954 BC females were identified, 89.7% were Saudi with median age of 52 (20-73) years at diagnosis. Among them, 59.4% had invasive ductal carcinoma (IDC), 8.3% invasive lobular carcinoma (ILC), and 2.3% had other subtypes. 717 (75.2%) HR-positive, 123 (12.9%) TNBC, 106 (11.1%) TPBC, and 96 (10.1%) HER2-enriched patients were reported. A total of 237 (24.8) BC patients were confirmed to have de novo metastatic disease with BM being declared as the fourth most common site of metastasis following the bone, lung, and liver. About 57 (6%) patients were found to have BM, 10 of them had BM at the time of diagnosis. The incidence of developing BM is 47(5%), after excluding the 10 cases.. The mean age at BM development was 45 ± 10.6, with the majority having G3 disease. Among BM patients, stage IV was the most predominant (50.2%), followed by stage III (28.2%), stage II (17.3 %), and stage I (4.3). Regarding BM incidence

based on the BC molecular features , HR- patients were more likely to develop BM n=23(10%) Vs n= 24(3.4%) P<0.001. her2-enriched were more likely to develop BM 19.8 Vs 3.4,P, 0.001. no statistically significant different were detected among the TPBC nor TNBC groups ..

Among the 47 patients who developed brain metastases during their treatment, 38 had stage IV breast cancer (BC), out of 227 other stage IV patients, resulting in an incidence of 16.7%. Of these, 33 (57.9%) patients had oligometastatic brain disease with five or fewer brain lesions. Additionally, 20 (44.4%) received whole brain radiation (WBR), 19 (42.2%) were treated with stereotactic radiosurgery (SRS), and only 4 (7%) patients underwent surgery.Kaplan-Meier survival curve was employed to estimate the overall survival (OS) of the whole population. The mean survival of all breast cancer patients was 7 years, Median OS was not reached . The OS among patients with BM at the time of analysis showed that 28 (15.6%) were dead, while only 16 (2.4%) were Alive (P<0.0001). The median survival for stage VI patients who did not develop BM Vs those who developed BM was 5.5 years 95% CI [4.4-6.6] and 3.1 years 95% CI [2.2-4.1] ,(P value =0.015).

Conclusion: This study showed a significant increase in brain metastases among HER2-positive breast cancer at 19.8% compared to 6.7% in TPBC, 4.1% in TNBC, and 3.4% in HR-positive subtypes. This result lines up with several prior studies that have also reported a higher risk of brain metastases among HER2-positive and TNBC in comparison to HR-positive breast cancer subtype. Based on our research, we conclude that age under 50, grade 3, and stage 3 are significant risk factors for BM. Patients with brain involvement had shorter survival compared to those without BM, 3.1 years and 5.5 years, respectively, which is consistent with previous literature demonstrating the negative prognostic impact of brain involvement in this patient population.

P3-07-24: Real-World Treatment Patterns and Clinical Outcomes of Sacituzumab Govitecan in HER2 negative metastatic breast cancer patients in China

Huanhuan Zhou, Zhanhong Chen, Xiying Shao, Yabing Zheng, Wenming Cao, Junqing Chen, XiaoJia Wang

Background: Sacituzumab govitecan (SG), a first-in-class Trop-2–directed antibody–drug conjugate, has been shown to improve prognosis of patients with metastatic triple-negative breast cancer (mTNBC) in ASCENT and EVER-132-001 trial. These led to NMPA (China health authority) approval of SG in June 2022 for mTNBC and then was available on June 13, 2023. Based on TROPiCS-02 study, SG also got FDA and EMA approval for unresectable locally advanced or metastatic hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative (IHC0, IHC 1+ or IHC 2+/ISH–) breast cancer who have received endocrine-based therapy and at least two additional systemic therapies in the metastatic setting. The new indication is accepted and under procedure by NMPA in early

2024. The study aims to investigate the real-world efficacy and safety of SG for HER2 negative mBC in China.
Methods: Data was retrospectively collected from 5 hospitals in China. Patient had a diagnosis of mBC, received at least two cycles of SG. Data cut-off was in July 2024. The primary endpoint is real-world progression-free survival (rPFS) estimated by the Kaplan-Meier method. Secondary endpoints are real-world overall survival (rOS) and safety. Physician-reported acute and late toxicities were assessed using the Common Terminology Criteria for Adverse Events (CTCAE) 5.0.
Results: From June 2023 to July 2024, 44 patients were included in this study. The median age was 53 years (IQR range 31-80).Patients had previously received a median of 3 (1–10) prior lines of treatment in the metastatic setting. 77.3%(34pts） were TNBC , 22.7%(10pts ） were hormone receptor-positive, HER2-negative (HR+/HER2-) ;88.6%(39pts) had visceral metastases and 20.5%（9pts) had brain metastases. 68.2%（30pts）received SG monotherapy， 31.8%（14pts) received SG combined with other medications such as immunotherapy etc. Median (95% CI) real-world progression-free survival (mPFS) was 4.13 (3.86-5.80) months for all patients, 4.13（3.71-5.69） months in the mTNBC (n = 34) group and 5.25 months（2.78-6.91） in the HR+/HER2- group. 90% (9/10) had received treatment with CDK4/6 inhibitors and 70% (7/10) had received treatment with chemotherapy in the HR+/HER2- group. 18 (40.9%) Pts initiated low dose of SG treatment (less than 80% standard dose) considering the cost-saving and basic physical situation. The mPFS was 4.50 months (95% confidence interval [CI], 3.80-6.34) in standard dose group and 3.75 months (95% CI, 2.93-5.67) in low dose group (P=0.56). In this research group, no unanticipated toxicity was reported.
Conclusion: In the clinical practice of HER2 negative advanced breast cancer in China, for patients who have been rescued by CDK4/6 inhibitors or chemotherapy, the research results suggest that Sacituzumab govitecan (SG) has very good efficacy and safety. Despite limitations in the patient's PS status or economic conditions, the overall efficacy is still satisfactory.

P3-07-25: Current Treatment Strategies for PIK3CA-Mutated Metastatic Breast Cancer and Provider Perceptions of the INAVO120 Trial

Brooke Leon, Luke Jennings-Zhang, Robert N. Bone, Yolaine Jeune-Smith, Bruce Feinberg

Background: The development of PI3K targeting therapies is transforming the approach to care for patients with PIK3CA-mutated metastatic breast cancer (mBC). The phase III INAVO120 trial (NCT04191499) is evaluating the addition of inavolisib, an investigational PI3Kα inhibitor, to first-line (1L) palbociclib + fulvestrant in participants with PIK3CA-mutated, HR+/HER2– mBC who relapse on or within 12 months of completing adjuvant endocrine therapy. Primary findings demonstrated that the addition of inavolisib to palbociclib + fulvestrant more than doubled progression-free survival (PFS), meeting the study’s primary endpoint. This survey-based study aimed to elucidate current treatment strategies within the PIK3CA-mutated mBC space and evaluate oncologists’ perceptions of

the INAVO120 data.
Methods: US-based oncologists convened at a live meeting in March 2024 to review clinical updates presented at SABCS 2023. Participant characteristics and demographic data were collected via an online survey prior to the meeting. Perceptions/reactions to queries on clinical updates were captured in real-time via an audience response system. Not all participants answered every question. Responses were aggregated and summarized using descriptive statistics.
Results: Among 61 respondents, 74% identified as community providers. Additionally, respondents indicated that they have 20.2 mean years of clinical experience and see approximately 18 patients per clinic day. Prior to reviewing the INAVO120 trial data, respondents selected alpelisib + fulvestrant (42%; N=50) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) + aromatase inhibitor (36%; N=50) as their top two preferred 1L treatment regimens for patients with PIK3CA-mutated mBC. Notably, half of respondents cited ribociclib as their preferred CDK4/6i for this patient population. After reviewing the INAVO120 trial, 84% of respondents (N=56) reported being likely to incorporate inavolisib into their patients' 1L CDK4/6i + hormone therapy-based treatment regimen, if FDA-approved and/or guideline-recommended. A majority of respondents (62%; N=55) cited the superior PFS associated with inavolisib + palbociclib + fulvestrant as the most compelling outcome from the trial. Hyperglycemia (52%; N=56) and stomatitis/mucosal inflammation (41%; N=56) were selected as the top two most concerning adverse events associated with the triplet regimen.
Conclusions: Overall, the INAVO120 data were viewed favorably by this cohort of physicians, as evidenced by most respondents indicating that they would incorporate inavolisib into their patients' 1L CDK4/6i + hormone therapy-based regimen. Although a minority of patients with HR+/HER2– mBC are both PIK3CA-mutated and rapidly progress on or after adjuvant endocrine therapy completion, respondents' willingness to adopt the INAVO120 treatment strategy suggests that it fulfills an unmet need for this niche patient population. Interestingly, the INAVO120 trial utilized palbociclib as its CDK4/6i backbone, whereas a majority of respondents prefer ribociclib in this setting. If approved by the FDA, the INAVO120 regimen will bolster the armamentarium of available treatment options for patients with PIK3CA-mutated mBC. However, it remains to be seen if physicians will opt for this triplet regimen over currently approved doublet regimens in the real-world setting given inavolisib's unique toxicity profile and it is unclear how much influence the CDK4/6i partner (i.e., palbociclib vs. ribociclib) will have on the adoption of the INAVO120 regimen into routine clinical practice if approved.

P3-07-26: Inpatient outcomes and predictors of mortality in Leptomeningeal carcinomatosis in patients with breast cancer

Raj Shah, Abdul Rahman Akkawi, Anas Alqam, Vaibhavi Mukhtyar, Jared Ojile, Jeremy Deutsch

Objective: To assess baseline characteristics, comorbidities, and factors associated with poor outcomes in hospitalized breast cancer patients with Leptomeningeal carcinomatosis
Introduction:
Leptomeningeal carcinomatosis (LC), defined as the infiltration of cancer cells into the leptomeninges, is a rare but severe complication occurring in up to 5% of breast cancer patients. It causes significant morbidity and mortality, with poor outcomes even in patients receiving aggressive treatment. Identifying risk factors can help with deciding management plans and improving physician-patient communication.
Method: We analyzed data from the National Inpatient Sample to identify patients who were admitted with a diagnosis of breast cancer in 2021. Among this population, we isolated patients with LC. To ensure that LC was secondary to breast cancer, we excluded other most common causes of LC such as primary central nervous system (CNS) tumors, lung cancer, and melanoma. We investigated the baseline characteristics of those with and without LC. The primary endpoint was in-hospital mortality, stratified by the presence of LC. We also examined other outcomes such as length of stay (LOS), total charge (TOTCH), sepsis, and mechanical ventilation. Additionally, we explored independent predictors of in-hospital mortality.
Result: A total of 659,989 admissions for breast cancer occurred between January and December 2021; out of this cohort, 22,664 (3.4%) had LC. The mean age of those with LC was 59.5 compared to 71.6 in those without LC ($p<0.01$). The in-hospital mortality rate for those with LC was significantly higher (8% vs 3%, $p<0.01$). After adjusting for demographic and patient-related variables, independent predictors of mortality with p-value <0.01 were lung metastases (aOR 1.95, CI 1.73-2.19), bone metastases (aOR 1.72, CI 1.57-1.88), protein-energy malnutrition (aOR 1.61, CI 1.46-1.78), cachexia (aOR 2.22, CI 1.90-2.60), CKD (aOR 1.30, CI 1.14-1.49), liver disease (aOR 1.33, CI 1.18-1.50), and CHF (aOR 1.26, CI 1.16-1.37). Patients with LC also had a longer length of stay (6.5 d vs 5 d), more palliative care referrals (25% vs 7%), and an increased cost of hospitalization ($90,163 vs $69,598).
Conclusion: Treatment of Leptomeningeal disease in breast cancer patients is exceedingly challenging. Identifying risk factors like nutritional status, presence of metastatic disease, and comorbidities including liver disease, CKD, and CHF remain crucial and can help in deciding the overall management plan. Considering the high inpatient mortality of patients with multiple comorbidities, utilizing early palliative care services might be beneficial. Studies on risk stratification will help in navigating care for these patients.
KEYWORDS: Leptomeningeal carcinomatosis, Breast cancerDESIGN: Retrospective cross-sectional studySETTING: National Inpatient Database 2021 using ICD 10 codesSTATISTICS: Logistic regression assessed patient and hospital factors influencing outcomes in patients with Leptomeningeal carcinomatosis (LC) and its association with inpatient mortality using the STATA BE 18.0 software. Results were adjusted for age, race, smoking, alcohol, liver disease, diabetes, hypertension, chronic kidney disease (CKD), and congestive heart failure (CHF). Nutritional factors like protein energy malnutrition (PEM) and BMI were also assessed and adjusted for outcomes.

P3-07-27: Selective De-Escalation of Surgery: Trends in Surgical Management of de Novo Stage IV Breast Cancer Over the Past Decade

Jennifer Chen, Yajie Liu, Salyna Meas, Suprateek Kundu, Anthony Lucci, Shruti Zaveri

Background: Previous studies have demonstrated declining rates of surgery for de novo stage IV breast cancer given the lack of prospective randomized evidence in support of surgical resection. We aimed to characterize trends in utilization of breast and axillary surgery in a contemporary cohort of de novo stage IV patients at our institution.
Methods: This was a retrospective review of all patients treated for de novo stage IV breast cancer at University of Texas MD Anderson Cancer Center from 2014-2022. All patients received systemic treatment with or without surgical resection of the primary breast tumor (systemic therapy alone vs. surgery cohort). Chi-squared and Mann-Whitney U tests were used to compare group differences. Linear regression and mixed-effects model were used to identify temporal variability in patient and tumor characteristics among the surgery cohort.
Results: In total, 1290 patients with de novo stage IV breast cancer were treated at our institution over an 8-year period. Of these, 16.7% (215) underwent surgery of the primary breast tumor. The median age at diagnosis was 54 years (IQR 32.4-63.0) and BMI was 28.2 kg/m2 (IQR 24.4-33.1). Patients were predominantly White (903, 70%) with T2 or higher (999, 77.4%), node-positive (1020, 79.1%), ductal disease (1016, 78.8%). The most common site of metastasis was visceral (637, 49.4%), followed by bone-only (491, 38.1%), and soft tissue and distant lymph nodes (131, 10.2%). Compared to the systemic therapy cohort, patients in the surgery cohort were younger (median age 49 vs. 55, $p < 0.001$), had higher nodal burden (N2-3, 48.8% vs. 28.2%, $p < 0.001$), and were more likely to have higher grade (52.1% vs. 31.4% $p = 0.002$), HER2-positive disease (34.4% vs. 19.8%, $p < 0.001$). Patients with inflammatory breast cancer (IBC) were significantly more likely to undergo surgery (35.3% vs. 9%, $p < 0.001$). With regard to site of metastasis, patients with soft tissue/lymph node metastases were more likely to undergo surgery (30.5% vs. 6.4%, $p < 0.001$) while those with visceral metastases were less likely (33.3% vs. 54.1%, $p < 0.001$). Over the 8-year period, there were no significant changes in the overall percentage of stage IV patients undergoing surgery ($p = 0.46$); however, surgery rates significantly decreased for patients with clinical T2 ($p = 0.042$) and N1 tumors ($p = 0.02$) and increased for IBC patients ($p = 0.037$). Overall, rate of surgery significantly decreased for HR+/HER2+ tumors ($p = 0.003$) while there were no differences in surgery utilization by receptor subtype among IBC patients. There were no changes over time in age, BMI, race/ethnicity, histology, grade, type of metastasis, and type of breast surgery performed within the surgery cohort. However, the percentage of patients undergoing ALND significantly decreased over time ($p = 0.04$), with a 1.8% decrease annually.
Conclusion: We found temporal variability with an overall decrease in primary tumor resection in de novo stage IV breast cancer but significantly increased rates of surgery in patients with IBC. These findings suggest providers are increasingly more selective in offering surgical resection to stage IV patients, in accordance with current evidence, with the exception of stage IV IBC patients who were excluded from prospective randomized trials.

P3-07-28: Anxiety, Depression and Coping Mechanisms Among Young Women Diagnosed with De Novo Metastatic Breast Cancer

Leticia Varella, Yue Zheng, Kate E Dibble, Shoshana M Rosenberg, Gregory J. Kirkner, Craig Snow, Kathryn J. Ruddy, Rulla M. Tamimi, Jeffrey M. Peppercorn,, Lidia Schapira, Virginia F. Borges, Steven E. Come, Ann H Partridge,

Background: Prior research has demonstrated that young patients presenting with stage IV breast cancer (de novo metastatic disease) have a high prevalence of anxiety and, less commonly, depression. Little is known about factors that help young women to cope with the diagnosis and treatment of metastatic breast cancer. We sought to study coping mechanisms in young patients with de novo metastatic disease, and their associations with anxiety and depression, to inform future interventions.

Methods: The Young Women's Breast Cancer Study (YWS) is a multisite, prospective cohort that enrolled 1,302 women diagnosed with stage 0-IV breast cancer at age ≤40 from 13 North American academic and community sites from 2006-2016. Participants completed surveys at study baseline (median of 5 months post-diagnosis), 6 months, and 12 months after enrollment, then were surveyed every 6 months through 3 years, and annually thereafter. Coping was assessed at 18 and 24 months using an 18-item investigator-developed survey designed to understand how participants have coped with their diagnosis and treatment. Anxiety and depression were assessed at 12 months using the Hospital Anxiety and Depression Scale (HADS), a 14-item validated instrument. The current median follow-up is 10.5 (range 0.4-17.6) years. Medical record review was used to assess disease characteristics. We excluded women with stage 0-III disease (n=1,238) and women who did not answer at least one survey at the four time points (n=6). Descriptive analyses were used to characterize the baseline demographics. We used univariable analysis to examine the relationship between coping strategies and anxiety and depression.

Results: Among 58 patients with de novo metastatic breast cancer included in this analysis, most patients were white (n=52, 89.7%), 3.4% were Black (n=2), 3.4% Asian (n=2), and 3.4% Native American (n=2). Two (3.4%) patients were Hispanic. Median age at diagnosis was 37 years; 38 (65.5%) were married or living with a domestic partner, 6 (10.3%) were widowed, and 12 (20.7%) were never married at baseline. Emotional support from a partner/spouse/significant other was commonly reported to help with coping at both 6 and 18 months, 76% and 62%, respectively, followed by emotional support from parents at 6 months (15%) and taking care of close ones at 18 months (19%). Approximately 50% of the patients reported coping with exercising and/or diet at both 6 and 18 months. Four patients reported moderate or greater reliance on recreational drugs and one patient, on drinking alcohol. The mean HADS anxiety score at 12 months was 7.71 (SD, 5.09) and mean HADS depression score was 3.96 (SD, 3.33). Moderate or high anxiety (HADS score ≥11) symptoms were present in 18 patients (31.0%), and 2 patients (3.4%) scored moderate or high in the depression subscale. In univariate analysis, there was no statistically significant association between specific coping strategies and anxiety or depression.

Conclusion: Young patients with de novo metastatic breast cancer most commonly rely on emotional support from their partners and family/friends to cope with their disease. Lifestyle changes including diet and physical exercise were also commonly reported coping strategies. While approximately one third of patients experienced moderate or severe anxiety, we did not observe an association between specific coping strategies used and anxiety or depressive symptoms. Additional research may further inform interventions that support coping amongst young survivors living with de novo metastatic breast cancer.

P3-07-29: ACT-MBC: A Prospective Observational Impact Study of Circulating Tumor Cells in Metastatic Breast Cancer

Karthik Giridhar, Amrit Singh, Eyad Al-Hattab, Jamie Carroll, Deanne Smith, Tamara O'Brien, Jenna Hoppenworth, Tufia Haddad, Amye Tevaarwerk, Bongi Rudder, Grace M. Choong, Sandeep Basu, Lisette Stork-Sloots, Femke de Snoo, Sara Lazaro, Ryan Prendergast, Frank K. Kuhr, Daryl S. Spinner, Mina Hanna, Matthew Goetz

Introduction: The FDA-cleared CellSearch® Circulating Tumor Cell (CTC) assay is a non-invasive liquid biopsy approved for metastatic disease monitoring. In metastatic breast cancer (MBC), prospective phase III data supports a positivity threshold of ≥5 CTC. Positive CTCs (≥5 CTCs) at baseline (BL), persistent CTC positivity, and increases in CTC count over time outperform serum tumor markers such as CA 27-29 and CA 15-3 and predict radiographic disease progression. Nevertheless, CTC enumeration has not been utilized broadly in real-world clinical practice. Therefore, we sought to evaluate provider perception of clinical utility of CTC enumeration in routine clinical practice for treatment decisions and/or response assessment.
Methods: The ACT-MBC study is A Prospective Observational Impact Study of Circulating Tumor Cells (CTCs) in Metastatic Breast Cancer (MBC) in which patients receive CTC enumeration and biomarker testing. Provider perception of CTC testing is measured with questionnaires at baseline (PQ1), at each patient's restaging visit (PQ2), and at study end (PQ3). The study also evaluates if CTC results correlate with response assessment and disease progression as defined by standard of care imaging, and whether CTC results influence the timing of radiographic assessment. The study includes metastatic Hormone Receptor (HR)+/HER2- patients who are starting ≥2nd line and metastatic Triple Negative (TN) patients at any line of systemic therapy. We present the interim results from PQ1, PQ2 and patient baseline CTC results.
Results: Thirty providers completed PQ1 (16 from academic sites and 14 from three community US sites). In PQ1, most (83%) had no prior use of CTCs during routine practice, and the remaining 17% reported rare CTC test use. Eighteen (60%) agreed or strongly agreed that CTC offered prognostic information with the remaining 12 (40%) as neutral. The most common barriers to utilizing CTCs in routine practice included concerns about insurance reimbursement (90%), lack of familiarity with CTC testing (73%), uncertainty on logistics of test ordering (66%). Thus far, 34 subjects were enrolled; clinical data were

available for 24 subjects. The median age of subjects was 63 years (range 41-82 years); 80% had ductal, 20% had lobular histology; 75% were HR+/HER2- and 25% were TN; 83% of subjects had visceral metastases and 17% had bone only disease. Three subjects received 2 prior lines of therapy, 6 subjects 3 lines, and 15 subjects 4 lines or more. 14/24 subjects had a baseline CTC assessment of ≥ 5 CTCs, 4 subjects had 1-4 CTCs; and 4 subjects had zero CTCs (for 2 subjects the BL CTC results could not be analyzed).
Nineteen available provider questionnaires were completed after the first restaging visit (PQ2). Providers indicated that for 13 of 19 subjects, CTC results were concordant with imaging results (for 5 subjects the provider was unsure about concordance). For 12 subjects, providers indicated that assessing CTCs along with standard modalities enhanced the ability to assess treatment response [strongly agree (n=9); agree (n=3); neutral (n=5); disagree (n=2)]. For 10 subjects, CTC assessment helped guide physician decision to continue or change therapy (strongly agree (n=6); agree (n=4); neutral (n=3); disagree (n=5); strongly disagree (n=1). In those subjects without disease progression at first restaging, providers indicated that CTC assessment influenced timing of future restaging imaging assessments in 4 out of 10 subjects.
Conclusions: The ACT-MBC analyses to date show that assessing CTCs along with standard modalities enhanced the ability of physicians to assess treatment response, guide treatment decisions and may additionally alter the timing of restaging scans. In summary, these data suggest that assessment of CTCs may provide an important tool for clinical treatment decision making.

P3-07-30: Mesenchymal Stem Cells Regulate E-cadherin Level, Proliferation, and Immuno-Resistance on Breast Cancer Cells

Bei Dai

Breast cancer is the most common cancer in women worldwide. Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, while estrogen receptor-positive breast cancer (ER+BC) exhibits the longest dormancy phenomenon, wherein breast cancers recur as distant metastases even decades after removal of the primary tumor. Therefore, this study will focus on both TNBC and ER+BC.
The majority of breast cancer-related deaths are attributed to breast cancer metastasis, while E-cadherin is integral in the metastasis process with its downregulation enabling escape from the primary tumor site, and its re-expression enabling the survival of disseminated tumor cells (DTCs) when they seed the metastatic site. Mesenchymal stem cells (MSCs) were previously shown to be recruited to the primary breast cancer site and also to be present in the breast cancer metastasis. Their wide distribution allows them to act on both primary and metastatic tumor cells.
We are expanding this research area to determine how MSCs regulate the more epithelial-mesenchymal phenotypes including immuno-resistance, proliferation, and E-cadherin-mediated interactions with parenchymal cells. Our preliminary results demonstrate that MSCs inhibit the E-cadherin level of specific TNBC cell lines and enhance the proliferation of

TNBC cells and ER+BC cells; thus driving a more progressive phenotype. Fas ligand (FasL)-induced apoptosis will be measured to represent the non-specific immune responses. After that, whether this signal is paracrine or juxtacrine will be determined by the results of direct co-culture and indirect co-culture experiments including Transwell co-culture and conditioned media (CM) experiments. Signaling molecule screening will be performed by siRNA library screening, multiplex immunoassay, or small RNA sequencing to look for possible therapeutic targets, with the specific screening method is dependent on the co-culture results. Finally, we will confirm our conclusions including the effect on epithelial-mesenchymal phenotypes of BCCs and screened signal molecules in animal models and ex vivo MPS models which mimic human liver microenvironments. By studying the mechanism behind this regulation, we hope to define a new therapeutic approach to suppress the metastatic outgrowth of dormant breast cancer.

P3-08-01: Cardiovascular and Non-cardiovascular Risks among Female Breast Cancer Survivors in Japan: A Matched Cohort Study

Chitose Kawamura, Krishnan Bhaskaran, Takaaki Konishi, Yasuaki Sagara, Yasuaki Sagara, Angel YS Wong, Nanako Tamiya, Masao Iwagami

Background: With improvements in the detection and treatment of breast cancer (BC), the number of BC survivors has increased worldwide. However, the landscape of their non-cancer disease risks, including cardiovascular and non-cardiovascular risks remains unclear, especially among Asian women.

Methods: We conducted a matched cohort study using data from the JMDC claims database (https://www.jmdc.co.jp/en/) that covers company employees and their family members in Japan. Between January 2005 and December 2019, women aged 18–74 years with and without an incident BC (defined as the BC diagnosis and surgery) were matched with 1:4 ratio for age and entry timing to the database. Using stratified Cox regression analysis, we estimated and compared the risks for six cardiovascular diseases (acute myocardial infarction, acute heart failure, atrial fibrillation/flutter, ischemic stroke, intracranial hemorrhage, and pulmonary embolism) and six non-cardiovascular diseases (major osteoporotic fractures, other fractures, gastrointestinal bleeding, urinary tract infection, infectious pneumonia, and anxiety/depression) between the groups, overall and by follow-up time (<1 year and 1-10 year from the BC diagnosis, separately). In addition, risk by chemotherapy (anthracycline, taxane, anthracycline&taxane, and no anthracycline/taxane) and hormone therapy (tamoxifen, aromatase inhibitors, no tamoxifen/aromatase inhibitors) were estimated using non-stratified Cox regression analysis, with the reference group being women without BC. The treatment regimens were identified and classified during the first year from the BC diagnosis and follow-up was started at 1 year from the diagnosis. For this analysis, we adjusted for hormone therapy (tamoxifen and aromatase inhibitors) when analyzed by chemotherapy, and chemotherapy (anthracyclines and taxanes) when analyzed by hormone therapy.

Results: We included 24,017 BC survivors and 96,068 matched women in the analysis. The incidence rates of acute heart failure, atrial fibrillation/flutter, and all non-cardiovascular diseases were higher in the BC survivors than in the matched cohort group. For cardiovascular diseases, the highest adjusted hazard ratio was marked by heart failure (3·88, [95% confidence interval 2·55–5·90]), followed by atrial fibrillation/flutter (1·83, [1·40–2·39]). For non-cardiovascular diseases, the highest adjusted hazard ratio was marked by gastrointestinal bleeding (3·55, [3·10–4·06]), followed by anxiety/depression (3·06, [2·86–3·28]). Of the diseases with significant increases over the entire period, the hazard ratio at <1 year was larger than that at 1–10 years from the BC diagnosis in most outcomes; however, major osteoporotic fractures and other fractures had a larger hazard ratio in 1–10 years than in <1 year. For osteoporotic fracture and other fractures, the hazard ratio in 1–10 years was 1·77 (1·46–2·15) and 2·09 (1·86–2·34) respectively, whereas that in < 1 year was 1·30 (0·92–1·85), and 1·28 (1·05–1·56), respectively. By chemotherapy, hazard ratios for acute heart failure, atrial fibrillation/flutter, other fractures, gastrointestinal bleeding, infectious pneumonia, and anxiety/depression tended to be higher in the anthracycline&taxane group than in the other groups. By hormone therapy, a higher risk of fractures and gastrointestinal bleeding was observed among aromatase inhibitor users.

Conclusion: The BC survivors in Japan showed an increased risk of acute heart failure, atrial fibrillation/flutter, and six non-cardiovascular diseases than women without BC. Most risks increased more steeply during the first year of intensive multidisciplinary care of BC, whereas the risk of fractures increased later. It is important for healthcare providers and patients to understand the risks of these diseases and link them to screening, prevention, and early treatment.

P3-08-02: Real-world Evidence: Pegylated Liposomal Doxorubicin 40mg/m2 versus 50 mg/m2 in Patients with Metastatic Breast Cancer.

Daniel Agustin Vasquez, Erika Bushatsky, Lilian Arruda do Rego Barros, Felipe José Silva Melo Cruz, Luis Felipe Gastaldo Poletti, Alayne M. T. Domingues Yamada

Background: The use of anthracyclines in breast cancer treatment remains essential despite their known adverse effects, prompting the development of new formulations. Pegylated liposomal doxorubicin (DLP) encapsulates doxorubicin in a lipid coating, altering its bioavailability and side effect profile, notably increasing the incidence of hand-foot syndrome (HFS). Our experience in an oncology center in Brazil suggests that a standardized dose of 50 mg/m2 every four weeks in the metastatic setting is less tolerated, while the reduced dose of 40mg/m2 with the same interval has the same clinical benefit with better toxicity profile. The present study aims to assess whether dose reduction maintains clinical efficacy while minimizing adverse effects. Methods: This is a retrospective, observational, cohort study that analyzed electronic medical records of adult

female patients with metastatic breast cancer diagnosed between 2018 and 2023 at an oncology hospital in São Paulo, Brazil, treated with DLP at either dose of 40mg/m2 and 50mg/m2 every four weeks. Data were reviewed and collected from June to November 2023. Toxicities were classified using CTCAE v6.0. Logistic regression and Cox proportional hazards models, adjusted for potential confounders, were used to assess clinical response and progression-free survival. Results: A total of 193 patients were treated with pegylated liposomal doxorubicin (DLP) between 2018 and 2023. Among them, 98 patients received a standard dose of 50 mg/m2, while 95 patients received a reduced dose of 40 mg/m2, both every four weeks. The mean ages were 57.10 years (range 23-82) in the 50 mg/m2 group and 55.89 years (range 34-83) in the 40 mg/m2 group. In the standard dose group, 81 patients (85.3%) had an ECOG performance status of 0-1, whereas in the reduced dose group, 27 patients (28.4%) had an ECOG performance status of 2-3. Progression-free survival was 7.4 months (95% CI 5.3–11.3) in the 50 mg/m2 group and 6.7 months (95% CI 4.5–8.1) in the 40 mg/m2 group (adjusted HR 1.11; 95% CI 0.75-1.61, p = 0.623). Notably, prior re-exposure to anthracyclines in the reduced dose group had an HR of 1.72 (95% CI 1.02-2.90, p = 0.04), while in the standard dose group, the HR was 0.69 (95% CI 0.37-1.28, p = 0.25). Grade 3 toxicity related to the dose was more frequent in the 50 mg/m2 group with 33 cases (34.74%) compared to 10 cases (10.20%) in the 40 mg/m2 group. The most prevalent toxicity in both arms was hand-foot syndrome (18.88%). Dose reductions occurred more frequently in the 50 mg/m2 group, affecting 39 cases (41.05%). Conclusions: There was no difference in progression-free survival comparing 40mg/m2 vs 50mg/m2 protocols, emphasizing better tolerance with reduced adverse events for those treated with reduced dose. For patients previously treated with anthracyclines, the 50mg/m2 every four weeks might provide greater benefit by increasing progression-free survival.

P3-08-03: Trends in Presentation of HER2+ Breast Cancer: A Retrospective study of De Novo Versus Recurrent Metastatic Breast Cancer (MBC) in the Real-World French National ESME Cohort (2008-2022)

Thomas Grinda, Amélie Lusque, Stefania Morganti, David Pasquier, Aurélie Bertaut, Thierry Petit, Thomas Bachelot, Monica Arnedos, Fanny Le Du, Vincent Massard, Anthony Gonçalves, Caroline Bailleux, Jean-Sebastien Frenel, Paul Cottu, Christelle Levy, Aude-Marie Savoye, Nathalie Olympios, Marie-Ange Mouret-Reynier, Harold J. Burstein, Heather A. Pearsons, Lise Bosquet, Thomas Filleron, Suzette Delaloge, William Jacot, Nancy U. Lin

Background: In HER2-positive (HER2+) metastatic breast cancer (MBC), the clinical presentation at metastatic diagnosis (dg), de novo (dnMBC) or recurrent (rMBC), is an independent prognostic factor. In contemporary clinical trials, the proportion of patients (pts) with dnMBC is high, likely due to improvements in the efficacy of (neo)adjuvant therapy. ESME-MBC, a national cohort of real-world data, recruiting pts consecutively treated for MBC in all comprehensive cancer centers in France since 2008, allows capturing of this evolution over time.
Methods: We selected pts with HER2+ (immunohistochemistry, IHC 3+ or ISH

amplified) MBC diagnosed between 2008 and 2022, excluding pts whose hormone receptor (HR) and HER2 status were unknown and those who did not receive systemic treatment for MBC. We compared clinicopathologic characteristics based on presentation at metastatic dg (dnMBC i.e. metastasis found within 6 months from initial diagnosis, or rMBC). We evaluated the trends in presentation according to year of MBC dg (YOD) using a Cochran-Armitage test, and studied factors associated with first-line progression-free survival (PFS1) and overall survival (OS) using multivariable Cox models.
Results: Among the 35,687 pts in the ESME MBC cohort, 5,573 pts were treated for HER2+ MBC, including 2,800 (50.2%) with rMBC and 2,773 (49.8%) with dnMBC. Most pts were women (99.4%) with a median age of 57 years (range, 19-97). Compared with rMBC pts, dnMBC pts had significantly more often a premenopausal status (41.6% vs 35.9%, p <0.0001), have a BMI ≥30 (23.5% vs 17.8%; p <0.0001) and have ductal tumors (86.8% vs 78.8%; p <0.0001). In dnMBC pts compared with rMBC pts, there were more visceral involvement in absence of central nervous system (CNS) disease (54.1% vs 42.6%; p <0.0001), and less CNS involvement (4.7% vs 16.9%; p <0.0001), respectively. HR-positive status was similar in both categories (dnMBC vs rMBC, 60.5% vs 59.7%, p= 0.54) while HER2 score 3+ on IHC was more frequent in dnMBC (86.8% vs 82.5%, p <0.0001).
Types of therapy by dnMBC and rMBC differed: first-line anti-HER2 treatment + chemotherapy +/- endocrine therapy (ET), anti-HER2 treatment + ET, anti-HER2 treatment alone or no anti-HER2 treatment in 88.4% and 66.6%, 3.2% and 6.6%, 1.6% and 7.6%, and 6.8% and 19.1% of pts, respectively.
The proportion of rMBC significantly decreased from 63.5% in 2008 to 32.9% in 2022 (Cochran–Armitage test; p < 0.0001), whereas the proportion of HR+ tumors significantly increased from 53.2% in 2008 to 68.3% in 2022 (Cochran–Armitage test; p < 0.0001) both in dnMBC (50.0% to 67.0%) and rMBC (55.0% to 70.9%) pts from 2008 to 2022 (Cochran–Armitage test; p=0.0197 and 0.0008, respectively).
With a median follow-up of 82.8 months (mo) (95%CI: 79.7-84.6), the median OS of dnMBC vs rMBC pts were 72.5 mo (95%CI: 66.4-77.3) vs 43.8 mo (95%CI: 41.6-46.4) and the median PFS1 were 18.9 mo (95%CI: 17.7-20.3) vs 9.4 mo (95%CI: 8.9-9.9). In the multivariable analysis, dnMBC was associated with better OS (adjusted hazard ratio (aHR): 0.65 (95%CI: 0.61-0.70); p < 0.001) and PFS1 (aHR: 0.64 (95% CI: 0.60-0.68); p < 0.001). In both categories of pts, HR- status, older age at metastatic diagnosis, presence of CNS disease, and multiple metastases were independently associated with poorer OS and PFS1. HER2 3+ status was an independent favorable factor for PFS1 in both dnMBC and rMBC pts, and for OS in dnMBC pts only.
Conclusion: Between 2008 and 2022, in a large national cohort of pts with HER2+ MBC, we observed an epidemiological shift from a majority of rMBC pts to a vast majority of dnMBC pts, along with an increase in the proportion of HR+ pts among those with HER2+ cancer. Patients with dnMBC experienced significantly longer PFS1 and OS than those with rMBC. Attention to dnMBC vs rMBC enrollment in studies of HER2+ MBC is needed in the design and contextualization of study results.

P3-08-04: Prevalence of HER2-ultralow subtype and outcome among patients with HR-positive (HR+) HER2-negative (HER2-) metastatic breast cancer receiving first line chemotherapy. A real-world single center study.

Laurent Mathiot, Olivier Kerdraon, Florent Le Borgne, Véronique Verriele, Anne Patsouris, Marie Robert, Jérôme Chetritt, Delphine Loussouarn, Mario Campone, François Bocquet, Jean-Sébastien Frenel

Background: Recently, the DESTINY-Breast06 study has shown that Trastuzumab deruxtecan (T-DXd) outperforms standard of care (SOC) chemotherapy (CT) in terms of progression-free survival (PFS) as first-line treatment for HER2-low (L) and ultralow (UL) metastatic breast cancer (MBC) progressing after 1 or 2 lines of endocrine therapy including CDK4/6 inhibitor. Real world data on the prevalence of HER2-UL subtype and outcome with first-line SOC chemotherapy of HER2-L and HER2-UL MBC are needed to precise the medical need.
Methods: All cases of HR+/HER2-negative MBC (IHC scores of 0, 1+, and 2+/ISH-) and treated with first-line SOC chemotherapy at the Institut de Cancerologie de l'Ouest (ICO) were retrieved. All archived HER2 IHC slides of patients known as HER2-zero were subjected to rescoring by a pathologist according to ASCO CAP guidelines to distinguish HER2-null tumors (infiltrating cancer cells completely free of staining) and HER2-UL tumors (IHC 0 with incomplete and faint staining in ≤10% of tumor cells). Demographics, clinical characteristics, and treatments patterns were recorded. Kaplan-Meier method was used to estimate the real world PFS (rwPFS), time to next treatment (TTNT), and overall survival achieved with first-line SOC chemotherapy in the HER2-UL, L and null population.
Results: Between January 2016 and February 2023, 320 patients were included (HER2-L, n=198; HER2-zero n=122). After HER2 rescoring, historical HER2-zero group was finally reclassified in HER2-UL (n=50) and HER2-null (n=72). Overall, HER2-UL subtype accounted for 15.6% of the HR+/HER2-negative (IHC scores of 0, 1+, and 2+/ISH-) population. In the HER2-L and UL population (n=248), median age was 62.8 (IQR, 52.3-71.13) years, 73.0% and 16.9% of patients had visceral metastases or bone only disease respectively. Median number of previous endocrine therapy for MBC was 1 (IQR, 0-1) and 42.7% of patients had received previous CDK4/6i. First-line CT included taxane monotherapy (48.1%), combined with anthracyclines (1.6%), capecitabine (20.6%), anthracycline (19.7%), or other (10.0%). After a median follow up of 39.4 months [95% CI, 37.1-47.6], median PFS with first line CT was 7.9 months [95% CI, 4.6-19], 7.3 months [95% CI, 6.4-9.1] and 6.2 months [95% CI, 4.6-8.9] in the HER2-UL, L and null groups respectively. Median TTNT was 8.7 months [95% CI, 4.8-19.5], 8.2 months [95% CI, 7.0-9.9] and 7.0 months [95% CI, 5.1-10.3] in the HER2-UL, L and null groups. Patients with visceral metastases had a median PFS of 7.5 months [95% CI, 4.6-12.9], 6.6 months [95% CI, 5.6-7.8] and 5.1 months [95% CI, 3.8-7.6] in the HER2-UL, L and null groups. Median OS was 19.5 months [95% CI, 10.7-33.4], 21.5 months [95% CI, 19.0-25.8] and 16.6 months [95% CI, 11.9-23.6] in the in the HER2-UL, L and null groups respectively.
Conclusion: After HER2 rescoring following DESTINY-Breast06 trial presentation, HER2-UL MBC represents around 15% of HR+/HER2-negative MBC patients in our institution.

Outcome of HER2-UL and L MBC patients with SOC CT in a real-world setting is similar to those reported in the DESTINY-Breast06 trial.

P3-08-05: Cyclin inhibitors for breast cancer: A comparative real world data analysis

Julio Cesar Betiol, Beatriz Bueno, Pedro Exman

Background: More than 70% of patients (pts) with advanced breast cancer have hormone receptor positive disease and almost all pts will develop endocrine resistance during disease progression. CDK 4/6 inhibitors (CDK 4/6i) represent a new paradigm shift in treatment and currently ribociclib (Rib), palbociclib (Palb) and abemaciclib (Abem) are available. To date, Rib is the only to demonstrate a statistically significant (ss) median overall survival (mOS) gain in phase III trials, but data for Palb and Abem are still relevant despite the lack of statistical benefit. As there is no head-to-head study, we aim to evaluate the impact of these different CDK 4/6i as first-line therapy on mOS (median overall survival) in a contemporary real-world setting.
Methods: Data from TriNetX (a global dataset of electronic medical records of patients from 111 healthcare organizations) were analyzed and queried for patients with specific terms between 2004 and 2024. A propensity score matching (PSM) analysis balanced the cohort. Rib, Palb and Abem were compared using a 2x2 group selection method. Analysis 1 compared Rib versus (vs) Abem; Analysis 2 compared Rib vs Palb; and analysis 3 compared Palb vs Abem. mOS was evaluated with Kaplan–Meier method. Statistical comparison was made with a stratified log-rank test.
Results: No difference of risk for death were identified at Analysis 1 (n=271 pts in each arm), with a not reached mOS for both cohorts (5yrs OS = 61.82% vs 53.66%), x2=0.03, p 0.863, HR = 0.964, 95% CI = 0.634 – 1.467. Analysis 2 (n=980 pts in each arm) revealed a ss increased risk for death when receiving palb over rib, RR 2.42 (95% CI=-0.202, 0.280; p= <0.0001). with mOS of 1286 vs 1946 days (x2=15.447, p <0.0001, HR = 1.441, 95% CI = 1,200 – 1.731). Analysis 3 (n=318 in each arm), revealed a ss increased risk for death when receiving palb over rib RR 2.47 (95% CI=-0.231, 0.372; p= <0.0001) with mOS of 1124 vs 1706 (x2=9.025, p <0.003, HR = 1.56, 95% CI = 1,165 – 2.091).
Conclusions: Our study revealed that patients treated with Palb instead of rib or abem achieved a lower mOS with increased risk for death of breast cancer. Additionally, when comparing rib to abem, despite a percentual trend favoring rib, no ss difference were found in regards of overall survival analysis for risk of death of breast cancer.

P3-08-06: Clinical Activity of Sacituzumab Govitecan in Metastatic Triple Negative and Hormone Receptor Positive, HER-2 Negative Breast Cancer

Nicole Yun, Laura Owczarzak, Koosha Payadry, Trevor N Christ, Ruta Rao

Background: Sacituzumab govitecan (SG) is an antibody-drug conjugate approved for the treatment of metastatic triple negative breast cancer (mTNBC) and hormone receptor positive (HR+), HER-2 negative breast cancer. Dose reductions may be necessary to manage adverse events (AE) such as neutropenia and diarrhea. We evaluated the clinical safety and efficacy of SG as well as incidence of SG dose reduction and utility of granulocyte colony stimulating factor (GCSF) support in patients with mTNBC and HR+, HER-2 negative breast cancer.
Methods: This study is a single institution retrospective review of patients with locally recurrent/inoperable or metastatic HR+/HER-2 negative (IHC 0, IHC 1+, or IHC 2+/ISH negative) or TNBC treated with SG at Rush University Medical Center from April 2020 to May 2024, with outcomes followed through July 2024. The use of GCSF with SG therapy for management of neutropenia, the need for dose reductions based on treatment-related AE, and survival data were collected.
Results: 49 total patients were included for retrospective chart review. Median age at the time of receiving SG was 58 years, while 41 patients (83.7%) had mTNBC and 8 (16.3%) shad HR+, HER-2 negative disease. Median number of lines of prior treatment in the metastatic setting was two (range 0-11). Patient race was 53.1% white, 28.6% African American, 10.2% Asian, 6.1% Hispanic/Latino and 2% identified as other race. Total of 18 (36.7%) patients required dose reductions at any time throughout course of SG treatment and 16 (32.7%) patients experienced delays or interruptions in treatment. The most common reason for SG discontinuation was disease progression (59%), followed by intolerable AE (12%), death/hospice enrollment (10%), and loss of follow-up (4%). Seven (14%) patients in the study cohort remain on treatment. Regarding neutropenia, the incidence of grade 1/2, grade 3 or higher and febrile neutropenia was 61.2%, 42.9% and 8.2%, respectively. One patient died as a complication of severe neutropenia. Twenty-seven (55.1%) patients required the use of GCSF due to treatment-related neutropenia. Of those patients that required GCSF, median number of cycles for which it was administered was over 4 cycles (range 1-48).
Among evaluable patients, the overall median progression free survival (mPFS) and median overall survival (mOS) were 4.25 and 9 months, respectively. Among 41 evaluable patients, the mPFS was higher in patients who received GCSF (n=23, mPFS 6.5 vs 3.89 months). Among 29 patients with OS data, those who received GCSF had longer OS (n=16; 9.0 vs 6.5 months). The mPFS among patients who required dose reduction (n=13) and patients who did not require dose reduction (n=27) were 5.75 and 3 months, respectively. The mOS among patients who required dose reduction (n=8) and patients who did not require dose reduction (n=20) were 13.53 and 9.63 months, respectively.
Conclusion: The safety and efficacy of SG for treatment of patients with mTNBC or metastatic HR+/HER-2 negative breast cancer in a real-world setting is comparable to results from the IMMU-132 and ASCENT trials. Guidelines for treating clinicians to manage side effects and optimize drug tolerability while limiting dose reductions/interruptions to treatment warrant further exploration, especially in a heavily pre-treated patient population.

P3-08-07: A real-world analysis of clinical characteristics and outcomes of early-stage, triple-negative breast cancer patients receiving anthracycline-sparing neoadjuvant chemoimmunotherapy: the Mayo Clinic experience

Tanmayi Pai, Blake McKinley, Sonam Sonam, Miglena K. Komforti, Rohit Rao

Background: While anthracyclines are frequently utilized in the treatment of early-stage breast cancer (BC) patients (pts), they are associated with serious toxicities including dose-dependent cardiotoxicity and secondary myelodysplastic syndrome/acute myeloid leukemia. Neoadjuvant therapy (NAT) combining anthracycline-based chemotherapy and immunotherapy has become the standard of care for early-stage triple-negative BC per the pivotal KEYNOTE-522 study [1]. However, pts aged ≥65 represented <20% of KEYNOTE-522 pts. Here, we assessed the clinical and surgical outcomes of older adult pts who received anthracycline-sparing NAT for early-stage, triple-negative BC.
Methods: In this retrospective case series, 34 Mayo Clinic enterprise pts aged ≥65 who were documented to have 1) received anthracycline-sparing NAT with immunotherapy +/- chemotherapy and 2) completed surgery for nonmetastatic, HER2-negative BC between 6/2019 and 3/2024 were reviewed. We did include pts with low hormone receptor (ER +/- PR) expression. One pt who had a concomitant non-BC malignancy was excluded. Demographics, baseline clinical and tumor characteristics including stromal tumor-infiltrating lymphocytes (sTILs), reasons for anthracycline omission, NAT-related toxicities, and surgical outcomes were assessed. The primary endpoint was pathological complete response (pCR).
Results: Thirty-three pts were included. Median pt age was 75 (range, 65-89), and most pts (28/33, 84.8%) were Non-Hispanic White. Nine pts (27.3%) had a prior history of cancer, and 4/33 (12.1%) had a history of anthracycline use. Only 3/33 (6.1%) had documented LVEF ≤50% prior to NAT, one of whom had received an anthracycline previously. Most had grade 3 (24/33, 72.7%), cT2 (22/33, 66.7%), and cN1 (17/33, 51.5%) disease pre-NAT. Baseline sTIL % ranged from 0 to 80% for the 16 pts for whom these data were available. The most frequently administered NAT regimen was carboplatin, paclitaxel, and pembrolizumab (25/33, 75.8%). The most-often cited reasons for anthracycline omission were medical comorbidities including cardiac comorbidities (7/33, 21.2%), favorable clinical response to anthracycline-sparing NAT (7/33), and difficulty tolerating anthracycline-sparing NAT (7/33). Over half of pts (17/33, 51.5%) had a documented grade ≥3 adverse event (AE) of any type, of whom 6 pts had a grade ≥3 immune-related AE. Similarly, 17/33 pts had to discontinue all or part of NAT due to NAT-related toxicities. No pts had a documented grade 4-5 AE.
pCR was achieved by 11/33 (33.3%) pts, most of whom had cT2 (7/11, 63.6%), node-positive (7/11) BC pre-NAT. None had axillary nodal disease only. 2/11 (18.2%) had a BRCA mutation or variant of unknown significance, and 3/11 had ER +/- PR-low BC. All but 1 received carboplatin as part of NAT. Most pts (8/11, 72.7%) had a documented grade ≥3 AE, half of which were immune related, and 7/11 (63.6%) had to discontinue all or part of NAT due to NAT-related toxicities. Only 4/11 received adjuvant pembrolizumab (36.4%).
Conclusion: One third of elderly pts achieved pCR with a non-anthracycline-based NAT

regimen. However, over half of our sample (51.5%) experienced grade ≥3 AEs, including 72.7% of pts with pCR. Our institutional experience was limited by a small sample size. Analysis of pCR based on sTILs is ongoing.

P3-08-08: Clinical and financial impact of implementation of Oncotype Dx in women with HR positive HER2 negative early breast cancer treated in a Chilean Cancer Center.

Roxana Allende, Isabel Saffie, Maria Canals, Catalina Gonzalez, Felipe Reyes, Francisca Torres, Nelson Saez, Macarena Vera, Badir Chahuan, Carolina Selman, Mauricio Mahave

Introduction: Fundación Arturo López Pérez Foundation (FALP) is a non-profit oncology institute located in Santiago, Chile. It serves patients from the public and private health system, associated or not to an oncology insurance offered by the same institution. Since 2022, this insurance covers Oncotype Dx genomic platform for its affiliates. We present real-world clinical and financial data associated with its application, with the aim of optimizing this resource in our institution.

Method: Ninety-one patients with HER2-negative hormone receptor-positive early breast cancer were prospectively analyzed between January 2022 and April 2024. In all of them Oncotype Dx was applied to define the indication for adjuvant chemotherapy (ChT).

The following clinicopathological variables were described in lymph node positive (N1) and negative (N0) patients: age, tumor size, estrogen and progesterone receptors, Ki67, grade and menopausal status. The association between the aforementioned variables and the recurrence score by Oncotype Dx (RS) for each group of patients was studied by Fisher's exact test. In addition, for both N0 and N1, the Predict score was calculated and its predictive ability to obtain a RS >25 was evaluated by means of ROC curves and area under the curve, identifying the best cut-off point.

From a financial point of view, costs were estimated by analyzing two scenarios. The first corresponds to the cohort with Oncotype. The second was simulated assuming that N0 patients with Predict ≥ 3 and 100% of N1 patients, in the absence of Oncotype Dx, would receive ChT.

Results: The median age was 61 years (48-77 y). 48% were diagnosed by screening. 59% were T1, with an average size of 1.8 cm (0.8 - 3.5 cm). 91% were ductal carcinomas and 22% were grade 3. 33 patients were N0. The mean age was 48.1 years, 33.3% were menopausal. There was a higher percentage of patients with T2 and grade 3 tumors. 58 patients were N1. The mean age was 61.1 years, all postmenopausal. A higher mean estrogen receptor and a lower mean Ki67 were observed. RS distribution had significant association with: progesterone receptors, Ki67, T and tumor grade, in both groups. The predictive ability of Predict for RS>25 was higher in N0 (AUC = 0.984) than in N1 (AUC = 0.793).

After analysis, in the N0 cohort, the best Predict cutoff point was 4. If tumor grade equal to 3 is also considered, the negative predictive value of Predict for SR>25 is 100%. In N1, a Predict cut-off point of 3.7 was calculated, obtaining a negative predictive value of 94.1%, leaving 2 patients with SR >25 undetected.
There was a 74% reduction in the total cost of ChT in the N1 cohort. When adding the cost of Oncotype Dx, the total expense is reduced by 32% in this group. When analyzing the N0 cohort, there is a 17% reduction in ChT costs. However, when including platform costs, there is a 41% increase in cost in this group. If we consider both cohorts, there is a 59% reduction in treatment costs, but only a 1% reduction in total costs.
Conclusions: There is a significant change in the indication for ChT by RS, de-escalating by 74% in the N1 group, and changing the indication by 32% in N0.
With respect to the financial analysis, and taking into account the costs in both groups, the savings are marginal.
Although more data are still required, in this study, the results suggest that Oncotype Dx should be indicated in N1 and only in N0 patients with Predict less than 4 and tumor grade 1 and 2, optimizing resources and improving cost-effectiveness.

P3-08-09: Clinicopathological feature based risk of recurrence in pT2N0 HR-positive and HER2-negative early breast cancer as included in NATALEE-trial: a retrospective, real-world, monocentric study

Rik Van Severen, Hans Wildiers, Giuseppe Floris, Chantal Remmerie, Sileny Han, Maxime Van Houdt, Anne Deblander, Ann Smeets, Ines Nevelsteen, Caroline Weltens, Hilde Janssen, Adinda Baten, Jelle Verhoeven, Chantal Van Ongeval, Machteld Keupers, Helen De Boodt, Renate Prevos, Annelies Coessens, Valerie Celis, Kaat Van Herck, Christine Desmedt, Annouschka Laenen, Patrick Neven

Introduction: In the NATALEE-trial, Ribociclib added to adjuvant endocrine therapy significantly reduced breast cancer recurrence in the subgroup of women with high-risk, lymph node negative, hormone receptor (HR) positive, HER2 negative early stage disease. To assess the prognostic value of clinicopathological features alongside tumour stage, we compared breast cancer outcome between patients with high risk pT2N0 breast cancer (as eligible in the NATALEE-trial) and patients with a pT1-2N1 breast cancer.
Methods: This is a retrospective, monocentric study with real-world data of patients with HR-positive, HER2-negative early breast cancer treated in University Hospital Leuven (UHL) between January 2000 and October 2023. We defined high risk pT2N0 disease as grade 3 tumours or grade 2 with a K67 >20% or MammaPrint (MP) clinical high risk. pT1-2N1 patients were included regardless of grade, Ki67 index or MP clinical risk score. As per intern protocol, the Ki67 index was not determined for grade 3 tumours. All patients received adjuvant radiotherapy and systemic treatment according to institutional guidelines. Our endpoints were distant disease free survival (DDFS), invasive disease free survival (IDFS) and breast cancer specific survival (BCSS). We used Kaplan–Meier analyses for the estimation of the 5,10 and 15yr DDFS and IDFS and cumulative incidence function

(CIF) for BCSS, to evaluate the associations of the breast cancer's clinicopathological features with patients' outcomes. Analyses have been performed using SAS software.
Results: We included 711 patients with pT2N0 high risk breast cancer [median age: 62yrs; (neo-)adjuvant chemotherapy 42,5%]. 538 (75.7%) were grade 3 and 173 (24.3%) grade 2 with a high Ki67 or MP clinical high risk. 1902 patients with pT1-2N1 disease were included [median age: 58yrs; (neo-)adjuvant chemotherapy 49.2%]. 533 (28.0%) were grade 3 and 1356 patients had a lower grade of which 119 (6.2%) had a Ki67 >20% while 594 (31.2%) had a Ki67 <20% and 643 (33.8%) did not have Ki67 testing. Tumours that did not have Ki67 testing were MP clinical high risk. After 15 years, DDFS were 61.5% (95% CI [56.7;65.8]) and 64.0% (95% CI [61.2;66.7]) in the pT2N0 and pT1-2N1 groups respectively (HR 1.179 [1.008;1.378], p-value 0.0392). IDFS was 57.1% (95% CI [52.4;61.5]) for the pT2N0 group and 60.6% (95% CI [57.8;63.3]) for the pT1-2N1 group (HR 1.220 [1.052;1.414], p-value 0.0085). BCSS was 85.4% (95% CI [81.8;88.6]) in the pT2N0 group and 88.3% (95% CI [86.4;90.1]) in the pT1-2N1 group.
Conclusion: In this retrospective analysis DDFS, IDFS and BCSS were all numerically worse in a NATALEE eligible high risk pT2N0 population compared to a population with pT1-2N1 tumours of any grade or Ki67 index. These findings suggest that tumour biology may have a more important prognostic value than the tumour stage in HR-positive HER2 negative early stage breast cancer. Longer follow-up in the NATALEE-trial is needed to investigate the possible benefit of adding Ribociclib to adjuvant therapy based on clinicopathological features.

P3-08-10: Real-world treatment patterns and clinical outcomes for patients with metastatic triple-negative breast cancer (mTNBC) in the United States: an electronic health records observational study

Tiffany Traina, Sam Hillman, Manali Bhave, Chantal H. Shah, Reema Tank, Simon Collin

Background: Survival outcomes for patients with mTNBC have improved with the approval of immunotherapy for PD-L1-positive disease; however, chemotherapy remains the standard of care for patients who are PD-L1-negative and those who cannot receive immunotherapy. This study was initiated to assess real-world treatment patterns and clinical outcomes for patients with mTNBC in the United States.
Methods: This was a retrospective, observational study utilizing electronic health record data from the Flatiron Enhanced Datamart. Patients (≥18 years of age) diagnosed with mTNBC between January 01, 2018 and June 30, 2023, who received at least one line of therapy (LoT) in the metastatic setting were included. Patients diagnosed with other primary cancers (except non-melanoma skin cancer) ≤3 years prior to mTNBC diagnosis and patients enrolled in clinical trials were excluded. Patients were followed until date of death or last recorded activity in the Flatiron database, or data cut off (November 30, 2023). Baseline and clinical characteristics, treatments received, and clinical outcomes were captured. The primary endpoint of the study was the type of drug given for LoT1. Secondary endpoints included treatment patterns for LoT1–5, and clinical outcomes by LoT.

Results: The cohort comprised 1,044 patients with mTNBC. Most patients were female (99.2%); median age was 61 years (interquartile range 52–71) and 52.1% were White. The most common drug class in all LoTs was chemotherapy given as monotherapy or in combination with other agents: LoT1 87.5%, LoT2 76.8%, LoT3 69.8%, LoT4 70.7%, and LoT5 75.0%. Median (95% CI) real-world overall survival (rwOS) was 14.0 (12.9–16.0) months; real-world progression-free survival from mTNBC diagnosis was 5.8 (5.4–6.3) months. Among patients with confirmed PD-L1 status (n=367), 109 (29.7%) were PD-L1-positive and 258 (70.3%) were PD-L1-negative. Median rwOS (95% CI) was 18.6 months (15.2–24.4) in the PD-L1-positive cohort compared with 12.7 months (11.0–16.0) in the PD-L1-negative cohort. From 01 Jan 2021 onwards, immunotherapy was received by 21/39 (53.8%) patients who had PD-L1-positive tumors in LoT1, and by 33/39 (84.6%) patients with PD-L1-positive tumors across all LoTs. Median rwOS (95% CI) was longer for patients with PD-L1-positive tumors who received immunotherapy (18.6 months [15.2–26.3]) months than for those who did not (15.5 months [18.3–not estimable]).
Conclusions: In this real-world study in the United States, clinical outcomes in patients with mTNBC remain poor, particularly among those with PD-L1-negative disease. There is a high unmet need for more efficacious and tolerable treatments for mTNBC, including targeted agents that may be more effective and less toxic compared to conventional chemotherapy.

P3-08-11: Clinico-Pathological Features of Breast Cancer Patients Who Recured After Achieving pCR with Neoadjuvant Chemotherapy before Surgery (KBCSG-18)

Jee Hung Kim, Joon Jeong, Kyung Hae Jung, Jai Min Ryu, Han-Byoel Lee, Hyun-Ah Kim, Jieun Lee, Airi Han, Hee Kyung Ahn, Tae In Yoon, Sung Yong Kim, Eun Young Kim, Ku Sang Kim, Joohyuk Sohn

Background: Patients who achieve a pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) before surgery have been reported to have higher long-term survival rates. However, despite a better prognosis, pCR patients have a potential for local and/or distant recurrence. Herein, we report clinico-pathological features of breast cancer patients who recurred after achieving pCR with NAC.
Methods: This study retrospectively reviewed the data of patients diagnosed with breast cancer who experienced recurrence after achieving pCR following NAC between January 1999 and April 2022 from 13 cancer hospitals in the Korean Breast Cancer Society Group (KBCSG). The patients were identified in a database that had been managed in each hospital. pCR was defined as no residual invasive cancer in the breast and axillary nodes (ypT0 or ypTis with ypN0). Breast cancers were classified into three subtypes based on hormone receptors (HR) and human epidermal growth factor receptor 2 (HER2) status. The primary purpose of the study was to identify the clinicopathologic characteristics, recurrence patterns, and overall survival of patients who experienced recurrence after achieving pCR following NAC. This study was approved by an institutional review board in each hospital.
Results

A total of 131 patients were identified to have achieved pCR and relapsed thereafter. The median age of the patients was 48 years (range 27-72), with a median follow-up duration of 25.6 months (range 0.5 - 136.7). The median recurrence-free survival (RFS) was 17.0 months (95% CI 13.5-20.5). The distribution of initial clinical TNM stages was as follows: stage IB in 1 (0.8%), stage IIA in 16 (12.2%), stage IIB in 27 (20.6%), stage IIIA in 29 (22.1%), stage IIIB in 11 (8.4%), and stage IIIC in 45 (34.4%) patients. This study included 70 (53.4%) HER2-positive, 50 (38.2%) triple-negative and 8 (6.1%) HR-positive breast cancer patients. Among these populations, 81 (61.8%) had systemic recurrence, 33 (25.2%) experienced local recurrence, and 17 (13.0%) had both local and distant recurrence. Upon reviewing the first presented recurrence patterns of 131 patients, they showed brain (n=45, 34.4%), lung (n=26, 19.8%), liver (n=14, 12.2%), bone (n=14, 10.7%), locoregional lymph node (n=16, 12.2%), ipsilateral breast (n=24, 18.3%), and contralateral breast (n=8, 6.1%) recurrence. After recurrence, median overall survival was 76.7 months (95% CI 41.2-112.2) in the HER2-positive, 45.8 months (95% CI 16.5-75.1) in TNBC, and 40.3 months (95% CI 2.7-77.8) in HR-positive subtypes.
Conclusion: Given the limitation of retrospective study, such as selection bias, patients with pCR after NAC followed by relapse showed a high incidence of brain metastasis as the first relapse site and favorable overall survival compared to historical data.

P3-08-12: Poor Response of Metaplastic Triple-Negative Breast Cancer to Neoadjuvant Chemoimmunotherapy: An Unmet Oncological Need

Sara B. Cartwright, Heng Jiang, Lina Elsayed, Shivani Modi, Samia Asif, Meghana Kesireddy, Amulya Yellala, Andrew O. Wahl, Jessica E. Maxwell, David G. Wagner, Subodh M. Lele, Jairam Krishnamurthy, Juan A. Santamaria-Barria

Introduction: Metaplastic breast cancer (MpBC) is a rare and aggressive subtype characterized by clinical and pathological heterogeneity, advanced stage at presentation, frequent chemoresistance, and distant spread. The majority of MpBCs are hormone receptor and HER2 negative and thus treatment protocols and guidelines tend to follow those of triple-negative breast cancer (TNBC). Oncology teams have begun to use the KEYNOTE-522 (KN-522) neoadjuvant chemoimmunotherapy regimen to treat TNBC MpBC. Real-world data on MpBC responses to this regimen are limited, and the KN-522 trial did not report the inclusion of patients with MpBC.

Methods: We conducted a real-world review of patients with biopsy-proven, non-metastatic, TNBC MpBC who were treated with the KN-522 neoadjuvant regimen at our institution. This regimen consists of neoadjuvant paclitaxel, carboplatin, doxorubicin, and cyclophosphamide, combined with neoadjuvant and adjuvant pembrolizumab, an immune checkpoint inhibitor monoclonal antibody against programmed cell death protein 1. Institutional Review Board (0430-23-EP) approval and consent from all patients were obtained. Demographic, clinical, and pathological data were collected. The primary outcome was pathological complete response (pCR) defined as ypT0/Tis ypN0. The secondary

outcomes were adverse events (AEs) and recurrence-free survival.

Results: Between July 2021 (KN-522 regulatory approval) and July 2024, seven female patients aged 39-78 presented to our cancer center with T2 (>2 cm) or larger, and/or node-positive, biopsy-proven TNBC MpBC. Three patients were Non-Hispanic White, two were Non-Hispanic Black, and two were Hispanic. One patient had a pathogenic variant on CHEK2 and another on BRCA1. Prognostic stages ranged from stage IIB to IIIC. Metaplastic carcinoma differentiation included squamous keratin-producing, chondroid, chondromyxoid, and mesenchymal spindle cell types. All patients were recommended to receive the KN-522 neoadjuvant regimen consisting of four cycles of pembrolizumab, paclitaxel, and carboplatin, followed by four cycles of pembrolizumab, doxorubicin, and cyclophosphamide, followed by nine cycles of adjuvant pembrolizumab. Three patients discontinued their neoadjuvant regimen and proceeded directly to surgery due to intolerance of AEs for two and local tumor progression for the other. Five patients underwent dose reductions of the regimen due to AEs, and one patient discontinued pembrolizumab due to grade III immune-related colitis. Another patient did not receive adjuvant pembrolizumab due to high-dose steroid treatments for kidney transplant rejection. Five patients underwent lumpectomy with sentinel lymph node biopsy (SLNB) and two underwent mastectomy with SLNB with targeted axillary dissection, with one of these undergoing a completion axillary lymph node dissection. No patient sustained a pCR on final pathology (0%), with residual cancer burden (RCB) classes of two patients with RCB-III, four patients with RCB-II, and one patient with RCB-I. At the last follow up, no patient had experienced breast cancer recurrence, with a median follow-up of only 9 months after completion of all loco-regional treatments (range, 2-19 months).

Conclusion: In this real-world experience, none of our patients with TNBC MpBC treated with the KN-522 neoadjuvant regimen achieved a pCR. These patients also exhibited poor tolerance, requiring frequent dose reductions and discontinuations. Despite no patient has experienced recurred to date, the follow-up period is still immature. This experience highlights the need to evaluate whether KN-522 is an appropriate neoadjuvant regimen for TNBC MpBC, and underscores the distinct heterogeneous biology of MpBC and its unmet oncological needs.

P3-08-13: Measuring the impact of Komen's Financial Assistance program on the treatment experience of those living with MBC

Shelby Lautner, Janet Okamoto, Ariana Roman, Ruth Schlesinger, Dustin Scott, Kari Wojtanik

Background: The American Cancer Society published that 61% of cancer patients find it difficult to pay for their care (2021). Additionally, lower income groups often delay or skip filling prescriptions to save money or cut pills to reduce care costs (ACS, 2021). Patients

also report making financial sacrifices to pay for their care or avoiding scheduling or cancelling previously scheduled appointments due to associated costs. Susan G. Komen's Komen Financial Assistance Program provides direct cash assistance to qualifying individuals diagnosed with breast cancer. Meeting the needs of those living with metastatic breast cancer (MBC) is a priority for Komen, and last year, 27% of those who received funds though the Komen Financial Assistance Program identified as living with MBC.
Methods: When a patient applies for assistance through the program, an application is completed that collects demographic information, the primary financial need, information about their diagnosis, and income information. To measure the impact of Komen's Financial Assistance program, an evaluation survey is distributed 30 days after the assistance is provided. Survey questions ask patients about their experience with the program and how the assistance was used. Questions included are meant to determine if the assistance provided by Komen affected the financial stressors experienced by patients that has been documented in peer reviewed literature. The survey asks if the assistance helped patients continue their care, if they were able to avoid skipping breast cancer related appointments, if they were able to avoid skipping medications, and if the assistance allowed them to make fewer financial sacrifices. For analysis, the data was sorted by breast cancer stage, and an in-depth analysis was completed for recipients who are living with metastatic breast cancer.
Results: Though analysis of the application data, it was found that, across all approved applicants (Stages 0 - IV), the highest reported financial need was for rent or housing (31.4%). When stratified by stage, it was found that the highest reported financial need of those living with MBC was oral treatment medications (40.6%). Of survey respondents living with MBC (N=1,668), 54.3% said that the assistance helped them avoid skipping medications. Sixty-one percent of respondents living with MBC indicated that the assistance helped them avoid delaying or skipping breast cancer related appointments. Additionally, 97.7% of those living with MBC agreed that, after receiving the assistance, they were better able to continue their breast cancer care. Finally, 92.3% of survey respondents living with MBC said that, after receiving the assistance, they had to make fewer financial sacrifices to cover the cost of their breast cancer care.
Conclusion: Through the evaluation of Komen's Financial Assistance Program, results show that direct cash financial assistance to patients helps alleviate financial stressors, particularly for those living with MBC. Komen's Financial Assistance Program substantially impacts those it serves who are living with MBC. However, financial toxicity is a complex issue and requires intervention at multiple levels for systemic change. This includes support from policy makers for expanded health care coverage, continued funding of programs like Komen's financial assistance program, and addressing the unique needs of specific groups.

P3-08-14: Analysis of the Occurrence Time of Bone Metastasis and Disease Treatment Patterns in 737 Patients with Breast Cancer Bone Metastasis: A Retrospective Study from China

Xiaojia Wang, Mengyu Ding, Hai Hu, Zhanhong Chen, Yabing Zhen, Wenming Cao, Xiying Shao, Junqing Chen, Huanhuan Zhou

Background:Bone is the most frequent site of metastasis in breast cancer, with a significant proportion of patients experiencing bone involvement at the initial metastasis. Identifying the critical time periods for its occurrence is crucial for guiding bone metastasis screening, enabling early detection, and facilitating prompt treatment. Since bone targeted agents(BTAs) are vital component of systemic therapy for advanced breast cancer, elucidating real-world treatment patterns holds significant importance for guiding clinical practice advancements.
Methods:This single-center retrospective study analyzed patients with advanced breast cancer and bone metastasis admitted to Zhejiang Cancer Hospital between January 1, 2021, and February 28, 2023. Subgroup analyses were performed to analyze correlations between the time from diagnosis to bone metastasis and clinical factors. The skeletal-related events (SREs) were collected during the follow-up. For quantitative indicators that conformed to normal distribution, independent sample t-tests or analysis of variance (ANOVA) were employed; otherwise, non-parametric Mann-Whitney U tests or Kruskal-Wallis tests were used. Bone CT values were quantitatively assessed to evaluate the therapeutic efficacy of bone metastases.
Results:Among 737 breast cancer patients with bone metastasis, 416 (71.1%) had bone metastases at the initial metastasis, and within this group, 180 patients (43.8%) had bone as the only site of metastasis; the other 169 patients (28.9%) did not exhibit bone metastasis initially but developed it during subsequent treatment and follow-up. The time from breast cancer diagnosis to the first occurrence of bone metastasis (median, months[mos]) was significantly associated with factors such as receipt of neoadjuvant therapy (73.7mos for no neoadjuvant therapy received, 50.6mos for neoadjuvant therapy received; $p<0.001$), surgical approach (radical surgery 71.2mos, palliative surgery 24.8mos; $p=0.001$), number of postoperative pathological lymph node metastases (N0 72.5mos, N1 72.8mos, N2 60.9mos, N3 51.5mos; $p=0.001$); vascular tumor thrombus invasion (positive 48.2mos, negative 65.1mos; $p=0.001$); postoperative stage (Stage I 54.6mos, Stage II 64.1mos, Stage III 53.5mos; $p<0.001$); molecular subtype (HER2+ 48.6mos, Luminal A 77.6mos, Luminal B HER2+ 65.2mos, Luminal B HER2- 63.9mos, TNBC 43.5mos; $p<0.001$); and Ki 67 expression (73.3ms for Ki 67<15%, 55.4ms for Ki 67≥15%; $p=0.005$). Of which, the shorter time to bone metastasis were observed with higher Ki 67 values. However, no significant correlation was found between the time from breast cancer diagnosis to bone metastasis and tumor size, histological grade, or pathological type. Among these patients, 90.4% received BTA treatment, and 95.8% of them adhered to the treatment schedule. Furthermore, 35.6% of the patients changed the type of BTA during treatment. Quantitative assessment of bone lesion efficacy using CT values revealed a median pre-treatment CT value of 306.0, which increased to 445.6 post-treatment ($p<0.001$). During follow-up, 176

patients (23.9%) experienced SREs, primarily bone radiation therapy (47.4%), pathological fractures (35.8%), and bone surgery (27.8%).
Conclusion:The timing of bone metastasis after breast cancer diagnosis is significantly correlated with factors such as whether or not neoadjuvant therapy was administered, the surgical approach used, the number of metastatic lymph nodes, the postoperative staging, the molecular subtype, the expression of Ki 67, and the presence of vascular invasion by tumor thrombus. Real-world data from this center suggests that bone targeted agents for breast cancer patients with bone metastasis contribute to improving bone lesion CT values.

P3-08-15: Overall Survival and Economic Impact of Triple-Negative Breast Cancer in Brazilian Public Healthcare: A Real-World Study

André Mattar, Marcelo Antonini, Andressa Gonçalves Amorim, Marina Diógenes Teixeira, Cristiano Augusto Andrade de Resende, Francisco Pimentel Cavalcante, Felipe Zerwes, Renata Arakelian, Eduardo de Camargo Millen, Fabricio Palermo Brenelli, Antonio Luiz Frasson, Isadora Santello Leonardo, Ana Luisa de Souza Lopes, Paulo Leonardo Miranda Sposito, Marina Fleury de Figueiredo, Daniele Arbache, Gabriela Amorim Baia, Luiz Henrique Gebrim

Background: Triple-negative breast cancer (TNBC) represents considerable treatment challenges, particularly in public healthcare systems within low- and middle-income countries, where access to the most advanced treatment options, such as Antibody-Drug Conjugates (ADCs), immunotherapies, and PARP inhibitors, is often limited. This study seeks to fill the knowledge gap on TNBC, analyzing the clinical, epidemiological, and economic impact of these characteristics affecting survival rates in Brazilian public healthcare system.
Methods: A real-world, retrospective cohort study was conducted at Pérola Byington Hospital in São Paulo, Brazil, involving all TNBC patients treated between 2010 and 2019. Stage-specific overall survival (OS) rates were calculated, and OS was compared among patients who received neoadjuvant or adjuvant treatment, those with and without a complete pathological response, black and non-black patients, and those treated with or without carboplatin-based neoadjuvant therapy. Cox proportional hazards regression models were fitted to estimate Hazard Ratios (HR) with 95% confidence intervals (CI). The annual costs for each stage of systemic TNBC treatment were estimated from AHCP (Authorization for High Complexity Procedures) data for the year 2023.
Results: 1.266 patients had TNBC, and 710 met the eligibility criteria for inclusion. Kaplan-Meier analyses highlight the disparities in TNBC patient outcomes across stages, with stage II patients experiencing a 47% lower mortality risk compared to stage III (HR=0.53; 95% CI 0.33 to0.85; p=0.009). Moreover, patients in the adjuvant treatment group had a reduction in the risk (HR= 0.48; 95% CI 0.34 to 0.69) compared to those in the neoadjuvant treatment. Patients achieving a complete pathological response (pCR) substantially improved OS (HR=0.21; 95% CI 0.11 to 0.43; p<0.001). (HR=0.24, 95% CI 0.13 to 0.46; p<0.001). Black patients have better survival compared to non-black patients (HR=0.58; 95% CI 0.40 to

0.86; p=0.006). The use of Carboplatin in treatment does not show a significant improvement in OS compared to treatments without Carboplatin (HR=0.96; 95% CI 0.65 to 1.43; p=0.857). The average monthly cost for systemic TNBC treatment increases with disease progression: $101.87 for Stage I and up to $314.77 for Stage IV second-line therapy. The total cumulative cost ranges from $11,918.98 for Stage I to $28,9685.24 for Stage IV treatment of TNBC.
Conclusions: This study offered a comprehensive description of the clinical and epidemiological profiles of TNBC patients within Brazil's public healthcare framework. It has demonstrated that the OS rates for TNBC patients decline as the disease progresses to advanced stages and was better for black population. Additionally, the data indicates that achieving a pCR after treatment and received adjuvant treatment is associated with a marked improvement in survival rates. Direct costs escalate substantially as patients progress to higher stages, underscoring the economic burden and the increased complexity of managing advanced TNBC.

P3-08-16: TADPOLE: A multicentre, pragmatic, phase III randomised controlled trial comparing Targeted Axillary Dissection vs axillary node clearance in patients with POsitive axillary Lymph nodes in Early breast cancer

Shelley Potter, Kerry Avery, Ramsey Cutress, David Dodwell, Nisha Sharma, Katherine Fairhurst, Tim Robinson, Indrani Bhattacharya, Natalie Blencowe, Hannah Markham, Elsa Marques, Lucy Culliford, Petra Baji, Kirsty Roberts, Jessica Harris, Sophie Rees, Adrienne Morgan, Margaret Perkins, Stuart A McIntosh

Background: In the UK, all patients with newly diagnosed invasive breast cancer have axillary staging with an axillary USS +/- biopsy of abnormal/equivocal nodes and currently UK NICE guidelines recommend axillary node clearance (ANC) for allpatients with biopsy proven node positive breast cancer having primary surgery, irrespective of the number of nodes involved (~20% of all patients). This highly morbid procedure leads to life-long complications in 1 in 3 patients including lymphoedema and chronic pain which dramatically impact quality of life.
ANC aims to reduce locoregional recurrence (LRR) and improve breast cancer survival but there is no evidence to support these benefits for patients with limited nodal involvement (cN0, radiologically detected disease). These patients would meet the criteria for omission of ANC based on eligibility for the ACOSOG Z0011 trial, but this approach has not been adopted in the UK due to concerns regarding false negative sentinel node biopsy (SNB) in node positive patients.
Targeted axillary dissection (TAD) which combines removal of the localised biopsy proven involved node(s) in combination with a SNB may offer an alternative to ANC, effectively addressing concerns regarding false negative rates while reducing the risk of life-changing complications
The TADPOLE study aims to determine if TAD is a clinically and cost-effective alternative to

ANC in patients with low volume node positive breast cancer having primary surgery.
Methods: TADPOLE is a multicentre pragmatic phase 3 randomised controlled trial comparing TAD and ANC in breast cancer patients with low volume nodal disease having primary surgery.
All patients with cN0 biopsy proven low volume axillary nodal disease will be eligible to participate. Excluded will be patients with >3 nodes on USS, those who have recurrent disease, previous axillary surgery or neoadjuvant systemic therapy. Participants will be randomised 2:1 to TAD or ANC. Surgical quality assurance (QA) processes will promote standardised introduction of 'primary' TAD in the UK and ensure procedure fidelity within the trial. Participants will have adjuvant therapy as per standard of care but axillary radiotherapy (ART) will be prohibited in the TAD group. Robust radiotherapy quality assurance (RTTQA) will be embedded throughout.
The co-primary end-points are:
i) Patient reported and objective lymphoedema at 12 months
ii) Single arm analysis of LRR at 5 years in the TAD cohort.
Recruitment of 390 patients in the TAD arm will be required to detect a 50% reduction in lymphoedema at 12 months with 90% power and a type 1 error of 5% and exclude an undesirable LRR of <5% in the TAD cohort at 5 years with one sided 2.5% alpha and 90% power. Inflating for multiplicity and allowing for 5% dropout and 5% crossover a total of 861 patients (574 TAD:287 ANC) will be required for the trial. 40 UK breast units will recruit to the trial.
An embedded qualitative study will optimise recruitment and a SWAT (study within a trial) will optimise the inclusion of non-English speaking participants.
Results: Consensus work with UK breast surgeons to agree how to standardise axillary surgery within the trial is underway and will underpin the surgical QA within TADPOLE. The trial will commence recruitment early 2025 and include a 9 month internal pilot phase. Recruitment is planned for 28 months with a target of 1 participant/centre/m at 40 sites.
Conclusion: TADPOLE has been designed with extensive patient and public involvement and will address the top UK breast surgery research priority identified in the James Lind Alliance Priority Setting Process. If TAD causes less lymphoedema and is oncologically safe, TADPOLE will change practice, improving outcomes for thousands of patients with node positive breast cancer each year.

P3-08-17: TBCRC 058: A Randomized Phase II Study of Enzalutamide, Enzalutamide with Mifepristone, & Treatment of Physician's Choice in Patients with Androgen Receptor-Positive Metastatic Triple-Negative or Estrogen Receptor-Low Breast Cancer (NCT06099769)

Rita Nanda, Yuan Chen, Katia Khoury, Hope S. Rugo, Erica L. Mayer, Lisa A. Carey, Michelle Melisko, Angemael Syldor, Chaya Friedman, Jennifer Savoie, Fresia Pareja, Britta Weigelt, Sarat Chandarlapaty, Nicholas Turner, Joshua Lang, Marina Sharifi, Suzanne Conzen, Tiffany Traina

Background: Triple-negative breast cancer (TNBC) refers to a heterogenous group of breast cancers that lack expression of ER, PR, and HER2. Despite recent advances with immunotherapy (IO) and antibody-drug conjugates (ADCs), TNBC remains the most aggressive subtype, characterized by a high risk of recurrence and a short overall survival in the metastatic setting. Breast tumors with low levels of ER and PR expression (1-10%) clinically behave like TNBC, and clinical management follows the TNBC treatment (tx) paradigm. We and others have identified a subset of breast tumors which are ER/PR/HER2 negative and express the androgen receptor (AR). Enzalutamide (enza), an AR-antagonist, had demonstrated activity in AR+ metastatic TNBC (Traina et al, JCO 2018). Activation of the glucocorticoid receptor (GR) has been implicated as a mechanism of resistance to AR inhibition in prostate and breast cancers (Kach et al, Sci Transl Med 2015). Advanced TNBC remains an area of high unmet need, particularly in patients who are ineligible for or progress following a checkpoint inhibitor. This randomized study will evaluate the efficacy of enzalutamide or enzalutamide plus the GR antagonist mifepristone (mif) as compared to physician's choice chemotherapy (TPC).
Methods: This is a randomized phase II trial; 201 patients (pts) will be randomized in a 1:1:1 fashion to enza, enza with mif, or TPC (carboplatin, paclitaxel, eribulin, or capecitabine). The primary endpoint (endpt) is progression free survival (PFS), and the trial is designed to test the hypothesis that PFS in the pooled enzalutamide arms is superior to TPC; there is 80% power to detect a hazard ratio (HR) of 0.70, corresponding to increase in PFS from 3.5 months (mos) with TPC to 5.0 mos with enza-based tx. Secondary endpts include comparisons of PFS among 3 arms and evaluation of response rate, clinical benefit rate, duration of response, overall survival, safety/toxicity, and patient-reported outcomes by arm. Exploratory endpts include correlation of tumor and circulating markers (AR-V7 in circulating tumor cells and circulating tumor cell DNA) with tx response. Eligible pts must have: ECOG 0-2, metastatic ER/PR low or negative, HER2 negative breast cancer (BC), measurable or evaluable disease (dz), < 2 prior lines of chemotx, any # prior endocrine txs, no prior anti-AR tx, no prior mif, concurrent CYP17 inhibitors prohibited. Pts with PD-L1+ BC must have received prior IO if not contraindicated. Tumors must have AR >/= 10%, normal organ function, no history of brain mets. As of 7/1/2024, 7 of 201 pts have begun protocol-specified tx.
This trial is supported by the TBCRC, BCRF, The TaTa Sisterhood Foundation, Pfizer/Astellas, and Corcept Therapeutics.

P3-08-18: The AmeliaTM-1 study: A phase 1b/2 study assessing the safety and efficacy of evexomostat (SDX-7320) plus a PI3K/Akt inhibitor and fulvestrant in patients with advanced HR+/Her2- breast cancer

Peter Cornelius, David Browning, Benjamin Mayes, Pierre Dufour, James Shanahan, Bradley Carver, Margaret Fletcher, Hope S. Rugo, Srilata Gundala, Chaitali S. Nangia, Brent N. Rexer

Clinical Rationale: Breast cancer patients with alterations in the PI3K pathway (eg, mutations in PIK3CA, Akt or loss of PTEN) have more aggressive disease and worse

outcomes relative to patients without these alterations. Agents approved or in late-stage development for treating this patient population (alpelisib, capivasertib, inavolisib) can cause on-target hyperglycemia leading to hyperinsulinemia which may limit effectiveness of these drugs by overcoming pathway inhibition and/or secondary to reduced dose-density. Restoring insulin sensitivity (which reduces systemic levels of insulin) has been shown to improve the efficacy of PI3K inhibitors in preclinical models of breast cancer.
Evexomostat is a polymer-drug conjugate of a novel small molecule methionine aminopeptidase 2 (MetAP2) inhibitor that in a xenograft model of HR+/Her2-/PIK3CA-mutant breast cancer showed synergistic anti-tumor activity with alpelisib, and in a xenograft model of HR+/Her2+ breast cancer enhanced the efficacy of capivasertib. Studies conducted in normal mice demonstrated that evexomostat significantly reduced hyperglycemia and hyperinsulinemia induced by these PI3K/Akt pathway inhibitors. Evexomostat was well-tolerated in a phase 1 monotherapy safety study in late-stage cancer patients and improved insulin resistance in patients with elevated insulin at baseline, along with improvements in other metabolic and angiogenic markers,
Study Design: This is a phase 1b/2, open-label, single-arm proof-of-concept study in postmenopausal women with HR+, HER2- metastatic breast cancer harboring alterations in the PI3K pathway who progressed following endocrine therapy plus a CDK4/6 inhibitor (www.amelia1.com; NCT05455619).
The primary objective is to determine the safety of evexomostat plus standard of care treatment (physician's choice of alpelisib or capivasertib) and fulvestrant (combined, the 'triplet therapy'), to measure the severity and number of hyperglycemic events, and to assess anti-tumor benefit of the triplet therapy.
The trial consists of a dose-escalation cohort (n=6) with evexomostat dosed at 36 mg/m2 (one dose below the phase I monotherapy MTD of 49 mg/m2) in combination with either alpelisib or capivasertib and fulvestrant dosed in accordance with their respective labels. Based on safety data from the first 6 patients in each triplet combination to complete two cycles, the safety review committee may alter the evexomostat dose for the next safety cohort of six patients.
Once the MTD of the triplet therapy is defined, additional patients will be enrolled until a total of up to 20 patients have completed at least two cycles of triplet therapy at that dose. If warranted, an additional 20 patients may be enrolled to further characterize the efficacy and safety of the triplet therapy. To date, eight patients have been enrolled.
Planned Analyses: Primary safety analysis consists of the number of patients with grade 3 or 4 hyperglycemia during the first 2 cycles of triplet therapy plus the type, frequency, and severity of treatment-emergent adverse events (TEAEs) per the NCI CTCAE, v5.0. Efficacy analyses include calculation of the ORR, consisting of complete response (CR) and partial response (PR). The number of patients alive without disease progression six months from the start of evexomostat and fulvestrant dosing will also be assessed. The CBR of CRs, PRs plus stable disease ≥24 weeks from C1D1 will be calculated.
QoL will be analyzed according to functional scores and recommendations in the EORTC scoring manual. ECOG performance status and change from baseline will be summarized.

P3-08-19: Preliminary results from PIKture-01, a First-in-Human Study of OKI-219, a mutant selective inhibitor of PI3Kα-H1047R, in mutant selected solid tumors including breast cancer.

Samuel Agresta, Alexander Spira, Andreas Varkaris, Seock-Ah Im, Peter Kabos, Ramon Yarza, Yeon Hee Park, Kevin Litwiler, Guy Gammon, Amy Heim, Brian Tunquist, Robbie Alton, Duncan Walker

Background: Aberrant activation of the PI3Ka pathway contributes to tumorigenesis and is associated with resistance to anticancer therapies, making this pathway an attractive target for new therapies[1]. PI3Kα is one of the most commonly mutated oncogenes, found in approximately 13% of human cancers and 29% of breast cancer [2]. There are three predominate mutations in PI3Kα important in cancer. The H1047R mutation in the kinase domain is the most common of the three, found in 40% of HR+/HER2– breast cancers and 10-15% of HER2+ breast cancers [3]. The currently approved PI3Kα inhibitors such as alpelisib target both wild-type and mutant forms, leading to significant on-target toxicities, including hyperglycemia, rash, and diarrhea [4,5]. OKI-219, a mutant-selective PI3Kα inhibitor, has shown preclinical efficacy in PI3Kα-H1047R-mutated models, without the metabolic dysfunction associated with wild-type inhibition, supporting a potential improved therapeutic profile. We hypothesize OKI-219 may achieve greater mutant target coverage with a wider therapeutic window compared to other non-selective PI3Kα inhibitors.
Methods: PIKture-01 is a global, multi-center, first-in-human phase 1a/1b study evaluating OKI-219 as monotherapy and in combination with fulvestrant or trastuzumab in subjects with advanced solid tumors including breast cancer harboring a PI3Kα-H1047R mutation. In Phase 1a, subjects receive escalating oral doses of OKI-219 starting at 300 mg BID continuously. Phase 1b will assess OKI-219 in combination with fulvestrant in patients with HR+ breast cancer, or with trastuzumab in patients with HER2+ breast cancer. The study also includes a dose optimization phase to evaluate the optimal combination doses of OKI-219 with fulvestrant or trastuzumab.
Results: As of 30 September 2024, OKI-219 has been dosed at three dose levels as a single agent: 300 mg BID, 600 mg BID, and 900 mg BID, continuously. Across all dose levels to date, a total of ten subjects have been dosed: six subjects with HR+/HER2- breast cancer, two with HER2+ positive breast cancer, and two with colorectal cancer in the single agent dose escalation. Eight of the ten subjects remain on study. OKI-219 has been very well tolerated, with no dose-limiting toxicities, dose interruptions, or dose reductions required. The most common treatment-emergent adverse events (TEAE) that occurred in >15% of subjects were urinary tract infection, upper extremity cellulitis and pruritus. The most common treatment-related adverse events (TRAE) were grade 1 pruritus. Single-dose pharmacokinetic (PK) results of OKI-219 are consistent with predicted human exposures. At steady state, the exposures of OKI-219 exceed exposures associated with robust antitumor activity in preclinical models.
Conclusion: OKI-219 has been very well tolerated with a favorable safety profile, and only Grade 1 TRAEs observed at exposures that are consistent with preclinical activity, even at

the lowest dose level. As a single agent, OKI-219 has shown favorable PK that support pharmacologically relevant exposures, even at the lowest assessed dose levels, with a safety profile that suggests little or no inhibition of WT PI3Kα. We anticipate near completion of enrollment of the single agent portion of the study as well as the initiation of combination expansion of OKI-219 with fulvestrant by the end of the year. Data will be updated accordingly.

P3-08-20: The PREDICT II Registry: A Prospective Study to Evaluate the Clinical Utility of a 7-Gene Predictive Biosignature on Treatment Decisions in Patients with Ductal Carcinoma In Situ

Rachel Rabinovitch, Pat W. Whitworth, Patrick I. Borgen, Karuna Mittal, Steven C. Shivers, Troy Bremer

Purpose/Objective(s): For women with ductal carcinoma in situ (DCIS) treated with breast conserving surgery (BCS), the benefit of adjuvant radiation therapy (RT) remains controversial. Since level 1 evidence supports the role of RT in reducing the risk of local recurrence, current guidelines generally recommend RT for all women having BCS even though 70-80% do not recur after BCS alone. In response to the need for prognostic and predictive tools for DCIS, a 7-gene predictive biosignature was developed to better assess risk of recurrence and RT benefit. The test provides a validated Decision Score (DS) for assessing 10-year risk of recurrence and RT benefit using individual tumor biology, as assessed by clinical and pathologic biomarkers. The primary objective of the PREDICT registries is to understand the decision impact such a tool has on treatment decisions.
Materials/Methods: This is a multicenter, prospective, observational registry for women diagnosed with DCIS. The primary endpoints are changes in treatment recommendations for surgical, radiation, and hormonal therapy. Secondary endpoints are identification of key drivers for treatment recommendations, such as age, size, grade, patient preference and biosignature status. The study includes females age 26-89 who are candidates for BCS and eligible for RT and/or systemic treatment. Subjects must not have been previously treated

for DCIS or have previous or current invasive or microinvasive breast cancer. After DCIS diagnosis, sites will send the most representative tissue block or sections to a CLIA lab for biosignature testing. Treating physicians will complete a treatment recommendation survey before and after receiving the biosignature test results. Test results, treatment recommendations, patient preferences and clinicopathologic features will be stored in a de-identified registry. Women will be followed for up to 10 years. Changes in pre- and post-test treatment recommendations will be analyzed using McNemar's test (alpha level = 0.05). Multivariate logistic regression will be used to determine odds ratios of clinicopathologic factors leading to pre- and post-test treatment recommendations. Pre-test covariates include patient age, tumor size, palpability, margin status, hormone receptor status, nuclear grade, tumor necrosis, family history of breast cancer, race, ethnicity and patient preference, as well as physician specialty (surgeons vs. radiation oncologists) and post-test covariates will also include the biosignature score. Differences in recurrence-free and overall survival will be assessed by Kaplan-Meier survival analysis using the log-rank test and/or the Cox Proportional Hazards model. The study will enroll up to 3,000 women from about 30 sites across the US. The study has been approved by WCG IRB (Tracking #20172841) and/or local IRBs at each site. ClinicalTrials.gov: NCT03448926.

P3-08-21: Trastuzumab-deruxtecan in HER2-low metastatic breast cancer patients with newly diagnosed or progressing brain metastases: The TUXEDO-4 phase II trial

Maximilian Marhold, Marta Vaz-Batista, María Gión, Manuel Ruíz-Borrego, Isabel Blancas, Cristina Morales, Cristina Saavedra, Felipe Slebe, Marta Campolier, Juliana Carvalho Santos, José Antonio Guerrero-Martínez, Miguel Sampayo-Cordero, Rupert Bartsch, Matthias Preusser

Breast cancer (BC) is the second most common cause of brain metastases (BM) among all solid malignancies, and the leading cause of leptomeningeal disease (LMD). Both BM and LMD are associated with high morbidity and mortality and treatment options are limited. While BM are commonly diagnosed late during the course of metastatic disease in patients with luminal BC, LMD is often diagnosed simultanously and no established systemic treatment option exists to date. Trastuzumab deruxtecan (T-DXd), an antibody drug conjugate combining a HER2-directed antibody with a topoisomerase I inhibitor, showed promising results in mBC patients, including HER2-positive mBC patients with active BM and patients with low HER2 expression (IHC 1+ or 2+ in the absence of ERBB2 amplification). We therefore hypothesized that T-DXd could exhibit relevant clinical activity in HER2-low mBC patients with BM with or without type II LMD. The TUXEDO-4 study is an international, multicenter, single-arm, two-stage optimal Simon's design, phase II trial (NCT06048718). A total of 27 patients (13 in stage 1, and 14 in stage 2 depending on responses in stage 1) will be included in the trial. Key inclusion criteria are: male or female adult patients with HER2-low mBC with newly diagnosed or radiological progressing BM with or without type II LMD (patients with type I LMD cannot be enrolled in the study),

Eastern Cooperative Oncology Group (ECOG) performance status 0-2, ≥1 measurable brain lesions, left ventricular ejection fraction ≥50%, and ≥1 prior line of systemic treatment in the metastatic setting. Patients will receive T-DXd 5.4 mg/kg intravenously every 21 days until unacceptable toxicity, progressive disease, death, or discontinuation for any other reason. The primary endpoint is treatment efficacy, as defined per central nervous system (CNS) objective response rate (ORR) according to Response Assessment in Neuro-Oncology (RANO)-BM criteria. Secondary endpoints are extracranial ORR, bicompartmental-clinical benefit rate, bicompartmental-disease control rate, time to response, duration of response, progression-free survival, overall survival, safety (adverse events, coagulation, and hematological monitoring) and tolerability according to the NCI-CTCAE v.5.0, quality of life, and neurologic function using the Neurologic Assessment in Neuro-Oncology (NANO) scale. Simon's two-stage design was set at a one-sided type I nominal alpha error of 5% to attain 90% power. Alternative hypothesis is CNS ORR ≥42%. Null hypothesis is CNS ORR ≤16%. The study will be stopped for futility if there are ≤2 patients (15.5%) with intracranial responses in the first stage. The primary endpoint will be met with ≥ 8 (29.6%) patients with CNS response among all patients included in the study. If positive, TUXEDO-4 could introduce T-DXd as a promising treatment for HER2-low mBC patients with newly diagnosed or progressing BM with or without type II LMD. TUXEDO-4 was activated for accrual on June 5th.

P3-08-22: Tucatinib, Trastuzumab and Capecitabine with brain and/or spinal radiotherapy (XRT) in patients with HER2+ metastatic breast cancer and leptomeningeal disease: A multi-centre phase II, single arm feasibility study ("CLIMB LMD"; NCT06016387)

Katarzyna J. Jerzak, Marie-France Savard, Mary-Jane Lim-Fat, Gregory Pond, Hany Soliman, Arjun Sahgal

Background: As patients with HER2+ metastatic breast cancer (MBC) live longer and survive to experience spread of cancer to the brain, the incidence of leptomeningeal disease (LMD) is increasing. Unfortunately, patients with HER2+ LMD have a very poor prognosis with limited treatment options. Patients with LMD were excluded from the pivotal HER2CLIMB trial, which demonstrated intra-cranial activity of tucatinib, trastuzumab and capecitabine and prolonged survival among patients with HER2+ MBC.
Methods: A multi-center phase II, single arm feasibility study with a safety run-in of 6 patients. The sample size will include 30 patients in total across participating centres in Ontario, Canada.
Intervention: In phase 1, brain and/or spinal radiotherapy (XRT) will be administered. Areas in the brain and spine will be treated as per the discretion of the treating radiation oncologist. In phase 2, patients will commence systemic therapy between 7 days and up to 21 days after completion of brain and/or spinal XRT. Tucatinib, trastuzumab (Ogivri; MYL-1401O) and capecitabine will be administered as per the HER2CLIMB protocol; however, the addition of capecitabine may be delayed and commence during Cycle 2, at the discretion

of the treating physician to allow for adequate recovery from XRT. Treatment will continue until disease progression or unacceptable toxicity.
Patients who receive XRT but do not pass through the second phase of eligibility will not be counted towards the total patient number and will be followed for survival only. If >70% of enrolled patients experience one or more grade 3+ attributable AEs or SAEs, or >25% experience one or more grade 4+ attributable AEs or SAEs, these instances will be reported to the Data and Safety Monitoring Board (DSMB) in a timely fashion and will trigger review by the DSMB. The trial will continue until the DSMB reviews AE reports and decides whether or not the trial needs to be halted or terminated.
Key inclusion criteria: 1. Men or women with HER2+ MBC. HER2+ status will be defined in accordance with ASCO-CAP 2018 guidelines, and can be diagnosed at any time prior to enrolment; 2. Evidence of LMD* in the brain and/or spine (either positive cerebral spinal fluid cytology and/or magnetic resonance imaging evidence of LMD). Measurable disease in the central nervous system is not required. *The diagnosis of LMD can occur at any time prior to enrolment; 3. Age 18+ at time of consent; 4. ECOG ≤ 2.
Key exclusion criteria: 1. Prior whole brain radiotherapy (prior stereotactic radiosurgery for parenchymal brain metastases received ≥7 days prior to consent is permitted); 2. Prior therapy specifically directed at LMD, including prior radiotherapy or systemic therapy; 3. Prior use of tucatinib at any time prior to enrollment.
Primary outcome: Overall survival (OS) from the start of XRT.
Secondary outcomes: i) Time to central nervous system (CNS) progression from the start of XRT; ii) Safety and tolerability (CTCAE v.5.0); iii) Progression free survival from the start of XRT; iv) CNS specific objective response (RANO-BM); v) Extracranial objective response (RECIST v1.1); vi) Neurologic-specific quality of life (QoL) (FACT-BR v.4); vii) Overall QoL (EORTC QLQ-C30 v.3).
Analyses: OS will be measured from start of XRT until the date of death (from any cause, assessed up to 3 years), or censored at the last known follow-up. Kaplan-Meier curves will be used to present the time to event data. In addition to the median and 95% confidence interval, estimates of OS at different time points from the Kaplan-Meier survival curve will be tabulated.
Accrual: This study opened for enrollment at the Sunnybrook Odette Cancer Centre in December 2023 and will open at the Ottawa Hospital Cancer Centre in July 2024. To-date (July 3, 2024), 4 patients have enrolled. The expected accrual period is 18 to 24 months.

P3-08-23: Using a SMART Approach to Culturally-Adapt and Remotely Deliver a Weight Loss Intervention for Latina Breast Cancer Survivors: The ¡Vida! Study Methods

Blake Langley, Eileen Rillamas-Sun, Jennifer Whitten, Yarizel Herrera, Sheryl Rothmuller, Sara Buzali, Jennifer Dearden, Ashkan Ertefaie, Chongzhi Di, Nancy Davidson, Rachel Yung, India Ornelas, Heather Greenlee

Background: Cancer is the leading cause of death in the US Hispanic/Latinx population and Latina women are 20% more likely to die from breast cancer (BC) compared to non-Latina women. An estimated 80% of US Latina women have overweight or obesity, which is a major contributor to BC incidence and recurrence. Culturally tailored, effective, and accessible weight loss interventions for Latina BC survivors are needed.
Aims: The ¡Vida! Study primary aim is to compare the effectiveness of adaptive weight loss interventions in decreasing total body weight by ≥7% at 12 months in Latinas with early-stage BC and obesity not on current chemoradiotherapy. The secondary aim will investigate baseline characteristics as moderators of the intervention effects to inform personalized strategies for weight management. Exploratory aims will examine other moderators and mediators of intervention effects, effects of the intervention on cardiometabolic biomarkers, and contextual factors that contribute to study outcomes.
Design: Participants will be recruited from NCI SEER registries in California and Washington. This study is a 4-group, 2-stage, sequential multiple assignment randomized trial (SMART) of: 1) the ¡Vida! Program, 2) ¡Vida! + Experiential Learning (EL), 3) ¡Vida! + EL + health coaching (HC), or 4) ¡Vida! + EL + HC + delivered groceries (DG). In Stage One, participants will be randomized to ¡Vida! or ¡Vida! + EL. In Stage Two, at week 8 participants who do not respond to the intervention (i.e., loss of <2% of their body weight) will be re-randomized to receive additional components. A community advisory board of project stakeholders, community-based organizations in Washington and California representing medical services, social services, and patient-advocates will provide input throughout the study process.
Intervention:

The ¡Vida! Program adapts the National Diabetes Prevention Program to Latina BC survivors using the Framework for Reporting Adaptations and Modifications. Live, remotely delivered, nutritional and physical activity (PA) educational sessions through the Fred Hutch Cancer Center Cook for Your Life website will be delivered over 12 months.
The EL component will include live, virtual, hands-on sessions delivered by lifestyle health educators (promotoras) and will focus on increasing knowledge, skills, and self-efficacy to achieve and maintain weight, diet and PA goals.
The HC component will include individualized remote sessions. Health coaches will identify patient diet and PA goals, and support weight loss self-efficacy, motivation for adopting a hypocaloric high-quality diet, and increasing moderate-to-vigorous PA.
The DG component will include a bag of supplemental fresh vegetables, whole grains, and healthy oils. DG will include ingredients used in recommended recipes and recipes prepared in the EL sessions.

Data Collected: Baseline data will be collected on participant demographics, clinical characteristics, acculturation, and taste preferences. Body weight, daily PA, and accelerometry; patient-reported food intake and diet quality, global quality of life, social support, perceived stress, and self-efficacy for healthy eating and PA; and dried blood spot biomarkers will be monitored for change between baseline and 12 months.

Conclusion: The ¡Vida! trial is on track to open in Fall 2024. The results of this adaptive, remotely delivered, and culturally tailored weight loss trial in Latina early-stage BC survivors will identify scalable, effective, personalized strategies to support weight loss and improve BC related outcomes due to obesity in this population with high cancer health disparities.

P3-08-24: Valemetostat and Trastuzumab Deruxtecan in Patients With HER2-Low, Previously Treated, Unresectable or Metastatic Breast Cancer

Sara M. Tolaney, Senthil Damodaran, Funda Meric-Bernstam, Shanu Modi, Yoichi Naito, Avani Mohapatra, Yuka Iko, Siwen He, Keiko Nakajima, Naoto T. Ueno

Background: Human epidermal receptor (HER)2-low breast cancer, defined as either 1+ by immunohistochemistry (IHC), or IHC2+ and HER2-negative by in situ hybridization (ISH), accounts for ~ 60% of breast cancer cases and is associated with particularly poor outcomes, including decreased progression-free survival (PFS). Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody–drug conjugate (ADC) approved in more than 55 countries, including the US, for patients with HER2-low breast cancer previously treated with chemotherapy in the metastatic setting or with disease recurrence within 6 months of completing adjuvant chemotherapy. Regulatory approval was based primarily on results from the phase 3 DESTINY-Breast04 trial, where T-DXd significantly prolonged PFS compared with the physician's choice of chemotherapy (hazard ratio, 0.51 [95% confidence interval, 0.40, 0.64], $P < 0.0001$; median PFS 10.1 vs 5.4 months, respectively) in patients with HER2-low advanced breast cancer.

Valemetostat tosylate (valemetostat) is a novel, potent, and selective dual inhibitor of enhancer of zeste homolog (EZH)2 and EZH1. Valemetostat 200 mg PO QD has demonstrated clinical efficacy and favorable tolerability in multiple hematologic malignancies. EZH2 regulates gene expression, including those involved in the DNA damage response, such as DNA/RNA helicase Schlafen 11 (SLFN11). In response to DNA damage, SLFN11 binds to chromatin, causing a replication block and inducing apoptosis. Inhibition of EZH2 with valemetostat may upregulate SLFN11 and sensitize tumor cells to DNA-damaging agents, including ADCs such as T-DXd. Preclinical data suggest synergistic effects of valemetostat in combination with T-DXd and datopotamab deruxtecan.

This ongoing Master Protocol study evaluates valemetostat in combination with DXd-ADCs in solid tumors. A sub-protocol of this study evaluates the clinical activity and safety of valemetostat in combination with T-DXd in patients with HER2-low, previously treated, unresectable, or metastatic breast cancer.

Study design: This global, phase 1b, multicenter, open-label Master Protocol study (NCT06244485) will enroll ~ 70 patients per sub-protocol in the US and Japan. The breast cancer sub-protocol will enroll patients with unresectable or metastatic breast cancer, 1–2

prior lines of chemotherapy in the recurrent or metastatic setting, and adequate organ function. All patients must have HER2-low expression (IHC1+ or IHC2+/ISH-). Hormone receptor-positive disease must have progressed on endocrine therapy or the patient would no longer benefit from endocrine therapy in the investigator's opinion. Patients who have received treatment with an ADC that consists of an exatecan derivative that is a topoisomerase I inhibitor are excluded.

The study consists of two parts: dose-escalation (Part 1; ~ 30 patients) and dose-expansion (Part 2; ~ 40 patients). In Part 1, patients will receive valemetostat doses of 50–200 mg PO QD (continuous) and fixed-dose T-DXd 5.4 mg/kg IV Q3W until disease progression. The dose-limiting toxicity evaluation period will be the first treatment cycle (21 days). In Part 2, patients will receive valemetostat and T-DXd at the recommended dose for expansion identified in Part 1. The primary study endpoints are safety and tolerability in Part 1, and overall response rate (ORR), safety, and tolerability in Part 2. The secondary endpoints include ORR in Part 1, and pharmacokinetics, PFS, duration of response and overall survival in Part 1 and 2. Clinical responses will be determined by investigator assessment and defined according to Response Evaluation Criteria in Solid Tumors v1.1 criteria. The relationship between HER2 expression and clinical response will also be explored.

P3-08-25: randomized phase III study comparing the digital telemonitoring platform "CUREETY TECHCARE" to usual standard of care in patients with triple negative metastatic breast cancer initiating a first-line systemic treatment: ALTERNATIVE

Martin Babau, Florence Joly, Frederic Fiteni, Aurore Caumont-Prim, Trevor Stanbury, David Perol, Charles Parnot, Francois-Guirec Champoiseau, Adeline Poitou, Jerome Lemoonier, Francois Montestruc

Background: Triple-negative breast cancer (TNBC), accounts for 15% to 20% of all breast cancers. It is characterized by the absence of 3 receptors (estrogen/progesterone/human epidermal growth factor 2) which limits the treatment options.
Currently a therapeutic sequence for patients with mTNBC is first-line chemotherapy with or without immunotherapy, followed by sacituzumab govitecan then by successive chemotherapy lines. Considering the toxicity of these treatments there is a need to identify and monitor the signs and symptoms (S&S) of adverse events (AE). Early identification of these S&S, with appropriate management may prevent severe and fatal AEs, reduce dose delays and treatment discontinuations, thus optimizing treatment and possibly improving survival outcomes.
Cureety is a digital remote monitoring platform, specifically designed to facilitate the monitoring of S&S of treatment-specific AEs and disease progression in cancer patients. Cureety integrates the Cureety TechCare algorithm for patient clinical classification, a CE-marked medical device.
We hypothesize that patients with mTNBC may benefit from Cureety during systemic

treatments by improving the identification of S&S of potentially severe/ AEs at early stages or early progression symptoms.
Trial design: ALTERNATIVE is a French, multicentre, randomized, phase III trial comparing standard of care (SoC) with or without telemonitoring. The telemonitoring will comprise weekly AE and S&S evaluations and their analyses by Cureety. The randomization will be stratified by planned first-line treatment (immunotherapy: yes vs no) and ECOG PS (0 vs 1-2).
Eligibility criteria: Patients aged ≥18 years, with mTNBC, ECOG PS ≤2, initiating first-line systemic treatment. The patient must be able and willing to complete web-based self-report questionnaires.
Specific aims: To assess the effectiveness of SoC with digital telemonitoring compared to SoC alone, in terms of Time to definitive Health-Related Quality-of-Life score Deterioration (TUDD), Hospitalization Free Survival (HFS) and OS.
The secondary objectives will include contribution on patient's safety, treatment compliance and extent of exposure, compliance with telemonitoring, patient and medical team satisfaction with telemonitoring, global patient satisfaction with care, and socio-economic data.
Sample size: A two-sided sequential logrank test with an overall sample size of 472 subjects for 384 events achieves 90% power at a 5% two-sided significance level to detect a hazard ratio (HR) of 0.72 when the median TUDD is 4.3 months without telemonitoring and 6 months with telemonitoring. The planned study duration is 42 months (18 months of accrual and 24 months of follow up). An interim futility analysis is planned after 157 TUDD events using an alpha-spending function of O'Brien-Fleming Analog.
Statistical methods: TUDD, defined as the time from randomization to the first deterioration of ≥ 10 points out of 100 in the global health status (GHS) score (items 29 and 30 of the QLQ-C30), will be analysed using the Kaplan-Meier method. The median and Q1, Q3 event times for each arm and the corresponding 2-sided 95% confidence intervals (CIs) will be provided. A two-sided log-rank test stratified for the randomization stratification factors will be used to compare TUDD between the two study groups.
The Cox regression model, stratified for the same stratification factors, will be fitted, and the estimated HR and 2-sided 95% CIs will be provided. To preserve the alpha risk at 5% for the two analyses, the p-value will be 0.00325 at the first analysis and 0.0492 at the final analysis.
To control the overall type I error at 5%, once the superiority with TUDD is established, and the study is conclusive, HFS then OS will also be tested at 5% significance level using a hierarchical order. If the study is not conclusive for TUDD these endpoints will still be analysed but will be interpreted as exploratory.

Bpifrance and Cureety

P3-08-26: Imipramine: A Promising Therapeutic Regimen for Breast Cancer Patients

Manjeet Rao, Arhan Rao, Santosh Timilsina, Subapriya Rajamanickam, Panneerdoss Subbarayalu, Ismail Jatoi, Yidong Chen, Kate Lathrop, Ratna Vadlamudi, Virginia Kaklamani

Introduction: Cancer cells continue to replicate their DNA and survive mainly due to their unique ability to repair damaged DNA using alternate DNA repair pathways. For example, cancer cells with a deficiency in homologous recombination (HR) proteins (such as BRCA1) can repair their DNA by either relying on other highly expressed HR-related proteins (such as RAD51 or PARP1) or by using backup DNA repair mechanisms such as ALT-NHEJ. Alterations in DNA repair pathways commonly occur during breast cancer (BC) progression. For example, TNBCs have dysfunctional BRCA1/2 but express high levels of RAD51. Further, ER+BC employs ALT- NHEJ, HR, or BER to repair their DNA. The objective of this study was to identify FDA-approved non-cancer drug/s capable of inhibiting DNA repair in BC cells, thereby inhibiting their growth, with potential clinical benefits for BC patients.

Methods: BC cells were treated with vehicle and FDA-approved drugs for 72 hours and were subjected to cell-titer Glo assay. The anti-tumor effect of imipramine alone and in combination with Olaparib and tamoxifen was validated using orthotopic xenograft mouse models. The effect of imipramine on DNA repair was determined by immunofluorescence using antibody against 53BP1, and functional DNA repair assays. Based on these results, a window of opportunity clinical trial was conducted to test the efficacy of imipramine in early-stage breast cancer patients. After having a breast core needle biopsy, 15 eligible patients with stage I-III breast cancer were enrolled in the trial and were treated with imipramine at a target dose of 200 mg PO daily for an average of 28 days. Patients were evaluated on day 7, day 14, day 21, and at the end of treatment for toxicity. The primary endpoint for the trial was the absolute change in the Ki67. IHC using an antibody against Ki67 was performed on core biopsy (pre-treatment) and tumor tissue after imipramine treatment. The secondary objectives of this trial were to further define the toxicity profile of imipramine.

Results: Imipramine treatment significantly reduced the viability of TNBC and ER+ BC cells. Further, imipramine treatment inhibited the migration and invasion of BC cells. Systemic delivery of imipramine suppressed the growth of BC. Importantly, imipramine blocked the DNA repair capacity of BC cells by inhibiting the expression of DNA repair proteins including FOXM1 and RAD51. Notably, imipramine treatment improved the efficacy of Olapraib in TNBC and sensitized the tamoxifen response in endocrine-resistant ER+ BC cells. The clinical trial on 15 patients treated with imipramine showed a marked reduction in Ki67-positive cells in post-surgical tumor tissues compared to core needle biopsy tissues. Toxicity was mild with only grade 1 and 2 toxicities that included some instances of dizziness and nausea. There was no dose reduction, interruption, or treatment discontinuation.

Discussion: Our preclinical and clinical studies showed that imipramine can block DNA

repair in both TNBC and HR+ breast cancer. Short-term treatment with imipramine can effectively decrease Ki67 in breast cancer patients. Future clinical trials will involve combining imipramine with other regimens such as Olaparib for TNBC patients and elacestrant/CDK4/6 inhibitor for therapy-resistant ER+ breast cancer patients.

P3-08-27: Novel Combination Immune Therapy for Metastatic Breast Cancers leveraging weaknesses in DNA damage response in p53 Mutant cancer

Ashley Guo, Priyanka Rajan, Mohammed Alruwaili, Joseph Barbi, Scott Abrams, Thomas Melendy, Christos Fountzilas, Andrei Bakin

Metastatic breast cancer (MBC) is a life-threatening disease with lowest 5-year survival rates in patients with metastatic triple-negative breast cancer (mTNBC). Most MBCs carry mutant p53 that drives cancer progression and metastasis in part by promoting the build-up of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs), major immune suppressive cells in the immune environment. At present, there are no effective treatment options for p53-mutant BC, while existing chemotherapy-based treatments exhibit low selectivity for p53mut status and high frequency of adverse side effects. We developed a novel therapeutic strategy for selective damaging p53-mutant tumors addressing the limitations mentioned above. Our novel strategy for p53mut cancers uses two drugs, one acting as an inducer (TAS102) and the other an amplifier (PARP inhibitor, PARPi), to achieve selective damage to p53mut cancers. Thymidine nucleotide analogue TAS102 does not block DNA synthesis but activates post-replicative repair leading to DNA breaks, while PARPi blocks repair of these DNA lesions. The two-drug strategy showed high efficacy, without adverse effects, in preclinical cancer models. Our first-in-human phase I study with the two-drug TAS102-PARPi regimen for colon cancer (NCT04511039, PI: Fountzilas) did not identify major signs of toxicity and the preliminary efficacy is promising. The dose-expansion part of the study is actively accruing patients with one patient already attaining a partial radiographic response. The present work investigates the impact of the two-drug TAS102-PARPi regimen on the immune landscape in mice implanted with mTNBC tumor cells. We observed that TAS102-PARPi reduced tumor growth and metastases to the lungs and liver. The two-drug regimen reduced levels of MDSCs and TAMs and increased levels of lymphocytes, indicating that the regimen may positively cooperate with immunotherapy directed to enhance anti-tumor activity of T cells. Depletion of CD8+ T cells markedly reduced anti-tumor activity of the TAS102-PARPi regimen. Immunophenotyping showed that the two-drug therapy increased tumor infiltration by CD8+ T cells expressing immune-checkpoint receptors PD1 and LAG3. Testing the two-drug therapy in combination with antibodies blocking the inhibitory receptors anti-PD1 or anti-LAG3 showed a dramatic reduction in tumor growth and metastases. Together these results demonstrate that the two-drug TAS102-PARPi regimen can be combined with immune checkpoint blockade therapy for effective treatment of MBCs including mTNBCs.

P3-08-28: VRTX531: A Novel Best-in-Class USP1 Inhibitor for the Treatment of Triple-Negative Breast Cancer

Rishi Rahangdale, Prashant Bhavar, Uday Surampudi, Partha Sarma, Murali Bokka, Anuj Kshirsagar, Appaji Mandhare

TNBC accounts for about 10-15% of all breast cancers and tends to have a poorer prognosis compared to other breast cancer subtypes and is more commonly seen in younger women under 40, who are Black, or who have a BRCA1 mutation. TNBC, especially those with BRCA1 mutations, tend to be more sensitive to DNA-damaging chemotherapies, such as platinum-based agents, due to their inability to repair DNA effectively. Tumors with BRCA mutations have shown vulnerability to PARP inhibitors (PARPi), targeting compensatory DNA repair pathway that is more active in BRCA-mutant tumors, effectively leading to synthetic lethality, i.e. the simultaneous loss of BRCA function and PARP inhibition leads to cancer cell death. However, only 20–40% of the patients benefit from PARPi and are alive 5-years after diagnosis.
Ubiquitin specific protease 1 (USP1) belongs to a group of deubiquitinating enzymes (DUB) and is a key regulator in the DNA damage repair (DDR) pathway. A deficiency in USP1 results in compromised genomic stability, making it a potential therapeutic target in tumors that exhibit defects in the DNA damage repair mechanism.
VRTX531 is a potent, selective, and allosteric oral inhibitor of USP1, specifically designed to target HRD Tumors. Treatment with VRTX531 resulted in decreased viability in cell lines with BRCA1/2 mutations and HRD+ tumors. USP1 inhibitors are anticipated to induce cell death via a pathway distinct from PARPi, and thus have the potential to overcome resistance to PARPi. The synergistic effect of VRTX531 combined with PARPi was demonstrated in cell-based assays and further validated in mice bearing TNBC tumors cells. In TNBC model of MDA-MB-436, treatment with PARPi alone led to a delayed onset of response with statistically significant variability between subjects, whereas the combination of VRTX531 and PARPi led to rapid onset of response, followed by complete tumor regression (TGI > 98%), across all subjects with near zero variability. Even after the treatment ended, the combination continued to show a durable response, whereas animal treated with PARPi alone experienced early relapse. USP1 inhibitors have the potential to overcome resistance to chemo and PARPi by targeting compensatory mechanisms that allow HR-deficient cancer cells to survive.
USP1 inhibitor VRTX531, exhibited best-in-class pharmacokinetics, with exemplary safety profile, that supports its further development.

P3-08-29: Early Clinical Experience with TTX-MC138, a First-in-Class Therapeutic Candidate for Metastatic Breast Cancer

Zdravka Medarova, Neil Robertson, Subrata Ghosh, Hsiao-Ying Wey, Mariane LeFur, Onofrio Catalano, Ciprian Catana, Peter Caravan, Susan Duggan, Andreas Varkaris

For the past 20 years our research has specifically focused on developing potential therapies targeting specific properties of tumor cells that have metastasized. Although the mechanisms and triggers of metastasis are not completely understood, cancer cells exhibit the ability to break out of the primary tumor mass, travel through the circulation, and colonize a new vital organ in the process of metastasis. Of therapeutic significance, these metastatic cells are genetically and phenotypically distinct from the majority of the cells in the tumor mass serving to limit the effectiveness of those therapies whose focus is the primary tumor itself. In our earlier discovery efforts, miRNA-10b was identified as a master regulator of the viability of metastatic tumor cells. miRNA-10b not only promotes the capacity of tumor cells to migrate and invade surrounding tissue (become metastatic) but, most notably, serves as a powerful master regulator of the viability of these cells and their capacity to survive outside of the primary tumor microenvironment. Detailed cellular and preclinical mechanistic studies confirmed the existence of a miR-10b-triggered pathway that regulates the viability and proliferation of tumor cells only after they have acquired the ability to metastasize. This knowledge allowed us to develop a therapeutic strategy based on miR-10b inhibition. The specific inhibition of miR-10b was achieved using inhibitory oligonucleotides (locked nucleic acid, LNA-based antagomirs) delivered to metastatic sites by aminated dextran-coated iron oxide nanoparticles (termed TTX-MC138). Our research demonstrated that TTX-MC138 could cause complete and persistent regression of metastases in cancer models with no evidence of systemic toxicity. On the path to clinical development of TTX-MC138, we conducted critical, exploratory IND enabling studies in rats, dogs, and non-human primates with TTX-MC138. Ultimately, the information generated resulted in FDA authorization under IND163800 allowing for initiation of an ongoing microdosing Phase 0 clinical trial in patients with advanced metastatic cancer. The strategy of conducting an initial Phase 0 study was not only to assist in the identification of susceptible tumor types (or patients) but also to support future clinical efforts by providing proof of concept and quantification of delivery to clinical metastases. The Phase 0 clinical trial involves a single injection of a microdose of Cu-64 labeled TTX-MC138 which allows for direct visualization in cancer patients via PET-MR imaging, with a primary endpoint of confirming its localization (%ID/cc) to the metastatic lesions. We have now obtained initial clinical data on drug PK and accumulation in clinical metastases to the lungs, bone, and liver, as well as drug stability, metabolism, and pharmacodynamic activity. We have demonstrated TTX-MC138 uptake by bone, lung, and liver metastases, as well as tumor to blood ratios reflective of selective retention of the drug by tumor tissue. We have established that the drug has a long circulation time of 20 hrs in humans. Remarkably, even at a 100 microgram microdose, the drug showed robust PD activity with a 70% inhibition of the miR-10b target in blood over the full time course of the study. The process leading to the implementation of TTX-MC138 in the clinic is critically dependent on the innate tropism of the TTX delivery platform to tumors and represents a first step towards developing effective nucleic-acid based therapeutics against cancer.

P3-08-30: Development of humanized anti-FABP4 monoclonal antibodies for potential treatment of breast cancer

Bing Li

Breast cancer is the most common cancer in women diagnosed in the U.S. and worldwide. Obesity increases breast cancer risk without clear underlying molecular mechanisms. Our studies demonstrate that circulating adipose fatty acid binding protein (A-FABP, or FABP4) links obesity-induced dysregulated lipid metabolism and breast cancer risk, thus potentially offering a new target for breast cancer treatment. We immunized FABP4 knockout mice with recombinant human FABP4 and screened hybridoma clones with specific binding to FABP4. The potential effects of antibodies on breast cancer cells in vitro were evaluated using migration, invasion, and limiting dilution assays. Tumor progression in vivo was evaluated in various types of tumorigenesis models including C57BL/6 mice, Balb/c mice, and SCID mice. We identified over 30 clones which specifically bound to FABP4. One clone, named 12G2, was shown to significantly inhibit mammary tumor growth. After further confirming the therapeutic efficacy of the chimeric 12G2 monoclonal antibody consisting of mouse variable regions and human IgG1 constant regions, 16 humanized 12G2 monoclonal antibody variants were generated by grafting its complementary determining regions to selected human germline sequences. Humanized V9 monoclonal antibody showed consistent results in inhibiting mammary tumor growth and metastasis by affecting tumor cell mitochondrial metabolism. Thus, our data suggest that targeting FABP4 with humanized monoclonal antibodies represents a novel strategy for the treatment of breast cancer and possibly other obesity-associated diseases.

P3-09-01: Time to postmastectomy radiotherapy in the setting of immediate implant-based breast reconstruction: does it impact on adjuvant treatment delay compared with mastectomy alone?

Lilian Paz, Jorge Biazús

Background: Immediate breast reconstruction (IBR) integrates with the surgical treatment of breast cancer, improves quality of life, psychological health and self-esteem. However, IBR following mastectomy has a higher rate of surgical complications compared to mastectomy without reconstruction, and also constitutes an independent risk factor for reoperation, which may result in delays regarding the administration of adjuvant therapies. The ideal timeframe in which to administer postmastectomy radiotherapy (PMRT) following surgery has not been well-established. The scope of this study was to evaluate whether IBR with implants has an impact on the time to start radiotherapy.
METHODS: The present retrospective study reviewed 1,898 medical records of women with breast cancer submitted to mastectomy between January 2018 and December 2022 at the Aristides Maltez Hospital, a reference institution for cancer care in the state of Bahia, Brazil. Of these, 506 participants classified between stages I-III who underwent PMRT without adjuvant chemotherapy were included for analysis. The study sample was divided into two

groups: women who underwent mastectomy only without reconstruction (n=416, 82.2%) and women who had undergone to mastectomy followed by IBR with subpectoral implant placement (n=90, 17.8%). The patients' demographic, oncological and surgical data were collected. Kaplan-Meier analysis with the log-rank test was used to estimate the interval from the last oncological surgical treatment until the time of the first administration of radiotherapy. Participants were additionally categorized into three groups according to the time since the onset of PMRT (≤8 weeks, >8 and <16 weeks, ≥16 weeks). Multivariable logistic regression analysis was used to explore the clinic-pathological variables hypothesized to be associated with time to start radiotherapy.
Results: Most of the studied individuals were black women (n=460, 90.9%) with stage III breast cancer (n=304, 68.5%) who were treated with neoadjuvant chemotherapy (447, 88.3%). The average time of follow-up was 102.6 ±29.8 days. The median age was 49 (39-53) years old. The participants who underwent IBR were younger at surgery, more often a pre-menopausal status, fewer comorbidities, lower body mass index, no history of smoking and a higher proportion of I-II clinical stage. Kaplan-Meier analysis revealed that the IBR group started radiotherapy earlier compared to those who underwent mastectomy alone [95.84 (95% CI: 89.66, 102.03) versus 104.09 (95% CI: 101.25, 106.93) days; log-rank p=0.04)]. The proportion of women who started radiotherapy after 16 weeks was higher in the group that did not undergo breast reconstruction [164 (39.4%) versus 22 (24.4%), p=0.006]. Interestingly, mastectomy without IBR (OR=1.99; 95% CI: 1.21, 3.27; p=0.007) and hormone receptor-positive breast cancer (OR=1.71; 95% CI: 1.19, 2.48; p=0.004) were associated with a greater chance of starting radiotherapy after 16 weeks; age was not significantly associated with delayed onset of radiotherapy under regression analysis.
Conclusion: The present real-world study found that patients underwent postmastectomy IBR in the absence of adjuvant chemotherapy started radiotherapy sooner than in the mastectomy without breast reconstruction group. In addition, mastectomy without IBR and hormone receptor-positive breast cancer were predictive factors for the delayed initiation of PMRT. We hypothesize that IBR could be considered a marker of higher socioeconomic status, which may explain the disparity in access to cancer treatment, even among patients treated at the same reference institution.

P3-09-03: Cost effectiveness analysis of approaches to axillary management in the setting of contralateral prophylactic mastectomy

Christopher Vetter, Judy C. Boughey, Jeffrey E. Johnson

Background: Occult malignancy (OM) found in contralateral prophylactic mastectomy (CPM) specimens presents challenges for axillary staging as post-mastectomy sentinel lymph node (SLN) surgery is not validated. No consensus exists on the optimal strategy for evaluating the axilla in this setting. Approaches include preoperative breast magnetic resonance imaging (MRI), selective SLN surgery determined by risk of OM, routinely performed SLN surgery, routinely omitted SLN surgery and selective SLN mapping for delayed SLN surgery using superparamagnetic iron oxide. Herein we evaluate the cost

effectiveness of these strategies.
Methods: A decision tree representing the possible choices and outcomes for axillary staging in the setting of OM in CPM was constructed. A literature review was conducted to determine event probabilities. For selective SLN mapping, a threshold of 7% preoperative risk of OM was based on previously identified risk factors. Cost data for surgical, anesthetic, pathology, and facility fees were obtained from FAIR Health. Quality-Adjusted Life Years (QALYs) were calculated using previously published values for the rate of lymphedema following axillary surgery, the associated health-related quality of life decrease, and expected survival following bilateral mastectomy. A cost-utility analysis was conducted to determine expected costs, impact on QALYs, and incremental cost effectiveness ratios (ICER) for each of the possible approaches relative to the historical standard, mastectomy followed by axillary dissection if occult malignancy is identified. A sensitivity analysis was performed to identify the risk threshold at which SLN mapping becomes cost effective.
Results: The pooled rate of OM in the contralateral breast for women diagnosed with unilateral breast cancer was 1.89%. Costs ranged from $12,728 for mastectomy alone to $15,295 for routine preoperative MRI. Minor differences in QALYs were noted, ranging from 34.006 for preoperative MRI to 34.027 for preoperative risk assessment and SLN mapping, due to the low incidence of OM and low need for axillary dissection. Cost per QALY ranged from $374.04 for mastectomy alone to $449.77 for preoperative MRI. Preoperative MRI was the only strategy that was not cost effective relative to historical standard, yielding increased cost with decreased QALYs. The most cost-effective strategies included mastectomy with no additional axillary surgery, mastectomy with selective SLN mapping, and mastectomy with postoperative SLN surgery. On sensitivity analysis, risk assessment with selective SLN mapping remained cost effective across the expected levels of risk.
Conclusions: Different strategies for axillary management for CPM yield minor differences in QALYs. Routine MRI is the least cost-effective strategy, resulting in highest cost and lowest QALY. Selective SLN surgery resulted in lower QALYs than no initial axillary staging or selective SLN mapping with no significant improvement in cost. Selective SLN mapping allows for axillary staging with an improvement in QALYs and lower cost and should be considered the optimal strategy for axillary staging in women undergoing CPM.

P3-09-04: Does additional margin excision during LumiSystem pegulicianine fluorescence-guided lumpectomy surgery affect patient breast satisfaction?

Abigail E Daly, Kyle J Anderman, Manna Chang, Kelly K Hunt, E Shelley Hwang, Irene L Wapnir, Peter W Blumencranz, David Carr, Kate Smith, Brian Schlossberg, Jorge Ferrer, Barbara L Smith

Background: Achieving microscopically negative breast cancer lumpectomy margins remains challenging. Trials of the LumiSystem for real time margin assessment in breast cancer lumpectomy surgery showed removal of additional tumor and reduction of 2nd surgeries compared with standard lumpectomy surgery. We asked if the additional margin

tissue removed with this system negatively impacted patient satisfaction with breast appearance.
Methods: Stage 0-3 breast cancer patients were randomized 3:1 to pegulicianine LumiSystem-assisted vs. standard lumpectomy surgery in a multicenter trial. Patients received an IV injection of pegulicianine 2-6 hours before surgery. After the standard lumpectomy was completed, additional LumiSystem-guided cavity margins were excised at sites of positive pegulicianine fluorescence in the lumpectomy cavity walls in device arm patients using a hand-held imaging device and patient-calibrated cancer detection software. Patient, tumor, and lumpectomy data was collected. BREAST-Q surveys with a scale of 0-100 and Patient Preference Information (PPI) surveys with a 1-5 scale were given at pre-op and post-op time points assessing breast satisfaction and preferences.
Results: Post-operative breast satisfaction surveys were completed 6-12 months after surgery by 63 patients (75% of participants), 14 in the control arm and 49 in the device arm. Among patients with postoperative satisfaction surveys, LumiSystem device readings prompted excision of additional margin tissue in 25 (51%) device arm patients, with median volume of 10.5cc. There was no significant difference in mean post-operative breast satisfaction scores between device and control arm patients (78.2 out of 100 for control arm patients vs. 79.8 out of 100 for device arm patients, $p = 0.359$). A total of 58 study patients (69% of participants) had both pre- and post-operative breast satisfaction scores available for comparison. Both the control and device arm patients exhibited an increase in breast satisfaction from the pre-operative timepoint to the post-operative timepoint. There was no significant difference in the change in breast satisfaction from pre-operative to post-operative time points between device and control arms (mean increase of 14.4 points for control arm patients vs. 10.8 points for device arm patients, $p = 0.649$). A total of 51 patients (61% of all participants) completed post-operative PPI questions weighing preference for optimizing cosmetic outcome versus avoiding a second surgery. The median PPI score in both study arms was 5, indicating a strong preference for avoiding a second surgery over optimizing cosmetic outcome. Overall, 70.6% of surveyed participants strongly preferred or preferred avoiding a second surgery, 17.6% had no preference, 11.8% preferred to optimize cosmetic outcomes and no patient strongly preferred to optimize cosmetic outcomes. Univariate and multivariate binomial logistic regression analyses were performed to identify predictors of decreased breast satisfaction after surgery. Excision of additional LumiSystem-guided margin specimens and total tissue volume excised were not significant predictors of decreased breast satisfaction. BMI, larger breast size, age > 50, use of neoadjuvant therapy, and oncoplastic lumpectomy closure also failed to correlate with post-operative breast satisfaction.
Conclusions: There was no decrease in breast satisfaction following use of the LumiSystem for intraoperative margin assessment in breast cancer lumpectomy surgery, despite excision of additional margin tissue. The majority of patients valued avoidance of a second surgery over maximization of cosmetic outcome.

P3-09-05: ROBOTIC VS. CONVENTIONAL NIPPLE-SPARING MASTECTOMY IN BREAST CANCER: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

Ana Thereza da Cunha Uchôa, Raíssa Emily Andrade Souza, Beatriz Pâmella Costa Bomfim, Isadora da Silveira, Gabriela Branquinho Guerra, Jacqueline Nunes de Menezes

Introduction: With the growing concern to improve cosmetic results and quality of life without compromising oncological outcomes, nipple-sparing mastectomy (NSM) has gained prominence, especially with novel techniques such as robotic-assisted, which allows for the absence of cosmetic scars and improves patient satisfaction.

Objective: Our aim is to compare conventional (C-NSM) and robotic-assisted NSM (R-NSM) in terms of clinical outcomes, such as intraoperative parameters and complication rates, as well as evaluating recurrence rates in both approaches METHODS: In accordance with the PRISMA Guidelines, the MEDLINE, Embase, and Cochrane databases were searched for studies comparing R-NSM versus C-NSM in patients with early-stage breast cancer, without evidence of lymph node metastasis or invasion of the nipple, skin, or chest wall. The main outcomes were mean operation time, postoperative hospital stay, overall and specific incidence of complications (nipple or areolar necrosis, seroma, hematoma, poor wound healing), blood loss and recurrence. Statistical analysis was performed using RStudio Version 4.4.0. Heterogeneity was assessed with I^2 statistics.

Results: We included 1810 patients from 9 studies comparing R-NSM versus C-NSM, with 569 (31,4%) of them undergoing robotic surgery, with a mean age of 45 years. Compared with the C-NSM group, the R-NSM group had longer surgical time (MD 51.69; 95%CI (20.47-82.92); $p < 0,01$; $I^2 = 91\%$) and longer postoperative hospital stay (MD 1.09; 95% CI (0.48-1.7); $p < 0.01$; $I^2 = 83\%$), although R-NSM was associated with less bleeding (MD -36.55; 95% CI (-65.38–7.72); $p = 0.01$; $I^2 = 88\%$). There was no statistical difference between the groups regarding recurrence (OR 0.77; 95% CI (0.28-2.11); $p = 0.612$; $I^2 = 36\%$), overall complications (OR 0.88; 95% CI (0.65-1.19); $p = 0.407$; $I^2 = 25\%$) and specific complications such as nipple or areolar necrosis (OR 0.64; 95% CI (0.35-1.19); $p = 0.159$; $I^2 = 39\%$), seroma (OR 1.16; 95% CI (0.53-2.53); $p = 0.708$; $I^2 = 0\%$), hematoma (OR 1,32; 95% CI (0.71-2.45); $p= 0,385$; $I^2=0\%$) or poor wound heal (OR 0.55; 95% CI (0.18-1.72); $p = 0.305$; $I^2 = 38\%$).

Conclusion: Both techniques do not differ in terms of recurrence and complications, however the robotic approach is associated with a longer surgical time and postoperative hospital stay. Although there is a trend towards improved aesthetic results and less bleeding in R-NSM, considering the costs, it should be indicated with caution.

P3-09-06: Predictors of axillary lymph node pathological complete response in clinical T4 breast cancer after neoadjuvant chemotherapy: results from a reference center in Brazil

Lilian Paz, Sabrina Fontana, Jorge Biazús

Background: Breast cancer of any size with direct extension to the chest wall and/or to skin (skin nodules or ulcerations) is defined as T4. In general, locally advanced breast cancer has a poor prognosis and increased likelihood of axillary lymph nodal disease. Upfront neoadjuvant systemic therapy is the standard care for clinical T4 (cT4) breast cancer and contributes to the downstaging of breast and axillary tumors. Current evidence has found that in patients with clinically node-positive breast cancer converted to node-negative with neoadjuvant chemotherapy, the false negative rate for sentinel lymph node biopsy (SLNB) performance is less than 10% when 3 or more sentinel lymph nodes are sampled. However, studies that evaluated the identification and false negative rate for SLNB following neoadjuvant chemotherapy included few cT4 tumors. Therefore, using SLNB in this setting is controversial and lacks established consensus. The prevailing standard approach today is still axillary lymph node dissection (ALND), especially for inflammatory carcinoma. Therefore, the objective of this study was to identify the factors predicting the nodal pathologic complete response (pCR) of patients with cT4 breast cancer who underwent neoadjuvant chemotherapy.
Methods: Women aged 18 or over diagnosed with cT4, cN0-N3, non-metastatic breast cancer who had received neoadjuvant chemotherapy followed by mastectomy with ALND and radiotherapy between 2018 and 2022 at Aristides Maltez Hospital in Bahia, Brazil, were eligible for the study. Demographics, clinical, tumor characteristics, and pathologic data were all collected through retrospective medical record review. For analysis, the resulting population was divided into two groups: one with node pCR; and another who had residual axillary nodal disease. Univariate and multivariate logistic regression analysis were used to explore the clinic-pathological variables hypothesized to be associated with nodal pCR.
RESULTS: The study included 202 patients with cT4, cN0-N3 breast cancer treated with neoadjuvant chemotherapy. Most were black women (162, 83.1%) with a median age of 51 years old and clinically node-positive breast cancer (174, 86.1%). Of all cases, 102 (55.4%) had residual axillary nodal disease and 90 (44.6%) had axillary nodal pCR. The proportion of patients with pCR in the breast and axilla was 22.4%. In univariate regression analysis, predictive factors of nodal pCR included breast pCR (OR=5.94; 95% IC: 3.09, 11.90), hormone receptor-positive status (OR=0.50; 95% IC: 0.28, 0.89), triple-negative subtype (OR=2.30; 95% IC: 1.21, 4.47), Ki-67 rate (OR=1.02; 95% IC: 1.01, 1.03), angiolymphatic invasion (OR=3.26; 95% IC: 1.46, 8.05), and pathologic invasion of the skin (OR=3.47; 95% IC: 1.33, 10.84). On multivariable analysis, the breast pCR and triple negative subtype remained strongly associated with nodal pCR, and clinically node-negative (cN0) was identified as a predictive factor as well.
Conclusion: For patients with cT4 cN0-N3, non-metastatic breast cancer undergoing neoadjuvant chemotherapy, we found that breast pCR, triple negative subtype, and clinically node-negative can be considered predictors of nodal pCR. While there was no consensus

regarding the axillary treatment approach for cT4 breast cancer, the predictive clinical and pathologic characteristics studied here can assist multidisciplinary teams in the decision to surgical de-escalation.

P3-09-07: Prospective cohort study of oncological outcomes following partial breast reconstruction with chest wall perforator flaps to facilitate breast conservation in breast cancer.

Pankaj Roy, Zita Jessop, Akriti Nanda, Bethany Elder, Sarun Thongvitokomarn

Purpose: The oncological safety of oncoplastic breast surgery lacks evidence. This prospective cohort study was undertaken to assess the long-term clinical and oncological outcomes of partial breast reconstruction (PBR) with lateral chest wall perforator flaps (LCWPF).

Participants: Patients diagnosed with DCIS or breast cancer undergoing breast conservation surgery (BCS) with PBR with LCWPF were included in the study. A prospective database has been maintained since 2011. The hospital electronic records were interrogated for women who have completed a minimum of 5 years follow-up and oncological outcomes were compared to published literature.

Findings: 105 patients underwent PBR with CWPFs between 2011 and 2018 with an average follow-up of 101 months (8.4 years, ranging 6.3 – 12.6 years). 65% were ER positive and Her-2 negative, 18.5% were triple negative whilst 16.5% were Her-2 positive. 15% were node positive at diagnosis and 50% had node positive disease after formal nodal assessment. The majority were T2 tumors, but 25% of these had either associated DCIS or multifocality which meant that larger volumes were excised than T status implies. 16.6% had neoadjuvant chemotherapy. 74% underwent cancer resection and PBR as one operation whilst 26% underwent PBR as two-stage approach. The median tumor size on pre-op imaging was 30.7 mm for one-stage approach and 39.9 mm for two-stage approach (p value=0.003). The re-operation rate for close margins was 10% with 4% requiring mastectomy. The local recurrence rate was 3.2%, contralateral breast cancer 2.1%, distant recurrence rate 12.3% which compares favorably to published literature. The disease-free survival was 83.2%, distant disease-free survival (DDFS) 88.4%, overall survival (OS) 88.4% and disease specific survival (DSS) 91.6% at 8.4 years median follow-up. All patients were followed up with clinical review for at least 5 years and >80% had very good to excellent and stable aesthetic outcome despite radiotherapy.

Conclusion: Our study establishes the oncological safety of this approach. To our knowledge, this is the first cohort study to publish evidence on long term oncological outcomes after BCS with CWPF. This approach can avoid mastectomy for relatively large or multifocal tumors and results in stable aesthetic results despite radiotherapy.

P3-09-08: Cryoablation in the Treatment of Early Breast Cancer - FIRST (FreezIng bReaST cancer in Brazil): A Before-and-After Study

Vanessa Monteiro Sanvido, Silvio Eduardo Bromberg, Jackeline Oliveira Gomes, Leticia Galvão Barbante, Bruna Mayumi Takaki Tachibana, Luis Ricardo Socolowski, Antônio Rahal Junior, Angela Flávia Logullo Waitzberg, Paula Martinez Vianna, Leonard Medeiros da Silva, Carla Venturineli, Eliana Vieira do Nascimento Martins, Karina do Lago Negrelli, Gabriela Vasconcelos Batista, Emerson Souza Santos, Alexandre Biasi Cavalcanti, Afonso Celso Pinto Nazário

Background: Image-guided tumor ablation is a non-surgical, minimally invasive therapy available for the local treatment of carcinomas, offering an alternative to surgery. However, studies evaluating this therapy in early breast cancer have reported variable success rates, raising the question of whether omitting surgery is a viable option. Objective: The primary objective of this study is to evaluate the efficacy of cryoablation for the local treatment of early breast cancer. Secondary objectives include analyzing the negative predictive value of magnetic resonance imaging (MRI) and evaluating the necessary size of the ice ball relative to the largest tumor size to achieve complete tumor ablation. Methods: This is a multicenter, non-randomized, single-arm, before-and-after clinical trial. Inclusion criteria are patients with unifocal invasive breast carcinoma, tumors ≤ 2.5 cm, lesions visualized by ultrasound, and surgery indicated as the first treatment option. Exclusion criteria include ductal carcinoma in situ, multifocal or multicentric tumors, clinical axillary involvement, lesion-to-skin distance less than 5 mm, presence of distant metastases, and neoadjuvant treatment. All patients will undergo local cryoablation treatment, followed by conventional surgical treatment 14 to 28 days later. Imaging exams (mammography, ultrasound, and breast MRI) will be performed before and after cryoablation. The efficacy of cryoablation will be evaluated based on the success rate, defined as the absence of malignant neoplastic cells, both invasive and in situ, in the surgical specimen. If the expected success rate of cryoablation is like the 92% rate presented in the ACOSOG Z1072 study for patients without multifocal disease, this study will require at least 32 patients to determine if the technique is satisfactory (success rate greater than 70%), with a statistical power of 95% and a significance level of 5%. The study was approved by the local Ethics Committee and registered at Clinical Trials (NCT05398497). Results: A total of 47 patients were included in the study. However, 6 patients were excluded due to screening failures, presenting with suspicious enhancement on MRI greater than 2.5 cm or multicentric lesions, and 1 patient withdrew at the time of the ablation procedure. Therefore, 40 patients were evaluated.The mean age of the patients was 61.5 years, and the mean tumor size was 1.2 cm (0.5 – 2.5 cm). All participants underwent two cycles of freezing and thawing, using either a protocol of 6 minutes of freezing and 4 minutes of thawing or 8 minutes of freezing and 8 minutes of thawing, with a single cryoprobe connected to an argon and helium gas system. The complete ablation rate was 92.5%, while the ablation rate, considering only the absence of invasive lesions, was 100%. For tumors smaller than 1 cm, the success rate was 100%. Considering all cases that underwent MRI and showed focal lesions with enhancement up to 2 cm, the complete ablation rate was also 100%. The negative predictive value of breast MRI

was 95%. The average diameter of the ice ball observed on ultrasound was 3.9 times the size of the breast lesion. Among the 3 cases of residual lesion, 3 cases of residual ductal carcinoma in situ (DCIS) were observed, with an average size of 1.3 mm. Among the cases of residual lesion, 2 patients had not undergone MRI due to contraindication from having a cardiac pacemaker, and the other 1 showed enhancement on MRI of 2.2 cm. Conclusions: This study highlights cryoablation as a promising therapy and a viable alternative to surgery for patients with early-stage breast cancer. With a high rate of complete ablation, the technique proves effective for tumors up to 2 cm. MRI is crucial in planning the ablation, enhancing the success rate. The advancement of minimally invasive therapies reinforces cryoablation as a significant and effective option for treating early-stage breast cancer.

P3-09-09: Axillary staging techniques and oncologic outcomes for breast cancer patients with high clinical nodal burden undergoing neoadjuvant systemic therapy: A cancer registry study

André Pfob, Daria B. Kokh, Irina Surovtsova, Joerg Heil, Philipp Morakis

Background: Evidence for de-escalated axillary surgical staging after neoadjuvant systemic therapy (NAST) mainly exists for breast cancer patients with cN1 disease but not for patients with higher clinical nodal burden (cN2/3). We aimed to evaluate the role of axillary lymph node dissection (ALND) vs. targeted approached like sentinel lymph node biopsy (SLNB) or targeted axillary dissection (TAD) for patients with cN2/3 breast cancer undergoing NAST in a real-world setting.

Methods: We identified patients with cN2/3 breast cancer undergoing NAST diagnosed between 2009 and 2022 within the Baden-Württemberg cancer registry (BWCR), Germany. Invasive disease-free survival (iDFS) was assessed using Kaplan-Meier statistics and multivariate Cox regression models (adjusted for age, ALND vs. targeted approach, cN stage, cT stage, ypN stage, use of radiation therapy, and tumor biology).

Results: A total of 261 patients with a median follow-up of 24.9 months were identified: 69% (180 of 261) with cN2 stage and 31% (81 of 261) with cN3 stage. Median patient age was 59.6 years. cT stage was cT1-2 in 58.5% (152) of patients, cT3-4 in 41.6% (108). Tumor biologic subtype was Luminal in 49.4% (124) of patients, HER2 positive in 32.7% (82), and triple-negative in 17.9% (45). ypN stage was ypN0 in 44.4% (108), ypN1 in 19.8% (48), ypN2 in 22.6% (55), and ypN3 in 13.2% (32).
Use of ALND vs. a targeted approach as primary surgery was 88.1% (230 of 261) vs. 11.9% (31 of 261) overall; it was 35.4% (81) vs. 22.6% (7) in patients with cT3-4 stage, and 48.7% (112) vs. 48.4% (15) in patients aged over 60years, respectively. ypN stage was ypN0-1 in 48.7% (134) following initial ALND vs. 81.5% (22) after an initial targeted approach and ypN2-3 in 38.0% (82) vs. 18.5% (5). Use of radiotherapy was 84.3% (194) vs. 74.2% (23). Of the 31 patients undergoing a primary targeted approach, 12.9% (4) underwent

secondary completion ALND.
Median iDFS was 61 months in the ALND group and not reached in the targeted approach group (>60% without event). Multivariate Cox regression analysis revealed no significant influence for the use of a targeted axillary approach as primary surgery on iDFS: HR 0.64 (95% CI 0.23 to 1.80) for targeted approach vs. ALND; cT4d (HR 3.27, 95% CI 1.57 to 6.80) and ypN2-3 (HR 1.90, 95% CI 1.16 to 3.10) were significantly associated with worse iDFS.

Conclusion: These data suggest that a targeted approach, such as SLNB or TAD , may not have a disadvantage (i.e. shortening of the disease-free survival) compared to ALND as the first axillary surgery for patients with high clinical nodal burden. Complete response in the axilla (ypN0) for patients with cN2/3 was frequent at 44% and only 13% of SLNB patients underwent a secondary completion ALND. Thus, targeted approaches may be considered as a primary surgical intervention for patients with high clinical nodal burden (i.e. cN2/3) undergoing NAST. Larger studies with longer follow-up are welcome to fully inform this discussion. This study also demonstrates the advantage of real-world data collected through cancer registries, which allow the analysis of small patients groups that are difficult to consider in a randomized trial.

P3-09-11: Effect of Removed Lymph Nodes Number on Survival in Node-negative Early Breast Cancer: A Multicenter Retrospective Study (CSOBO YOUNG-03)

Ke-Da Yu, Xin-Miao Yu, Liang Huang, Jun-jie Li, Qiao Cheng, Ye Du, Xin-hua Xie, Zhi-gang Zhuang, Xiao-yun Mao, Peng-fei Qiu, Hong-mei Zheng, Zhao Liu, Chen-guang Zhang, Ji-guang Han, Zhi-dong Lv

Background: Although Sentinel lymph node biopsy (SLNB) is the standard treatment for clinically node-negative early breast cancer patients, axillary lymph node dissection (ALND), which always removes more than ten lymph nodes, is still widely used. Moreover, in SLNB, although the increased number of sentinel lymph nodes (SLNs) reduces false-negative rates, the effect of extensive lymph node removal on regional immune function and prognosis is unclear. For patients with no lymph node metastasis post-ALND (pN0), the impact of such removal on local immune barriers and prognosis remains uncertain. This study explores the association between the number of lymph nodes removed and survival in pN0 early breast cancer patients, aiming to clarify the effects of extensive lymph node removal on regional immunity and long-term outcomes.
Method: This study included 31,278 breast cancer patients diagnosed between 2013 and 2020 who underwent SLNB/ALND in 12 hospitals in China. Patients with lymph node metastases and neoadjuvant treatment were excluded. Propensity scores were utilized to match confounding variables between patients with SLNB and ALND within each subtype of breast cancer. Univariate, multivariate, and Cox proportional hazard models were implemented to evaluate the effect of SLNB/ALND on recurrence-free survival (RFS).

Results: In the univariate analysis, patients undergoing ALND had a worse RFS compared with those receiving SLN (HR=1.64, 95% CI: 1.37-1.97, P<0.001); after adjustment for confound factors, the tendency is still observed (HR=1.45, P=0.055). After the propensity score matching (1:2), 17,350 breast cancer patients were included. The SLNB group (n=6886) showed a significant difference in RFS (HR=1.31, 95% CI: 1.08-1.59, P=0.007) compared to the ALND group (n=3,556). For different subtypes, patients in the SLNB group showed statistically significant differences from those in the ALND group with triple-negative breast cancers (TNBC) (HR=1.76, 95% CI: 1.81-2.63, P=0.006) and a similar trend in the Luminal subtype (HR=1.21, 95% CI: 0.94-1.56, P=0.141), but no difference in the HER2+ subtype (HR=0.99, 95% CI: 0.60-1.63, P=0.962). The observed significant survival benefit in the SLNB group is mainly contributed by the TNBC group.
We further analyzed the number of lymph nodes removed on survival in the SNLB and ALND groups, respectively. In the SLNB group, a significant difference in RFS was shown for patients who had SLN<3 (HR=1.52, 95% CI: 1.14-2.02, P=0.004) and SLN≥5 (HR=1.33, 95% CI: 0.98-1.81, P=0.063) when compared to SLN between 3 and 5. Likewise, in the TNBC subtype, SLN between 3 and 5 showed significantly better RFS (HR=5.96, 95% CI: 2.27-15.6, P<0.001) compared to SLN≥5, while no significant differences were observed in the luminal and HER2-positive subtypes. In the ALND group, across all subtypes, compared with the group with ≤15 lymph nodes removed, no RFS compromise was observed for those removing more than 15 lymph nodes.
Conclusion: In pN0 breast cancer patients, SLNB is associated with better RFS compared to ALND, especially in the TNBC subtype. In SLNB, removing 3-4 SLNs may provide optimal outcomes, whereas removing more than 5 does not confer additional benefit and may negatively impact prognosis; in ALND, removing more than 15 nodes does not further improve RFS. Our findings imply that surgical removal of lymph nodes may disrupt the lymphatic immune barrier, particularly affecting TNBC patients. Further research is needed to illustrate our clinical findings and to optimize axilla surgical strategies.

P3-09-12: Impact of Extracapsular Extension on Recurrence in Sentinel Lymph Node Positive Breast Cancer Patients: A Retrospective Cohort Study

Hyelim Kang, Min Jung Lee, Changhoon Lee, Jinyoung Byeon, Eunhye Kang, Ji-Jung Jung, Hong-Kyu Kim, Han-Byoel Lee, Hyeong-Gon Moon, Wonshik Han

Background: After the ACOSOG Z0011 trial, sentinel lymph node (SLN) biopsy became the standard for staging early breast cancer, demonstrating that in select patients with limited lymph node involvement, SLN biopsy alone was sufficient. However, this trial excluded patients with extracapsular extension (ECE), leaving its impact on recurrence rates unclear. This study evaluates the impact of ECE on recurrence rates in SLN-positive breast cancer patients and compares recurrence rates in patients with ECE based on the type of axillary surgery.

Methods: We conducted a cohort study of 1,579 SLN-positive breast cancer patients treated at Seoul National University Hospital from 2009 and 2018. Included were patients with invasive breast cancer, T1 or T2 tumor stage, and positive pathology results in both frozen and permanent SLN biopsy. Radiation status and type of surgery (breast-conserving or mastectomy) were not considered. Those who received neoadjuvant chemotherapy were excluded. Patients were divided into two groups based on the presence (N=266) or absence (N=1,313) of ECE. Recurrence rates were analyzed by evaluating disease free survival (DFS) using Kaplan-Meier and Cox regression models.

Results: The presence of ECE was associated with significant differences in patient characteristics. ECE-positive patients were older (51.8 vs 50.2 years, p=0.023) and more likely to undergo SLNB+ALND (82.0% vs 65.7%, p<0.001) compared to ECE-negative patients. They also had larger tumors and more advanced nodal disease (both p<0.001).
To reduce selection bias, we performed propensity score matching (PSM) with a 1:2 matching ratio. After PSM to account for pathologic T stage, number of positive SLNs, type of axillary surgery, and molecular subtype, the comparison between ECE-positive (N=252) and ECE-negative (N=441) patients showed no significant differences in DFS (log-rank p = 0.96). Using the same PSM data for multivariate Cox regression analysis, adjusted for tumor size, nodal involvement, and molecular subtype, there was no significant difference in DFS between ECE-positive and ECE-negative groups (HR = 0.936, 95% CI: 0.609-1.437, p = 0.762).
Among the 266 ECE-positive patients, we compared DFS between those who underwent SLNB alone and those who received SLNB followed by ALND. The addition of ALND did not significantly improve DFS among ECE-positive patients (log-rank p=0.33).

Conclusion: Our analysis revealed that the presence of ECE in SLN-positive breast cancer patients did not significantly affect recurrence rates. Furthermore, among ECE-positive patients, additional ALND after SLNB did not significantly improve DFS. These findings suggest that while ECE may indicate more advanced disease characteristics, it does not independently predict recurrence when other factors are adjusted for. Consequently, in certain cases, it may be feasible to omit ALND in ECE-positive patients with positive SLN. These results highlight the need for prospective studies to confirm these results and investigate potential therapeutic strategies.

P3-09-13: Applicability of SOUND trial in the practice of breast-conserving surgery at tertiary-care hospital in Thailand

Lakkana Adireklarpwong, Prakasit Chirappapha, Panuwat Lertsithichai, Ronnarat Suvikapakornkul, Thongchai Sukarayothin, Monchai Leesombatpaiboon, Yodying Wasuthit, Chomporn Sitathanee

Background: The SOUND trial investigated omitting SLNB in EBC, reporting low recurrence rates and suggesting a shift towards minimal axillary treatment. Despite a trend towards

less radiation therapy (RT), the majority of SOUND participants received whole breast radiation. Current de-escalating treatments for HER2-positive and escalating treatment in high-risk ER+/HER2- cancers still depend on nodal status. Our study targets patients eligible for the SOUND protocol to assess the applicability of our patient's impact of skipping SLNB on treatment decisions.

Methods: Patients with cT1N0M0 breast cancer meeting SOUND trial criteria underwent breast-conserving surgery from 2012 to 2023 at a Thai tertiary single institute and were reviewed. Chi-square and Wilcoxon rank-sum tests were compared to clinicopathologic characteristics, with significance set at $P < 0.05$. Study endpoints included the applicability of the SOUND trial and the impact on adjuvant treatment by studying APBI percentages per ASTRO criteria, eligibility for APT trial, adjuvant CDK4/6i based on monarchE and NATALEE trials, and recurrence rates.

Results: In a study of 355 patients, the average age was 55, with 53.26% being premenopausal and 70.14% over 50. The most common cancer subtype was IDC at 89.86%. Most patients did not have lymphovascular invasion (83.38%), had pT1c (52.68%), and pN0 (89.55%), with a median tumor size of 1.5 cm. Nodal positivity was observed in 9.6% without pN2. Grades 1 and 2 were predominant at 82.11%. For subtypes, 87.32% were ER+, and 62.04% had Ki-67 ≥ 20. Hormone therapy was used in 86.97% of patients, covering 98.08% of those ER+. Chemotherapy (CMT) was given to 46.46%, which was 87.88% of patients with nodal positive and 50.61% of premenopausal patients. Among ER+/HER2- patients, 35.76% received CMT. Patients under 40 and below 65 received CMT at higher rates (66.67% and 51.8%, respectively). Node-positive patients had more positive LVI, higher Ki-67, and larger tumor size (pT1c-2). Trastuzumab was given to 43.9% of HER2-positive patients. RT was provided to 95.69%, mainly as WBRT (88.29%). Locoregional recurrence was 2.27%. According to ASTRO criteria, 33.24% were "suitable" and 61.69% were "suitable/cautionary" for APBI. RT omission was possible for 4.35%, and 8.73% qualified for the APT trial. Eligibility for adjuvant CDK4/6i per monarchE and NATALEE was at 1.78% and 14.95%, respectively. This cohort essentially differed from the SOUND study by being younger, more premenopausal, with higher T stages, more ER-negative, less HER2-positive, higher Ki67 ≥ 20, fewer pN1 cases, receiving more CMT but less trastuzumab. Recurrence, distant metastasis, contralateral breast cancer, and mortality rates were comparable after a median follow-up of 5.02 years.

Conclusion: The omission of axillary surgery according to the SOUND trial criteria might be acceptable to Thai patients despite a different population background. This is essential because of less axillary disease and more frequent adjuvant CMT use in Thai patients. However, the decision to deescalate axillary treatment should be cautious, particularly in patients with larger tumors, LVI positivity, high Ki-67 levels, and lack of genomic data due to the potential impact of nodal status on CMT. SOUND's effect on RT is minimal as the

widespread use of WBRT continues. The importance of long-term monitoring for axillary recurrence is highlighted. Caution is advised for HER2+ patients considering APT trials. The adoption of abemaciclib had a minor effect, whereas ribociclib use in node-negative cases could be influenced, although this remains low. If nodal status is needed, a second operation for SLNB is viable. Further research is necessary to understand the effects of omitting SLNB on costs, patient satisfaction, arm morbidity, and lymphedema compared to traditional SLN surgery.

P3-09-14: SHIELD study: Reoperation Rate in Breast-Conserving Surgery using Confocal Histolog® Scanner for Intraoperative Margin Assessment

Michael P Lux, Mariana-Felicia Sandor, Sara Heimann, Zlatna Schuller

Objective: Immediate and accurate methods for the intraoperative assessment of surgical margins during breast conserving surgery (BCS) are expected to reduce the proportion of patients undergoing a re-operation due to cancer-positive margins identified post surgery. Previous studies suggest that the Histolog® Scanner is a promising tool to address this need by providing immediate microscopic images of ex-vivo specimens. The SHIELD study was conducted to prospectively quantify the reduction of re-operation rate of BCS when the Histolog Scanner is used intraoperatively to evaluate the margins.

Materials & Methods: Patients undergoing BCS due to invasive breast cancer and/or DCIS prior to any adjuvant treatment were enrolled in the study. Surgical excision specimens were imaged with the Histolog® Scanner during surgery immediately followed by margin assessment in the acquired Histolog® images by the surgeon. In addition, standard assessment techniques (visual inspection, palpation, ultrasonography and radiography) were performed at the discretion of the surgeon. Positive margin(s) identified in the Histolog images trigger the excision of additional tissue recuts during the same surgery. Subsequent re-operation rate was compared to historical data from the observational Polarhis study (Sandor MF et al. The Breast 2022, 66:118 - NCT05946759) performed at the same certified breast center by the same surgeons. Positive margin detection rates using Histolog® Scanner were compared to final pathology assessments.

Results: A total of 54 patients were screened, from which 2 did not fulfill the final inclusion and exclusion criteria and 2 did not adhere to the imaging protocol. Mean age was 63.56 years and tumor type distribution was 32% of pure invasive cancer(s), 18% of pure DCIS and 50% of invasive cancer(s) with associated DCIS. Rate of re-operation achieved using the Histolog® Scanner is 10% (5/50) while the historical rate from Polarhis study was 30% (12/40) corresponding to a 67% ($p = 0.016$) reduction of reoperation rates when using Histolog Scanner for intraoperative margin assessment. Among these five reoperations two patients had their positive margins correctly detected with the Histolog® Scanner but the corresponding intraoperative recuts were not sufficient to achieve cancer-negative status

and the protocol did not include the Histolog Scanner assessment of the recuts. 17/21 and 4/21 positive margins were intraoperatively identified respectively with the Histolog Scanner and with standard techniques used at the center. All positive margins detected using standard techniques were also identified using the Histolog® Scanner. Sensitivity of 80.9% and specificity 99.5% were achieved with the use of the Histolog® Scanner while the combined values of the standard techniques used at the center provided 17.4% and 97.3% respectively. Overall time of Histolog® Scanner margin assessment including specimen processing, imaging and analysis was 13.8 (+/- 5.5) min per patient.

Conclusion: Study results present that the use of the Histolog® Scanner for the intraoperative margin assessment during breast conserving surgery is providing a significant and substantial 2/3 reduction in the re-operation rate, with sustainable sensitivity and specificity for positive margin detection when performed by surgeons during BCS. Further studies are warranted to confirm these findings in a multicentric approach.

P3-09-15: Is it possible to recruit and randomise participants to an implant-based breast reconstruction trial in the UK? Results from the Best-BRA Study

Kirsty Roberts, Clare Clement, Nicola Mills, Shelley Potter

Background: Implant-based breast reconstruction (IBBR) is a rapidly evolving technique and evidence to support best practice is lacking. Randomised controlled trials (RCTs) in breast reconstruction are needed but are challenging due to patient and surgeon preference. Feasibility work prior to a full-scale trial is therefore essential.
The Best-BRA (Is subpectoral or pre-pectoral implant placement Best in immediate BReAst reconstruction?) pilot RCT aimed to determine whether it would be possible to recruit and randomise women to a study comparing two different approaches to implant-based breast reconstruction in the UK.

Methods: Best-BRA was a pragmatic, multicentre external pilot RCT in which women >18 who elected to undergo immediate IBBR for breast cancer or risk reduction and were considered eligible for both pre and subpectoral techniques by their operating surgeon were randomised 1:1 to either technique. Surgeons were permitted to perform the procedure according to their standard practice (e.g. patient/implant selection; use/type of mesh). The primary outcomes related to the feasibility of a future large-scale trial and included the number of participants who were recruited and consented to be randomised. A QuinteT Recruitment Intervention (QRI) was embedded to explore anticipated recruitment challenges and provide practical support for sites and the study team. The QRI involved two phases. In Phase 1, the sources of recruitment difficulties were investigated by: mapping eligibility and recruitment pathways; recording recruitment discussions between clinicians and patients; semi-structured interviews with the study team and site

staff; observing investigator meetings; reviewing screening logs and study documentation. Phase 2 involved supportive and responsive feedback to the study team and site staff and the implementation of recruitment intervention strategies informed by Phase 1. Phases 1 and 2 were undertaken in an iterative and cyclical manner.

Results: Best-BRA opened on 19/7/21 after a 20-month delay in set-up due to COVID-19. The average time to site opening was 310 days (range 71-557). A total of 12 UK sites were opened and 11 participants randomised over a 19-month period. The trial was closed in January 2023 due to poor recruitment. A future large-scale trial comparing pre and subpectoral IBBR in the UK was not considered feasible.
Screening logs revealed that only 22% participants screened were considered suitable for both IBBR techniques and, of these potentially eligible participants, only 41% were approached to take part in Best-BRA. Qualitative data from the QRI indicated both the lower-than-expected number of eligible patients and acceptability rates were due to a rapid adoption of pre-pectoral IBBR in the UK leading to a loss of equipoise. This change in practice was due to surgeons' perception that pre-pectoral reconstruction was a 'better' technique for patients. It was perceived as quicker and easier to perform and with improved cosmetic outcomes and less post-operative pain. The lack of high-quality evidence to support this change was acknowledged but surgeons felt the limited evidence that prepectoral IBBR was 'no worse', coupled with their personal experience of benefit was sufficient to change practice. This was coupled with a move away from IBBR techniques more generally due to high complication rates and poor long-term outcomes. These factors were further exacerbated by COVID-19-related delays and pressures and were beyond addressing by the QRI.

Conclusions: A large-scale RCT comparing pre and subpectoral IBBR is not feasible in the UK due to the widespread adoption of prepectoral reconstruction despite a lack of high-quality evidence. Prepectoral IBBR needs to be robustly evaluated and well-designed, large-scale studies such as iPREPARE will be essential support best practice.

P3-09-16: SerpinE2 mediated cell competition during breast cancer metastasis to the liver

Sakshi Mohta, Katherine E. Lake, Clayton A. Smith Lily Xu, Lily Xu, Kaitlyn Saunders, Venkata Repaka, Luis Chinea, Jacob Pena, Flavia S. Fernandes, Joshua Thomas, Simali A. Shah, Sangeetha M. Reddy, Heather L. McArthur, Christine Hodges, Julia Maues, Hannah L. Chang, Elizabeth Chen, Isaac S. Chan

Background: Patients with breast cancer liver metastasis (BCLM) have a 5-year survival rate of 8%, highlighting an urgent need for novel therapeutics to target liver-specific treatment for BCLM. The liver is a cellularly dense organ, and it remains unclear how metastatic cancer cells (MCC) colonize and expand in the liver. Cell competition is a

developmentally conserved process that explains how cells use fitness-sensing mechanisms leading to survival and expansion of one cell population, and the induction of cell death through apoptosis in the other. This process is critical to organogenesis and tumorigenesis. We previously showed that MCC are able to create space during metastatic colonization of the liver by causing apoptosis in neighboring hepatocytes (HEP), which make up 80% of liver mass. Through a biological and bioinformatic screen, we found that MCC expresses SerpinE2, a serine protease inhibitor. SerpinE2 has been shown to correlate with increased metastatic potential but the mechanistic cause is still unknown. In this study, we tested the hypothesis that MCC engage in SerpinE2-mediated cell competition with HEP to create space and expand within the liver by eliminating neighboring HEP through apoptosis resulting in tumor expansion.

Methods: We develop new in-vitro and mouse lineage-traced models to model cell competition between MCC and HEP using syngeneic mouse breast cancer cells and hepatocytes. These models directly capture cell-cell interaction between MCC and HEP so we can assess for apoptotic and extrusion events, known modes of cell competition, through immunostaining and live imaging. We used hydrodynamic tail vein injections (HDTVI) to engraft mice livers with MCC. Prior literature suggests that the developing mammary gland informs both cell competition and metastasis, so we performed a bioinformatics screen to identify signals contributing to cell competition between MCC and HEP. We generated a new single-cell RNA-seq dataset incorporating information from the developing mammary gland and breast cancer cells. Through this, we identified a target gene, SerpinE2, enriched in both breast cancer and the developing mammary gland. We validated that SerpinE2 is more highly expressed in MCC compared to HEP. We used CRISPR-Cas9 technology to generate a SerpinE2 knock-out (KO) 4T1 cell line and lentiviral gene editing to restore the full length SerpinE2 gene in SerpinE2 KO MCC to generate a genetic rescue line. We then used our previously established in vitro and in vivo models to evaluate the functional role of SerpinE2 in cell competition and metastatic colonization in the liver.

Results/Discussion: Using our in vitro coculture models we demonstrated that wild-type (WT) MCC induce apoptosis in neighboring HEP through cell competition. MCC-induced apoptosis in neighboring HEP is 7.62-fold higher compared to apoptosis in neighboring MCC. KO of SerpinE2 in MCC did not affect their viability or growth rates in monocultures. In coculture with HEP, SerpinE2 KO resulted in increased apoptosis in MCC by 9.04-fold compared to WT MCC that neighbor HEP. There was a 4.75-fold decrease in HEP apoptosis compared to HEP in coculture with WT MCC. We then used our genetic rescue of SerpinE2 in MCC and cocultured them with HEP. SerpinE2 KO MCC with SerpinE2 restored increased apoptosis in HEP by 5.89-fold while decreasing MCC apoptosis by 4.10-fold when compared to cocultures with SerpinE2 KO MCC, similar to WT MCC. HDTVI of SerpinE2 KO MCC in mice showed a 10-fold decrease in micrometastasis in livers compared to those injected with WT MCC. These data suggest SerpinE2 regulates competition between MCC and HEP. Future work involves understanding the mechanistic regulation of metastatic colonization by SerpinE2 in the liver. These findings may suggest a novel therapy for BCLM patients that reduces MCC fitness or restores HEP fitness during liver colonization by MCC.

P3-09-17: Trastuzumab deruxtecan (T-DXd) in combination with capecitabine or capivasertib in patients with HER2-low metastatic breast cancer: a Phase 1b, multicenter, open-label study (DESTINY-Breast08)

Komal Jhaveri, Fabrice André, Erika Hamilton, Peter Schmid, Carey K Anders, Hans Wildiers, Yeon Hee Park, Shin-Cheh Chen, Caron Lloyd, Karen Cui, Cuihong Zhang, Sherene Loi

Background: T-DXd is approved in over 55 countries for patients with HER2-low (immunohistochemistry [IHC] 1+, IHC 2+ / negative results on in situ hybridization), unresectable/metastatic breast cancer (mBC) who received prior chemotherapy in the metastatic setting or developed disease recurrence during or within 6 months of completing adjuvant chemotherapy. DESTINY-Breast08 explored the safety, tolerability, and antitumor activity of T-DXd combinations in HER2-low mBC (NCT04556773). Results reported here are from the final data cutoff (DCO) of the dose-expansion phase (Part 2) of DESTINY-Breast08, for T-DXd + capecitabine (CAPE) and T-DXd + capivasertib (CAPI).

Methods: Eligible patients had locally confirmed HER2-low mBC with measurable disease per RECIST 1.1. In the T-DXd + CAPE arm, patients with hormone receptor–negative (HR–) or HR-positive (HR+) disease were eligible. In the T-DXd + CAPI arm, patients with HR– disease were eligible. Across both arms, patients with HR– mBC were allowed ≤1 prior line of chemotherapy. In the T-DXd + CAPE arm, patients with HR+ mBC were allowed ≤1 prior line of endocrine therapy ± a targeted therapy for mBC, with no prior chemotherapy in the metastatic setting. Patients received T-DXd 5.4 mg/kg intravenously (IV) every 3 weeks (Q3W) + CAPE 750 mg/m^2 orally (PO) twice daily (BID) on Days 1–14 Q3W, or 5.4 mg/kg T-DXd IV Q3W + CAPI 400 mg PO BID every week on Days 1–4 within a 21-day treatment cycle. Primary objectives were safety and tolerability; key secondary endpoints were objective response rate (ORR) and progression-free survival (PFS) by investigator per RECIST 1.1, overall survival (OS), and duration of response (DOR).

Results: As of August 16, 2023, 20 patients in the T-DXd + CAPE arm and 40 patients in the T-DXd + CAPI arm had received study treatment. Median age was 57.5 and 56.0 years, respectively. In the T-DXd + CAPE arm, 30.0% (n=6/20) of patients had HR– mBC, and 70.0% (n=14/20) of patients had HR+ mBC. In the T-DXd + CAPI arm, 32.5% (n=13/40) of patients had centrally confirmed AKT/PTEN/PIK3CA alterations detected by ctDNA assays. In patients with HR– disease, 83.3% (n=5/6) and 45.0% (n=18/40) received first-line chemotherapy for mBC in the T-DXd + CAPE and T-DXd + CAPI arms, respectively. In patients with HR+ disease in the T-DXd + CAPE arm, 64.3% (n=9/14) had received first-line hormonal therapy ± a targeted therapy for mBC. Median actual treatment duration was 11.1 months for T-DXd and 7.0 months for CAPE in the T-DXd + CAPE arm, and 6.2 months for T-DXd and 5.5 months for CAPI in the T-DXd + CAPI arm. Grade ≥3 adverse events (AEs) occurred in 55.0% (n=11/20) and 67.5% (n=27/40) of patients treated with T-DXd + CAPE and T-DXd + CAPI, respectively. Serious AEs were reported in two patients (10.0%) in the T-DXd + CAPE arm, and 13 patients (32.5%) in the T-DXd + CAPI arm. Three (15.0%) adjudicated drug-related interstitial lung disease / pneumonitis events were reported in the

T-DXd + CAPE arm (Grade 2, n=2; Grade 5, n=1) and eight (20.0%) in the T-DXd + CAPI arm (Grade 1, n=1; Grade 2, n=7). Confirmed ORR was 60.0% for both T-DXd + CAPE and T-DXd + CAPI. At final DCO, median DOR was not reached for T-DXd + CAPE but was 7.1 months for T-DXd + CAPI. Median PFS was 13.4 months and 9.0 months for T-DXd + CAPE and T-DXd + CAPI, respectively. Median follow-up duration was 15.2 months and 8.6 months for T-DXd + CAPE and T-DXd + CAPI, respectively. OS was not mature at final DCO for either arm; the survival rate at 12 months was 78.0% (95% confidence interval [CI] 51.5, 91.1) for T-DXd + CAPE and 92.0% (95% CI 77.2, 97.4) for T-DXd + CAPI.

Conclusion: Safety profiles for T-DXd + CAPE and T-DXd + CAPI were generally consistent with the known safety profile of each agent, and both combinations demonstrated antitumor activity; further research is warranted.

P3-09-18: Comparative analysis of protein and gene expression of biomarkers and therapeutic targets in patients with metastatic hormone-receptor positive breast cancer of no-special type versus invasive lobular breast cancer

Gitte Zels, Karen Van Baelen, Anirudh Pabba, Kristien Borremans, Josephine Van Cauwenberge, Marion Maetens, Maxim De Schepper, Tatjana Geukens, Amena Mahdami, Ha-Linh Nguyen, Sophia Leduc, Bram Boeckx, Evy Vanderheyden, Thomas Van Brussel, Diether Lambrechts, Patrick Neven, Hans Wildiers, Wouter Van Den Bogaert, François Richard, Giuseppe Floris, Christine Desmedt

Background: Invasive lobular breast cancer (ILC) represents 15% of all breast cancer (BC). As of today, patients with metastatic ILC are treated similarly to patients with metastatic invasive BC of no-special type (IBC-NST), mainly due to the lack of dedicated research. In this study, we compared the expression levels of standard histopathological markers (estrogen receptor (ER), human epidermal growth factor receptor 2 (HER2), stromal tumor-infiltrating lymphocytes (sTIL)) as well as gene expression levels of targets for antibody-drug conjugates (ADC) and immune checkpoint inhibitors (ICI) in 503 metastatic samples from 22 patients with metastatic ILC versus IBC-NST obtained in the context of our post-mortem tissue donation program UPTIDER (NCT04531696).
Methods: In this study, we considered histopathological data from 22 UPTIDER patients who were diagnosed with primary HR+/HER2- BC (5 ILC, 14 IBC-NST, 2 mixed IBC-NST/ILC, 1 ILC with medical history of contralateral IBC-NST) and analyzed the markers according to the histology of the metastases (IBC-NST=303, ILC (originating from both primary ILC and mixed IBC-NST/ILC)=200). sTIL were scored according to international guidelines. ER expression was scored according to the Allred scoring system, with a cut-off of 1% for positivity in line with the ASCO/CAP 2020 guidelines. HER2 was scored according to the ASCO/CAP 2023 guidelines. Expression levels of 72 ADC and 23 ICI targets from established drugs or drugs under active clinical development were retrieved from complementary bulk RNA sequencing data. Associations between gene expression

(outcome) and histological subtype (co-variate of interest: ILC vs IBC-NST) was assessed by linear mixed quantile regression with random effect on patient ID.
Results: Although all but one patients had a primary ER+ tumor, 23% of patients with IBC-NST metastases and 40% of patients with ILC metastases displayed at least one ER- metastasis. A median percentage of 0% ER- IBC-NST metastases (range: 0-92.3%) and 0% ER- ILC metastases (range 0-59.1%) was observed per patient. sTIL levels were significantly lower in ILC (0.3% (range: 0-13.3%)) versus IBC-NST (median: 1.7% (range: 0-25%))) metastases (p<.001). A median of 63.6% HER2-low (range: 0-88.6%) and 48.69% (17.4-80%) metastases was observed in the 7 patients with IBC-NST and 3 patients with ILC analyzed so far. Regarding ADC targets, mRNA expression levels of FGFR2, CDH3, FN1, F3 and PTK7 were higher in IBC-NST metastases and expression levels of GUCY2C, ITGAV and VTCN1 were higher in ILC metastases (p<.05). There was no evidence of differences in mRNA expression levels regarding HER2 and HER3, while TROP2 levels were non-significantly higher in IBC-NST versus ILC metastases (p= .12). Regarding ICI targets, mRNA expression levels of HVEM were higher in IBC-NST metastases (p=.04). CD137 and TIM3 levels were non-significantly higher in IBC-NST metastases (p=.07 and .08, respectively). No differences were observed for PD-1 and PD-L1.
Conclusions: This work reports on the differences in the expression of clinical biomarkers and therapeutic targets of interest between patients with IBC-NST and ILC metastases. This further emphasizes the notion to consider, at least for some markers, ILC as a distinct BC entity.

P3-09-19: Tumor genomics in young patients with metastatic breast cancer

Kristen Brantley, Ananya Kodali, Gregory J. Kirkner, Melissa E. Hughes, Yvonne Li, Janet Files, Anne-Marie Feeney, Ayesha Mohammed-Abreu, Romualdo Barroso Sousa, Brittany Bychkovsky, Tari King, Bruce E. Johnson, Lynette Sholl, Deborah Dillon, Sara M. Tolaney, Andrew Cherniack, Ann H. Partridge, Nancy U. Lin, Ana C. Garrido-Castro

Background: Breast cancer (BC) patients diagnosed at young ages (≤40y) often present with more aggressive tumors than older patients, highlighting the need to define differences in tumor biology by age. Limited data exists on tumor genomics in young metastatic BC (MBC) patients.

Methods: The Ending Metastatic Breast Cancer for Everyone (EMBRACE) study is a prospective cohort enrolling women with MBC who receive care at Dana-Farber Cancer Institute. Women in EMBRACE with targeted sequencing conducted via Oncopanel for at least one tumor sample (collected at metastatic or primary diagnosis), were included. Tumors were classified by molecular subtype [HR+/HER2- (classified as luminal A- or B-like, with luminal-B like defined by primary tumor grade=3 or metastatic tumor progesterone receptor staining <10%), HR+/HER2+, HR-/HER2+, and HR-/HER2-]. After filtering for germline SNPs, oncogenic and likely oncogenic variants were selected. Tumor

mutational burden (TMB) and variant frequencies were compared by age at MBC diagnosis (≤40y, >40-55y, >55y) using Fisher's exact test, overall and within tumor molecular subtypes. Odds of individual gene mutations within age groups were compared using multivariable logistic regression models, adjusting for molecular subtype, histology, race, TMB, de novo v. recurrent MBC, and primary v. metastatic sample type. Kaplan-Meier curves, stratified by age group, assessed overall survival (OS, measured from MBC diagnosis) by genetic mutation status. Multivariable Cox regression analysis, adjusting for MBC diagnosis age, tumor factors, and race, was used to estimate hazard ratios (HR) and 95% confidence intervals (CIs) for OS by gene mutation.

Results: Tumor samples from 2,363 patients (1,594 metastatic, 769 primary) tested between July 2013-December 2020 were included. Median age at MBC diagnosis was 54 years (range: 18-91y). Median disease-free interval was 2.4 years (range: 0-33y), and younger women more likely to have de novo MBC (≤40y: 37% v. >55y: 23%, p<0.001). High TMB (≥10) was more common in older women with recurrent MBC (>55y: 28% v. ≤40y: 13%, p<0.001), though TMB did not differ by age for those with de novo MBC. After adjusting for tumor factors and race, compared to those >55y, patients ≤40y at MBC diagnosis were two to three times more likely to harbor mutations in BRCA1 [Odds ratio (OR) (95% CI)=3.11 (1.36-7.10), p<0.001], BRCA2 [OR (95% CI)=2.46 (1.15-5.27), p<0.001], and ERBB2 [OR (95% CI)=2.68 (1.46-4.90), p<0.001]. Mutations in GATA3 and TP53 were also more frequent among younger patients [OR (95% CI) GATA3 =1.68 (1.06-2.67), p<0.05; TP53=1.83 (1.22-2.73), p<0.01]. Mutations in CDH1 and PIK3CA were more common in older individuals [OR (95% CI) CDH1=0.07 (0.02-0.30), p<0.001, PIK3CA=0.45 (0.30-0.68), p<0.001]. Differences in OS by age were not statistically significant for de novo MBC patients, though OS was worse for recurrent MBC patients ≤40y v. >55y [median OS (95% CI)=2.8 (2.4-3.4y) v. 3.6 (3.3-3.9y), p=0.04]. In multivariable Cox models, mutations in TP53, MYC, and AKT1 were associated with shorter OS [HR (95% CI) TP53=2.05 (1.79-2.34), MYC=1.26 (1.01-1.56), AKT1=1.42 (1.10-1.84)], while mutations in GATA3, ERBB2, and MAP3K1 were associated with longer OS [HR (95% CI) GATA3=0.83 (0.69-1.00), ERBB2=0.53 (0.41-0.69), MAP3K1=0.75 (0.57-0.99)]. TMB was not associated with OS. Mutation-specific associations with survival did not differ by age group at diagnosis.

Conclusions: In EMBRACE, differences in mutational frequency of several genes were observed by age at MBC diagnosis among patients with recurrent MBC, most notably for HR+/HER2- patients. Lower OS among younger recurrent MBC patients may be driven by these differences, particularly by high frequency of TP53 mutations in this age group. Further investigation of these genes is warranted to elucidate pathways leading to metastasis and to improve survival for young MBC patients.

P3-09-20: Re-evaluation of Human Epidermal Growth Factor Receptor 2 (HER2) Immunohistochemistry (IHC) 0 or 1+ in Metastatic Breast Cancer (mBC) Samples to Characterize the Proportion of HER2-ultralow (IHC 0 With Membrane Staining)

Savitri Krishnamurthy, Clara Lam, Linlin Luo, Rosalind Baverstock, Nick Pyrih, Stella Redpath, Michele Sue-Ann Woo, Simon M. Collin, Caryn Davies, Victoria Gannon, Simone T. Sredni

Background: The efficacy of fam-trastuzumab deruxtecan-nxki (T-DXd) in patients with HER2-low (IHC 1+ or IHC 2+/ISH negative) mBC was established by results of DESTINY-Breast04 and substantiated in DESTINY-Breast06 (HR+/HER2-low), which explored T-DXd efficacy in HER2-ultralow (IHC 0 with ≤10% cells with faint, incomplete membrane staining) as a secondary endpoint. Published evidence on the prevalence and characterization of HER2-ultralow in patients with mBC is limited. In this study, whole slide images (WSI) originally scored HER2 IHC 0 (with or without membrane staining) and 1+ were rescored to generate insights into identification of HER2-ultralow and scoring concordance.

Methods: WSI from 2020 or later, originally scored as HER2 IHC 0 (n = 400) or IHC 1+ (n = 200) stained by VENTANA HER2 4B5 (Roche), were manually rescored by 3 pathologists according to 2023 American Society of Clinical Oncology-College of American Pathologists (ASCO-CAP) guidelines. No training for ultralow was provided. Following a washout period of 2-10 weeks, each pathologist performed a second reading; readings were blinded and WSI were randomized. The review time and the percentage of cells with incomplete, faint membrane staining were recorded. WSI were rescored as either IHC 0 without membrane staining, HER2-ultralow, or IHC 1+/2+. The primary objective was to estimate the proportion of HER2 IHC 0 WSI rescored as HER2-ultralow. Secondary objectives included evaluating inter- and intraobserver concordance and observer concordance with the original scores. Concordance analyses were described by overall percentage agreement (OPA) and Cohen Kappa. Consensus was defined as a score that either 2/3 or 3/3 pathologists agreed on.

Results: Rescoring of the 600 WSI assessed, 2/3 pathologists showed consensus in 250 (41.7%) and 3/3 showed consensus in 336 (56.0%); 255 WSI were classified as IHC 0 per consensus rescore, with 129 (21.5%) showing no membrane staining and 126 (21.0%) with membrane staining. Of the 400 WSI originally scored IHC 0, 263 (65.8%) were rescored as HER2-ultralow (113, 28.3%) or IHC 1+ (150, 37.5%); 125 (31.3%) were scored as IHC 0 without membrane staining. Of the 200 WSI originally scored IHC 1+, 4 (2.0%), 13 (6.5%), 175 (87.5%), and 6 (3.0%) were rescored as IHC 0 without membrane staining, HER2-ultralow, IHC 1+, and IHC 2+, respectively.
Concordance

Concordance between pathologists varied from substantial (OPA [95% CI], 86.5% [83.5%-89.1%]; Cohen Kappa [95% CI], 0.774 [0.729-0.818]) to moderate (OPA [95% CI], 61.2% [57.1%-65.1%]; Cohen Kappa [95% CI], 0.427 [0.378-0.476]). Average interobserver concordance (average OPA) was 69.9%. Intraobserver concordance was high (OPA [95% CI] values ranged from 88.2% [85.3%-90.6%] to 84.7% [81.5%-87.5%]; Cohen Kappa [95% CI] values ranged from 0.805 [0.763-0.846] to 0.765 [0.722-0.807]). Agreement between pathologists' consensus scores and original scores was moderate (OPA [95% CI], 70.8% [67.0%-74.4%]; Cohen Kappa [95% CI], 0.439 [0.376-0.502]).
Review Time
Median review time in minutes (min) was shorter for WSI rescored as HER2 IHC 0 without membrane staining (5.7 min) than WSI with any staining up to 10% (HER2-ultralow [7.5 min] or IHC 1+ [7.0 min]).

Conclusions: While 28.3% of IHC 0 WSI were rescored as HER2-ultralow, 65.8% could be reclassified with a clinically actionable level of expression (HER2-ultralow or IHC 1+). The discrepancies in scoring and a trend to extended review times for HER2-ultralow and IHC 1+ highlight the need for training, digital tools for decision support, and increased awareness of the available therapies for HER2-ultralow and IHC 1+ cases, to motivate pathologists to improve consistency in scoring for optimal patient care and treatment selection.

P3-09-21: Phase IB/II Trial of Alpelisib with iNOS Inhibitor and Nab-paclitaxel in Patients with HER2 negative Metastatic or Locally Advanced Metaplastic Breast Cancer

Polly Niravath, Kai Sun, Hanh Mai, Clinton Yam, Funda Meric-Bernstam, M. Florencia Chervo, Kelsey Banaglorioso, David Wink, Kevin Conlan, Stanley Lipkowitz, Sunil Mathur, Jenny Chang

Introduction: Metaplastic breast cancer (MpBC) comprises only about 1.2% of all breast cancer cases, but this rare form of triple negative breast cancer is extremely aggressive and chemo-refractory, with median overall survival of only 3-8 months in the metastatic setting. Inducible nitric oxide synthase (iNOS) is critical for triple negative (TNBC) and MpBC because of nitric oxide's important role in many oncogenic pathways, such as PIK3CA/AKT (often mutated in MpBc), RAS/ERK, HIF1α, and NF-κB. Through combined blockade of iNOS and PIK3CA, with L-NMMA and alpelsib, along with nab-paclitaxel chemotherapy, we aimed to improve outcomes for patients with metastatic or locally advanced MpBC. We report here the results from the Phase IB portion of this trial.

Methods: Patients with metastatic or locally advanced, unresectable triple negative MpBC received nab-paclitaxel 260 mg/m2 every 3 weeks, and L-NMMA 20 mg/kg (given on days 1-5 of each cycle) every 3 weeks. Varying doses of alpelisib were given, starting at dose

level 0 (250 mg on days 1-21), and eventually reduced to dose level -1 (250 mg on days 1-10). Co-primary objectives were as follows: 1) to define the recommended phase II dose (RP2D) of alpelisib in combination with nab-paclitaxel and L-NMMA, and 2) to determine the objective response rate (ORR) of this combination therapy in MpBC.

Results: Nine female patients were enrolled on this trial, with median age of 58 years. Four patients (44.4%) carried a PIK3CA mutation. Three patients received dose level 0, and 6 patients received dose level -1. With only 2 dose-limiting toxicities (DLT's) at dose level -1, this was determined to be the recommended phase 2 dose, planned for the remainder of the trial. DLT's at dose level 0 included grade 3 rash and mucositis. At dose level -1, two patients experienced grade 3 rash. The ORR was 44.4%, and Clinical Benefit Rate (CBR) was 77.8% (1 CR, 3 PR's, 3 SD's). Two responders were able to stay on treatment for >6 months without progression. One stopped due to grade 3 neuropathy from nab-paclitaxel, and the other stopped because she wanted to return home. Only 22.2% (2 patients) experienced progressive disease after 2 cycles of therapy. Reponses were especially robust in the 4 patients with PIK3CA mutation – one experienced CR, two had PR, and one had SD.

Conclusion: In this highly refractory group of patients, this novel, rationally designed therapy has shown remarkable efficacy, not previously demonstrated in MpBC, including some sustained responses, particularly in those subjects with PIK3CA mutations. Equally as important, the regimen was also found to be safe and tolerable, as we begin the multi-center phase II portion of this trial.

P3-09-22: Phenomenal: Efficacy and safety of liposomal irinotecan in patients with HER2-negative breast cancer and brain metastases

Manuel Ruiz Borrego, David Páez López-Bravo, Mireia Margelí Vila, José Manuel Pérez-García, María Fernández, Salvador Blanch Tormo, José Ángel García, Laura Lema, Isabel Garau, Patricia Cortez, Antonio Antón Torres, Emilio Alba Conejo, María Isabel Calvo, Neus Ferrer, María Isabel Blancas, Kepa Amillano, Marta Bertrán, Daniel Alcalá-López, Miguel Sampayo-Cordero, Javier Cortés, Antonio Llombart-Cussac

Background: Liposomal irinotecan (nal-IRI) is a novel formulation of irinotecan, a topoisomerase 1 inhibitor encapsulated in a liposome drug delivery system that has shown promising activity in patients (pts) with brain metastases (BMs). Phenomenal is a non-randomized phase IIa study evaluating the efficacy and safety of nal-IRI as single agent in HER2-negative (HER2[-]) breast cancer pts with previously untreated, stable or progressive BMs following local treatment.

Methods: Phenomenal (NCT03328884) is an open-label, single-arm, multicenter, Simon two-stage phase IIa trial. Pts aged >18 years with pretreated HER2[-] breast cancer with previously untreated, stable, or progressive BMs were enrolled. Pts received intravenous nal-IRI at 60 mg/m2 (if based on irinotecan hydrochloride trihydrate [salt base]) or 50 mg/m2 (if based on irinotecan anhydrous [free-base]) on day 1 of a 14-day cycle until disease progression, unacceptable toxicity, or consent withdrawal. Primary endpoint was intracranial objective response rate (IC-ORR) according to RANO-BM in pts with progressive BMs. It was locally confirmed at the next tumor assessment (after 6 weeks) or with a ≥65% volumetric reduction of IC lesions by blinded independent central review. Secondary endpoints included IC, extracranial (EC) and overall (IC + EC) ORR, progression-free survival (PFS), overall survival (OS), duration of response) and clinical benefit rate at 12 weeks according to RECIST v.1.1; and safety and tolerability as per NCI-CTCAE v.4.0. Primary analysis estimated the IC-ORR (H0≤5.0%; H1: IC-ORR ≥15.0%); 95% CI and p-value were calculated with the method of Jung and Koyama. Sample size was planned to attain an 80% power at a nominal α level of 0.05.

Results: Between July 2017 and April 2024, 56 pts were allocated at 16 sites in Spain. Median age was 52 (range 32-83) years. A total of 3 and 51 pts had previously untreated and progressive BMs, respectively. Two patients had stable BMs. Twenty-seven pts (48.2%) had HR[+]/HER2[-] tumors and 29 pts (51.8%) had triple-negative breast cancer. The median number of previous lines of therapy for advanced disease was 3 (range, 1-8). At data cutoff (May 15th, 2024), with a median follow-up of 5.7 months (mo) (range, 0.4-56.5), 2 pts (3.6%) remained on therapy. The primary endpoint of the study was met with 10 pts out of 51 (19.6%; 95% CI 11.1-28.9) with progressive BMs achieving a confirmed IC-ORR ($p<0.001$). IC-ORR in all pts was 19.6% (11/56 pts; 95% CI, 10.2–32.4). EC-ORR in pts with measurable extracranial disease was 2.7% (1/37 pts; 95% CI, 0.0-14.2) and overall (IC + EC) ORR in all pts was 5.4% (3/56 pts; 95% CI, 1.1–14.9). Median PFS was 1.5 mo (95% CI, 1.4-2.8). Median OS was 6.4 mo (95% CI, 4.3-10.8). The most common treatment emergent adverse events of any grade (G) were fatigue (55.4%; 7.1% G≥3) and headache (44.6%; 1.8% G≥3). There were no treatment-related deaths and no new safety issues were reported.

Conclusions: Although the primary endpoint was achieved, nal-IRI showed limited antitumor activity in HER2[-] breast cancer pts with progressive BMs. These results do not support further evaluation of this treatment in this patient population.

P3-09-23: Investigating differences in the composition of circulating tumor cells (CTCs) clusters in invasive lobular and ductal carcinoma to decipher lobular breast cancer metastasis

Eleonora Nicolò, Elisabetta Molteni, Lorenzo Foffano, Lorenzo Gerratana, Mara S. Serafini, Letizia Pontolillo, Caterina Gianni, Laura Munoz-Arcos, Nadia Bayou, Kaylan Strickland, Hunter Gaudio, Brenno Pastò, Maroua Manai, Youbin Zhang, Paolo D'Amico, Andrew A. Davis, Jeannine Donahue, Huiping Liu, William J. Gradishar, Giuseppe Curigliano, Carolina Reduzzi, Massimo Cristofanilli

Background: Invasive lobular carcinoma (ILC) has distinctive clinical and genomic features compared to invasive ductal carcinoma (IDC); however, for patients (pts) with ILC treatment is selected according to the same guidelines as IDC. Better characterization of ILC and development of specific approaches for ILC pts is an unmet need. Liquid biopsy (LB) is a useful tool to achieve this goal. Our group showed that, compared to IDC, ILC has specific circulating tumor DNA (ctDNA) alterations and higher CTC count. Another study reported higher detection of CTC clusters (CTC-CL), considered the main seed of metastasis, in ILC. This finding is paradoxical since cell-cell adhesion (a key feature of CTC-CL) is impaired in ILC. Interestingly, an association between CTC-CL counts and ctDNA CDH1 alterations (a hallmark of ILC) was reported, regardless of histology. To investigate whether different mechanisms are responsible for CTC clustering in ILC and IDC, in this study we characterized CTC-CL according to the breast cancer (BC) histotype.

Methods: Blood samples were collected from 351 pts with stage IV BC before starting a new line of therapy at Northwestern University (Chicago, IL) between 2016 and 2021 (NU16B06 trial). Blood samples were processed with the CellSearch system for CTC and CTC-CL enumeration by a single expert operator. CTC-CL were defined as groups of ≥2 CTCs , or ≥1 CTC clustered with ≥2 white blood cells (WBCs). The number and size of CTC-CL, and the presence of WBCs in CTC-CL (heterotypic) were compared between ILC and IDC. Also, the association between CTC-CL and overall survival (OS) was tested. To further explore mechanisms of CTC-CL formations, we assessed potential differences in the association between CTC-CL presence and ctDNA alterations in ILC vs IDC. For ctDNA analysis, matched plasma samples were analyzed using Guardant360 and tested for the 10 most altered genes and CDH1.

Results: Of the 351 pts included, 255 (73%) had IDC while 45 (13%) had ILC. Overall, CTC-CL were identified in 45 (13%) pts and only in those with ≥ 5 CTCs. The presence of CTC-CL was significantly higher among ILC pts (27% vs 11% in IDC, p=0.004) but the total number of clustered CTCs was significantly lower in ILC than IDC (median 4.5 vs 9.5, p=0.039), suggesting a smaller size of CTC-CL in ILC. Indeed, the median and maximum number of CTCs per CTC-CL was numerically lower in ILC than IDC. Heterotypic CTC-CL were identified in 6 (50%) and 10 (36%) of ILC and IDC pts, respectively. Among these pts, there

was a trend for a higher median (0 vs 2, p=0.37) and maximum number of WBCs (2.5 vs 3.5, p=0.26) in CTC-CL in ILC than IDC. Overall, the presence of >3 CTC-CL was associated with shorter OS (6 vs 21 months, p=0.001). A matched plasma sample for ctDNA analysis was available for 129 IDC and 19 ILC pts. CDH1 alterations were detected in 2 IDC and 1 ILC pts and associated with CTC-CL (p=0.015) only in IDC. No significant association between ctDNA alterations and CTC-CL was observed in ILC possibly due to the small sample size; further analysis is ongoing.

Conclusion: ILC is characterized by a higher number of CTC-CL than IDC. CTC-CL in ILC appear to be different from IDC, being smaller but more frequently associated with WBCs. This suggests a possible different biology for CTC-CL formation in ILC related to the impaired cell-cell adhesion and a specific role played by the CTC-CL microenvironment. Indeed, the interaction with immune cells in ILC may promote the survival in the bloodstream of smaller CTC-CL thus enhancing metastatic efficacy. Further studies including a larger number of pts are needed to validate and better elucidate these findings. The study of CTC-CL could shed light on the distinct pattern of metastatic spread of ILC, potentially offering therapeutic opportunities, and serving as a useful prognostic factor.

P3-09-24: PLEURAL T CELLS FROM PATIENTS WITH METASTATIC INVASIVE LOBULAR CARCINOMA PRODUCE EFFECTOR CYTOKINES AND MOUNT ANTI-TUMOR IMMUNITY

Vera Donnenberg, Albert Donnenberg, James Luketich, Shannon Puhalla, Christie Hilton, David Bartlett

Breast cancer (BC) metastatic to the pleura is uniformly fatal with a median survival of six months and quality of life that is diminished by dyspnea, pain and discomfort. There are currently no curative treatments once malignant pleural effusions (MPE) have occurred. Despite significant clinical progress in immuno-oncology, there has been almost no change in survival or quality of life for patients with MPE. We have shown that BC MPE are characterized by a distinct and complex pleural secretome that varies little between breast cancer subtypes. Our studies on freshly isolated pleural T cells (PIT) from breast cancer MPE of all subtypes indicate that these cells are quiescent rather than exhausted, and poised to mount potent anti-autologous tumor effector responses, but locally suppressed by the pleural environment. To date, there are no reports on cytokine secretion and immune checkpoint expression in pleural T cells isolated from patients with invasive lobular carcinoma (ILC) metastatic to the pleura. In this abstract we show that freshly isolated pleural T cells from patients with ILC secrete T-cell effector cytokines (IL-2 or IFNγ), are not exhausted (lack or have low expression of PD1, TIM3, LAG3, TIGIT, CTLA4) and a minority express CD137/4-1BB activation/signal transduction molecule, critical to anti-tumor effectors. Consistent with our findings in BC grouped by HR status, the 8 most prevalent cytokines in the pleural secretome (CXCL10, CCL2, sIL-6Rα, IL-6, CXCL1, TGFβ, CCL11, IL-

10) are indistinguishable between ILC and IDC. However, ILC cases clustered together in hierarchical clustering across 40 measured cytokines, due chiefly to a paucity of G-CSF, VEGF, IL-7, and an excess of IL-4. The data suggest that ILC PIT are immunologically competent when removed from their suppressive environment and can be used to generate an adoptive cellular therapeutic.

P3-09-25: Fam-trastuzumab Deruxtecan-nxki Versus Chemotherapy as Post-Chemotherapy Treatment in Patients with HER2-Low Metastatic Breast Cancer: An Analysis Of Real-World Data from the IntegraConnect PrecisionQ De-Identified Database

Stephan Rosenfeld, Vikram Gorantla, Rushir Choski, Debra Patt, Anupama Vasudevan, Anna Rui, Dawn Brenneman, Mike Gart, Prateesh Varughese, Brandon Wang, Lisa Morere, Simon Blanc

Background: The HER2-targeting antibody-drug conjugate fam-trastuzumab deruxtecan-nxki (T-DXd) is indicated for the treatment of metastatic HER2-low breast cancer. This real-world study sought to characterize the use of T-DXd in the post-chemotherapy setting and compare the outcomes between patients treated with T-DXd versus subsequent chemotherapy after chemotherapy failure. Methods: This was a retrospective, observational analysis of data from patients in the IntegraConnect PrecisionQ real-world de-identified database, enriched with information obtained by curation. The study included adults (age ≥18 years) with HER2-low metastatic breast cancer (mBC) who initiated systemic chemotherapy after mBC diagnosis and subsequently initiated a later line of therapy (LOT; chemotherapy or T-DXd) between June 1, 2022 and February 29, 2024. The index date was the date of subsequent treatment initiation, with follow-up through May 20, 2024. The primary outcome was overall survival (OS); also included were patient demographics, clinical characteristics, and the type of post-chemotherapy treatments used. Data are presented using descriptive statistics. Results: Of the 347 patients with HER2-low mBC and post-chemotherapy treatment included in the analysis, most were female (99.4%) and white (75.8%). The distribution of Eastern Cooperative Oncology Group score was as follows: ECOG 0: 33.2%; ECOG 1: 50.2%; ECOG 2: 13.8%; ECOG 3: 2.5%; ECOG 4: 0.3%. Most patients were on metastatic LOT2 (38.3%), followed by LOT4+ (35.2%) and LOT3 (26.5%). Baseline demographics were generally similar between patients treated with T-DXd versus chemotherapy in the post-chemotherapy setting. Overall, 155 patients received T-DXd and 192 received chemotherapy as the post-chemotherapy LOT. Over a median follow-up (IQR) of 9.2 (4.4, 15.0) months in the T-DXd group and 7.9 (4.5, 12.9) months in the chemotherapy group, a total of 47 (30.3%) patients and 84 (43.8%) patients died, respectively. T-DXd was the second most common post-chemotherapy treatment (27.3%) and was used more frequently in the LOT4+ setting than the LOT2 setting (37.6% versus 19.6%, respectively). Across all post-chemotherapy LOTs, the median OS was not reached (NR) (14.3, NR) in the T-DXd group and was 13.6 (11.3, 17.2) months in the chemotherapy group. At 6 months, the probability (95% confidence interval) of survival was 84.1% (76.8, 89.3) and 76% (69,

81.7) in the T-DXd and chemotherapy groups, respectively. At 12 months, these values were 69% (59.4, 76.7) and 54.1% (45.2, 62.1), respectively, and at 21 months, they were 53.9% (42.5, 64) and 31.2% (21.2, 41.7). Conclusion: Patients with HER2-low mBC treated with T-DXd after failing chemotherapy have higher survival probability than those treated with chemotherapy. These data support the use of T-DXd in the second- and later-line metastatic settings. Limitations of this analysis include a limited follow-up time and those inherent in observational, real-world studies. Future research will build on these insights to help inform treatment choice in this setting.

P3-09-26: Efficacy of trastuzumab deruxtecan (T-DXd) in patients with metastatic lobular breast cancer with or without HER2 mutations: the MSKCC experience

Sherry Shen, Anton Safonov, Jimmitti Teysir, Mithat Gonen, Mehnaj Ahmed, Pedram Razavi, Komal Jhaveri

Background: In patients with HER2-low metastatic breast cancer (MBC), T-DXd improves outcomes compared to chemotherapy. Metastatic invasive lobular carcinoma (mILC) is associated with lower rates of HER2 amplification compared to invasive ductal carcinoma, but higher rates of HER2 (ERBB2) mutations, which are found in 14-15% of mILC. The SUMMIT trial demonstrated meaningful activity of neratinib + fulvestrant + trastuzumab in patients with HR+, HER2 non-amplified, HER2-mutant MBC. In DESTINY-PanTumor01, patients with solid tumors with HER2 mutations, 20% of whom had MBC, received T-DXd; median progression-free survival (PFS) was 5.4 months (95%CI 2.7-7.1). The activity of T-DXd in HER2-low is not well described by histology, nor for HER2-mutant ILC.
Methods: This single-center retrospective cohort study identified patients with HER2-negative mILC treated with T-DXd from 2018-2024 at Memorial Sloan Kettering Cancer Center (MSKCC). We abstracted patient demographics, clinicopathologic characteristics, T-DXd treatment history, and dates of disease progression (defined as radiographic or clinical progression leading to treatment change) from medical records. Presence or absence of HER2 or PIK3CA/AKT/PTEN mutations was determined using the MSK-IMPACT next generation sequencing platform from tissue samples taken prior to initiation of T-DXd. Median time to progression was computed using the Kaplan-Meier method.
Results: Among 41 patients, 34 (83%) had HR+ disease and 7 (17%) had TNBC. The median number of prior therapies in the metastatic setting was 5 (range 2-21); median number of prior chemotherapies was 1 (range 0-6). Among HR+ patients, the number of median prior endocrine therapies was 3 (range 1-10), 31/34 (91%) had prior CDK4/6 inhibitor, and median duration of CDK4/6 inhibitor was 11 months (range 1-72). Across all metastatic site biopsies, the highest degree of HER2 expression per IHC was 0 in 3 patients (7%), 1+ in 23 patients (56%), and 2+ in 14 patients (34%). 10 (24%) patients had HER2 mutations and 18 (44%) had PIK3CA/AKT/PTEN mutations. Median time to progression (TTP) in the total cohort was 7.2 months (95%CI 4.6-13.1). In patients with HER2 mutations, TTP was not reached (95%CI 6.6-NR) vs. 6.4 months (95%CI 4.0-12.4) in patients without HER2

mutations (p=0.09). In patients with PIK3CA/AKT/PTEN mutations, TTP was 4.6 months (95%CI 3.6-8.7) vs. 9.2 (95%CI 6.6-NR) in patients without pathway mutations (p=0.01). There were no significant differences for HR+ vs. TNBC or HER2 IHC 0/1+ vs. 2+. 27 (66%) patients discontinued T-DXd for disease progression, 3 (7%) for toxicity, and T-DXd treatment was ongoing in 11 (27%). Median overall survival in the total cohort was 18.2 months (95%CI 15.8-NR). 1 patient with HER2 mutation and HER2 IHC 0 on all biopsies in the early-stage and metastatic setting has been on T-DXd for 32 months; treatment is ongoing. Additional data on prior neratinib use in this cohort will be presented at the meeting.
Conclusions: In patients with mILC and HER2 mutation, there was a trend toward longer TTP with T-DXd. Genomic data could aid in prognostication in patients with mILC treated with T-DXd. These findings warrant confirmation in larger cohorts.

P3-09-27: Identification of glucocorticoid receptor dependence in metastasis of invasive lobular carcinoma using an in vivo xenograft MIND model

Baylee A. Porter, Muriel Laine, Hazel M. Borges, Geoffrey L. Greene, Lynda Bennett, Kevin M. Dean, Suzanne D. Conzen

Invasive lobular carcinoma (ILC) originates in the milk-producing glands of the breast and exhibits a nearly 100% five-year survival rate when confined to local invasion of nearby tissues. However, distant metastatic spread significantly reduces the five-year survival rate to approximately 22%, highlighting the unmet clinical need for added treatment options. Advancements in clinical management of ILC may benefit from a comprehensive understanding of metastatic tumor biology. Estrogen receptor (ER)-positive ILC relies on ER for growth and proliferation, yet little is known about the biological factors that drive metastatic proclivity and how the interplay with the body's stress response hormone, glucocorticoid receptor (GR), mitigates this cascade.
Previously, it was shown that ligand activation of tumor GR could impede ER transcriptional activity through displacement of both wild-type and mutant ER, leading to reduced activation of ER-mediated pro-proliferation gene expression (Tonsing-Carter et al., 2019). It has also been shown that activation of tumor cell GR in ILC cell lines has a similar anti-proliferative effect on ER-mediated gene expression (Porter et al, 2023). While ILC growth at the primary site has been well studied, there is limited data characterizing the establishment of the pre-metastatic niche by circulating tumor cells and elucidation of tumor biology at metastatic sites in the context of tumor cell GR.
Circulating tumor cells are highly prevalent in lobular carcinoma making it a good model for studying their molecular characteristics using the established in vivo xenograft MIND model (Behbod et al. 2009). We hypothesize that the prevalence of circulating tumor cells correlates with tumor cell GR status and may drive metastasis to secondary organs such as bone and brain. Utilizing in vivo models to collect ILC circulating tumor cells (SUM44, MM134, BCK4) at 60, 90, 120, 160 days will help us better understand the role of tumor cell

GR in the timing of the metastatic cascade and establishment of the pre-metastatic niche. Here, we show the presence of tumor cells within the vascular regions (blood) of intact femurs using highly specialized microscopic and tissue clearing techniques in our in vivo xenograft MIND model. Ongoing studies include the combination of circulating tumor cell collection and bone marrow extraction, to quantify the prevalence of tumor cells in high versus low tumor cell GR states among different ILC cell lines. Future studies include the use of GR modulators in xenograft MIND model to mitigate the establishment of metastatic tumors.

P3-09-28: Long-term follow-up on survival outcomes in patients developing ipsilateral breast tumor recurrences.

Changhoon Lee, Eunhye Kang, Jong-Ho Cheun, Hyelim Kang, Min Jung Lee, Jinyoung Byeon, Ji-Jung Jung, Hong-Kyu Kim, Han-Byoel Lee, Wonshik Han, Hyeong-Gon Moon

Background: As more patients are treated with breast conserving surgery, there are increasing cases of patients experiencing the development of ipsilateral breast tumor recurrences (IBTRs). In this study, we aimed to investigate factors affecting survival outcomes in patients with IBTR. We placed special interest in addressing the relative importance of IBTR tumor characteristics in predicting survival outcomes in comparison with the characteristics of the initial breast cancer.
Methods: This is a retrospective study that reviewed data of the patients who were treated at Seoul National University Hospital between January 2000 and March 2022 for their IBTRs. The study included only cases of invasive breast cancer recurrence, excluding cases of ductal carcinoma in situ IBTR. To identify the factors influencing distant metastasis-free survival (DMFS), we performed multivariate Cox proportional hazards regression analysis.
Results: A total of 235 patients with IBTR were identified. The median follow-up period is 141.7 months and 60 patients developed distant metastasis during the follow-up.
Survival analysis associated with both initial and IBTR tumor characteristics revealed distinct patterns of prognostic impact showing the features of IBTR tumors showing more significant associations with DMFS compared to the features of the initial tumors. Compared to T1 stage, T2 stage IBTR showed a two-fold increase in the risk of developing distant metastasis (95% CI, 1.03-3.87), while T3 or T4 stage tumors had a 4.2-fold higher risk(95% CI, 2.16-8.13). Triple-negative breast cancer (TNBC) IBTR demonstrated a 2.2-fold higher risk compared to HR+/HER2- subtypes (95% CI, 1.16-4.29). The presence of lymphovascular invasion in IBTR was associated with a 2.6-fold increase in risk(95% CI, 1.44-4.63). Notably, node-positive recurrence tumors did not show significant differences in DMFS compared to node-negative or non-dissected cases. In contrast, when examining the impact of initial tumor characteristics on DMFS, only lymphovascular invasion showed significant prognostic importance, with a 1.9-fold increased risk (95% CI, 1.12-3.34). The T stage, N stage, and subtype of the initial tumors did not significantly affect DMFS after the development of IBTR.
Conclusion: In patients with IBTR, the characteristics of the recurrent tumor demonstrated

more significant prognostic impact on DMFS compared to those of the initial tumors. These findings suggest that the biological features of the recurrent tumor, rather than those of the initial tumor, can be the primary basis for determining the risk of subsequent distant metastasis and guiding treatment decisions for patients with IBTR.

P3-09-29: A Novel BBB-permeable Agent for Breast Cancer Brain Metastases

Mariana K. Najjar, Daniel Doheny, Sara Manore, Chuling Zhuang, Munazza Samar Khan, Terrence Smalley, Hui-Wen Lo

Metastatic breast cancer is the second leading cause of cancer-related deaths among American women. The most common sites of breast cancer metastases are the bones, lungs, brain, and liver. Among the different sites, breast cancer brain metastasis (BCBM) constitutes approximately 10-30% of metastatic breast cancer and is associated with worst dismal prognoses, with a median survival time of 7.9 months. The poor outcomes are attributed to the limited understanding of the driving factors of BCBM and the scarcity of drugs that can cross the blood-brain barrier (BBB) and blood-tumor barrier (BTB). This underscores the critical need to develop new therapies for BCBM. Our lab identified truncated glioma-associated oncogene homolog 1 (tGLI1) as an alternatively spliced, gain-of-function, tumor-specific variant of GLI1. Since its discovery, tGLI1 has been reported to promote breast cancer stem cells (CSC) and breast cancer preferential metastasis to the brain. Additionally, we recently identified the FDA-approved antifungal ketoconazole to selectively target tGLI1-positive breast cancer cells in vitro. Ketoconazole was also found to prevent the preferential metastasis of tGLI1-positive breast cancer to the brain and suppress the progression of established tGLI1-positive BCBM in vivo (Doheny et al., Cancers 14:4256, 2022). Ketoconazole is a potent inhibitor of the cytochrome P450 enzyme CYP3A4 and has been associated with liver damage, adrenal insufficiency, and drug interactions. To mitigate this issue with potential toxicities, we modified the chemical moieties of ketoconazole and generated novel derivatives. We screened the compounds using isogenic brain-tropic breast cancer cell lines engineered to stably express the vector, GLI1, or tGLI1 and identified the novel derivative WF-229A to selectively target tGLI1-positive breast cancer stem cells. Foremost, our data shows that WF-229A lost the ability to inhibit CYP3A4 enzymatic activity in vitro. Additionally, WF-229A showed no toxic effects on normal brain cells (astrocytes) or the liver cells (HepG2). In efforts to evaluate the pharmacological properties of WF-229A, we conducted an in vivo maximum tolerated dose (MTD) study. Our results demonstrated that, unlike ketoconazole, increasing doses of WF-229A did not elevate serum alanine transaminase (ALT) levels, indicating no liver toxicity. Additionally, increasing doses of WF-229A did not cause an increase in serum Adrenocorticotropic hormone (ACTH) levels suggesting, no adrenal insufficiency, unlike ketoconazole. Furthermore, our experimental mouse metastasis study using intracardiac inoculation demonstrated that systemic administration of WF-229A suppressed the progression of tGLI1-positive BCBM. WF-229A can penetrates the BBB in mice. For further

characterization of WF-229A, we conducted a cellular thermal shift assay (CETSA) and found that WF-229A directly binds to tGLI1 protein, but not GLI1. Additional mechanistic studies showed that WF-229A suppresses the CD44+/CD24- stem cell population, hampers migration, and induces apoptosis in tGLI1-positive BCBM cells. Our study establishes the rationale to further characterize the pharmacological properties of WF-229A for fine-tuned targeting of BCBM, and to examine WF-229A's ability to offer additional therapeutic benefits including the prevention of BCBM in vivo.

P3-09-30: Sequential ADC Treatments in Metastatic Breast Cancer

Hannah Chang, Katherine Lei, Flavia Soares Fernandes, Mayuri Vaish, Sai Movva, Christine Hodgdon, Julia Maues, Isaac Chan

Background: The clinical activity of antibody-drug conjugates (ADCs) when used sequentially remains uncertain. Given the increasing utilization of ADCs in both HER2-positive and HER2-negative metastatic breast cancer, our aim was to assess the efficacy of sequential ADC treatments in metastatic breast cancer patients across subtypes.
Methods: We conducted a retrospective analysis using data from the Dallas Metastatic Breast Cancer Study, which encompasses all metastatic breast cancer patients treated at multiple hospitals within a single academic medical center. Clinical data were gathered through retrospective chart reviews. Progression-free survival (PFS) was defined from the initiation of ADC treatment to disease progression or death.
Results: At our institution, 156 metastatic breast cancer patients were treated with ADCs between March 21, 2013 and March 29, 2024. Among these, 35 patients received sequential ADC treatments. In our analysis, we included 32 patients who switched to a second ADC after disease progression on their first ADC. Patients who switched ADCs due to side effects were excluded from our analysis. The median age at metastatic diagnosis was 52 years (range: 34-75 years). The cohort consisted of 21 patients with HER2-positive breast cancer and 13 patients with HER2-negative breast cancer. Of the patients with HER2-negative disease, six patients had hormone receptor positive disease and 12 had HER2-low disease. Overall survival for the entire cohort was 17 months (range: 6-78 months).
In the HER2-positive subgroup, 15 patients initially treated with trastuzumab emtansine (T-DM1) had a median PFS of 4 months (95% CI: 0.44-7.55). Subsequent treatment with trastuzumab deruxtecan (T-DXd) resulted in a median PFS of 8 months (95% CI: 3.41-12.58). Four patients initially treated with T-DXd had a median PFS of 4.5 months (95% CI: 0-26.67) and subsequent treatment with T-DM1 resulted in a median PFS of 4 months (95% CI: 0-11.98).
In the HER2-negative subgroup, eight patients initially treated with sacituzumab govitecan (SG) had a median PFS of 7.5 months (95% CI: 3.84-11.15). Subsequent T-DXd treatment resulted in a median PFS of 4.5 months (95% CI: 2.01-6.98). Looking closer specifically within the HER2-low subset, the median PFS of SG remained at 7.5 months (95% CI: 3.31-11.68), while subsequent PFS on T-DXd was slightly higher at 5 months (95% CI: 1.65-8.34). Five patients initially treated with T-DXd had a median PFS of 5 months (95% CI: 0-11.00) and subsequent treatment with SG resulted in a median PFS of 2 months (95% CI: 0-14.70).

Conclusions: Our findings indicate that in the HER2-positive metastatic setting, treatment with T-DXd, despite sequential use after disease progression on T-DM1, results in a longer PFS compared to the initial T-DM1 treatment. This suggests that T-DXd retains its efficacy even after disease progression on T-DM1 despite both treatments targeting the same HER2 antigen. Conversely, in the HER2-negative metastatic setting, the sequential use of SG and T-DXd, which share the same payload, resulted in a lower PFS compared to initial treatment with SG or T-DXd. These data suggest and contribute to growing evidence that payload resistance may reduce clinical benefit across subtypes instead of antigen resistance. Future studies into novel ADC development should focus on using different payloads.

P3-10-01: Interval Improvement in Overall Survival of Patients with De Novo Metastatic Breast Cancer. Real World Data from a Resource-Restricted Country

Hikmat Abdel-Razeq, Faris Tamimi, Baha' Sharaf, Suhaib Khater, Mariam Al-Atrash, Sarah Abdel-Razeq, Mahmoud Abu-Nasser, Sarah Edaily, Hira Bani Hani, Hala Abu Jaish, Tamer Al-Batsh, Hanan Khalil, Mohammad Al-Rawashdeh, Tala Ghatasheh, Tala Radaideh, Anas Zayed, Yosra Al-Masri

Introduction: Despite the advances attained in early detection of breast cancer, 5% or more of newly diagnosed breast cancer in developed countries, and much more (10-30%) in resource-restricted countries, like ours, present with distant metastatic disease at the time of diagnosis (de novo MBC). The recent introduction of many new anti-breast cancer drugs has significantly improved patients' outcomes. These drugs include the cyclin-dependent kinases 4/6 (CDK4/6) inhibitors which has revolutionized the management of advanced hormone receptor (HR)-positive/HER2-negative MBC. In addition to targeting HR, drugs that are directed at downstream elements of the molecular pathways have been developed to overcome endocrine resistance. Many anti-HER2 drugs, including antibody-drug conjugates (ADCs) are in use to treat HER2-positive MBC. In this study, we aim to review the overall survival of breast cancer patients diagnosed with de novo metastatic disease treated at our institution across two intervals to identify if the prognosis resulted from the introduction of new therapeutic intervention has improved the outcome of patients with de novo MBC.
Methods: This is a retrospective cohort study analyzing patients' records from 2011 to 2022. All consecutive patients whose first presentation was with pathologically-confirmed diagnosis of MBC (de novo MBC) were enrolled. Patients were divided into two cohorts; those diagnosed and treated prior to 2017 and those diagnosed and treated in 2017 and beyond. To allow for longer follow-up, patients diagnosed in the last two years were not enrolled. Data was collected from a well-structured hospital-based cancer registry. In year 2017, many of the new endocrine treatments including CDK4/6 inhibitors and new anti-HER2 drugs were introduced at the center. Immunotherapy, specifically pembrolizumab and PARP inhibitors were not formulary drugs during the study period.
Results: During the study period, a total of 1,512 patients with de novo MBC were

diagnosed, treated, and followed up at King Hussein Cancer Center; 641 (42.4%) were treated before 2017, while 871 (57.6%) others were treated in 2017 or after. Median age at diagnosis was 51 (26-89) years, and except for 16, all were female. Majority (n=1,286, 85.1%) had invasive ductal carcinoma (IDC), 168 (11.1%) invasive lobular carcinoma (ILC), while 58 (3.8%) had other subtypes. Hormone-receptors (HR) were positive in 1,248 (82.5%), HER2 positive in 417 (27.6%), while 109 (7.2%) others had triple-negative (TN) disease. Patients treated prior to 2017 had a median overall survival (OS) of 33.8 months (95% CI, 30.3-36.1) while it was unreached (95% CI, 40.0-NA) in patients treated in 2017 or after, P <0.001. Difference in median OS was more prominent in patients with HER2-positive disease; 29.7 months (95% CI, 22.9-33.8) in patients treated prior to 2017 while it was unreached (95% CI, 37.9-NA) in those tread more recently, P<0.001. Additionally, patients with HR-positive had better OS if treated recently where the median OS was not reached (95% CI, NA-NA) compared to 36.7 months (95% CI, 34.1-NA) for those treated prior to 2017, P<0.001. However, across the study period, patients with TN disease had no improvement in median OS; 19.7 (95% CI 16.9-29) for those treated in recent years, compared to 29.2 months (95% CI, 18.4-36.1), in patients treated before 2017, P=0.065. Conclusions: Our study clearly showed remarkable and significant improvement in median OS of patients with de novo MBC and such improvement was more notable in patients with HER2-positive disease and in those with HR-positive/HER2-negative. No improvement observed, during the study period, in patients with TN disease which may be a reflection of late introduction of immunotherapy.

P3-10-02: Real-world study of Abemaciclib in Patients with Hormone Receptor-Positive/Human Epidermal Growth Factor Receptor 2-Negative Breast Cancer: a Multi-Institutional Prospective Study

Elena Fountzilas, Panagiota Economopoulou, Katerina Dadouli, Ioannis Binas, Anastasia Vernadou, Evangelia Moirogiorgou, Eleftherios Vorrias, Adamantia Nikolaidi, Sofia Karageorgopoulou, Anna Koumarianou, Ioannis Boukovinas, Davide Mauri, Stefania Kokkali, Athina Christopoulou, Anastasios Vagionas, Avraam Assi, Achilleas Nikolakopoulos, Zacharenia Saridaki, Nikolaos Spathas, Paris Kosmidis, George Fountzilas, Amanda Psyrri

Background: Abemaciclib has been approved in combination with endocrine therapy in adult patients with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative, early breast cancer (BC) at high risk of recurrence and locally advanced or metastatic BC. We aimed to assess real-world toxicity and efficacy data of patients with BC who received treatment with abemaciclib.
Methods: This was a prospective collection of clinicopathological, toxicity and outcome data from patients with early- or advanced- stage HR-positive/HER2-negative BC who received treatment with abemaciclib in combination with endocrine therapy. Treatment combinations of abemaciclib with any endocrine therapy were accepted. Patients needed to have received at least two months of treatment with abemaciclib. The primary end point was toxicity rate in all patients of the study, both with early and advanced BC.

Results: From June/2021 to May/2024, 227 women received abemaciclib/endocrine combination therapy; median age was 56 years, and 152 (70.4%) patients were postmenopausal. Hormonal therapies given in combination with abemaciclib in advanced BC were fulvestrant (0.7%), aromatase inhibitors (88.6%) and tamoxifen (10.7%). Abemaciclib was administered as adjuvant treatment in 157 (69.1%) patients. At the time of the data cutoff (May 2024), 4 (2.5%) patients had completed the 2-year treatment period, and 133 (84.7%) patients remained in the 2-year treatment period. The most common adverse events (AEs) were diarrhea (46.5%), fatigue (18.5%), ALT/AST increase (7.0%) and arthralgia (6.4%). Grade 3 diarrhea was reported in 8 (5.1%) patients; no Grade 4 diarrhea was observed. Diarrhea was observed at a median of 6 days from treatment initiation (range 1 to 270 days). No thrombotic event was reported. AEs led to dose modification and treatment discontinuation in 42 (26.8%) and 8 (5.1%) patients, respectively. There was no difference in modification/discontinuation rates between older patients (>65 years) and the remaining patients. Patients who received abemacilib as adjuvant treatment had similar toxicity rates with patients with advanced BC. The median 1-year and 2-year disease-free survival rate for patients who received adjuvant treatment with abemaciclib was 100% and 98.7%, respectively. Almost half (47.1%, 33/70) of the patients were diagnosed with de novo metastatic disease. In patients with advanced cancer (70, 30.8%), a median of one site of metastasis was reported at diagnosis of advanced disease (most commonly bones, 54,3%). With a median follow up of 11.8 months, 14 patients had disease progression; median progression-free survival (PFS) was not reached yet and 12-month PFS rate was 79.3%.
Conclusions: This study provides prospectively collected real-world data on abemaciclib in combination with endocrine treatment, confirming the safety and efficacy in an unselected patient population. These results are consistent with the registration trials and no new safety concerns were reported.
Clinical trial registration: ClinicalTrials.gov NCT04985058

P3-10-03: Real-world first-line immunotherapy use and overall survival rates for triple-negative breast cancer: analyses from a 2018-2020 US population-based cohort

Dionisia Quiroga, Julie A Stephens, Gilbert Bader, Mathew A Cherian, Ashley P Davenport, Kai CC Johnson, Sagar Sardesai, Daniel Stover, Robert Wesolowski, Nicole Williams, Nerea Lopetegui-Lia, Arya M Roy, Samilia Obeng-Gyasi, Bridget A Oppong, Sachin R Jhawar, Margaret E Gatti-Mays

Background: Combination immunotherapy (IO) and chemotherapy (CT) for triple-negative breast cancer (TNBC) improves overall survival (OS) over CT alone in both the neoadjuvant and metastatic setting. Large-scale real-world analysis of IO +/- CT for TNBC has been limited to date. We present prescribing patterns and OS of initial chemo-immunotherapy treatments in a large US population-based cohort of TNBC patients.

Methods: Patients with TNBC diagnosed from 2018-2020 were identified in the National Cancer Database (NCDB), a US-wide oncology outcomes database. Those with undocumented staging and stage 0 disease were excluded. The primary outcome, OS, was evaluated by initial treatment: chemotherapy/IO (CT/IO), chemotherapy/no IO (CT), IO/no chemotherapy (IO), or no chemotherapy/no IO (NT), using cox proportional hazards models and Kaplan-Meier methods. The secondary objective was real world practice patterns. Categorical variables were compared between the groups using a Chi-square test. Age was compared using a Kruskal-Wallis test.

Results: 58,128 new TNBC diagnoses were identified in NCDB between 2018-2020, with 6.7% de novo metastatic. IO use steadily increased over time (2018 = 19.5%, 2019 = 31.0%, 2020 = 49.5%). Academic research programs most commonly used IO.

Most patients received CT (73.3%, n = 32,858), with 5.6% (n=3276) receiving CT/IO, 0.1% (n=66) receiving IO, and 20.5% (n=11,926) NT following initial diagnosis. CT +/- IO use was associated with younger age, whereas IO alone or NT was more common in older patients (median age: CT/IO = 55 years [y], CT = 58y, IO = 71y, NT = 72y; p< 0.001). Treatment with CT/IO or CT was most common among private insurers (57.6% and 53.3%, respectively) whereas Medicare was the most common payor for IO or NT (59.1% and 64.1%, respectively; p<0.001). Proportionally, stage I TNBC received less treatment (CT/IO 13.3%, CT 34.1%, IO 18.2%, NT 55.3%; p< 0.001) and single agent IO treatment was more common in stage IV TNBC (CT/IO 24.3%, CT 4.9%, IO 53.0%, NT 8.4%; p< 0.001). Pathologic complete response (pCR) rates after neoadjuvant chemotherapy (NACT; n = 27,900) differed by treatment group, with pCR most common following CT (CT/IO 27.6%, CT 29.6%, IO 16.7%, NT 1.8%; p<0.001). OS was similar among treatment groups in the full TNBC population, with median survival for NT at 36 months.

Race differed significantly between treatment (p<0.001). Among White patients with TNBC (70.9%), 72.1% received CT/IO and 70.5% received CT. However, among Black patients with TNBC (11.9%), 19.4% received CT/IO and 23.6% received CT. OS was highest in the CT group, whereas the IO only group had the worst survival outcome – even worse than NT (hazard ratio (HR) CT 0.52, IO 2.22, NT 1.17; ref CT/IO, p< 0.001 each HR). Nonetheless, Black race was associated with worse OS than White race and the addition of IO to CT did not fully mitigate the OS racial gap (HR Black CT/IO 1.38, White CT 0.52, Black CT 0.65; ref White CT/IO, p< 0.001 each HR).

Conclusions: This large NCDB cohort analysis of newly diagnosed TNBC cases revealed practice patterns for initial TNBC treatment varies widely. Furthermore, this analysis captured new TNBC diagnoses from 2018 to 2020 and describes significant off-label use of IO+/- CT in both the NACT (Keynote-522 FDA approval 2021) and metastatic (ImPassion130 FDA accelerated approval 2019) settings with some relation to the payor. In addition, single agent IO use was higher than expected for stage IV and resulted in worse OS, again raising concerns of off-label use of the tumor agnostic IO approvals (tumor mutation

burden-high, microsatellite instability). Finally, racial discrepancies of use and efficacy of IO was present. Further studies and interventions are needed to address TNBC treatment disparities.

P3-10-04: Outcomes following less-than-standard therapy in operable breast cancer patients

Alan Celik, Tobias Berg, Maj-Britt Jensen, Ann Knoop, Bent Ejlertsen

BackgroundThe primary purpose of this study was to evaluate the use of less-than-standard surgical therapy in early-stage operable breast cancer nationwide in Denmark. A secondary purpose was to evaluate the use primary endocrine therapy (PET).
MethodsWe assembled a nationwide, population-based cohort of early-stage operable breast cancer patients registered between 2000 and 2020 in Denmark using the Danish Breast Cancer Group Database, National Patient Registry, and National Pathology Registry. Patients were divided into two groups: those who underwent up-front surgery within 182 days of diagnosis and those who did not, with the latter group further subdivided by use of primary endocrine therapy versus not. We performed Cox regression analyses to assess all-cause mortality risk, adjusting for tumor size, age, comorbidity, estrogen receptor status and year of diagnosis.
ResultsWe identified 84,487 patients with early-stage operable breast cancer. Of these 5,916 patients received less-than-standard therapy, and hereof 2,576 patients received PET. The number of patients for whom surgery was omitted increased from 226 (6.3%) in 2000 to 433 (11.8%) in 2020 and while none of the patients diagnosed in 2000 received PET 296 (8.1%) patients diagnosed in 2020 did. Less-than-standard therapy was associated with a significant higher rate of all-cause mortality.
ConclusionFrom 2000 to 2020 there was a significant increase in both omittance of surgery and the use of PET among breast cancer patients. Omitted surgery both with or without PET was associated with increased mortality, even after adjusting for tumor size, age, comorbidity, estrogen receptor status and year of diagnosis.

P3-10-05: Real-World Efficacy of Fam-Trastuzumab Deruxtecan in HER2-Low Metastatic Breast Cancer

Sarah Blocker, Qamar Khan, Priyanka Sharma

Background: Fam-trastuzumab deruxtecan (T-DXd) is recommended after 1-2 prior lines of chemotherapy for HER2-low metastatic breast cancer (MBC). In the Destiny Breast-04 (DB-04) clinical trial, median progression free survival (PFS) with T-DXd was 9.9 months in the overall population and 10.1 months in the HR+ cohort. The purpose of this study was to evaluate the real-world (RW) safety and efficacy of T-DXd in patients with HER2-low MBC.
Methods:
This RW analysis includes female patients with HER2-low MBC who received at least 1 dose

of T-DXd from June 1, 2022, to May 14, 2024, at a single institution. Efficacy and toxicity related to T-DXd were extracted from medical charts. The primary endpoint was RW investigator assessed PFS (rwPFS). Hormone receptor (HR)-positive was defined as estrogen or progesterone receptor expression >0%.

Results: Ninety-one patients were included with a median age of 61 years (range 33-84). Seventy-two (79%) patients had HR-positive disease, and 19 (21%) had HR-negative disease. HER2 immunohistochemistry (IHC) was 1+ in 76% of patients and was 2+[PS1] /ISH- in 24%. Ninety-one percent had visceral disease, and 4.4% had bone-only disease. Prior to T-DXd initiation, patients had received zero (11%), one (42%), two (24%), or > three (23%) lines of cytotoxic chemotherapy. Eleven percent of patients had received prior sacituzumab govitecan. After a median follow-up of 16.2 months, the median rwPFS was 6.8 months (95% CI, 5.4 to 8.2)[QK2] . Among HR+ and HR- subgroups, the rwPFS was 6.4 months (95% CI, 5.4 to 8.7) and 6.1 months (95% CI, 3.6 to 8.8), respectively. Dose reductions and discontinuation due to toxicity occurred in 29 (32%) and 9 (10%) patients, respectively. Investigator assessed pneumonitis associated with T-DXd was reported in 12 (13%) patients on therapy.

Conclusions: This RW analysis shows that T-DXd is prescribed to a more heavily pre-treated population. The rwPFS of 6.8 months in patients with HER2-low breast cancer treated with T-DXd is lower than expected and may be due to the more pre-treated population.

P3-10-06: Missed opportunities: understanding the factors contributing to non-receipt of neoadjuvant chemotherapy in breast cancer patients

Daniela Vazquez-Juarez, Alejandro Aranda-Gutierrez, Giovanni Miguel Carrillo Becerril, Monserrat Garcia de Ochoa, Marlene Cordova-Garza, Mauricio Canavati, Jaime Tamez-Salazar, Teresa Mireles-Aguilar, Servando Cardona, Cynthia Villarreal-Garza

Neoadjuvant chemotherapy (NACT) for breast cancer (BC) offers benefits such as tumor downstaging, enabling breast-conserving surgery, and customization of adjuvant therapies. However, some eligible patients do not receive it. Identifying the reasons behind this is crucial for refining patient care and improving outcomes.
We conducted a retrospective study of women who received care in a BC referral center. Eligible patients were those with stage III HR+/HER2- BC or stage II-III triple-negative or HER2-overexpressed BC, which are accepted indications for NACT. Independent samples T-test, X2, and Fisher's exact tests were used to evaluate associations between variables, employing logistic regressions to calculate odds ratios (OR) when appropriate.
Among 255 patients, 105 (41%) did not receive NACT. Women who did not receive NACT were more likely to be >65 years (16% vs. 7%, p=0.015), have stage III (61% vs. 40%, p=0.001), HR+/HER2- (42% vs. 14%, p<0.001), or low grade (63% vs. 43%, p=0.002) disease, had more out of site surgeries (62% vs. 34%), and underwent more axillary

dissections (58% vs. 40%, p=0.021). The reasons for not receiving NACT were initial care in another center (53%), upstaging following surgery (29%), patient decision (7%), discordant immunophenotypes between biopsy and surgical specimen (5%), and relative contraindication due to comorbidities or advanced age (5%). Predictive factors for upstaging following surgery included grade 3 disease in the initial biopsy (OR 12.3) and HER2-negative status (OR 10.6).
In our study, 41% of eligible patients did not receive NACT, mainly due to out of site surgeries, highlighting the need to educate providers about the benefits of NACT. In addition, some patients missed NACT due to upstaging following surgery, stressing the need for thorough preoperative staging, particularly with high-risk characteristics like grade 3 and HER2-negative disease.

P3-10-07: 10y overall survival (OS) in patients (pts) with breast cancer (BC) at a comprehensive cancer center in Colombia

Ana Fidalgo, Milton Alberto Lombana Quiñonez, Guido Ricardo Gonzales Fontal, Sergio Cafiero Ballesteros, Juan Carlos Avila Valencia

In Colombia, approximately 17,000 new cases are diagnosed each year with an incidence of 50 cases/100 hab/year [1]. Access to screening [2], integration of curative with adjuvant therapies [3-6], and new systemic treatments [7,8,9] in ABC have been shown to improve survival outcomes. However, the impact on long-term overall survival has not been reported in the Colombian population.

Methods: Pts with BC, complete relevant clinical information and long term follow up between January 2013 to December 2023 at The Comprehensive Cancer Center Clinica de Occidente in Cali-Colombia, were retrospectively identified. We collected relevant variables from electronic medical records. Our primary objective was to determine the 10 years OS by stage and important clinical variables. We performed Kaplan Meier, and cox regression analysis. The study was approved by the institutional ethics committee.

Results: We identified 831pts with complete clinical information and adequate follow-up. Demographic characteristics are described in table 1.
De novo metastatic disease was found in 10% of pts. This was higher when health insurance was exclusively subsidized by the state (15%) vs. mixed insurance (9%) (private + public), OR 1.7 (95% CI 1.0-2.9), P=0.01.
Table 2 and Figure 1 describes the 10y OS by stage, with 88% in stage I vs. 23% in stage IV. Multivariate analysis showed that density of lymph node involvement, metastasis at diagnosis, poor PS, and advanced age were significantly associated with increased risk of death. However, living in rural areas or small cities, type of health insurance, history of DM2, hypertension, smoking, family history of breast cancer, or HER2-positive subtype did not significantly affect survival.

The 10y OS was 62% in non-Luminal A subtypes (figure 2), 44% in T4 tumors, 41% in patients with Age^{3}80y, 32% in N3 lymph node involvement and only 5% in patients with PS ECOG^{3}2 (figure 3).

Conclusions: We report the longest follow up for overall survival in a cohort of pts with BC from an comprehensive cancer center in Colombia and confirm that the prognosis in survival has improved, especially for luminal tumors, but it is still poor if it is detected late in a locally advanced or metastatic stage (approximately 27% of all cases) or with deteriorated functional status. Therefore, increasing early detection and the inclusion of new systemic therapies are necessary to improve the probability of survival in higher-risk subgroups.

P3-10-08: Elacestrant real-world progression-free survival (rwPFS) of adult patients with ER+/HER2-, advanced breast cancer: a retrospective analysis using insurance claims in the United States

Elyse Swallow, Jessica Maitland, Kirthana Sarathy, Ellen Sears, Yasir Nagarwala, Janelle DePalantino, Eric Kruep, Corey Pelletier, Sebastian Kloss, Tomer Wasserman

Background: Endocrine therapy (ET) + CDK4/6i is the standard-of-care (SOC) for 1st-line treatment of ER+/HER2- advanced or metastatic breast cancer (mBC). In current practice, sequential endocrine monotherapy or combination therapies are used in the 2nd-line post ET+CDK4/6i as recommended by guidelines. Combination regimens in ≥2nd-line mBC can be associated with significant toxicities and high discontinuation rates. ESR1 mutations represent a type of acquired resistance that eventually emerges in up to 50% of patients during ET for ER+/HER2- mBC. The EMERALD trial (NCT03778931) demonstrated median PFS of 3.8 months for elacestrant vs 1.9 months for SOC ET (HR = 0.55; 95% CI, 0.39-0.77; P = 0.0005) with manageable safety in patients with ER+/HER2- mBC and ESR1-mutated tumors previously treated with ET+CDK4/6i (Bidard, 2022). Elacestrant is the first and only oral SERD approved targeting ESR1-mutated tumors. Sufficient time has passed since approval in January 2023 to characterize the real-world use of elacestrant in the current

treatment landscape. This study aims to describe the rwPFS of patients who received elacestrant after Food and Drug Administration (FDA) approval in the United States.
Methods: Adults with newly diagnosed ER+/HER2- mBC who initiated elacestrant in a real-world setting between January 2023 and December 2023 were identified in the Komodo Research Database (KRD+). Demographic information was described at the time of first administration of elacestrant (index date); metastatic sites were identified during the 6-month baseline period prior to the index date; and prior treatments received in the mBC setting were described among patients with sufficient health plan enrollment between the first observed mBC diagnosis and the index date. rwPFS, defined as time from index date until the earliest outcome (start of the next line of therapy or death), was assessed using time-to-event and Kaplan-Meier methods. Patients were censored at the first occurrence of the following: discontinuation of all therapy, end of data availability, or end of health plan enrollment. Elacestrant is indicated for the treatment of postmenopausal women or adult men with ER+/HER2- ESR1-mutated advanced or mBC with disease progression following at least one line of ET. ESR1-mutation status was not available in the database at the time of analysis.
Results: A total of 212 patients treated with elacestrant with sufficient health plan enrollment were evaluated (median age was 63 years, 97% were female). Prior to initiating elacestrant, 89% of patients received prior treatment with a CDK4/6i, 58% were treated with only 1-2 prior lines of ET in the metastatic setting, and 62% had visceral metastases. The median follow-up time was 5.2 months. In the overall population analysis, median rwPFS (95% CI) was 6.8 months (5.4-not reached [NR]). Median rwPFS for patients with 1-2 lines of prior ET in mBC was 8 months (4.9-NR), and median rwPFS for patients with visceral metastases was 6.1 months (4.7-NR). Updated results and additional information will be presented based on longer follow-up.
Conclusion: This retrospective observational study expands our understanding of elacestrant's activity in ER+/HER2- mBC patients with prior exposure to ET in a real-world setting.

P3-10-09: Prognostic implications of HER2 changes after neoadjuvant chemotherapy: A real world data of matched breast cancers with the inclusion of HER2-Low category

Marcelo Antonini, Andre Mattar, Leticia Xavier Felix, Francisco Pimentel Cavalcante, Felipe Zerwes, Fabrício Palermo Brenelli, Eduardo de Camargo Millen, Antônio Luiz Frasson, Denise Joffily Pereira da Costa Pinheiro, Marina Fleury de Figueiredo, Odair Ferraro

Objectives: The aim of this study was to evaluate the changes in HER2 status after neoadjuvant chemotherapy (NAC) and the implications of HER2 changes for clinical outcomes, including the HER2-low category.
Methods: This retrospective cohort study included female patients over 18 years of age diagnosed with non-metastatic breast cancer undergoing NAC from 2011 to 2023. Patients who did not achieve complete pathological responses were evaluated for changes in

immunohistochemistry (IHC) before and after NAC. HER2 IHC was re-evaluated with consensus according to the current ASCO/CAP guidelines. Tumors were categorized into HER2-negative (IHC 0), HER2-low (IHC1+ or IHC2+/ISH-), and HER2-positive (IHC3+ or IHC2+/ISH+) subgroups. Quantitative and qualitative factors related to changes in IHC were assessed. he prognosis of these patients were assessed by examining OS and DFS.. The study received approval from the research ethics committee (CAAE 80127724.1.0000.5463).
Results: We included 369 patients, most of whom (215/58.3%) did not change their IHC profile. Baseline statuses were HER2-negative (24/6.5%), HER2-low (256/69.4%), and HER2-positive (89/24.1%). Tumors with HR+ were observed in 227 patients (61.5%). HER2-positive tumors exhibited more changes in IHC (63/63.0%, p<0.0001) compared to HER2-negative (5/20.8%) and HER2-low tumors (92/35.9%). Significant differences were found in the changes: all HER2-negative tumors changed to HER2-low; HER2-positive tumors changed to HER2-low in 30 cases (43.7%) and to HER2-negative in 26 cases (41.2%). Most HER2-low tumors (51/55.4%) remained HER2-low or changed to HER2-negative (26/29.2%). The presence of HR+ was significantly associated with greater changes to HER2-negative (125/55.0%) and HER2-low (83/36.5%). We did not observe a significant difference in the number of deaths, loco-regional recurrences, and distant metastases when evaluating patients according to HER-2 status. Initially, HER-2 low patients had more unfavorable outcomes, and after NAC, those who converted to HER-2 negative had worse outcomes. Overall Survival (OS) was significantly worse in HER-2 low patients, both pre-NAC and post-NAC, with median OS of 51.6 months and 53.6 months, respectively. Disease-Free Survival (DFS) was significantly longer only in patients initially classified as HER-2 low, with a median DFS of 50.9 months.
Conclusions: Our findings indicate that changes in IHC profiles post-NAC are common, particularly among HER2-positive and HER2-low tumors. Significant alterations in HER2 status were observed, with many HER2-positive tumors shifting to HER2-low or HER2-negative post-NAC. Additionally, the presence of hormone receptors (HR+) is associated with a higher likelihood of conversion to HER2-negative. These changes are clinically relevant, as they correlate with increased mortality rates, underscoring the importance of re-evaluating HER2 profiles post-NAC as potential prognostic indicators in breast cancer patients.

P3-10-10: Sequencing PIK3CA and AKT Inhibitors in Hormone Receptor-Positive, HER2-Negative Metastatic Breast Cancer: A Retrospective Analysis

Rachel Abelman, Amanda Jung, Laura M. Spring, Geoffrey Fell, Neelima Vidula, Arielle Medford, Janice Kim, Steven J. Isakoff, Beverly Moy, Leif W. Ellisen, Dejan Juric, Aditya Bardia, Andreas Varkaris, Seth A. Wander

Background: PI3K/AKT/PTEN signaling pathway alterations are present in approximately half of patients with hormone receptor positive (HR+), HER2 negative breast cancer (BC). The PI3K alpha-selective inhibitor (PI3Ki) alpelisib in combination with fulvestrant is

approved for patients with PIK3CA-mutated HR+ advanced breast cancer, and the AKT inhibitor (AKTi) capivasertib in combination with fulvestrant is approved for patients with advanced/metastatic HR+/HER2- breast cancer (MBC) with alterations in PIK3CA, AKT1, or PTEN. Patients with PIK3CA mutant MBC are now candidates for both therapies, but there is minimal data to guide sequencing of these agents. Here we report our single-institution experience.

Methods: All patients with HR+/HER2- MBC treated at the Mass General Cancer Center who received AKTi (either capivasertib or an experimental AKTi in a clinical trial/TAKTIC) were included. Patients were divided into three categories: those who received AKTi only (control), those who received PI3Ki first and then AKTi (PI3K > AKT) and those who received AKTi and later PI3Ki (AKT > PI3K). Patients could have intervening therapies between sequential PI3Ki/AKTi. Clinical information was abstracted by chart review. Progression-free survival (PFS) was evaluated as time from start of treatment to disease progression or death from any cause. Time on treatment was defined as the start of treatment to discontinuation. 95% confidence intervals were calculated for all mean and median estimates.

Results: 56 patients were identified who received AKTi with/without PI3Ki for advanced/metastatic HR+/HER2- breast cancer from August 2019-June 2024. The median age at start of first PI3Ki/AKTi was 61.5 years. 42 patients (76.4%) experienced disease progression on their first AKTi/PI3Ki. 49 patients (89.1%) had known alterations in PIK3CA/AKT/PTEN pathway, and six patients (10.9%) had no known alterations and were treated on trial. Mutations of PIK3CA were present in 30 patients (54.5%), AKT in 8 patients (14.5%), and PTEN in 8 patients (14.5%). 39 patients (69.6%) received AKTi only, 10 patients (17.9%) were in the PI3K > AKT group, and 4 (7.1%) received AKT > PI3K, and the remaining 3 patients (5.4%) received 3 or more AKTi/PI3Ki. Overall median time on first treatment was 5.8 months (95% CI 4.6-11.0 months) and median time on second treatment was 5.4 months (95% CI 2.0-NR). Median progression-free survival (PFS) for patients who received AKTi alone was 5.5 months (95% CI 3.7-9.2 months). For patients who received PI3Ki before AKTi, the median PFS on second treatment (AKTi) was 4.6 months (95% CI 2.0-NR). An analysis of genomic predictors of response is in process and a multi-institution follow-up analysis is planned. Further updates to be presented at the meeting.

Conclusions: In this single-institution study, we report median treatment times for patients treated with PI3Ki prior to AKTi and AKTi alone. Patients may still benefit from receiving second-line AKTi after PI3Ki. Biomarker data is needed to drive personalized selection of sequential use of agents targeting the same pathway.

P3-10-11: Breast Cancer Patient Navigation Program Saves Lives: Brazilian Experience in a Real-World Setting in the Public Health System

Sandra Gioia, Lucia Brigagão, Maicon Rocha, Liliani dos Santos, Claudia Viana, Luciana Fonseca, Isabella Santos, Ricardo Costa, Mauro Moraes, Pedro Martins, Anderson Andrade, Ben Ho Park, Alfredo Carlos de Barros

Background: In 2012, the Brazilian government issued Law No. 12.732/12 from the Ministry of Health, the "60-Day Law". This law mandates that cancer treatment for public health system patients must start within 60 days of definitive diagnosis. The average treatment time is up to 31 days in private health with 18% of cases diagnosed in stages III and IV, while in the public system, it averages 93 days, sometimes reaching 180 days with 40% of cases in these advanced stages.
Aim: To evaluate whether a Breast Cancer (BC) Patient Navigation Program (PNP) contributes to increasing compliance with the "60-Day Law". Consequently, to assess if complying with this Brazilian federal law helps reduce BC mortality in public health system patients.
Methods: We conducted a longitudinal observational and retrospective study with women over 18 years diagnosed with BC. Data were collected from medical records via the PNP. The sample was selected based on exploratory evaluation of records from the Rio Imagem Diagnostic Center and Heloneida Studart State Hospital in Rio de Janeiro, from 2017 to 2022. Active case follow-up involved cross-referencing medical records and contact via phone or text messages. The Kaplan-Meier method estimated the 5-year specific survival probability. The independent effect of survival variables was identified using univariate and multivariate Cox proportional hazards models (Hazard Ratio – HR), with a significance level of α=0.05.
Results: Out of 1,022 women diagnosed with BC, 840 were eligible after excluding those lost to follow-up, who refused treatment, died of unrelated causes, or received palliative care. 79 patients died from BC. The 5-year specific survival rate was 92.6%. Survival was higher for patients treated initially with surgery (97.9%, $p < 0.0001$), histological grade 1 (94.5%, $p = 0.002$), Luminal biological profiles (98.4%, $p < 0.0001$), and treatment within 60 days (95.3%, $p = 0.005$). Stratifying 5-year mortality risk by advanced stage revealed higher mortality among women who were not treated within 60 days as per the law (HR=2.00[1.23; 3.24]).
Conclusion: Failure to comply with the “60-Day law” doubled the risk of mortality from BC. Patients starting treatment within 60 days had higher survival rates compared to those who did not. In Brazil, the PNP could be an opportunity to properly implement existing legislation, potentially significantly impacting BC control.

P3-10-12: Retrospective analysis of adverse events and outcomes of patients receiving neoadjuvant pembrolizumab for triple negative breast cancer in Australia.

Evon Jude, Jasmine Grisold, Sarah Jaboury, Qing Ze Fang, Josephine Stewart, Frances Barnett, Bianca Devitt, Belinda Yeo

Introduction and objectives:Neoadjuvant pembrolizumab combined with chemotherapy has become the standard of care since 2022, for patients with triple negative breast cancer (TNBC) in Australia, following the KEYNOTE-522 trial, which identified significantly higher pathological complete response (pCR) compared to placebo, acknowledging the serious immune-related adverse events (irAEs) (1). A secondary analysis of this trial included patients enrolled in Asia and found similar rates of grade 3-4 irAEs in the pembrolizumab and placebo groups (3). Reports of adverse outcomes are often overshadowed by the significant benefit of pembrolizumab in TNBC, a subtype of breast cancer with significant risk of recurrence and mortality (2). Our objective was to collect real-world data relating to the use of neoadjuvant pembrolizumab in patients with TNBC, to identify the pattern of adverse events and outcomes.

Methods: Retrospective data was collected across three tertiary hospitals in Melbourne, Australia, for patients diagnosed with TNBC, who received neoadjuvant pembrolizumab; baseline demographics, medical background, primary tumour details, pembrolizumab and chemotherapy regimen, serious adverse events and their management, breast surgery and pathological response.

Results: There were 54 female patients who received neoadjuvant pembrolizumab; median age 52 years and median follow up of 11 months. 4 patients had a history of autoimmune disease and 2 had immunosuppressant therapy during or within 2 years prior to treatment with pembrolizumab. At primary diagnosis, 69% had nodal involvement.
At least one irAE occurred in 54% of patients; thyroiditis (22%), adrenal insufficiency (20%), colitis (7%), hepatitis (6%) rash of at least grade 3 severity (4%) and pneumonitis (4%). Other less frequent irAEs include autoimmune haemolytic anaemia, transverse myelitis, arthralgia and type 1 diabetes mellitus. Of those with irAEs, 45% were hospitalised, 1 patient required intensive care and 69% have ongoing sequelae. The median time from commencement of pembrolizumab to irAE onset was 84 days. An interruption in pembrolizumab dose occurred in 23 patients, with 70% of these discontinuing therapy early. 41 patients underwent surgical intervention, and 40 had lymph node dissection. pCR was achieved in 37%, while 60% of those who achieved pCR experienced at least one irAE.

Conclusion: There are significant immune related adverse events associated with the use of neoadjuvant pembrolizumab, a notable proportion of whom required hospitalisation, which poses an important and concerning burden for patients and the healthcare system. These

real-world outcomes will continue to be monitored. Further work should also look at survival outcomes and quality of life, to better inform shared-decision making.

P3-10-13: A Comprehensive Analysis of Dysregulation in the PTEN/PI3K/AKT Pathway in Breast Cancer Among the Chinese Population

Ziang Li, Meizhen Hu, Fei Pang, Bo Peng, Aodi Wang, Huanwen Wu

Background: Breast cancer (BC) has the highest incidence rate among cancers in females in China. The PTEN/PI3K/AKT pathway regulates key biological processes, including apoptosis, metabolism, cell proliferation and growth in BC. This is the first comprehensive study to explore the association between these pathway gene alterations and clinical outcomes in a large cohort of Chinese BC patients.

Methods: We retrospectively reviewed 1018 Chinese BC patients with clinical information from OrigiMed Chinese Real-World Database between 2016 and 2023. Tumor tissue samples and paired peripheral blood leukocytes were analyzed using an OrigiMed 450 gene next-generation sequencing panel. Chi-square test and Fisher's exact test assessed differences in these genetic alterations across different subgroups and to examine the co-occurrence of alterations between these genes and other genes.

Results: A total of 38.5%, 5.3% and 8.4% of Chinese BC patients exhibited alterations in PIK3CA, AKT1 and PTEN genes, respectively, which is similar to the Caucasian-dominated MSK-IMPACT cohort (PIK3CA: 38.5% vs. 35.2%, P =0.102; AKT1: 5.3% vs. 5.3%, P =0.995; PTEN : 8.4% vs. 7.0%, P =0.232). Subgroup analysis revealed higher PTEN alteration in stage IV patients compared to stage I-III (12.7% vs. 6.4%, P =0.001). Furthermore, HR+/HER2- BC patients exhibited a significantly higher incidence of PIK3CA (45.2% vs. 30.8%, P <0.001) and AKT1 (7.7% vs. 2.5%, P <0.001) gene alterations, compared to other subtypes. The overall incidence of alterations in the PTEN/PI3K/AKT pathway was 50.9%, which was higher among HR+/HER2- BC patients compared to other subtypes (57.0% vs. 43.9%, P <0.001). PIK3CA alterations were associated with lower AKT1 alterations (3.1% vs. 6.7%, P =0.011). ERBB2 alterations were associated with lower AKT1 (0.4% vs. 6.9%, P<0.001) and PTEN (4.4% vs. 9.7%, P =0.009) alterations. TP53 alterations were associated

with higher PTEN/PI3K/AKT pathway alterations (55.4% vs. 45.9%, P =0.002). No significant differences in PIK3CA (25.6% vs. 21.4%), AKT1 (7.0% vs. 9.5%), and PTEN (14.0% vs. 23.8%) gene alterations were observed between primary and metastatic lesions in the same patients (N=41, P >0.05). No significant differences were found in the alterations of PIK3CA (38.7% vs. 41.1%), AKT1 (5.8% vs. 5.4%), and PTEN (10.4% vs. 7.6%) between samples taken before and after treatments such as chemo-immunotherapy and targeted therapy (N=840, P >0.05). Survival analysis (median follow-up: 32.7 months) showed PTEN alterations correlated with higher mortality risk (HR 2.779, 95% CI 1.083-7.132, P =0.034), while PIK3CA alterations were associated with reduced mortality risk (HR 0.338, 95% CI 0.141-0.820, P =0.016), with overall survival (OS) as the outcome.

Conclusion: This study highlights the significant role of PIK3CA, AKT1 and PTEN gene alterations in Chinese BC patients. In Chinese BC patients, alterations in the PTEN/PI3K/AKT signaling pathway are common, and the frequencies of PIK3CA, AKT1 and PTEN gene are similar to that observed in Western countries. The gene alterations in this pathway are associated with clinicopathological features as well as prognosis, such as disease stage and BC subtypes, but not with primary/metastatic status or treatment. PIK3CA alterations were a benign predictor of survival, whereas PTEN alterations were a negative predictor. These findings suggest that genetic profiling of the PTEN/PI3K/AKT pathway could guide treatment strategies and prognosis prediction in Chinese BC patients. Future studies should focus on validating these findings in prospective cohorts and exploring targeted therapies based on these genetic alterations.

P3-10-14: Tolerability of First-Line (1L) Treatment (tx) With Ribociclib (RIB) for Metastatic Breast Cancer (MBC) Using 2 Large US Data Sources

Sarah L. Sammons, Priyanka Sharma, Yara Abdou, VK Gadi, Taavy A. Miller, Spencer S. Langerman, Dominick Latremouille-Viau, Annie Guerin, Carmine Rossi, Emily McGovern, Gary Sopher, Vamsi Bollu, Natalia Bolotova, Şerban R. Iorga, Liz Santarsiero, Susan Dent

Background: In addition to PFS and OS benefits, 1L RIB + endocrine therapy (ET) demonstrated a tolerable and manageable safety profile across all phase 3 MONALEESA (ML) randomized controlled trials (RCTs). RIB + ET is recommended by the National Comprehensive Cancer Network® (NCCN®) as NCCN category 1 preferred CDK4/6 inhibitor for 1L tx of HR+/HER2− MBC with no visceral crisis in postmenopausal patients (pts) or premenopausal pts with ovarian ablation/suppression.a In the real world (RW) setting, observed tolerability for RIB can reassure clinicians and complement RCTs. Here, we describe RW adverse events (AEs) of interest with RIB (as available) in 2 large US datasets: administrative healthcare claims and enriched electronic health records, both notably including pts ≥65 y of age.
Methods: Two independent, observational, retrospective cohort analyses were conducted in the nationwide Flatiron Health EHR-derived deidentified database (EHR) and the deidentified Komodo Research Database (KRD; commercially insured, managed-Medicare

[excluding fee for service] and Medicaid-insured administrative claims). The study cohorts consisted of adult pts with HR+/HER2− MBC who initiated 1L RIB + ET between Mar 2017 and Aug 2022 (EHR) and between Feb 2018 and Dec 2022 (KRD), with follow-up up to Nov 2022 (EHR) and June 2023 (KRD). New onset of medical conditions of interest, selected from AEs reported in 1L RIB + ET RCTs, were summarized. Cardiovascular (CV) conditions, as reported in claims data, were only available in KRD. All pts, including those aged ≥65 y, are described. Variables are based on clinician documentation in enriched EHR and diagnosis codes in KRD. Some measures are not included for both datasets due to limitations of the databases.
Results: A total of 373 (EHR) and 350 (KRD) pts who received 1L RIB + ET (of whom 5.9% and 9.4%, respectively, self-identified as Black/African American) were included. In EHR, the mean age was 62.6 (SD ± 12.6) y, 183 pts (49.1%) were aged ≥65 y, and 65 pts (17.4%) were ≥75 y. In KRD, the mean age was 56.5 (SD ± 10.5) y, 57 pts (16.3%) were aged ≥65 y, and 16 pts (4.6%) were ≥75 y. The majority of pts received an aromatase inhibitor as ET partner (76.1%, EHR; 79.7%, KRD). Furthermore, the data suggest an increase in the use of RIB in the 1L in RW clinical practices in 2022; as observed in KRD more pts initiated 1L RIB + ET in 2022 (40.6%), the remainder started 1L RIB between 2018 and 2021.
New onset any-grade AEs in pts treated with 1L RIB + ET were as follows: neutropenia in 53.4% (EHR) and 21.3% (KRD) of pts, elevated liver enzymes in 9.0% (EHR) and 4.6% (KRD) of pts, and QTc prolongation in 4.0% (EHR) and 2.0% (KRD) of pts. Evidence of newly diagnosed or suspected CV medical conditions (cardiomyopathy, CHF, CAD, cardiac arrhythmias, cardiac conduction abnormalities, hypertension, IHD, hypercholesterolemia, and pericardial disease), available only in KRD, was relatively low. Incidence of AEs for pts aged ≥65 y was consistent with the overall cohort.
Conclusions: In this retrospective cohort study, data from 2 large US databases reaffirm the safety of 1L RIB seen across the ML trials, with no new RW safety signals observed among medical conditions of interest. In the RW setting, 1L RIB + ET is consistently well tolerated for pts with HR+/HER2− MBC, including older pts.

P3-10-15: Prognostic impact of progesterone receptor status in patients with breast cancer and with isolated locoregional recurrence: A retrospective cohort study based on the Japanese Breast Cancer Registry

Takeshi Murata, Hiraku Kumamaru, Masayuki Yoshida, Shin Takayama, Akihiko Suto, Naoki Niikura, Shigehira Saji

Aims: Clinical evidence for treatment strategies for breast cancer (BC) patients with isolated locoregional recurrence (ILRR) is insufficient due to the various recurrence patterns and treatment options for individual patient with ILRR. Furthermore, the clinical impact of progesterone receptor (PR) status of ILRR tumor in patients with estrogen receptor (ER)-positive/humane epidermal growth factor receptor 2 (HER2)-negative ILRR has not been well investigated. This study aimed to evaluate the prognostic impact of PR status of ILRR tumor in patients with ER-positive/HER2-negative ILRR.
Methods: Using data from the Japanese National Clinical Database from 2004 to 2015, we enrolled breast cancer patients with ER-positive/HER2-netative ILRR. We divided enrolled patients into three groups according to their PR status of primary and recurrent tumors; patients with primary PR-positive/recurrent PR-positive tumors (pPR+/rPR+), patients with primary PR-positive/recurrent PR-negative (pPR+/rPR-) tumors, and primary PR-negative/recurrent PR-negative (pRP-/rPR-) tumors. Based on the registry, we classified the recurrent sites into the following three categories; ipsilateral breast tumor recurrence (IBTR), axillary lymph node (ALN), and chest wall (CW)/skin/regional node (RN). Overall survival (OS) and breast cancer-specific survival (BCSS) after ILRR diagnosis among the 3 groups were estimated using the Kaplan-Meier method, and survival estimates were compared using the log-rank test. Multivariable Cox proportional-hazards model from patients' age, primary surgical procedure, primary tumor size, primary lymph node positivity, disease free interval, recurrence site, PR status, use of post-recurrence treatments (surgery, chemo, endocrine, radiation) were constructed to identify the prognostic factors on OS and BCSS after ILRR.

Results: Among 1625 patients enrolled, 1180 patients (72.6%) had pPR+/rPR+ tumors (Group1), 306 (18.8%) had pPR+/rPR- tumors (Group2), and 139 (8.6%) had pPR-/rPR-tumors (Group3), respectively. The median follow-up time after ILRR diagnosis was 1254 days. During the follow-up period, 129 patients died from breast cancer and 19 patients died from causes other than breast cancer. The distribution of recurrence sites was as follows: group 1: IBTR 47%, ALN 28%, CW/skin/RN 35%; group 2: IBTR 38%, ALN 38%, CW/skin/RN 42%; group 3: IBTR 34%, ALN 31%, CW/skin/RN 48%. There were no differences in treatment for ILRR among the 3 groups, with surgical resection, chemotherapy, endocrine therapy, and radiotherapy given to approximately 80%, 30%, 80%, and 30%, respectively. Regarding OS, patients in Group2 and patients in Group3 had significant worse 5-year OS after ILRR than patients in Group1 (72.5% vs. 88.3%, P<0.0001; 74.7% vs 88.3%, P<0.0001, respectively). Multivariable analysis revealed that the factors associated with worse OS after ILRR diagnosis were lymph node metastasis at primary BC diagnosis (HR 2.37; 95% CI 1.63-3.44; P<0.001), disease-free interval (DFI) shorter than 24 months (HR 2.04; 95% CI 1.41-2.94; P<0.001), pPR(+)/rPR(-) tumor (HR 1.77; 95% CI 1.21-2.61; P=0.004) and pPR(-)/rPR(-) tumor (HR 2.08; 95% CI 1.25-3.44; P=0.005) as compared with pPR(+)/rPR(+), and chemotherapy administered for ILRR (HR 1.77; 95% CI 1.24-2.54; P=0.002). Those undergoing resection of ILRR tumor had longer OS after ILRR diagnosis (HR 0.35; 95% 0.24-0.52; P<0.001) compare with those who did not. Regarding BCSS, patients in Group2 and patients in Group3 had significant worse 5-year BCSS after ILRR

than patients in Group1 (74.4% vs. 89.9%, P<0.0001; 77.2% vs 89.9%, P<0.0001, respectively). Multivariable analysis revealed that factors associated with worse BCSS after ILRR diagnosis were similar to those for OS. As with OS, resection of ILRR tumor was significantly associated with favorable BCSS after ILRR diagnosis.

Conclusions: The results from this nationwide database study demonstrated that PR-negativity of ER-positive/HER2-negative ILRR is one of the poor prognostic factors after ILRR diagnosis regardless of the PR status of the primary BC.

P3-10-16: Phase I/II of Personalized Neoantigen Peptide-Based Vaccine (PNeoVCA) in Combination with Pembrolizumab in Patients with Early-Stage Triple-Negative Breast Cancer with Residual Disease after Neoadjuvant Chemotherapy

Saranya Chumsri, Yanyan Lou, Qian Shi, Jordan Reynolds, Brian Necela, Nadine Norton, Rohit Rao, Pooja Advani, Kostandinos Sideras, Michael Gustafson, Yan Asmann, Keith Knutson

Background: While immune checkpoint inhibitor (ICI) has significantly improved outcomes in patients with early-stage triple-negative breast cancer (TNBC), patients with residual disease after pembrolizumab-based neoadjuvant chemotherapy continue to have particularly poor outcomes. Patients with larger amounts of residual disease with residual cancer burden (RCB)-III and RCB-II had extremely poor outcomes, with 72.5% and 25.5% of patients developing recurrence within the first 3 years, respectively. Recent breakthroughs in identifying personal neoantigens via a comprehensive analysis of cancer sequencing data have brought increased attention to neoantigen cancer vaccines. Personalized cancer vaccines targeting neoantigens have shown early promising results in melanoma. While neoantigens have recently been investigated in some cancer types, the current neoantigen prediction algorithms have often focused on the MHC class-I subtype, single nucleotide mutations (SNM), small insertions, and deletions (INDEL). We recently developed an informatics workflow, REAL-neo, for the identification, quality control (QC), and prioritization of both class-I and class-II human leukocyte antigen (HLA) bound neoantigens that arise from somatic SNM, INDEL, aberrant RNA splicing, and gene fusions, generating much more potent neoantigen candidates. Furthermore, we demonstrated robust T-cell response and prolonged survival by combining ICI and cancer vaccines in preclinical models. This phase I/II clinical trial is in progress to assess the safety, feasibility, and immunogenicity of personalized neoantigen vaccines in combination with pembrolizumab in patients with advanced solid cancers with a phase II extension cohort in patients with early-stage TNBC with residual disease after neoadjuvant chemotherapy.
Methods: Key eligibility criteria include females ≥ 18 years old with histologically confirmed stage I-III TNBC (ER<10%, PR <10%, and HER2 negative per ASCO/CAP guideline. Patients with evidence of residual disease ≥ 1 cm after neoadjuvant pembrolizumab-based

chemotherapy on imaging will be enrolled in the pre-screening phase prior to surgery to collect fresh frozen samples for sequencing. After surgery, patients with histologically confirmed RCB-II and RCB-III will be pre-registered, and patient samples will be sequenced to identify patient-specific neoantigens using the REAL-neo algorithm. Patients will continue with standard-of-care therapy based on the treating physician's choice. Once PNeoVCA vaccine production is completed, eligible patients will receive the vaccine consisting of up to 20 peptides delivered with GM-CSF as an adjuvant. PNeoVCA will be administered with 4-5 peptides at 300 mcg/peptide and GM-CSF 125 mcg per injection site in each limb in combination with Pembrolizumab 200 mg i.v. PNeoVCA will be given via subcutaneous injection on days 1, 4, 8, 15, and 21, with boosters in weeks 5 and 8.
Clinical trial information: NCT05269381

P3-10-17:Phase I/II study of the novel radioligand therapy [177Lu]Lu-NeoB plus capecitabine in patients w/ ER+/HER2- advanced breast cancer (ABC) w/GRPR expression after progression on prior endocrine therapy (ET) plus a CDK4/6 inhibitor (CDK4/6i) for ABC

Mario Campone, Louise Emmett, Dejan Juric, Debasish Tripathy, Sonia Pernas, Monica Zuradelli, Kevin Perraud, Aleix Prat

Background: A CDK4/6i in combination with ET has become standard of care in first-line ER+/HER2− ABC, but despite significant improvements in survival, these patients will eventually experience disease progression. The optimal treatment sequence following progression on a CDK4/6i + ET has not yet been established and is dependent on various factors. Thus, new targeted treatments are needed for patients with ET-resistant ABC. [177Lu]Lu-NeoB (177Lu-NeoB) is a first-in-class radioligand therapy that binds selectively to GRPR, which is expressed in ER+ breast cancer, including in primary lesions, lymph nodes, and distant metastases. NeoRay is a first-in-human trial testing 177Lu-NeoB in advanced solid tumors. We describe the CAAA603D12101 study (NeoB D1), a phase I/II, open-label, multicenter study evaluating 177Lu-NeoB in combination with capecitabine, a known radiosensitizer, in patients with ER+/HER2− ABC with GRPR expression after progression on prior ET plus a CDK4/6i.

Methods: The NeoB D1 study includes dose-escalation and dose-optimization parts for 177Lu-NeoB. Eligible patients include adult men and pre/peri/postmenopausal women with histologically or cytologically confirmed ER+/HER2− ABC and measurable disease per RECIST v1.1. Pre/perimenopausal women are only included in the phase II part of the trial and will require, along with men, the addition of a gonadotropin-releasing hormone analogue. Patients can have received one to three prior lines of ET in the ABC setting, one of which is required to have included a CDK4/6i. If the participant has progressive disease while on or within 12 months of adjuvant treatment, this is considered a line of therapy. For patients with a confirmed deleterious or suspected deleterious germline BRCA1/2

mutation, prior treatment with a PARP inhibitor is allowed. For patients with HER2-low disease, prior treatment with trastuzumab deruxtecan is allowed. All patients are required to have diagnostic screening with a target lesion showing uptake of [68Ga]Ga-NeoB.
In the phase I part of the study, patients will receive 177Lu-NeoB at 150 millicurie (mCi) Q6W plus capecitabine (1000 mg/m2 BID for 14 days, followed by 7 days off). If dose escalation is supported, then patients will be randomized to the two higher dose levels (200 mCi Q6W or 100 mCi Q3W); if dose escalation is not supported, then lower dose levels will be explored. The phase II part will randomize patients to two dose levels of 177Lu-NeoB plus capecitabine based on multiple different scenarios. Treatment duration of 177Lu-NeoB is planned to be six administrations for the Q6W regimen and 12 administrations for the Q3W regimen.
The primary objectives of the dose-escalation part are the incidence and severity of dose-limiting toxicities and adverse events and dose modifications of 177Lu-NeoB plus capecitabine. The dose-optimization primary objectives are objective response rate, clinical benefit rate, time to response, duration of response, progression-free survival, and overall survival. Secondary objectives include pharmacokinetic and biodistribution (dosimetry) data. Planned enrollment is approximately 58 patients across both phases. Patient enrollment is currently open. ClinicalTrials.gov ID: NCT06247995.

P3-10-18: Phase II Single Arm Trial of Low Dose Capecitabine in Patients with Advanced Breast Cancer (NCT06105684)

Vinod Kumar, Nusrat Jahan, Gabrielle B. Rocque, Lisle Nabell, Sejong Bae, Anethea Tolliver, Nuzhat Rahman Siddiqui, Grant Williams, John Carpenter, Erica M. Stringer-Reasor, Katia Khoury

Background: Capecitabine (Xeloda), an oral prodrug of fluorouracil, is approved for adjuvant and advanced stage treatment of breast cancer. The approved dose of capecitabine is determined based on studies in heavily pretreated patients, which demonstrated responses at the maximum tolerated dose of 1000-1250 mg/m2 on days 1-14 of a 21-day cycle. However, higher doses of other chemotherapy agents have resulted in increased toxicity without necessarily improving response rates.
Multiple studies used capecitabine at lower, fixed doses, demonstrating maintained efficacy and notable reductions in toxicities (diarrhea, palmar-plantar erythrodysesthesia, mucositis, and neutropenia). Older adults and frail individuals experience more severe treatment-related side effects and are often underrepresented in clinical trials due to presumed frailty or implicit bias of investigators. This study aims to evaluate both efficacy and tolerability of a daily lower dose of capecitabine in the treatment of advanced HER2-negative breast cancer in aging and frail populations.
Methods: This single-arm, open-label phase 2 study will evaluate the anti-tumor effect of continuous daily oral low-dose capecitabine at 1500mg in 40 patients of age 60 years or older, and/ or considered frail at any age (ECOG 0-2). Frailty is defined by the investigator as an individual at greater risk of complications and poorer outcomes with systemic

therapy, secondary to a lower physiologic reserve and higher comorbidities and functional deficits. Eligible patients include those with HER2-negative unresectable or metastatic breast cancer (hormone positive or triple negative) with measurable disease, who have progressed on at least 1 prior line of therapy. Major exclusion criteria include HER2-positive breast cancer, severe hepatic or renal failure, inability to swallow pills, and uncontrolled CNS/ leptomeningeal disease. Patients will be evaluated for toxicity every 4 weeks and for response every three cycles using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 criteria. Therapy will be continued until evidence of disease progression or unacceptable toxicity. The primary objective is the clinical activity of daily low dose capecitabine by overall response rates (ORR) per RECIST. The secondary objectives include progression-free survival (PFS), overall survival (OS), and determining the safety and tolerability of daily low dose capecitabine using the Common Terminology Criteria for Adverse Events (CTCAE) v.6.0. Exploratory analyses include evaluating quality of life using the European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire 30 (EORTC QLQ-C30), and the PRO-CTCAE (Patient reported outcomes-Common Terminology Criteria for Adverse Events) questionnaire. Other exploratory analyses include measurement of sarcopenia: measuring body composition including skeletal muscle index (SMI) calculated from skeletal muscle area on CT scan before, during, and after treatment, as well as evaluating geriatric assessment using the CARE (Cancer and Aging Resilience Evaluation) tool prior to registration and at the end of treatment, and evaluating adherence to capecitabine. Simon's two-stage minimax design will be used with a type I error rate of 0.05 and power of 80%. The null hypothesis response rate of 10% will be tested against a one-sided alternative response rate of 25%. In the first stage, 22 patients will be accrued. If there are 2 or fewer responses in the first 22 patients enrolled, the study will be discontinued. The trial was approved by the Institutional Review Board at the University of Alabama at Birmingham (UAB) and opened to accrual July 2024.

P3-10-19: Phase II Trial of Pembrolizumab in Combination with Olaparib in Advanced Breast Cancer with BRCA-mutation or Homologous Recombination Defect (HRD)

Jin Sun Bitar, Monica Mita, Philomena McAndrew, Dorothy Park, Reva Basho, Joey Di Padova, Marie Lauzon, Yuan Yuan

Background: Tumors with HRD showed similar propensity to be sensitive to poly ADP-ribose polymerase inhibitors (PARPi) inhibitors as BRCA-mutated tumors. The rationale for combining PARP inhibitors with immune checkpoint inhibitors (ICIs) comes from the observation that PARPi induces PD-L1 and triggers robust local and systemic antitumor immunity via STING-dependent pathways, which in turn synergizes with ICIs. This study was designed to test the effectiveness of this combination in breast cancer patients with HRD defects or BRCA mutations.
Methods: This is an open-label, single-center, phase 2 study for breast cancer with BRCA-mutated or HRD cancer progressing on prior therapies for metastatic or locally advanced

disease with no restriction of receptor status. All commercially available HRD assays are acceptable. Eligible pts received pembrolizumab 200 mg IV every 21 days combined with olaparib 300 mg PO daily. Treatment was continued until documented progression by RECIST 1.1 or unacceptable toxicity. The primary objective was the overall response rate (ORR) of the combination therapy, with secondary objectives being progression-free survival (PFS), overall survival (OS), and duration of response (DOR). Adverse events (AEs) were monitored using CTCAE v.5.0.
Results: Twelve pts were included in this preliminary analysis. The median age at study entry was 50 (Range 33-73). Of these, 8 pts(66.7%) were White, including 1 Hispanic; 1 pt was African American, and 1 pt was Asian. Ten pts had hormone receptor-positive HER2-negative disease, and 2 patients had triple-negative disease. The pts had received median 4 lines of treatment (Range 1-10) prior to study entry. Six pts and 2 pts had received prior PARPi and ICI respectively, including 1pt who had received both agents at separate times. Treatment response was not evaluable for 2 patients: 1 withdrew consent after cycle 1, and 1 had disease progression during cycle 1 of treatment. Germline BRCA1 and BRCA2 mutations were found in 3 patients (25.0%) and 4 patients (33.3%), respectively. ORR was 33.3% (3 partial responses and 0 complete responses). Median PFS was 3.7 months, and median OS was 5.7 months. Median DOR was 2.2 months. Currently, one pt has been on treatment for over 8 months, with stable disease after 4 months of partial response. The most common adverse events were nausea (7 patients; 4 pt with grade 1-2, 3 pt with grade 3) and anemia (5 patients, all grade 1-2). Other grade 3 toxicities were muscular-skeletal pain in 1pt, fatigue in 1pt, leukopenia in 1pt and pneumonia in 1pt. There was no grade 4-5 toxicity.
Conclusions: The combination of olaparib and pembrolizumab was well tolerated, with ORR of 33.3% in heavily pretreated breast cancer patients, including patients with prior PARPi exposure. This trial is ongoing to finalize the clinical benefits assessment. Clinical trial information: NCT03025035
Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA provided pembrolizumab, olaparib, and financial support for the study.

P3-10-20: Phase II study of talazoparib, a PARP inhibitor, in HER2- metastatic breast cancer (MBC) with a somatic BRCA1/2 mutation identified in cell-free DNA or tumor tissue genotyping

Neelima Vidula, Senthil Damodaran, Manali Bhave, Erica Blouch, Ogadinma Ogbenna, Vandana Abramson, Ami Shah, Lisa Flaum, Massimo Cristofanilli, Joseph Sparano, Harry Ostrer, Nora Horick, Hope S. Rugo, Aditya Bardia

Background: PARP inhibitors are associated with improved progression free survival (PFS) and patient quality of life in germline BRCA1/2 mutant MBC, leading to their approval in this setting, but their applicability is limited as germline BRCA1/2 mutations are present in 5% of breast cancer. We previously demonstrated that a subset of patients with MBC who are not germline BRCA1/2 carriers may harbor pathogenic somatic BRCA1/2 mutations

that are identified by cell-free DNA and/or tumor tissue genotyping. We developed a circulating tumor cell culture from a patient with MBC harboring a pathogenic somatic BRCA1 mutation, and demonstrated that a PARP inhibitor induced cell growth inhibition similar to a germline BRCA1/2 mutant culture. Thus, we hypothesize that a PARP inhibitor may be effective in treating somatic BRCA1/2 mutant MBC. In this clinical trial, we are studying the efficacy of a PARP inhibitor in somatic BRCA1/2 mutant MBC. Our work may expand the clinical application of PARP inhibitors in MBC.
Trial Design: This phase II investigator-initiated clinical trial is enrolling 30 patients with MBC with a pathogenic somatic BRCA1/2 mutation identified by a CLIA certified cell-free DNA and/or tumor tissue genotyping assay. Patients are treated with the PARP inhibitor talazoparib 1 mg/day until progression of disease. Imaging (CT chest, abdomen and pelvis, and bone scan) occurs for disease assessment at baseline and every 3 months. Cell-free DNA is collected at baseline and then monthly to evaluate changes in the genomic environment. Patients also undergo Cancer Risk B (CR-B) assay, a novel flow variant test to identify double-strand break repair mutations in circulating blood cells, at baseline.
Eligibility Criteria: Patients must have MBC with a pathogenic somatic BRCA1/2 mutation identified in a cell-free DNA and/or tumor tissue genotyping assay, with pathogenicity confirmed by a genetics counselor using validated genomic databases such as ClinVar. Patients may have triple-negative (receipt of at least 1 prior chemotherapy) or hormone receptor positive/HER2- (receipt of at least 1 prior hormone therapy) MBC. Patients must not be known germline BRCA1/2 carriers. Any number of prior therapies including a prior platinum (in absence of progressive disease on a platinum) are allowed, but patients should not have received a prior PARP inhibitor. Patients must have adequate organ function and performance status.
Specific Aims: The primary aim is to determine PFS (RECIST 1.1). Secondary aims include determining the objective response rate and toxicity (NCI CTCAE v 5.0). Exploratory aims include evaluating serial changes in BRCA1/2 mutant allelic frequency in cell-free DNA, understanding the impact of BRCA1/2 reversion mutations in cell-free DNA, comparing pre- and post-treatment cell-free DNA results to understand changes in the genomic environment, studying the CR-B assay positivity rate, and correlating these biomarker analyses with treatment response.
Statistical Methods: This study has 81% power to demonstrate that the 12-week PFS is 53% or higher. In contrast, there is a 4% (alpha) probability of concluding that the 12-week PFS is ≥ 53% if the true 12-week PFS is 30% or lower. If 14 or more of 30 total patients achieve PFS > 12 weeks, the null hypothesis (12-week PFS ≤ 30%) will be rejected.
Present accrual and target accrual: This study (NCT03990896) is open at Massachusetts General Hospital, MD Anderson, University of California San Francisco, Emory, Northwestern, Vanderbilt, and Cornell. As of 7/2024, 21/30 patients are enrolled.
Funding: A Pfizer ASPIRE award and Conquer Cancer Foundation of ASCO–Breast Cancer Research Foundation- Career Development Award fund this study.

P3-10-21: Phase Ib dose-finding study of [177Lu]Lu-NeoB + ribociclib + fulvestrant in patients w/ ER+/HER2- advanced breast cancer (ABC) w/ GRPR expression w/ early relapse from (neo)adjuvant endocrine therapy (ET) or progression on ET + CDK4/6i for ABC

Debasish Tripathy, Dejan Juric, Sonia Pernas, Francois-Clement Bidard, Ana Sofia Ferreira, Kevin Perraud, Louise Emmett

Background:
Ribociclib (RIB) + ET has shown significant progression-free survival and overall survival benefit in patients (pts) with HR+/HER2− ABC. However, there is still an unmet need for novel therapies for pts with disease progression on or after ET +/− a CDK4/6 inhibitor (CDK4/6i). Radioligand therapies (RLTs) have shown improvements in survival vs standard of care in castration-resistant metastatic prostate cancer and gastroenteropancreatic neuroendocrine tumors. Given their known benefit in other disease settings, RLTs are now being evaluated in ABC. We describe the CAAA603B12101 study, evaluating the addition of 177Lu-NeoB, a first-in-class RLT that selectively binds to GRPR, which is overexpressed in ER+ breast cancer cells, to the currently approved and recommended combination of ET + CDK4/6i for pts with ER+/HER2− ABC with GRPR expression who experienced early recurrence from (neo)adjuvant ET +/− a CDK4/6i or progression on ET + a CDK4/6i for ABC.
Methods:
The purpose of this Phase Ib, single-arm, multicenter, open-label, dose-finding study is to estimate the recommended dose (RD) of 177Lu-NeoB in combination with RIB and fulvestrant (FUL). Eligible pts include adult women (regardless of menopausal status) and men with ER+/HER2− ABC with GRPR expression who meet one of the following criteria: (i) experienced recurrence ≤12 mo from completion of (neo)adjuvant ET (+/− CDK4/6i) with no treatment for ABC, (ii) experienced recurrence >12 mo from completion of (neo)adjuvant ET and then subsequent progression after one line of ET (except FUL) + a CDK4/6i for ABC, or (iii) had ABC at diagnosis that progressed after one line of ET (except FUL) in combination with a CDK4/6i. Pts are required to have one target lesion (measurable per RECIST 1.1) in the baseline stand-alone CT or MRI. All pts are required to have diagnostic screening with a target lesion showing uptake of [68Ga]Ga-NeoB.
This study comprises a dose-escalation part and a concurrent backfill part. In the dose-escalation part, four provisional dose levels are planned to be tested: 100 mCi (initial dose), 150 mCi, 200 mCi and 250 mCi in cohorts of three to six pts. The initial dose of 177Lu-NeoB will be 100 mCi (every 28d for six cycles) in combination with RIB (600 mg/d; 3 wk on/1wk off) and FUL (500 mg on d1 of a 28-d cycle with an additional single dose on d15 of cycle 1). Pre/perimenopausal pts will also receive goserelin (3.6 mg on d1 of a 28-d cycle).
After inclusion of pts in each cohort, the incidence rate of dose-limiting toxicities (DLTs) will be compared with the predefined toxicity rate boundaries to decide whether the next cohort will receive a lower, higher, or same dose or whether the trial will be terminated. The backfill part will allow enrollment to a previously cleared dose level (during escalation

part) to obtain additional safety, tolerability, and preliminary efficacy data. During the backfill part, the cumulative incidence rate of DLTs will also be compared with the predefined toxicity rate boundaries to determine if escalation should be restarted from a lower dose level.
Primary outcomes include incidence and nature of DLTs, incidence and severity of adverse events (AEs) and serious AEs, and incidence of dose interruptions, discontinuations, and dose reductions. Secondary outcomes include preliminary antitumor activity and pharmacokinetic and biodistribution (dosimetry) data. The RD will be determined considering all available data from the escalation and backfill parts. Planned enrollment is approximately 48 pts. Pt enrollment is currently open. Clinical trial ID: NCT05870579.

P3-10-22: Preoperative radiotherapy versus postoperative radiotherapy after neoadjuvant chemotherapy in high-risk breast cancer: a prospective, randomized, international multicentre Phase III trial—NeoRad

Christiane Matuschek, Tanja Fehm, Maria Hufnagel, Vesna Bjelic-Radisic, Michael Untch, Michael Golatta, Danny Jazmati, Thorsten Kühn, David Krug, Jens Blohmer, Carsten Denkert, Beyhan Ataseven, Carolin Nestle-Krämling, Stefanie Corradini, Jens Huober, Jens Huober, Eugen Ruckhaeberle, Andreas Hartkopf, Theresa Link, Kerstin Rhiem, Elmar Stickeler, Claus Hanusch, Jörg Heil, Christine Solbach, Mattea Reinisch, Inga Bekes, Johannes Holtschmidt, Valentina Nekljudova, Sibylle Loibl, Wilfried Budach

Background: Preoperative radiotherapy is a well-established treatment for various tumor types (rectal cancer, sarcoma, bronchial carcinoma). Promising studies on preoperative radiotherapy also exist for breast cancer, but most of them were not randomized or very old. Recent studies suggest that preoperative radiotherapy followed by immediate reconstruction or flap reconstruction is a low-complication method. There is evidence that the immunogenic effects of radiotherapy may lead to improved immune recognition of tumor cells. These potential immunogenic effects make preoperative radiotherapy a promising modality in interdisciplinary cancer therapy. In addition, preoperative radiotherapy may obviate the need to irradiate implants, expanders, or autologous transplants.
NeoRad (NCT04261244, GBG116) is a multicenter, prospective, international randomized Phase III trial. It aims to investigate whether pre- versus postoperative radiotherapy after neoadjuvant chemotherapy (NACT) improves disease-free survival in patients with high-risk breast cancer and show superiority of preoperative radiotherapy (PRT) of the experimental treatment schedule in terms of disease-free survival (DFS). In addition, several secondary endpoints (cosmetic outcomes, quality of life, overall survival, etc.) will be assessed to better understand the benefits and risks of preoperative radiotherapy compared to the current standard of care.

Study Design: Only patients with high-risk breast cancer who are eligible for NACT will be enrolled and randomly assigned in a 1:1 ratio to two study arms. In the standard arm, patients will undergo surgery, sentinel lymph node biopsy, possibly axillary dissection or targeted axillary dissection according to current S3/AGO guidelines. After surgery, patients will receive adjuvant radiotherapy +/- lymphatic pathways and, if indicated, systemic treatment according to S3/AGO guidelines.
In the experimental arm, patients will receive whole-breast irradiation (WBRT) +/- lymphatic pathway irradiation after NACT. Approximately 3-6 weeks after radiotherapy, patients will undergo surgery including sentinel lymph node biopsy or axillary dissection, followed, if indicated, by post-neoadjuvant systemic therapy according to S3/AGO guidelines. Enrolment in post-neoadjuvant studies is allowed. To assess the response to NACT before radiotherapy, a biopsy of the primary tumor and suspicious lymph nodes is recommended in the experimental arm.
An interim analysis on wound healing will be conducted after 100 patients have received breast-conserving surgery or autologous flap reconstruction (in both arms combined) and after 40 and 100 patients have been reconstructed with an implant (also combined from both arms).
The recruitment period will be four years. The total study duration, including follow-ups, is ten years.

Recruitment: The first patients were enrolled in 02/24 at the University Hospital of Düsseldorf. A total of 1826 patients will be recruited across 40 centers within 4 years.
Funding: This study was supported by a grant from Deutsche Krebshilfe.

P3-10-23: RecurIndex Predicts Risk of Recurrence in Early-stage Luminal Breast Cancer: APRIL Trial

Lei Lei, P. Fu, G. Qiao, O. Wang, L. Huang, Y. Chen, X. Wang, H. Zheng, X. Xie, J. Liu, J. Luo, Y. Li, Y. Tan, X. Wang

Background: Evidence has shown that Oncotype DX® (ODx) may overestimate the risk of recurrence among Asian populations. To fill this gap, RecurIndex® (RI) based on the gene-expression profiling of Asian breast cancer patients was developed. This multicenter prospective observational study named the APRIL trial aims to validate the predictive performance of the RI testing for recurrence risk prediction in Chinese women with early-stage luminal breast cancer. This trial will provide prospective evidence of the predictive value of RI testing in the adjuvant setting.

Method: The study was planning to enroll 500 individuals with stage I-II (pT1-2N0-1M0 or pT3N0M0) hormone receptor-positive, HER2-negative breast cancer treated with breast-conserving surgery or mastectomy. The patients were treated according to the low or high risk of relapse measured by RI and in conjunction with clinicopathological risk factors. The

choice of adjuvant therapy was determined by the physician's choice. This study design evaluated the utility of RI for refining recurrence risk prediction to guide personalized adjuvant management. Follow-up visits included every three months for the first two years after the definitive surgery and every six months for three to five years afterward. The primary endpoints included 5-year invasive disease-free survival (iDFS) and 5-year recurrence-free survival (RFS). Secondary endpoints included 5-year distance metastasis-free interval (DMFI), 5-year local-regional recurrence-free interval (LRFI), and 5-year overall survival (OS).
Statistical analysis: This study will test two hypotheses: 1) After 690 person-years of follow-up, the annual distant metastasis-free rate of RI low-risk patients is ≤1%. Statistically, this hypothesis is considered to fail with $p<0.05$, and the test power is 80%; 2) After 690 person-years of follow-up, the annual distant metastasis-free rate of RI high-risk patients is >2%. Statistically, this hypothesis is considered to fail with $p<0.05$, and the test power is 80%. Based on our previous results of the parallel comparison study between RI and ODx, 80% of N0 and 43% of N1 patients will be classified as RI low-risk group, indicating that 2/3 of early luminal breast cancer patients will be at low risk of recurrence. Five hundred patients will be enrolled (333 low-risk and 167 high-risk). When 690 person-years of follow-up are completed, the pre-set rate of no distant metastasis in low-risk patients will be ≤1% and these patients will be advised to receive only adjuvant endocrine therapy. It is expected that data will be collected every four months and reported to the Data and Safety Monitoring Board (DSMB). If it involves changes in patient treatment, the department will make an independent decision based on relevant policies.
Role of the funding source: The study sponsor, National Key R&D Program, oversaw data management and statistics. This study was registered with ClinicalTrials.gov, NCT04972448.

Results: The APRIL Trial opened for recruitment in May 2022 and is in progress. A total of 323 patients enrolled: 120 (37.2%) of 323 patients had clinical high-risk and genomic low-risk, 159 (49.2%) of 323 patients had clinical and genomic low-risk, 43 (13.3%) of 323 patients had clinical and genomic high-risk, and 1 (0.3%) of 323 patients had clinical low-risk and genomic high-risk.
Conclusions: In conclusion, this study will be the first prospective multicenter study to evaluate the risk-prediction value of RI testing in the Chinese population. Those findings will provide valuable evidence for the recommendation of RI testing for guiding adjuvant chemotherapy in early luminal breast cancer patients in China.

P3-10-24: Refusal of sentinel lymph node biopsy in patients with luminal A subtype of early breast cancer

Alexander Emelyanov, Zhanna Bryantseva, Irina Akulova, Pavel Krzhivitskiy, Sergey Novikov, Petr Krivorotko, Amirov Nikolay

This study is a randomized, single-center, prospective observational study that aims to de-escalate surgical treatment for patients with early breast cancer. First of all, the safety of avoiding SLNB in patients with early luminal A breast cancer (T1-2N0).

Study aim: Conduct a comparative analysis of the axillary reccurence incidence in patients without sentinel lymph node biopsy followed by radiation therapy to the remaining breast tissue and axillary lymph nodes and in patients who received standard treatment with SLNB.
Study objectives: Compare the axillary reccurence incidence in patients with early breast cancer who did not undergo SLNB and in patients who underwent standard treatment with SLNB (Time frame: 2, 3 and 5 years)
- Compare locoregional disease-free survival in the studied groups of patients with early breast cancer (Time frame: 5 and 10 years)
- Compare overall and disease-free survival in the studied groups of patients with early breast cancer (Time frame: 5 and 10 years)
- Compare the incidence and severity of adverse events using the current CTCAE version 5.0 (Time frame: 3, 5 and 10 years)
Methods of surgical and radiation treatment
1. Before surgical treatment, all patients included in the study undergo SPECT-CT of the breast with 99mTc-Technetril and SPECT-CT of sentinel lymph nodes with Tc99m-colloid. The patient undergoes a BCS, followed by a histological examination of the removed material. If the patient is allocated to group 1, then she additionally undergoes an SLNB procedure. If the patient is randomized to group 2, then SLNB is not performed.
2. At the next stage, 4 to 12 weeks after surgical treatment, 3D conformal radiation therapy of the remaining breast tissue is carried out with the inclusion of signal lymph nodes in the volume in the group of patients without SLNB (group 2). In patients after SLNB (group 1), only irradiation of the remaining breast tissue is performed without irradiation of the axillary region. In the presence of metastatic lesions of sentinel lymph nodes, additional irradiation of the axillary region is performed.
Radiation therapy to the area of non-removed sentinel lymph nodes will be carried out using modified (high) tangential fields and 3D modeling according to the atlas of sentinel lymph nodes, depending on their location (cent., pect [S], pect [Th II], pect [Th III], pect [ThIV], IP, Lat.)
To date, 21 patients have already been included in the study, and enrollment is ongoing.

P3-10-25:Repeat Breast Conserving Surgery Followed by Daily Partial Irradiation for Patients w/ Ipsilateral Breast Tumor Recurrence or new Ipsilateral Primary Breast Cancer, Previously Treated w/ Breast Conserving Surgery & Whole Breast Radiation Therapy

Courtney Pisano, Corey Speers, Yilun Sun, Amanda Amin, Chirag Shah, Alberto Montero, Pamela Li, Lisa Rock, Megan Miller

Introduction: Breast cancer survival rates have improved with advances in screening and treatment. Standard of care for early-stage and selected locally advanced breast cancers involves breast-conserving therapy, which includes partial mastectomy followed by radiation. For patients with ipsilateral breast tumor recurrence/new ipsilateral primary breast cancers, traditional treatment has been salvage mastectomy. However, many patients prefer to avoid mastectomy, leading to interest in repeat breast-conserving surgery (reBCS) with partial breast re-irradiation. Based on the RTOG 1014 trial, the current standard of care for external beam re-irradiation involves partial breast re-irradiation to a dose of 45Gy delivered twice daily over 3 weeks (30 fractions), which can be burdensome for patients and lead to increased time off work, travel time and childcare challenges. We hypothesize that daily hypofractionated partial breast external beam radiation therapy after repeat BCS will be well-tolerated, achieve good local control, demonstrate comparable toxicity profiles, and offer a more convenient option than the current standard.

Methods: This multicenter, single-arm prospective phase II study is enrolling patients >18 years of age with histologically confirmed ductal carcinoma in situ (DCIS) or invasive unifocal breast cancer recurrence or new ipsilateral breast primary breast cancer measuring <3 cm after repeat BCS, with a minimum of 3 years since previous whole breast irradiation. Patients receive radiation within 21 days after treatment planning CT and no more than 15 weeks post-surgery. Hormonal therapy is allowed and chemotherapy follows radiation if planned, though neoadjuvant chemotherapy is allowed. The radiation dose is 40.05 Gy in 15 fractions of 2.67 Gy, with an option for 48 Gy in 15 fractions of 3.2 Gy for high-risk patients requiring a boost. Target volumes are defined based on the excision cavity, surgical changes, and clips.

Findings: The trial opened in October 2023, aiming to accrue 55 patients over six years (powered similar to RTOG 1014). The primary endpoint is the rate of grade 3+ treatment-related skin, fibrosis and breast pain adverse events within one year post-reirradiation, graded by CTCAE criteria. Secondary endpoints include in-breast tumor recurrence, freedom from mastectomy, overall survival, and mastectomy-free survival. Cosmesis will be evaluated at 1 and 3 years using the BCTOS quality of life questionnaire (ePRO), the Global Cosmesis Score (ePRO) and Worksheet for Breast condition (ePRO). By July 2024, seven patients were screened, with three enrolled. Of those enrolled, 2 completed treatment and one is currently on treatment. For the two patients that have completed treatment, there has been no significant acute toxicity. Two patients with tumors >3 cm were deemed ineligible and treated off-trial with this regimen. Two others are pending further procedures.

Conclusion: This trial has shown high patient interest and acceptance. If outcomes match the current standard, this approach will provide a more convenient option and increase acceptance of repeat attempts at breast conservation reBCS.

P3-10-26: SERIES: SEquencing Sacituzumab Govitecan (SG) AfteR Trastuzumab Deruxtecan (T-DXd) In ER+/HER2 LOW MetaStatic Breast Cancer

Reshma L. Mahtani, Aditya Bardia, Ana Sandoval, Maria Abreu, Manmeet Ahluwalia, Kelly McCann, Ruth Sacks, Kevin Kalinsky

Background: SG is approved for patients (pts) with unresectable locally advanced or metastatic hormone receptor-positive, HER 2-negative breast cancer who have received endocrine-based therapy and at least 2 additional systemic therapies in the metastatic setting. T-DXd is approved in pts with unresectable or metastatic HER2-low breast cancer who have received a prior chemotherapy in the metastatic setting or developed disease recurrence during or within 6 months of completing adjuvant chemotherapy. Currently, there are no prospective data evaluating the efficacy of sequential use of these antibody drug conjugates. Tissue and blood biomarkers are needed to clarify mechanisms of response and resistance. Trial Design: This multi-center phase 2 trial includes pts (N=75) with ER+/HER2 low MBC, who progressed or were intolerant to T-DXd in the metastatic setting and will receive SG on day 1 and 8 every 21 days until disease progression or intolerable toxicity. To be eligible, pts must have ECOG PS ≤2 , be considered endocrine refractory, pre-treated with a CDK4/6 inhibitor (in adjuvant/metastatic setting) and must have received ≥ 1 but ≤ 4 lines of chemotherapy in the metastatic setting. T-DXd is not required as the immediate prior therapy to SG. Clinically inactive brain metastases are permitted. Pts must have ≥1 measurable lesion per RECIST 1.1. Correlative NGS analyses will be conducted on tissue and blood at various timepoints: archival tissue (prior to T-DXd, if available), tissue biopsy prior to SG and at study discontinuation, blood at baseline, cycle 3, day 1 of SG, and at study discontinuation. The primary endpoint is investigator assessed overall response rate. Secondary endpoints include clinical benefit rate, progression free survival, overall survival, duration of response, global quality of life, and adverse events. The trial is currently enrolling patients (NCT06263543).

P3-10-27: SMALL: Open Surgery versus Minimally invasive vacuum-Assisted excision for small screen-detected breast cancer – a UK phase III randomized multi-centre trial

Stuart A McIntosh, Charlotte E Coles, David Dodwell, Kenneth Elder, Jessica Foster, Claire Gaunt, Amanda Kirkham, Iain D Lyburn, Jenna Morgan, Sangeetha Paramasivan, Sarah Pinder, Sarah Pirrie, Shelley Potter, Tracy Roberts, Nisha Sharma, Hilary Stobart, Elizabeth Southgate, Sian Taylor-Phillips, Matthew Wallis, Dan Rea

Background: Mammographic screening programmes reduce breast cancer mortality but detect many small good-prognosis tumours which may not progress. Screen-detected cancers are currently treated with standard surgery and adjuvant therapies, with associated morbidities. There is a need to reduce overtreatment of good prognosis tumours and

numerous studies are evaluating omission of radiotherapy in low-risk disease. However, there is little evidence to support surgical de-escalation, although percutaneous minimally invasive treatment approaches have been described. Vacuum-assisted excision (VAE) is in widespread use for management of lesions of uncertain malignant potential and benign lesions. SMALL (ISRCTN 12240119) is designed to determine the feasibility of using this approach to treat small invasive tumours detected within the UK NHS Breast Screening Programme.

Methods: SMALL is a phase III multicentre randomised trial comparing standard surgery with VAE for screen-detected cancers. Main eligibility criteria are age ≥47 years, unifocal grade 1 tumours with maximum diameter 15mm, strongly ER/PR+ve and HER2-ve, with negative axillary staging. Patients are randomised 2:1 to VAE or surgery, with no axillary surgery in the VAE arm. Completeness of excision is assessed radiologically, and if excision is incomplete, patients undergo surgery. Adjuvant radiotherapy and endocrine therapy are mandated in the VAE arm but may be omitted following surgery.
Co-primary end-points are:
1. Non-inferiority comparison of the requirement for a second procedure following excision
2. Single arm analysis of local recurrence (LR) at 5 years following VAE

Recruitment of 800 patients will permit demonstration of 10% non-inferiority of VAE for requirement of a second procedure. This ensures sufficient patients for single arm analysis of LR rates, where expected LR free survival is 99% at 5 years, with an undesirable survival probability after VAE of 97%. To ensure that the trial as a whole only has 5% alpha, the significance level for each co-primary outcome is set at 2.5% with 90% power. The Data Monitoring Committee will monitor LR events to ensure these do not exceed 3% per year. Secondary outcome measures include time to ipsilateral recurrence, overall survival, complications, quality of life and health economic analysis.
A novel feature of SMALL is the integration of a QuinteT Recruitment Intervention (QRI), which aims to optimise recruitment to the study. Recruitment challenges are identified by analysing recruiter/patient interviews and audio-recordings of trial discussions, and by review of trial screening logs, eligibility and recruitment data and study documentation. Solutions to address these are developed collaboratively, including individual/group recruiter feedback and recruitment tips documents.

Results: SMALL opened in December 2019, but recruitment halted in 2020 for 5 months due to COVID-19. At 8th July 2024, 46 centres are open, with 449 patients randomised, with a randomisation rate of approximately 45%, and a per site recruitment rate of 0.4-0.5 patients/month.
Drawing from preliminary QRI findings and insights from patient representatives, a recruitment tips document has been circulated (on providing balanced information about treatments, encouraging recruiters to engage with patient preferences, and explaining randomisation). Individual recruiter feedback has commenced, and wider feedback is being delivered across sites via recruitment training workshops. Patient interviews are ongoing to

explore patient views and experiences of the trial.

Conclusion: SMALL continues to have excellent recruitment, is expected to complete recruitment in 2025 and to have a global impact on treatment of breast cancer within mammographic screening programmes.

SMALL is funded by the UK NIHR HTA programme award 17/42/32

P3-10-28: Sentinel Lymph Node Biopsy vs Observation After Neoadjuvant Treatment (SLOAN)

Alexander Emelyanov, Petr Krivorotko, Nikolay Amirov, Zhanna Bryantseva, Irina Akulova, Pavel Krzhivitskiy, Sergey Novikov

Study design: SLOAN is a prospective study to evaluate the incidence of axillary recurrence and survival of breast cancer patients who received neoadjuvant therapy and achieved pCR of the primary lesion in the breast without surgical staging of the axillary region.
The hypothesis of the SLOAN study is to prove the oncological safety of excluding SLNB when achieving pCR of the tumor in breast after NST in patients with HER2-positive and TNBC with initially clinically negative lymph nodes (cN0).
SLOAN is a prospective, non-randomized, single-arm surgical trial. A randomized design is not useful because of the expected extremely low rates of axillary recurrence at 3 and 5 years for the experimental group. In the case of a two-arm randomization, the risk of insufficient testing power due to a small number of events would be significantly higher.
Primary endpoints:
- 3-year assessment of axillary recurrence (AR) rate, defined as the presence of tumor in the lymph nodes of the ipsilateral axilla, sub/supraclavicular fossa, or interpectoral region. Recurrences must be confirmed by biopsy or local surgical excision (open biopsy).
Secondary endpoints:
5-year disease-free survival (RFS)
5-year overall survival (OS)
5-year locoregional disease-free survival (LRFS)
5-year distant metastasis-free survival (DFFS)
3-year survival without axillary recurrence
5-year survival without axillary recurrence
Inclusion criteria
- Signed informed consent form
- Invasive HER2-positive or triple-negative breast cancer (confirmed by core biopsy)
- The tumor has not spread to the lymph nodes in the armpit.
- Tumor stage cT1 to cT2
- Planned chemotherapy before surgery OR chemotherapy already completed before surgery
- Female patients ≥ 18 years of age

- Achieving complete clinical regression of the tumor in the breast
- Patients suitable for breast-conserving treatment followed by radiation therapy
- Breast pCR after breast - conserving surgery

Exclusion criteria

- Distant metastases
- Recurrence of breast cancer
- Inflammatory forms of breast cancer
- Extramammary breast cancer
- Bilateral breast cancer
- History of breast cancer or any other type of cancer
- Surgical intervention performed on the axillary region before NCT
- Confirmed involvement of axillary lymph nodes
- Confirmed involvement of supraclavicular lymph nodes
- Confirmed involvement of parasternal lymph nodes
- Pregnancy
- Conducting less than 4 cycles of NCT
- Patients not suitable for surgical treatment

To date, 6 patients have already been included in the study, and enrollment is ongoing.

P3-10-29: Start of SerMa – EUBREAST 5 (Seroma of the Mammary Gland) study (NCT05899387) - On the way to identify women at risk of developing seroma after mastectomy

Nina Ditsch, Melitta Koepke, Nicole Pochert, Udo Jeschke, Mariella Schneider, Matthias Reiger, Claudia Traidl-Hoffmann, Angelika Mattmer, Shirin Hunstiger, Jacqueline Sagasser, Christian Dannecker, Mathis Wild, Christian Hinske, Sarah Friedrich, Steffi Hartmann, Henning Kahl, David Krug, Natalia Krawczyk, Kerstin Stemmer, Regina Fluhrer, Andreas Raue, Maria Luisa Gasparri, Roland Reitsamer, Justyna Jelinska, Güldeniz Cakmak, Eduard Bonci, Rachel Wuerstlein, Visnja Fink, Vesna Bjelic-Radisic, Marc Thill, Christoph Heitmann, Walter Weber, Annette Lebeau, Hans-Christian Kolberg, Toralf Reimer, Rosa di Micco, Jana de Boniface, Oreste Gentillini, Michael Untch, Maggie Banys-Paluchowski, Thorsten Kuehn

Background; Postoperative seroma formation is one of the most common and serious complications after breast surgery for primary breast cancer, especially in patients undergoing mastectomy with or without implant-based breast reconstruction. Seromas may lead to infections and wound dehiscence, which can result in implant loss. To date, the cause of seroma development has not yet been clarified. Recent data of the unicenter SerMa pilot study identified an association with immunological-inflammatory processes as a potential reason for seroma development. Trial Design:The main objective of the multicenter SerMa study is to identify a subgroup of patients with an increased risk of developing seromas based on immunological or inflammatory markers in a planned cohort of 2200 subjects. The study is designed as international, prospective cohort study in cooperation with the

EUBREAST Network (European Breast Cancer Research Association of Surgical Trialists). Currently participating study groups are AGO-B, AWOgyn and OPBC. Patients with primary breast cancer or ductal carcinoma in situ (DCIS) planned for mastectomy with or without implant insertion can participate in this study (study group 1 and 2). Study group 3 includes patients at high risk for breast cancer planned for risk-reducing subcutaneous mastectomy and implant reconstruction. Study group 4 includes healthy women with implant insertion for exclusively cosmetic reasons. Furthermore, it is planned to initiate a registry for postoperative breast seromas (SerMaReg). Primary endpoints: To achieve the primary endpoint – the identification of a patient group with an elevated risk of developing a seroma - it is planned to examine the groups with and without postoperative seroma formation regarding immunological markers in seroma fluid as well as in blood samples. In addition, local microbiome analyses, as well as tumor analyses with focus on microenvironment will be performed to differentiate possible carcinoma-specific immunological processes. Secondary endpoints: To answer the question whether differences are caused by immunological or cancer-related reasons, groups with and without postoperative seroma formation as well as groups with or without breast cancer are compared. Current status of the study: The study started recruiting in April 2024, the first patients have been enrolled and the protocol has been confirmed for practicability. The study is currently expanding worldwide. Target accrual: 550 participants per group, therefore 2200 participants in total.

P3-10-30: Stereotactic Body Radiation Therapy and FES PET/CT Imaging for the Treatment of Oligoprogressive Estrogen Receptor Positive Metastatic Breast Cancer

Jose Bazan, Joanne Mortimer, Yun Rose Li, Rebecca Nelson, Sharon Yim

Background: The term oligoprogression (OP) refers to a clinical scenario in which patients with diffuse metastatic disease on systemic therapy have a limited number of metastases that have progressed or are new whereas the majority of metastases are stable or improved. OP disease is increasingly being encountered in clinical practice due to improvements in systemic therapy. Treating OP disease with local ablative therapies may therefore prolong the time to more diffuse progression necessitating a change in systemic therapy and may therefore lead to improved overall survival in these patients. Only one study has evaluated the role of SBRT in patients with OP MBC. This trial accrued 47 patients with OP MBC, with 2/3 having triple negative disease. There was no difference in PFS between patients that received SBRT versus those that did not (4.2 months vs. 4.4 months, p=0.2). Whether ablative therapies are beneficial in subtypes of breast cancer that have many effective systemic therapies available, such as ER+ breast cancer, remains an open question and an unmet clinical need.

Trial Design: Phase II study for patients with OP ER+ MBC (1-4 new and/or progressing metastatic lesions). Eligible patients will receive stereotactic body radiation therapy (SBRT) to the OP lesions. SBRT will be delivered to each lesion in 3-5 fractions. Each patient's

systemic therapy regimen will be held during study therapy and will resume upon completion of study therapy. Patients will then be restaged at 12 weeks post-SBSRT. Patients that have at least stable disease at that time point will continue on their systemic therapy and then be re-staged 12 weeks later (24 weeks after SBRT). This study will also study the role of ER-targeted positron emission tomography (PET) imaging with 16α-18F-Fluoro-17β-Fluroestradiol (FES) in the OP ER+ patient population with FES PET scans obtained at baseline, and at each of the 2 follow-up imaging timepoints. A key secondary hypothesis is that the use of FES PET in addition to standard imaging at baseline and in follow-up will help confirm patients have OP disease and will help assess for new lesions on subsequent restaging.

Eligibility: Key inclusion criteria: age≥18 yo; histologically confirmed ER+/HER2- metastatic breast cancer; the presence of metastatic breast cancer at the time of study entry with progression in 1-4 lesions (including new lesions); SBRT must be feasible for all progressing lesions.

Key Exclusion Criteria: >2 lines of systemic therapy for metastatic disease; intracranial disease progression

Primary Objective: To determine whether using SBRT to treat OP lesions allows ER+ breast cancer patients to continue on their current systemic therapy for at least 24 weeks post SBRT.

Select Secondary Objectives: To assess whether FES-PET increases the number of lesions found prior to SBRT; To determine the impact of SBRT on patient quality of life; time to next line systemic therapy; PFS

Statistical Methods Simon 2 stage optimal design with $\alpha=0.05$ and $1-\beta=0.80$. The null hypothesis is that the proportion of patients that remain on their original systemic therapy ≥24 weeks (2 restaging scans) post-treatment is 20%. The alternative hypothesis is that the proportion of patients that remain on their original systemic therapy after 2 restaging scans is 50%. In stage 1, 8 patients that proceed to SBRT will be enrolled. The study will be terminated if only 0 or 1 subjects remain on original systemic therapy after 2 restaging scans. However, if ≥2 patients remain on original systemic therapy after 2 restaging, then an additional 10 patients would be enrolled for a total of 18 patients. The null hypothesis will be rejected if ≥6 patients remain on their original systemic therapy after 2 restaging scans.

P3-11-03: De-escalation of chemotherapy in patients with HER2-positive, hormone receptor negative, node-negative early breast cancer: primary results of the phase II DECRESCENDO trial

Elisa Agostinetto, Virginie Adam, Samantha Cambier, Orsolya Birta, Chloé Velghe, Vanessa Sofia Correia de Nobrega, Luca Arecco, Celine Callens, Elise Deluche, Etienne Brain, Alessandra Gennari, Kelly-Anne Phillips, Jee Hyun Kim, Einav Gal-Yam, Leslie Gilham, Judy Needham, Philippe L. Bedard, Roisin M Connolly, Alvaro Romera, Anne Vincent-Salomon, Gabriele Zoppoli, Martine Piccart

Background: Excellent survival outcomes have been achieved with anti-HER2 therapies in patients with HER2-positive early breast cancer. For these patients, the long-term and irreversible side effects of chemotherapy remain a major concern.
Methods: DECRESCENDO (NCT04675827) is an investigator-initiated multicenter, single-arm phase II trial in patients with HER2-positive, hormone receptor negative, node-negative early breast cancer with tumor size 15-50 mm. Patients received neoadjuvant treatment with taxanes and subcutaneous fixed dose combination pertuzumab and trastuzumab (P+T) for a total duration of 12 weeks followed by surgery. Adjuvant treatment was determined according to response at surgery: patients with a pathologic complete response (pCR, defined as pT0/Tis pN0) received adjuvant P+T for additional 14 cycles, while patients with residual disease received adjuvant trastuzumab emtansine (T-DM1) for 14 cycles. Patients with a residual cancer burden (RCB) score ≥2 received 3-4 cycles of anthracycline-based chemotherapy prior to T-DM1.
Primary endpoint is 3-year relapse-free survival in patients with pCR and PAM50 HER2-enriched subtype.
PAM50 subtypes were centrally determined on baseline tumor samples.
Results: DECRESCENDO was terminated early due to slow recruitment that led to financial support withdrawal. Among 139 patients enrolled, median age was 58 years (range 29-86) and median tumor size was 24.5 mm (range 15-50 mm). Most patients had no-special type histology (N=112, 81%), and grade 3 (N=71, 51%) or grade 2 (N=51, 37%) tumors.
131 patients underwent surgery, with 113 (86%) achieving pCR/RCB 0, 10 (8%) RCB 1, and 8 (6%) RCB ≥2.
No new safety signals were identified.
PAM50 subtype was successfully determined in 124 patients (insufficient material or non-contributive test in 7 patients).
Of these, among patients who achieved pCR/RCB 0 (n=107) the most represented PAM50 subtype was the HER2-enriched one (n=87, 81%) followed by the basal-like (n=13, 12%) and luminal-A (n=7, 7%) subtypes.
Among patients with RCB 1 (n=10), 7 (70%) had HER2-enriched and 3 (30%) basal PAM50 subtype.
Among patients with RCB2 ≥ 2 (n=7), 4 (57%) had HER2-enriched, and 3 (43%) basal-like PAM50 subtype.
Conclusions: Neoadjuvant treatment with an anthracycline-free regimen in patients with HER2-positive, hormone receptor negative, node-negative early breast cancer resulted in a

high rate of pCR.
The majority of patients achieving pCR had the HER2-enriched PAM50 subtype.

P3-11-04: Treatment Patterns and Outcomes associated with the use of Neoadjuvant Chemotherapy (NACT) among Patients with Early-stage HER2-Positive Breast Cancer (BC)

Inimfon Jackson, Xiudong Lei, Catalina Malinowski, Sharon H. Giordano, Mariana Chavez-MacGregor

Background: HER2-positive BC is a clinicopathologically aggressive subtype. The emergence of targeted therapies changed the treatment landscape of this disease by decreasing the risk of recurrence and improving survival. We examined the treatment patterns and trends of NACT use, subsequent pathological complete response (pCR), and the association between pCR and overall survival (OS) in a large cohort of patients with early-stage HER2-positive BC.

Methods: Patients 18 years with clinical stage I-III HER2-positive BC diagnosed between 2010-2021 who had surgery and received chemotherapy were identified in the National Cancer Database. Trends in NACT use and pCR were assessed using the Cochran-Armitage test for time trends. Multivariable logistic regression was used to evaluate the factors associated with NACT use and pCR. Furthermore, a multivariable cox proportional hazards model with propensity score (PS) adjustment and PS matching (1:1 matching performed by exact year of diagnosis, clinical stage, and hormone receptor [HR] status) was used to examine the impact of pCR on OS.

Results: Of the 179,202 patients with HER2-positive BC who received chemotherapy, 35.39% received NACT while the rest had chemotherapy in the adjuvant setting. The rate of NACT receipt increased from 18.4% in 2010 to 60.3% in 2021 ($p<0.001$). Among patients treated with NACT, pCR rates increased from 17.5% in 2010 to 38.6% in 2021 for HER2-positive/HR-positive disease ($p<0.001$) and from 27.1% in 2010 to 65.8% in 2021 for HER2-positive/HR-negative disease ($p<0.001$). In the multivariable model, compared to non-Hispanic Whites, Black patients (aOR=0.96; 95% CI 0.92–0.99) were less likely to receive NACT while Hispanic patients were more likely (aOR=1.10; 95%CI 1.05–1.15). Among patients who received NACT, Black patients were less likely (aOR=0.88; 95%CI 0.83–0.92) to achieve a pCR, but Hispanic (aOR=1.07; 95%CI 1.01–1.14) and other (aOR=1.07; 95%CI 1.01–1.14) patients were more likely to achieve a pCR relative to White patients after adjusting for confounders. More comorbidities, older age, negative HR status, and public insurance were associated with lower odds of NACT receipt and pCR. Conversely, higher income, treatment in academic centers or integrated network cancer programs were associated with higher odds of NACT receipt and pCR. Higher tumor size and nodal stage were associated with higher odds of NACT receipt but lower pCR.

Among patients treated with NACT, having a pCR was associated with a reduction in the risk of death (aHR= 0.44; 95%CI 0.41–0.47). Based on matched pairs, the 5-year OS in patients who achieved pCR was 96% versus 89% among patients who did not (p<0.001). The 3-year OS increased from 89% in 2010 to 96% in 2018 for patients without a pCR (p<0.001), and from 97% to 99% for patients with a pCR (p=0.005).

Conclusions: NACT receipt and rates of pCR among patients with HER2-positive BC have remarkably increased in the past decade. These coincide with the improvements in treatment regimens, especially the introduction of dual anti-HER2 targeted therapy in the management of this aggressive disease. Notably, OS trends have improved for patients with and without pCR. In contrast to the Hispanic patients, Blacks were less likely to receive NACT and achieve pCR, possibly contributing to the worse outcomes seen in Black patients when compared to Whites. Further investigation is warranted to understand and address these disparities to facilitate improvement in survival outcomes.

P3-11-05: Three-year efficacy and safety of neoadjuvant chemotherapy with pertuzumab, atezolizumab, docetaxel, and trastuzumab in patients with stage II/III ERBB2-positive breast cancer (NeoPATH): a nonrandomized, multi-institutional, phase 2 trial

Junghoon Shin, Hee Kyung Ahn, Sung Hoon Sim, Koung Jin Suh, Min Hwan Kim, Jae Ho Jeong, Ji-Yeon Kim, Dae-Won Lee, Jin-Hee Ahn, Heejung Chae, Kyung-Hun Lee, Jee Hyun Kim, Keun Seok Lee, Joo Hyuk Sohn, Yoon-La Choi, Seock-Ah Im, Kyung Hae Jung, Yeon Hee Park

Background: In the primary analysis of the NeoPATH trial, neoadjuvant pertuzumab, atezolizumab, docetaxel, and trastuzumab (PATH) led to 61% of patients with stage II/III ERBB2-positive breast cancer having a pathological complete response (pCR; defined as no invasive cancer cells in the breast and regional lymph nodes [ypT0/isN0] and the absence of lymphovascular cancer invasion). Here, we report the analysis of secondary endpoints, including a 3-year event-free survival rate, overall survival, and long-term safety.
Methods: In this nonrandomized, multi-institutional, single-arm phase 2 trial, patients with stage II/III ERBB2-positive breast cancer received up to six cycles of neoadjuvant PATH, followed by definitive surgery. Patients achieving pCR received 12 cycles of adjuvant atezolizumab, trastuzumab, and pertuzumab (AHP) every 3 weeks, while those without pCR received 14 cycles of atezolizumab plus trastuzumab emtansine (T-DM1) every 3 weeks.
Results: Of the 67 enrolled patients, 65 (97%) completed six cycles of neoadjuvant therapy, and 41 (61%) achieved pCR, all completing 12 cycles of adjuvant AHP. Among the 26 patients without pCR (including one with disease progression that precluded surgery), 21 (81%) completed the 14 cycles of adjuvant atezolizumab plus T-DM1. The median follow-up was 39.4 months. The estimated 3-year event-free survival rate was 89% (95% confidence interval [CI], 81–98) in the intention-to-treat population, with rates of 97% and 75% for patients with and without pCR, respectively (hazard ratio [HR], 0.1; 95% CI, 0.01–0.83).

Five events occurred: one local disease progression that precluded surgery, two distant breast cancer recurrences, and two second primary malignancies (thymic carcinoma and glioblastoma). Only two patients died; the estimated 3-year overall survival rate was 98% (95% CI, 96–100). Grade 3 or higher adverse events occurred in 29 patients (43%), primarily during the neoadjuvant phase, most commonly neutropenia (n=11) and febrile neutropenia (n=6). Grade 3 or higher immune-related adverse events (n=4) occurred exclusively during the neoadjuvant phase, and one patient died of sepsis during adjuvant treatment.
Conclusion: In patients with stage II/III ERBB2-positive breast cancer, replacing carboplatin with atezolizumab in neoadjuvant therapy and adding atezolizumab to adjuvant therapy shows promising long-term efficacy and acceptable safety profile.

P3-11-06: Predicting the pathological response to neoadjuvant therapy using untargeted metabolomics in HER2-positive breast cancer

Marija Križić, Morana Jaganjac, Ana Kulić, Neven Žarković, Tajana Silovski, Marina Popović, Maja Sirotković-Skerlev, Gordana Ivanac, Krešimir Bulić, Mirna Halasz, Natalija Dedić Plavetić

Background: The standard treatment for HER2-positive breast cancer is the use of neoadjuvant chemotherapy with dual HER2 blockade (trastuzumab+pertuzumab). In addition to providing equal efficacy in preventing cancer recurrence and a less invasive surgical approach, response to neoadjuvant therapy (NAT) provides prognostic information for determining further adjuvant treatment. Pathologic complete response (pCR) has become a surrogate endpoint in neoadjuvant randomized clinical trials because it has been found to correlate with better long-term treatment outcomes. Many studies are currently focused on discovering predictors of response to NAT. Metabolomics is a relatively new research field focused on the analysis of small molecules (metabolites) with promising applications in personalized medicine and oncology. Neoadjuvant chemotherapy with dual HER2 blockade has led to high pCR rates, but there is still a significant number of patients with early HER2-positive breast cancer who have a partial or no response to NAT and represent an unmet medical need. The aim of this study was to find differences in the pre-NAT serum metabolomic profile of patients who achieved pCR and those with residual disease in order to discover predictive biomarkers of response to NAT.
Methods: This prospective pilot study cohort included 36 patients with HER2-positive breast cancer treated with NAT at the University Hospital Center Zagreb from August 2017 to December 2021 with prior approval of the Ethics Committee. Patients' plasma samples were collected before the start of NAT and before the last cycle of NAT. Untargeted metabolomic analysis was performed using liquid chromatography-mass spectrometry (LC-MS) and gas chromatography-mass spectrometry (GC-MS). Multivariate statistical analyses, including principal component analysis (PCA) and partial least squares analysis (PLS-DA) models, were performed. Metabolites for which the observed Variable Influence in Projection (VIP) was higher than one were considered statistically significant. The tentative

identification of metabolites was confirmed by LC–MS/MS analysis. For univariate statistical comparisons between groups Student's t-test or Mann-Whitney U test were performed, depending on data distribution, followed by Bonferroni post hoc correction for multiple comparisons ($p \leq 0.050$).
Results: Of the 36 patients included in the study, 55.5% (N=20) had pCR, while 44.5% (N=16) were classified as non-PCR. PCA and PCA DA analyzes showed different plasma metabolomic profiles before NAT in the pCR group and the group with residual disease. By tentative identification of metabolites, three metabolites were found with different concentrations in the two observed groups. Ganglioside GD3 and norajmalin were significantly higher in the group with residual disease, while undecaketide was significantly higher in the pCR group. A comparison of samples before and after NAT revealed different metabolomic signatures in which discriminatory metabolites belong to different metabolic pathways. In the group with residual disease, the concentration of ganglioside GD3 was lower in control samples taken after NAT than before NAT.
Conclusion: This study demonstrated that there are distinct plasma metabolomic profiles in patients with HER2-positive breast cancer who achieve a pCR on NAT and those with residual disease after NAT. Ganglioside GD3, previously linked to tumor progression and aggressiveness, could be a potential predictive marker of poor response to NAT in patients with HER2-positive breast cancer treated with dual HER2 blockade combined with chemotherapy.

P3-11-07: HER2 determination by ERBB2-mRNA expression analysis

Martina Vetter, Lara Bender, Marcus Bauer, Sandy Kaufhold, Volker Hanf, Christoph Uleer, Tilmann Lantzsch, Susanne Peschel, Jutta John, Marleen Pöhler, Edith Weigert, Jörg Buchmann, Markus Wallwiener, Eva Johanna Kantelhardt, Christoph Thomssen

Background and Aim: The human epidermal growth factor receptor 2 (HER2) is overexpressed in 15-20% of breast carcinomas (BC). Patients with inoperable or metastatic BC and low HER2 expression (HER2-low) may benefit from trastuzumab-deruxtecan. The aim of this study was to compare HER2 status with ERBB2-mRNA expression analysis, and to analyze the association of ERBB2-mRNA expression with disease progression of the patients.

Material and Methods: The HER2 determination (i.e. clinical testing) in a sample of 694 BC patients from a prospective, multicentre cohort (n=1,270, NCT 01592825, 2009-2011) was performed according to ASCO/CAP of the respective time by the local pathology (n=3), and provided the following distribution: HER2-zero (IHC 0) 34% (n=237), HER2-low (IHC 1+, IHC 2+, ISH negative) 52% (n=360), and HER2-positive (IHC 2+, ISH positive, IHC 3+) 14% (n=97). ERBB2-mRNA expression was determined using high-throughput qPCR. The cut-off values for three ERBB2-mRNA categories were calculated by ROC analyses, adjusted to the HER2 results. The associations with prognostic markers and survival (recurrence-free interval, RFI) were estimated by linear regression (odds ratios, OR) and Kaplan-Meier

analyses.

Results: Relative mRNA expression < 9.7 classified samples as ERBB2-weak, ≥ 9.7 and < 23.2 as ERBB2-intermediate (AUC 0.72), and ≥ 23.2 as ERBB2-high (AUC 0.86). In our cohort 48% (n=333) of the samples were ERBB2-weak, 36% (n=252) ERBB2-intermediate and 16% (n=109) ERBB2-high tumours. Thus, compared to the tumors that were classified as HER2-low by clinical testing, ERBB2-mRNA expression analyses reduced the proportion by 30%. With regard to the HER2-zero samples, 32 % (n=76) were categorized as ERBB2-intermediate (n=61) or ERBB2-high (n=15), and 68% (n=161) were identified as ERBB2-weak. From 597 HER2-negative tumors, 43 (7.2%) tumors were classified as ERBB2-high, and from 97 HER2-positive tumors, 32% were reclassified as ERBB2-intermediate (n=21) or ERBB2-weak (n=10). Compared to ERBB2-weak, ERBB2-intermediate tumours were significantly more frequently associated with a positive hormone receptor status (HR) (OR 4.0; 95% CI 2.25-7.05), favourable grade (G1/2 vs 3; OR 2.1; 95% CI 1.45-3.04), and smaller tumor size (T1 vs >T1; OR 1.4; 95% CI 1.04-1.93).These patients had fewer disease related events after five years (no RFI events: 94%, 95% CI 90.9 – 97.1) than patients with an ERBB2-weak tumours (no RFI events 89%, 95% CI 86.0 – 92.6, p=0.008), presumably since they received endocrine therapy more frequently.

Conclusion: In this retrospective analysis, ERBB2-mRNA analyses provided results that were different from clinical HER2 testing, and may be more accurate to define HER2-zero, low and positive status. In our study, using routine clinical HER2-testing, the proportion of low HER2 expressors (i.e. ERBB2-intermediate) was reduced by 30%. On the other hand, ERBB2-mRNA analysis increased the proportion of tumours that potentially would respond to anti-HER2 therapy. Considering the tumor characteristics (e.g. HR, grade, size), our data suggest that ERBB2-intermediate/HER2-low may be an own entity.

P3-11-08: Treatment patterns and impact of adjuvant chemotherapy and targeted therapy on outcomes in HER2+ microinvasive breast cancer

Abha Kulkarni, Celine Yeh, Rachel Han, Charlie White, Yuan Chen, Edi Brogi, Andrew Seidman

Microinvasive breast carcinoma (MiBC) is defined as invasive breast carcinoma ≤1 mm in size. MiBC is most commonly encountered in the setting of high-grade human epidermal growth factor receptor (HER2) positive ductal carcinoma in situ (DCIS) and may consist of one or more foci. Most MiBC is HER2+, and some studies suggest it may be associated with a worse prognosis than pure DCIS. Evidence-based guidelines on the role for adjuvant systemic therapy in HER2+ lymph node negative (LN-) MiBC are lacking, particularly for cases with multifocal microinvasion. Our objectives were to analyze treatment patterns and assess clinical benefit of adjuvant chemotherapy with or without HER2-targeted therapy (CT/H2TT) in this subgroup. We conducted a retrospective analysis of patients with

HER2+ LN- MiBC treated at Memorial Sloan Kettering Cancer Center from 1/1/09-9/30/23. Patients with macroinvasive breast cancer in the preceding 20 years or concurrent to the index MiBC were excluded. Pathologic and clinical data were obtained by a review of pathology reports, slides, and medical records. Pathology slides were reviewed whenever available to confirm MiBC focality. The primary outcome was invasive disease-free survival (iDFS) defined as time from date of surgery to invasion, recurrence, or death. Alive patients without recurrence were censored at last known no evidence of disease (NED) date. The Kaplan-Meier method was used to estimate iDFS. The log-rank test was used to compare iDFS between different groups. We identified 213 patients with HER2+ LN- MiBC who met inclusion criteria. The number of MiBC foci ranged from 1 to 41. Most patients had <5 foci (141, 68%). Compared to patients with <5 foci of MiBC (n=141), patients with ≥5 foci (n=65) were more likely to undergo total mastectomy than breast conserving surgery (72% vs 55%, p=0.02), and receive adjuvant CT/H2TT (39% vs 6.4%, p<0.001), predominantly (94%) trastuzumab/paclitaxel. Age (56 vs 51 years, p=0.1), rates of ER/PR+ (27% vs 18%, p=0.12), adjuvant antiestrogen therapy (28% vs 22%, p=0.3), and adjuvant radiotherapy (44% vs 34%, p=0.2) did not differ significantly between the <5 foci and ≥5 foci cohorts. In the overall cohort, there were 12 invasive disease-free survival (iDFS) events: 2 distant recurrences, 7 local recurrences, 1 contralateral HER2-negative new breast primary, 1 non-BC related death, and 1 death from unknown cause. There was no significant difference in iDFS between patients with <5 vs ≥5 foci (p=0.7). The 5-year iDFS rates in patients with <5 and ≥5 foci were 94% and 95%, respectively. Among patients with ≥5 foci, there was no significant difference in iDFS between those who received adjuvant CT/H2TT (25, 39%) and those who did not (39, 61%) (p=0.4). iDFS did not differ between those with a single focus (n=58) and multiple foci (n=155) of MI (p=0.7). Our study found that there is no difference in iDFS between the patients with <5 and ≥5 foci or those with a single focus and multiple foci of MI. In the cohort with ≥5 foci, we did not detect a statistically significant iDFS advantage for adjuvant CT/H2TT compared to observation following local therapy. Although the small number of events limits statistical power, these findings suggest that patients with HER2+ LN- MiBC and ≥5 foci of MI are generally treated more aggressively than those with <5 foci without significant clinical benefit. Further investigation in a larger cohort is underway to determine optimal management of HER2+ LN- MiBC.

P3-11-09: Incidence and Treatment Patterns of High-Risk HER2+ Early-Stage Breast Cancer Patients in the United States Community Oncology Setting

Sandhya Mehta, Michael Danso, Ila Sruti, Karen Todoroff, Carlos Yugar, Paul Conkling

Background: Clinical staging of HER2+ early-stage breast cancer (eBC) is key to patients receiving appropriate care. Patients categorized as high-risk are at increased risk of recurrence, hence neoadjuvant treatment is recommended for these patients. With the advent of novel antibody drug conjugates for treatment of high-risk HER2+ eBC, it is

important to understand risk-status assessment and current treatment landscape. This real-world study aimed to describe the incidence of high-risk HER2+ eBC, treatment patterns and rates of recurrence with distant metastases during the follow-up period within community oncology settings in the United States (US).

Methods: A retrospective study utilizing electronic medical record data from The US Oncology Network was conducted. Adult (≥21 years) patients with diagnosis of HER2+ eBC and not enrolled in a clinical trial between 01/01/2017 and 03/31/2023 (earliest diagnosis date as index date) were included in the study and were followed until 09/30/2023. Risk assessment was defined as high risk (Tumor size: T0-T4, nodal involvement: N1-3, distant metastases: M0), moderate to high risk (T2, N0, M0), or low risk (T1a-T1c, N0, M0). Incidence of high-risk HER2+ eBC, patient characteristics, neoadjuvant and adjuvant treatment patterns, and rates of distant metastases during the follow-up period were analyzed descriptively. Among high-risk HER2+ eBC patients, factors associated with receipt of neoadjuvant treatment were assessed using multivariable logistic regression.

Results: 5,487 HER2+ eBC patients met study criteria, of which 4,125 had documented TNM staging. Among the 4,125 patients with available risk assessment, 38% were high-risk (n=1,567), 24.6% were moderate to high risk (n=1,016) and 37.4% were low risk (n=1,542). High-risk HER2+ eBC patients had a mean (SD) age of 56.6 (14.1) years, were majority White (n=967, 61.7%), with nodal involvement (n=1,413, 90.17%) and postmenopausal (n=909, 58%). Neoadjuvant and adjuvant treatments were initiated among 62.6% (n=981) and 91.4% (n=1,432) of high-risk patients, respectively. Of high-risk patients with neoadjuvant treatment (n=981), majority received TCHP (docetaxal + carboplatin + trastuzumab + pertuzumab) regimen (n=807, 82.3%). Of those with adjuvant treatment (n=1,432), about 35.9% (n=514) received trastuzumab+pertuzumab based regimen (±hormonal therapy), 22% (n=318) received T-DM1 and 14.4% (n=206) received TCHP. During the follow-up period (median 31.9 months), 4.6% (n=45) of high-risk patients with neoadjuvant treatment progressed to distant metastases compared to 10.9% (n=64) of high-risk patients without neoadjuvant treatment. Multivariable logistic regression model adjusting for age, race, practice location, menopausal status, and hormone receptor status revealed that older high-risk patients, those in perimenopausal phase (vs. premenopausal) were less likely to receive neoadjuvant treatment; whereas patients with a negative hormone receptor status (vs. positive) were more likely to receive neoadjuvant treatment (p-value <0.05).

Conclusion: In this large sample of real-world HER2+ eBC patients treated in the US community practice setting, over one-third of patients met criteria of being at a high-risk of recurrence. Neoadjuvant treatment for these patients primarily comprised of dual HER2 targeted treatment and two different chemotherapies and adjuvant treatment varied. Despite established guidelines for preoperative systemic therapy for high-risk HER2+ eBC

patients, many patients did not initiate neoadjuvant treatment and had higher rates of metastases, demonstrating unmet need and opportunity to improve health outcomes.

P3-11-10: Benefit/risk relationship of TCH versus AC-TH in BCIRG 006: analysis using generalized pairwise comparisons

Marc Buyse, Gonzalo Spera, Everardo D. Saad, Miguel Martin, Peter A. Fasching, Rodrigo Fresco, John Crown, Arlene Chan, Linnea Chap, Tadeusz Pienkowski, Vicente Valero, Valerie Bee, Hatem Alharazin, Samuel Salvaggio, Dennis Slamon

Purpose: Given the nominally superior disease-free and overall survival for doxorubicin, cyclophosphamide, docetaxel, and trastuzumab (AC-TH) versus docetaxel, carboplatin, and trastuzumab (TCH), but significantly improved cardiac safety and lower incidence of leukemia with TCH than with AC-TH, we formally assessed the benefit/risk relationship of these two regimens using Generalized Pairwise Comparisons, a novel method that yields a single efficacy measure that represents multiple outcomes under a single statistical test.

Patients and Methods: We used data from BCIRG 006 with a median follow-up of 10.5 years in order to compare AC-TH and TCH regarding the following outcomes analyzed in this order of priority: time to death; time to distant metastases; time to second primary cancer, including leukemia; time to locoregional relapse; occurrence of congestive heart failure; time to left-ventricular ejection fraction (LVEF) loss >30%; time to LVEF loss >25%; and time to LVEF loss >20%. We computed the Net Treatment Benefit (NTB), a measure of benefit/risk that can be interpreted as the net probability that a random patient from the TCH arm would have a more favorable outcome than a random patient from the AC-TH arm, given the prioritized outcomes.

Results: In keeping with the original analysis at a median follow-up of 65 months, there was no significant difference between TCH and AC-TH in individual outcomes related to survival or to cancer-related events but, TCH was significantly superior to AC-TH for all individual outcomes related to cardiac safety. In multivariate analysis with all outcomes combined in the prespecified order, 36.0% of the pairwise comparisons favored TCH and 29.1% favored AC-TH, resulting in an NTB of 6.9% in favor of TCH (P=0.025). This translates into a number needed-to-treat of approximately 15 patients in favor of TCH.
Conclusion: Using a methodologically rigorous, single measure of treatment effect, the NTB significantly favors TCH when outcomes are prioritized as specified here.

P3-11-11: Ductal Carcinoma in Situ: Molecular and Cellular Basis of Malignant Transition

Fariba Behbod, Emily Nissen, Yan Hong, Veena Kochat, Rashna Madan, Seema Khan, Andrew K. Godwin, Devin C. Koestler, Mahinur Maitituoheti, Kunal Rai

Background: The goal of this study is to test whether cellular stemness drives the metastatic progression of human DCIS. DCIS is the most common type of non-invasive breast cancer and is considered a precursor to invasive ductal carcinoma (IDC). The 20-year breast cancer-specific mortality rate following a DCIS diagnosis is approximately 3.3%. The current radiation and anti-hormonal therapy have not reduced mortality associated with DCIS, which is quite intriguing. Moreover, significant racial disparities exist in mortality outcomes since Black women with DCIS compared to White women demonstrate a 7.5-fold increase in breast cancer-related mortality as well as a 12-fold risk when diagnosed before the age of 50. While the reasons for these racial disparities are not known, previous studies have suggested increased stem cell-like characteristics in breast cancer cells from women of African ancestry as compared to those with Caucasian ancestry. Additionally, studies have shown that HER2 could be a potential biomarker for DCIS, indicating future risk of regional and distant metastasis. Approach: We have developed a model referred to as the Mouse INtraDuctal (MIND) model, which mimics the non-invasive to invasive transition of human breast cancers. To generate the models, DCIS tissues were obtained from the clinics and digested into single cells followed by their intraductal injection to generate the MIND models, and a portion of the cells were subjected to single-cell transcriptomic and epigenomic analysis. Patient DCIS and DCIS with associated IDC were also subjected to spatial transcriptomics. Results: We conducted scATAC/RNA sequencing on epithelial cells from ten patients with DCIS and DCIS with associated IDC. The analysis of stemness using CytoTRAE as defined by Gulati et al., revealed that two clusters (9 & 0) had the highest stemness scores. These two clusters also exhibited high expression of FOXA1, and a strong correlation was observed between stemness score and FOXA1 expression, particularly in HER2-3+ DCIS/IDC samples compared to HER2-3+ pure DCIS, luminal or TNBC. We also found that the open chromatin regions in the stemness clusters were highly enriched for FOXA1 binding motifs, particularly in HER2-3+ DCIS/IDC samples. Additionally, single-cell RNA sequencing was performed on 60,000 cells from 17 samples of DCIS, including 9 that progressed in the MIND models and 8 that remained non-invasive. The stemness scores, determined using CytoTRACE were significantly higher in progressed DCIS cells compared to non-progressed cells. There was also a notable correlation between the expression of FOXA1 and the stemness scores. Additionally, we performed spatial transcriptomics (10x Genomics-Xenium) on sixteen patient DCIS samples, including eleven HER2-3+ (five pure DCIS and six DCIS/IDC) and five HER2-negative (three pure DCIS and two DCIS/IDC). As expected, the CytoTRACE analysis indicated that luminal HR+ epithelial cells in DCIS/IDC HER2-3+ samples exhibited the highest overall level of stemness. FOXA1 was identified as one of the top 10 genes associated with stemness. Ligand receptor (LR) interaction analysis identified the highest dissimilar LR pairs was CEACAM6-EGFR. CEACAM6 was upregulated on luminal HR+ cells with the highest stemness scores and interacted with EGFR expressed

by luminal secretory, B cells, T cells, myeloid, mast cells vascular and lymphatic cells. High CEACAM6 expression is associated with poor survival and metastasis in several cancer types, including pancreatic cancers and breast cancers. Conclusion: The presence of a spatial niche containing stem-like cells with increased epigenetic activity of FOXA1 may drive the invasive and metastatic progression in DCIS. We suggest that targeting the activity of FOXA1 can inhibit the function of these stem-like cells and prevent metastatic or invasive progression of human DCIS. Additionally, CEACAM6-EGFR may facilitate communication between epithelial stem cells and their stromal niches, promoting progression.

P3-11-12: (Neo)adjuvant Therapy Patterns and Outcomes in Patients with HR-Positive/HER2-Positive Early or Locally Advanced Breast Cancer: a Real-World Study Using National Cancer Information Database, China

Zhenzhen Liu, Jiujun Zhu, Chengzheng Wang, Zhenduo Lu, Xiuchun Chen, Lianfang Li, Xianfu Sun, Chongjian Zhang, Jianghua Qiao, Min Yan

Background: Our previous national-wide analysis in representative large samples identified molecular subtype of hormone receptor-positive/human epidermal growth factor receptor 2-positive (HR+/HER2+) accounting for 18.0% of all breast cancers (BC), and 25.4% of HR+/HER2+ early or locally advanced (EBC or LABC) patients received neoadjuvant therapy in the real-world setting in China. This study reported further results regarding short-term response and mid-term survival outcomes.

Methods: A representative sample of 51 hospitals (31 cancer centers and 20 general hospitals) covering 27 provinces or municipalities from the National Cancer Information Database (NCID) in China was used. Anonymous individual patient data from electronic medical records (EMR) were retrieved to extract information on demographics, disease characteristics, clinical features, therapy modalities, and outcomes. HR+/HER2+ EBC or LBC patients initially diagnosed between 1 January 2019 and 31 May 2022 were included if they had (1) received surgery and adjuvant treatment and (2) had post-surgery pathologic reports. Descriptive statistics was used to illustrate the distribution of patients in different subgroups with or without neoadjuvant therapy. Survival probability was calculated by the Kaplan-Meier method.

Results: 13,323 Chinese patients initially diagnosed with HR+/HER2+ EBC or LABC were identified during the study period. Most patients' data were derived from tertiary hospitals (n = 13321 [99.98%]), Cancer Centers (n = 11212 [84.16%]), and second-tier cities (n = 10089 [75.73%]). For the clinical stage, patients with cT2 (58.87%), cN0 (45.83%), or cN1 (35.01%) tumors were predominated. 3,791/13323 patients received neoadjuvant therapy. Combinations of two anti-HER2 agents + Chemo (2089/3791) topped the list of neoadjuvant regimens, of which trastuzumab-pertuzumab (TP) + chemotherapy (Chemo) (1970/3791[52.0%]) was the most frequently used therapy, while TP+ a tyrosine kinase

inhibitor (n = 41) was used less frequently. T+ Chemo was reported in 649 patients and Chemo only was documented in 980 patients. Compared to neoadjuvant T + Chemo, combinations of two anti-HER2 agents + Chemo yielded significantly higher total pathological complete response (tpCR, 29.86% vs. 49.14%) and breast pCR (bpCR, 34.39% vs. 53.30%), both $p<0.0001$. Generally, patients who achieved tpCR had a lower recurrence rate than those who did not. Neoadjuvant TP followed by adjuvant TP appeared to be the most selected sequential regimen, the recurrence rate is 2.6% (3-yr-DFS: 94.83%) for patients with tpCR and 5.4% (3-yr-DFS: 80.86%) for who without tpCR. For patients that received neoadjuvant TP, following adjuvant TP led to a lower recurrence rate than T (2.6% vs. 4.9% in tpCR patients and 5.4% vs. 15.9% in patients without tpCR).

Conclusions: To our knowledge, this is the first and largest longitudinal real-world study focusing on perioperative therapy utilization patterns, and short-term and mid-term outcomes in HR+/HER2+ EBC or LABC patients in China. The study, whether in terms of geographical coverage, hospital level, number of patients population, or the study period (that followed the launch of pertuzumab, which is one of the current standard-of-care treatments for patients with HER2+ BC), can represent the up-to-date diagnosis and treatment status quo in China. Our results provide evidence from clinical practice to verify the remarkable pCR and DFS outcomes derived from perioperative dual HER2 blockade with TP.

P3-11-13: Efficacy and Safety of Chemo-Free Regimens in HER2-Positive Early Breast Cancer: A Comprehensive Systematic Review and Meta-Analysis

Zaheer Qureshi, Abdur Jamil, Faryal Altaf, Rimsha Siddique, Mohsin Ahmad, Moazzam Shahzad

Background: Human epidermal growth factor receptor-2 (HER2)-positive breast cancer is a rapidly growing cancer that has poor outcomes if left untreated. Generally, this cancer requires treatment with aggressive chemotherapy and HER2-targeting therapies. However, there is increasing evidence in randomized clinical trials (RCTs) that chemotherapy-free regimens can improve outcomes of HER2-positive early breast cancer while maintaining high oncogenic safety.

Objective: To examine the efficacy and safety of chemotherapy-free regimens in patients with HER2-positive early breast cancer.

Methods: A systematic literature search for randomized trials published until July 2024 was conducted on PubMed, CENTRAL, Google Scholar, and Embase. Trials were eligible if they compared chemotherapy-free HER2-targeted therapies to HER2-targeted therapies combined with chemotherapy in women with early-stage HER2-positive breast cancer. Conversely, trials that examined chemotherapy-free regimens in advanced HER2-positive breast cancer and observational studies were excluded. The primary endpoint of our study was pathological complete response (pCR), and the secondary outcomes were event-free survival (EFS), invasive Disease-free survival (iDFS), and discontinuation from treatment due to drug-related adverse events. EFS encompassed both relapse-free survival and progression-free survival. All outcomes were pooled together using the random-effects model. Moreover, subgroup analysis was performed to outline the effect of each chemo-free therapy on pCR and assess survival outcomes over different assessment periods. Furthermore, we examined the impact of hormone receptor (HR) status on pCR in patients receiving chemo-free therapies.

Results:Six randomized trials, including 1976 patients with early-stage HER2-positive breast cancer, met the inclusion criteria for this meta-analysis. The pooled results showed that about 35.5% (269/757) of patients receiving chemo-free therapies achieve pCR. However, the subgroup analysis revealed that patients treated with trastuzumab plus pertuzumab and those treated with trastuzumab emtansine plus pertuzumab had significantly inferior pCR than those receiving chemotherapy combined with anti-HER2 drugs (OR: 0.22, p=0.0002 and OR: 0.69, p=0.04). Additionally, the pooled results showed that among patients receiving chemo-free therapies, those with HR-positive disease had inferior pCR than those with HR-negative disease (OR: 2.92, p=0.05). The subgroup analyses also demonstrated that patients receiving chemo-free therapies have high 3-year and 5-year iDFS (96.84% and 87%) and EFS (94.75% and 81.13%). Regarding safety, the pooled results revealed that the discontinuation rates due to adverse events were statistically similar between the two groups (OR: 0.69, p=0.55).

Discussion/Conclusion: Chemotherapy-free regimens demonstrate promising responses and survival outcomes in patients with HER2-positive early breast cancer. However, combining anti-HER2 drugs with chemotherapy still demonstrates better clinical outcomes. Therefore, omitting chemotherapy outside clinical trials might expose patients to unnecessary risks. Moreover, pCR was more significant in patients with HR-negative disease, suggesting that chemo-free therapies might be more beneficial in these patients.

P3-11-14: Differential response to neoadjuvant antiHER2 therapy between HER2 2+ISH+ and HER2 3+ in HER2-positive breast cancer: Is HER2 2+ISH+ a distinct subtype?

Lingjun Ma, Lexin Wang, Xuan Li, Ran Zheng, Jingjing Ding, Yichun Gong, Hao Yao, Yuanyuan Wang, Xiaoming Zha, Jue Wang

Background: Neoadjuvant chemotherapy with dual anti-HER2 therapy has become the standard neoadjuvant systematic treatment (NST) for HER2-positive breast cancer patients. However, the efficacy of neoadjuvant anti-HER2 therapy varies greatly, different HER2 protein expression level of tumor cell is one of the reasons. Several studies have shown that the HER2 protein expression level is an independent impact factor of pathologic complete response (pCR) rate, HER2 2+ISH+ group patients have a poorer response to NST. However, few studies have explored the relationship between the use of single or dual anti-HER2 agents with HER2 protein expression and its impact of efficacy in pCR and survival.
This study analyzes the pCR rate of patients with different HER2 protein expression level receiving single or dual anti-HER2 therapies. We aimed to identify poor respondors to anti-HER2 therapy, whom in need of optimization and individualization of NST regimen.

Methods: A total of 575 HER2-positive breast cancer patients from multiple centers in Nanjing, China during 2013 to 2022 were retrospectively analyzed, containing of 117 HER2 2+ISH+ patients (20.3%) and 458 HER2 3+ patients (79.7%). All patients received neoadjuvant chemotherapy and anti-HER2 therapy, which is Trastuzumab with or without Pertuzumab. We performed subgroup analysis according to different HER2 IHC classes (HER2 2+ISH+ or HER2 3+), evaluating their difference in clinicopathological features, response to NST under different HR (hormone receptor)status and anti-HER2 therapy. Category changes of HER2 IHC from core needle biopsy(CNB) previous to NST to residue disease after NST and the impact of different HER2+classes on survival were analyzed as well.

Results: [Difference in Clinicopathologic characters]
The HER2 2+ISH+ subgroup had a higher proportion of HR+ status than HER2 3+ patients (76.1% vs 48.7%, $p < 0.001$).
[Different response of HER2+ classes to NST stratified by anti-HER2 therapy]
HER2 2+ISH+ subgroup had significantly lower pCR rate (16.24% vs 46.07%, $p < 0.001$). Multivariate regression analysis based on HER2 IHC subgroups showed that premenopausal status (OR=4.435, 95%CI 1.205-16.324, p=0.025) and HR-status (OR=4.863, 95%CI 1.373-17.228, p=0.014) were favorable factors for pCR in HER2 2+ISH+ patients. However, the use of single or dual anti-HER2 therapy was not an independent impact factor (OR=0.537, 95% CI 0.171-1.685, p=0.287), especially in HER2 2+ISH+/HR+ subgroup, the pCR rates were 11.11% and 13.21%, respectively, with no significant difference (OR=0.821, 95%CI 0.222-3.04, p=0.768). While in HER2 +ISH+/ER- subgroup, the pCR rates were 15.38% and 40.0%, respectively, showing an increase in pCR rate with the use of dual anti-HER2 therapy, but has no statistic significance (OR=0.273, 95%CI 0.044-1.695, p=0.163).

In HER2 3+ patients, dual anti-HER2 therapy were beneficial for pCR (OR= 2.760, 95%CI 1.734-4.392, p < 0.001), while HR status shows no significant impact (OR=1.382, 95%CI 0.934-2.044, p=0.105).
[Category change of HER2 IHC from CNB to residue disease]
We also found that HER2 2+ISH+ subgroup tend to has more HER2 protein expression loss than that in the HER2 3+ patients. The proportion of patients who converted to HER2 0 or 1+ after NST was 22.2% vs. 3.7%, respectively in HER2 2+ISH+ and HER2 3+ subgroup (Kappa=0.329, p < 0.001).
[Impact of different HER2+ classes to survivial]
After a median follow-up of 49.6 months, survival analysis showed that patients who received pCR had significantly better disease-free survival (DFS) rate than those who did not (Log-rank p=0.0003). There was a trend toward a longer DFS in patients with HER2 IHC 3+ than in HER2 2+ISH+ patients (the estimated 5-year DFS: 89.6% vs. 83.8%; estimated 10-year DFS: 89.6% vs. 67.1%), wheras with no statistic significance (p=0.354).

Conclusion: In HER2+ patients, HER2 2+ISH+ subgroup showed a poor response to NST. So we consider it to be a distinct subtype and define it as the HER2-weak subgroup. In HER2-weak subgroup, receiving dual anti-HER2 therapy did not exert significant improvement in pCR rate compared to single anti-HER2 therapy, especially in HR+ patients. Therefore, further optimize and individualize NST regimen is needed for HER2-weak patients, among which ADC drugs and neoadjuvant endocrine therapy are potential optimization agents. Additionally, considering the increasing HER2 protein expression loss in HER2-weak group, a secondary detection to HER2 IHC and after NST seems necessary. Furthermore, researches with large sample sizes and long time follow-up are still in need to confirm the impact of different HER2+ classes to survivial.

P3-11-15: De-escalating neoadjuvant chemotherapy in early HER2+ breast cancer: a retrospective case series

Patricia Avancena, Sabina Hajiyeva, Elena Katz, Sandy Ching, Sharon Rosenbaum-Smith, Janet Yeh, Paul Baron, Francisco J Esteva

Purpose: In HER2-positive breast cancer (HER2+ BC), neoadjuvant chemotherapy (NACT) with dual HER2-targeted therapy achieves high pathologic complete response (pCR) rates. One of the most used regimens is docetaxel, carboplatin, trastuzumab, and pertuzumab (TCHP). Several studies have shown that a shorter weekly paclitaxel and carboplatin (wPC) regimen can be as effective as the standard TCHP, with less toxicity. Here, we report our de-escalation experience using neoadjuvant wPCHP in early HER2+ BC. Methods: This retrospective review included patients diagnosed with non-metastatic HER2+ breast cancer who completed HER2-targeted neoadjuvant systemic therapy and underwent surgery at Lenox Hill Hospital between January 1, 2023, and May 2024. The clinical stage was calculated based on tumor size and nodal status. The received operative treatment was recorded to determine the pathologic stage and chemotherapy response. The chemotherapy

backbone consisted of weekly paclitaxel 80 mg/m^2 x 12, with or without weekly carboplatin AUC2. All patients received pertuzumab and trastuzumab hyaluronidase (Phesgo) subcutaneously every three weeks before surgery. The study endpoint, pCR, was assessed after definitive surgery. Residual cancer burden (RCB) was calculated using the method validated by I-SPY investigators. pCR was defined as no evidence of invasive disease in the breast or lymph nodes (RCB 0). Dose modifications and post-op therapy were at the physician's discretion.

Results: In patients treated with neoadjuvant wTHP (n=9), the pCR rate was 44%; 56% achieved pCR or RCB1, indicating a good prognosis. Within this RCB 0-1 subset, the pCR rate was 75% in patients with hormone receptor-negative BC. In the cohort treated with neoadjuvant wPCHP (n=21), the pCR rate was 62%; 67% scored in the RCB 0-1 range; of this subset, the pCR rate was 87% in patients with hormone receptor-negative disease. No patients transitioned to an anthracycline-based regimen for non-response. There were no episodes of febrile neutropenia or grade ≥3 peripheral neuropathy. The most common toxicities were neutropenia and grade 1-2 peripheral neuropathy. No patients developed heart failure. Postoperative treatment was based on pathological response, following national guidelines.

Conclusion: pCR rates with wPCHP are as high as those reported with the docetaxel-based TCHP regimen, with fewer grade ≥3 toxicities. A subset of patients, particularly those with stage I and ER/PR-negative disease, may not need carboplatin. The wPCHP regimen should be considered an alternative to standard TCHP as neoadjuvant therapy for HER2+ BC.

P3-11-16: Personalized Neoadjuvant Therapy Guided by Drug Screening of Patient-Derived Tumor-Like Cell Clusters in HER2-Positive Breast Cancer: A Prospective Phase II Study and Exploratory Analysis

Yaqian Xu, Chaobin Wang, Xiangui Zhang, Shenyi Yin, Houpu Yang, Fei Xie, Yuan Peng, Yang Yang, Wei Du, Jianzhong Xi, Shu Wang

Background: HER2-positive breast cancer exhibits unique characteristics that can significantly influence patients' response to neoadjuvant therapy. There is a critical need for a platform that facilitates in vitro drug screening and tailors personalized treatment regimens for such patients. Previously, we introduced an in vitro model named 'patient-derived tumor-like cell clusters' (PTCs), a cell cluster including tumor cells, mesenchymal cells, and lymphocytes, which accurately replicates the structural, functional, and micro-environmental features of the original tumors. Our retrospective research has shown that PTCs could serve as a reliable preclinical model for drug screening, and thereby, to guide neoadjuvant therapy strategies for patients with breast cancer. This prospective, phase II, open-label study (ClinicalTrials.gov No. NCT04750122) aims to prospectively investigate efficacy of personalized neoadjuvant therapy guided by drug sensitivity profiles of PTCs in HER2-positive breast cancer and to reveal biomarkers associated with resistance to anti-HER2 targeted therapies.

Methods: Tissues were obtained by core needle biopsy of candidate patients and cultured to generate PTCs, which were subsequently subjected to drug sensitivity testing and bulk RNA sequencing. Patients with HER2-positive breast cancer were assigned to neoadjuvant therapy according to their individual drug sensitivity profiles. The treatment regimens included THP (taxanes, trastuzumab, and pertuzumab), TCbHP (taxanes, carboplatin, trastuzumab, and pertuzumab), or treatment of physician's choice (TPC). After completing neoadjuvant therapy, surgery was performed to evaluate the pCR rates of PTC-guided treatment (PGT) and TPC. For the PTCs subjected to RNA-seq, drug sensitivity testing was conducted using H, P, trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-Dxd), respectively. The gene expression data was then analyzed to identify potential biomarkers by differentially-expressed-gene analysis and to establish a predictive model for therapeutic efficacy by logistic regression analysis.

Results: From April 2021 to July 2023, a total of 729 samples were collected by core needle biopsy from candidate patients, among whom 592 patients were diagnosed as invasive breast cancer. The success rate of generating PTCs through invasive breast cancer was 83.4%. Overall, 24 patients with HER2+ breast cancer that successfully constructed PTCs and drug sensitivity tests were enrolled in this study. Nineteen patients (79.2%) had T2-3 tumors and nineteen (79.2%) had node-positive disease. The in vitro drug sensitivity profiles suggested that 6 patients (25%) were sensitive to THP, 14 (58.3%) were sensitive to TCbHP, and 4 (16.7%) were resistant to both. Following neoadjuvant treatment, the patients that received THP treatment achieved a pCR rate of 83.3%, while the patients that were sensitive to TCbHP rather than THP achieved a pCR rate of 78.6%. Compared to only 1 out of the 4 patients with resistant PTCs achieved pCR, 16 of the 20 patients receiving PGT achieved pCR (80.0% vs 25.0%, p=0.027). In subgroup analyses of the PGT counterparts, the pCR rates were 62.5% for HR+/HER2+ patients and 91.7% for HR-/HER2+ patients. Besides, 14 PTC samples carried on bulk RNA sequencing. As a result, 5 co-upregulated genes (PLBD1, BMP3, HLA-DRB5, IGLV2-14, TIAF1) and 5 co-downregulated genes (EPN3, KCNK15, ACSF2, AC025048.2, PIP4K2B) were identified in the resistant group compared with the sensitive group. The multidrug resistance signature was utilized to establish a predictive model, of which the area under curves were 100.0% for predicting response to H, P, T-DM1, and T-Dxd.

Conclusion: The in vitro drug screening PTC platform could serve as a promising approach for tailoring personalized neoadjuvant treatment strategies for HER2-positive breast cancer. The identification of multidrug resistance signature emerges as a practical and effective biomarker for forecasting the response to anti-HER2 targeted therapies.

P3-11-17: A Randomized Phase II Trial of Neo-adjuvant Chemotherapy with Metformin or Placebo for HER-2 Positive Operable Breast Cancer (The HERMET Trial)

Maire Okoniewski, Cory Bivona, Colleen Bohnenkamp, Francisco Diaz, Junqiang Dai, Lauren Nye, Anne O'Dea, Kelsey Larson, Deepti Satelli, Jamie Wagner, Christa Balanoff, Lyndsey Kilgore, Stephanie Lafaver, Jamie Heldstab, Priyanka Sharma, Qamar Khan

Background: Human epidermal growth factor receptor 2 (HER-2) is overexpressed in 15-20% of breast cancer (BC). Pathologic complete response (pCR) after HER-2 directed chemotherapy is an important surrogate marker for survival in HER-2+ operable BC. Patients with diabetes who receive metformin have a lower risk of metastasis in HER-2+ breast cancer. Metformin's inhibition of PI3K/AKT/mTOR pathway through IGF receptor inhibition has been proposed as a possible mechanism. However, its clinical benefit as an anticancer agent is not clear. We conducted a randomized, placebo-controlled study to assess the impact of adding metformin or placebo to neoadjuvant docetaxel, carboplatin, trastuzumab and pertuzumab (TCH-P) in HER2 positive breast cancer.

Methods: Patients with HER-2+ operable breast cancer with at least 2 cm breast primary and/or axillary lymph node positive disease were eligible. HER-2 positivity was defined by the current ASCO-CAP guidelines. Patients were randomized 1:1 to receive neoadjuvant TCH-P every 3 weeks for 6 cycles, plus placebo (N=30) or metformin (N=31). Metformin dose was ramped up over the first 3 cycles to a target of 1500 mg twice daily on days 8-21 of each cycle. Breast surgery was performed 3-6 weeks after final chemotherapy cycle. The primary endpoint was pCR in breast and axilla. Subjects with unevaluable pCR were treated as non-responders for intent-to-treat analyses.

Results: 61 patients were enrolled between 8/17/2017 and 03/21/2023. Median age was 51 years. 51% of the patients had node positive disease and 67% had estrogen receptor (ER) positive breast cancer. Among all patients pCR in both breast and axilla was 43.3% in TCH-P plus placebo group and 54.8% in the metformin group (p= 0.37). In patients with ER+ breast cancer pCR was 42.9% in placebo group and 40.0% in metformin group (p=0.85).
Grade ≥3 adverse events occurred in 40% of placebo subjects and 48% of metformin subjects. Grade 3 diarrhea occurred in 29% of the patients in the metformin group compared to 17% in the placebo group.

Conclusions: Metformin added to TCH-P neoadjuvant chemotherapy does not significantly improve pCR rate in HER-2+ breast cancer. Grade ≥3 diarrhea was greater in the metformin group.

P3-11-18: Prognostic significance of lobular versus ductal histology in HER2-positive breast cancer

Alison Laws, Yue Yang, MDSA MEng, Yuan Xu, Lisa Barbera, May Lynn Quan

Background: Lobular HER2-positive (HER2+) breast cancer is a rare entity. As such, oncologic outcomes as compared to HER2+ breast cancer with ductal histology are not well-defined.

Methods: We identified all non-metastatic HER2+ breast cancers treated with surgery in the province of Alberta, Canada from 2010-2017. We excluded those who had no exposure to trastuzumab. We compared clinicopathologic characteristics by histologic type, categorized as lobular, mixed ductal/lobular or ductal. We used Kaplan Meier methods and the log-rank test to compare recurrence-free survival (RFS) by histologic type. Multivariable Cox proportional hazards analyses were performed to evaluate the association between histology and RFS, adjusting for age, grade, ER status, pT stage and pN stage.

Results: Among 1515 HER2+ breast cancer patients, 74 (4.9%) had lobular or mixed ductal/lobular histology (34 pure lobular and 40 mixed) and 1441 (95.1%) had ductal histology. Patients with lobular/mixed histology were older (median age 58.2 vs. 52.9, $p<0.001$) and had higher proportions of grade 1-2 disease (52.8% vs. 22.1%, $p<0.001$), ER-positive disease (95.9% vs. 74.3%, $p<0.001$) and pT3 disease (21.6% vs. 7.1%, $p<0.001$). Among 398 (26.3%) patients treated with neoadjuvant chemotherapy, the rate of pathologic complete response was 10.0% for lobular/mixed histology vs. 43.9% for ductal ($p=0.04$). At median follow-up of 4 years, there were 187 recurrences, 92 deaths with recurrence and 20 deaths without recurrence. 5-year RFS was 94.4% (95%CI: 66.6-99.2%) for lobular histology, 86.1% (95%CI: 66.7-94.6%) for mixed ductal/lobular histology and 87.0% (95%CI: 84.4-89.1%) for ductal histology ($p=0.75$) (Figure). In both unadjusted and adjusted analyses, neither lobular (adjusted HR 1.05, $p=0.93$) nor mixed histology (adjusted HR 0.71, $p=0.46$) were associated with worse RFS as compared to ductal histology. pT2-4 (vs. pT1) disease and pN2-3 (vs. pN0) disease were associated with worse RFS (all $p<0.01$). Results were unchanged in subgroup analysis restricted to ER-positive disease.

Conclusion: While lobular cancers are known to be less sensitive to cytotoxic chemotherapy, our data supports that for HER2+ breast cancer treated with HER2-directed antibody therapy, lobular or mixed ductal/lobular histology is not a poor prognostic factor.

P3-11-19: Efficacy of different neoadjuvant systemic treatment regimens in Chinese patients with HER2-positive advanced breast cancer: a real-world retrospective multi-center cohort study

Xiaoming Zha, Weiwei Zhang, Jue Wang

Background: Neoadjuvant systemic treatment (NST) is often used to treat inoperable locally advanced breast cancer. For human epidermal growth factor receptor 2 (HER2) positive patients, we usually choose chemotherapy combined with targeted therapy, such as epirubicin/cyclophosphamide followed by taxanes/trastuzumab (EC-TH), epirubicin/cyclophosphamide followed by taxanes/trastuzumab/pertuzumab (EC-THP), taxanes/trastuzumab/pertuzumab followed by epirubicin/cyclophosphamide (THP-EC), and taxanes/carboplatin/trastuzumab/pertuzumab (TCbHP).

Methods: The study aims to design a real-world study to retrospectively evaluate the effects of different regimens on the efficacy of NST with HER2-positive disease. The efficacy is further subdivided into total pathological complete response (tpCR), breast pathological complete response (bpCR), and axillary pathological complete response (apCR) for more detailed analysis.

Result: A total of 505 patients from 5 centers were included in this study from May 2014 to April 2022. In terms of tpCR and bpCR, the THP-EC regimen is superior to the EC-TH regimen ($p=0.046$ and 0.037), but there is no difference in efficacy compared to EC-THP and TCbHP (all $p>0.05$). The selection of four regimens has no effect on apCR. Patients with HER2 3+ in immunohistochemistry (IHC) are more likely to achieve pCR (tpCR, bpCR, and apCR) than those with HER2 2+ in IHC and HER2 amplification. Regarding the selection of taxanes for target therapy, in this study, liposomal paclitaxel, docetaxel, nanoparticle albumin-bound paclitaxel, and solvent-based paclitaxel have no significant difference in the efficacy of NST.

Conclusion: EC-THP, THP-EC, and TCbHP regimens are superior to the EC-TH regimen in NST with HER2-positive disease. The selection of chemotherapy regimens, medication sequence, and choice of taxanes have no effect on the efficacy of NST. The higher the expression of HER2, the more benefits it can benefit from targeted therapy.

P3-11-20: 2018 and 2024 surveys of clinical investigator (CI) use of postoperative systemic therapy after prior neoadjuvant treatment of HER2-positive breast cancer (HER2+BC)

Taylor Wallace, Kathryn Ziel, Joyce O'Shaughnessy, Trenton Cruse, Leijah Petelka, Kirsten Miller, Doug Paley, Jennifer Love Dvorkin, Gloria Kelly, Clayton Campbell, David Lyons, Kevin Pang, Neil Love

Background: The presentation in December 2018 of the KATHERINE trial data demonstrated the marked benefit of TDM-1 in patients with HER2+BC and residual disease at surgery after neoadjuvant treatment. Prior to that in 2017 the FDA approved "postadjuvant" neratinib (N) based on the ExteNET trial demonstrating significant benefit, particularly in patients with HER2+/ER+ disease. We were interested in how these data affected CI clinical practice and the potential benefits of treatment CIs were communicating to patients.

Methods: To evaluate not only how treatment practice patterns have changed during this time, but also the estimated impact on risk of recurrence, we surveyed 28 clinical investigators from multiple U.S. institutions shortly after the KATHERINE presentation in 2018 and in April 2024 surveyed 24 investigators, 14 of whom were 2018 participants. We asked respondents to provide not only their preferred management approaches but also what "numbers" they would provide to interested patients about the absolute impact of both adjuvant and "postadjuvant" treatment. Key variables in these HER2+ scenarios were ER/PR- and residual disease status.

Results: For scenarios with postneoadjuvant pathologic complete response (pCR), in 2018 there was heterogeneity in terms of whether to add pertuzumab (P) to trastuzumab (T). However, by 2024 TP had become standard. The use of N in the pCR setting was minimal at both time points. For patients with residual disease, in 2018 TP or T was used but by 2024, now years past the initial KATHERINE data, TDM-1 had become standard for patients with both minimal and more extensive residual disease. In terms of postadjuvant N, CIs were divided on whether to use N, with more use with greater residual disease and much greater use in patients with ER+ disease that was somewhat increased in 2024 compared to 2018. Interestingly, of the 285 treatment decisions related to postadjuvant N in the survey, in total there were 114 instances in which CIs believed a DFS advantage existed for N, but the agent was not recommended. Of these, 41 were situations where the perceived benefit was 1%, 37 where it was 2% and 17 situations in which a predicted benefit of 5% or greater was believed to exist but treatment was not given.
Of related interest, the predicted disease-free survival of the subsets in this survey shifted significantly upward in patients with residual disease, but was similar in 2018 and 2024 in scenarios of pCR.

Conclusions: Neoadjuvant treatment of localized HER2+BC has been utilized extensively for many years, but the postoperative management of the disease has shifted significantly since 2018 particularly for patients with residual disease, because TDM-1 became an almost instant standard when KATHERINE was presented. The use of postadjuvant neratinib — while increasingly utilized, particularly for patients with "triple-positive" disease — is more heterogenous and a number of CIs don't use this form of therapy despite their recognition that it likely improves outcomes. Additional efforts should be undertaken to understand

why some individuals decline to recommend a therapy with perceived benefits and one that is employed by many of their colleagues, and how factors such as treatment-related toxicities and shared decision-making factor into this decision.

P3-11-21: Sociodemographic Factors Associated with Use of Adjuvant Therapy in Stage I Human Epidermal Growth Factor Receptor 2 (HER2)-Positive Breast Cancer

Fauzia Riaz, Candice Thompson, Mina Satoyoshi, Kristen Cunanan, Archana Bhatt, Allison Kurian, Melinda L. Telli

Background: Approximately 40% of new HER2-positive (HER2+) breast cancer diagnoses are classified as Stage I. Extensive retrospective studies have failed to demonstrate a substantial improvement in breast cancer outcomes and survival rates for those with Stage I HER2+ breast cancer, irrespective of whether adjuvant therapy is administered. Large scale retrospective studies have demonstrated that even without adjuvant therapy, this patient population has a very favorable rate of 5-year breast cancer-specific survival ranging from 91% to 99%, particularly in those with T1a/b lesions. Despite this, many still receive adjuvant therapy. We investigated both clinical and sociodemographic factors associated with use of adjuvant HER2-targeted therapy with/without systemic chemotherapy in patients with Stage I HER2+ breast cancer.

Methods: This observational study used the Oncoshare database, which integrates electronic medical record and California Cancer Registry data for patients treated in Northern California in the Stanford University Health Care Alliance. We included patients treated for Stage I HER2+ breast cancer from 2000-2024. Descriptive statistics are reported, and a multivariate analysis is forthcoming.

Results: The study population included 512 patients with T1aN0/T1bN0 disease and 515 with T1cN0 disease. Approximately 68% of patients with pT1cN0 HER2+ breast cancer and 56% of patients with T1a or T1b disease received adjuvant therapy. We have collected extensive data on sociodemographic factors, including age, race and ethnicity, neighborhood socioeconomic status (reported as statewide quintiles), distance traveled for care, rurality, Charlson comorbidity scores, and insurance status.

Initial analysis was completed to determine the standardized mean differences between those who received adjuvant systemic therapy and those who did not. For those with T1aN0/T1bN0 HER2+ breast cancers, we found moderate differences between those who received adjuvant therapy and those who did not based on insurance type (SMD 0.416) and grade of the tumor (SMD 0.472). Of those who received adjuvant therapy, 54.5% had private insurance, whereas only 25.5% had government-based insurance. However, in those patients who did not receive adjuvant systemic therapy, 44.2% of patients had government-based insurance and 38.5% had private insurance. Patients with grade II and III tumors made up 75.9% of patients who received adjuvant therapy, whereas only 6.6% of

patients with grade I tumors received adjuvant therapy.
For T1cN0 HER2+ breast cancers, we found moderate differences in receipt of adjuvant therapy between insurance type (SMD 0.442), age (SMD 0.626), and grade of the tumor (SMD 0.424). Those with government-based insurance represented the highest number of patients who did not receive adjuvant therapy (51.8%), whereas those with private insurance represented the highest number of patients who did received adjuvant therapy (49.9%). In patients under 50, 84% received adjuvant therapy, whereas only 45% of those over 70 received adjuvant therapy. Of those patients who received adjuvant therapy, only 3.7% had a grade I tumor, whereas 40.4% and 55.6% had grade II and III tumors, respectively.

Conclusions: Despite excellent outcomes in patients with T1N0 HER2+ breast cancer regardless of receipt of adjuvant therapy, 62% of patients received adjuvant systemic therapy. Initial data shows that there are differences in the clinical/sociodemographic factors between the patients receiving adjuvant systemic therapy and those who are not. Although it is expected that younger patients and those with high grade tumors have higher adjuvant systemic therapy use, it was interesting to see that patients with government-based insurance received less adjuvant therapy than those with private insurance. Forthcoming multivariate analysis will help us better understand the association between sociodemographic factors and receipt of adjuvant therapy.

P3-11-22: Extended adjuvant neratinib in HER2+/HR+ early breast cancer (eBC) in clinical routine – interim analysis of the multinational, prospective, non-interventional study ELEANOR (n=300)

Diana Lüftner, Denise Wrobel, Dagmar Guth, Matthias Zaiss, Jürgen Terhaag, Mark-Oliver Zahn, Lidia Pervola-Griff, Andrea Distelrath, Rachel Würstlein, Klaus Appel, Natalija Deuerling, Corinne Vannier, Rupert Bartsch, Christian Jackisch, Volkmar Müller, Marcus Schmidt, Marija Balic, Gabriel Rinnerthaler, Urs Breitenstein, Khalil Zaman, Michael Schwitter, Nadia Harbeck

Background: Despite modern human epidermal growth factor receptor (HER2)-directed treatment options, relevant recurrence risk persists in patients (pts) with extensive local disease and/or lack of pathologic complete response (pCR) to neoadjuvant therapy. Neratinib is approved in Europe for extended adjuvant therapy in adult pts with HER2+/hormone receptor positive (HR+) eBC who completed adjuvant trastuzumab-based therapy less than one year ago. In this population, the ExteNET study demonstrated an absolute 5.1% improvement in 5-year invasive disease-free survival (iDFS) with neratinib compared to placebo (90.8% vs. 85.7%; hazard ratio 0.58 [95% confidence interval (CI), 0.41-0.82]). Exploratory post-hoc analyses demonstrated a more pronounced benefit in non-pCR pts and/or in those completing neratinib therapy. Diarrhea was the most common adverse event (AE) in the neratinib arm (39% grade 3 without primary diarrhea

prophylaxis). ELEANOR is the first non-interventional study of the real-world use and management of neratinib given after the current adjuvant standard of care in pts with HER2+/HR+ eBC in Germany, Austria, and Switzerland.

Methods: A total of 300 pts diagnosed with HER2+/HR+ eBC were planned to be enrolled in accordance with the EMA/Swissmedic product specifications. The primary objective is to assess patient adherence to neratinib (i.e., ≥75% of prescribed treatment days). Secondary objectives focus on patient and tumor characteristics, pretreatment and neratinib treatment details, effectiveness, safety, and health-related quality of life. Results of the preplanned interim analysis based on 300 enrolled pts observed for a minimum of three months are reported.

Results: At the data cut-off on 5th August 2023, 286 pts qualified for the main analysis set and 288 pts for the safety analysis set, respectively. Median age at inclusion was 52.0 years, 73.4% (210/286) of pts were at increased risk of disease recurrence having AJCC stage > I or N+ or non-pCR after neoadjuvant treatment. Overall, 37.4% (107/286) and 31.8% (91/286) of pts received adjuvant/post-neoadjuvant trastuzumab monotherapy or trastuzumab/pertuzumab, respectively, and 22.4% (64/286) of pts received post-neoadjuvant trastuzumab-emtansine (T-DM1). In pts who had non-pCR following neoadjuvant treatment, 55.4% (62/112) received post-neoadjuvant T-DM1. Dose escalation strategy (neratinib starting dose <240 mg) was used in 44.4% (128/288) of pts, and 86.8% (250/288) of pts received diarrhea prophylaxis. AEs were consistent with the known safety profile of neratinib with incidence of grade ≥3 diarrhea by worst grade less common in pts starting on a lower dose of neratinib (15.6% vs. 23.8%).
At the time of this preplanned interim analysis with an estimated median observation time for DFS of 14.0 months, six pts (6/286, 2.1%) had experienced a relapse and one patient died since starting neratinib treatment, resulting in a 12-month DFS rate of 97.4% (95% CI, 94.6-98.7). At the end of neratinib treatment, physicians evaluated treatment satisfaction for 85 pts with effectiveness and for 88 pts with safety. Satisfaction rates were 88.2% for effectiveness and 86.4% for safety.

Conclusion: This preplanned interim analysis provides data on the use of neratinib in a contemporary cohort of predominantly higher-risk pts and after completion of pertuzumab- and T-DM1-containing adjuvant regimens in routine clinical practice. Preliminary effectiveness data appears to be consistent with previous data and the integration of treatment management strategies such as diarrhea prophylaxis and neratinib dose escalation were shown to enhance treatment tolerability.

P3-11-23: A multicentre UK Study of the impact of progesterone receptor status on pathological complete response rate and outcomes in 1037 patients with HER-2 positive, early breast cancer treated with neoadjuvant chemotherapy, trastuzumab and pertuzumab

James Pearson, Henry Cain, Emily King, Mark Verill, Alicia Okines, Nicolò Matteo Luca Battisti, Sacha Howell, Rebecca Ward, Dinaksi Shah, Waleed Khalifa, Ian MacPherson, Andrew Kidd, Andrea Law, Vijay Sharma, Aswathy Nair, Richard Jackson, Carlo Palmieri

Background: Pathological complete response (pCR) rates are lower in ER positive, HER-2 positive early breast cancers (EBC) as compared to ER negative, HER2-positive disease when treated with neoadjuvant chemotherapy, trastuzumab and pertuzumab (T+P). To date, pivotal phase III neoadjuvant studies have not explored the impact of progesterone (PgR) status on pCR rates and outcomes. Given this, we explored the impact of PgR expression on pCR rates as well as clinical outcomes following neoadjuvant chemotherapy, and T+P in HER-2 positive EBC in patients treated at 4 cancer centres in the UK.

Methods: Patients with HER2-positive EBC, treated with neoadjuvant chemotherapy, and T+P, between 2013-2024 at 4 cancer centres in the UK were identified. Clinicopathological information including ER and PgR status taken from core biopsy, with positivity defined as Quick Score >2, histopathological response, disease relapse and survival outcomes were collected. Data cut off was 1st March 2024.

Results: 1037 patients were identified; 17 had bilateral disease making 1054 assessable tumours. Hormone receptor status was as follows: ER+, PgR+: 495 of 1054 (47%); ER+, PgR-: 158 of 1054 (15%); ER-, PgR+: 30 of 1054 (3%); ER-, PgR-: 297 of 1054 (28%); ER or PgR missing data: 74 of 1054 (7%). The overall pCR rate (ypT0/is, ypT0) was 52% (552/1054). pCR rates by ER status (regardless of PgR) were: ER+: 45% (293/653); ER-: 70% (229/327) (P < 0.0001). pCR rates by PgR status were: PgR+: 42% (221/524); PgR-: 66% (302/456) (P<0.0001). pCR rates by ER & PgR were: ER+, PgR+: 41% (204/495); ER+, PgR-: 56% (89/158); ER-/PgR+: 57% (17/30); ER-,PgR-: 71% (212/297). At a median follow-up of 34 months (95% CI 33-36) disease-free survival (DFS) and overall survival (OS), for the overall population was not reached. pCR was associated with improved DFS (HR 0.30, 95% CI 0.17-0.50) and OS (HR 0.29, 95% CI 0.13-0.62) in the overall patient group. In ER+ disease, regardless of PgR status, pCR was associated with improved DFS (HR 0.38, 95% CI 0.18-0.78) but not OS (HR 0.46, 95% CI 0.16-1.33). pCR in the ER- disease group, was associated with significantly improved DFS (HR 0.17 95% CI 0.07-0.38) and OS (HR 0.11, 95% CI 0.03-0.35). In PgR+ disease, achieving pCR lead to an improved DFS (DFS: HR 0.26, 95% CI 0.11-0.65) but not OS (HR 0.30, 0.08-1.09). In PgR- disease achieving pCR was associated with both improved DFS and OS (DFS: HR 0.29, 95% CI 0.15-0.59; OS: 0.22, 95% CI 0.08-0.58).
In ER+/ PgR+ disease, an association was found for DFS (HR 0.26, 95% CI 0.09-0.69) but not

for OS (HR 0.24, 95% CI 0.05-1.14). In ER+/ PgR- disease, pCR was not statistically significant for an improved DFS (HR 0.81, 95% CI 0.23-2.80) or OS (HR 1.22, 95% CI 0.20-7.34). pCR was significant for both DFS and OS in patients with ER-, PgR- disease (DFS: HR 0.18, 95% CI 0.07-0.42; OS: HR 0.10, 95% CI 0.02-0.36).
An updated analysis with data from an additional 1 centre will be presented as well as updated outcomes.

Discussion: In this multicentred, real-world study achieving pCR was associated with ER and PgR status, with higher rates in ER-/PgR- & ER+/PgR- cases versus ER+/PgR+ cases. DFS and OS in the overall population was associated with pCR, however this did not hold for all hormone receptor subgroups. Whilst an association was found for achieving pCR and DFS in the ER+/PgR+ patient group, only in ER-/PgR- disease was pCR significant for both DFS and OS. These data indicate that in ER+ HER2+ EBC PgR status can influence pCR, and survival outcomes.

P3-11-24: Neoadjuvant Nab-paclitaxel combined with Trastuzumab and Pyrotinib for HER2-enriched subtype of HER2-positive early or locally advanced breast cancer: A multicenter, single-arm, phase 2 trial

Pan Hong, Hui Xie, Yi Ren, Xiaoan Liu, Yi Zhao, Lin Chen, Xiaoming Zha, Tia song Xia, Linlin Zhen, Zhaoji Guo, Jing Lan, Jieqiong Liu, Changchun Li, Jun Zhou, Yanwu Zhang, Zhao Liu, Jing Tao, Shui Wang, Wenbin Zhou

Background: Target therapies significantly improved the pathological complete response rate (pCR) of human epidermal growth factor receptor 2 (HER2) positive breast cancer. A tyrosine kinase inhibitor (TKI) plus trastuzumab-based regimen showed inconsistent efficacy in neoadjuvant therapy. As we know, HER2-positive breast cancer consists of four intrinsic molecular subtypes of luminal A, luminal B, HER2-enriched, and basal-like. This trial was aimed to evaluate the efficacy of chemotherapy de-escalated neoadjuvant regimen of pyrotinib, trastuzumab and nab-paclitaxel in HER2-enriched subtype of HER2-positive early breast cancer.

Methods: This multicenter, single-arm, phase 2 trial was conducted in nine hospitals in China (ClinicalTrials.gov, NCT05659056). Simon's two-stage design was adopted, and 65 eligible patients with HER2-positive, stage IIA-IIIC invasive breast cancer regardless of hormone receptor status were scheduled to be enrolled. Patients received pyrotinib (400mg, continuous orally), trastuzumab (loading dose of 8 mg/kg, followed by 6 mg/kg every 3 weeks intravenously), and nab-paclitaxel (260mg/m2 every 3 weeks intravenously) for six cycles. The primary endpoint was the total pCR (tpCR, ypT0/Tis and ypN0) of HER2-enriched subtype patients. Intrinsic molecular subtypes of tumor biopsy samples taken at baseline were determined via the BluePrint predictor.
Findings: In the first stage, 21 patients were enrolled and tpCR exceeding 35%, so between

Nov 22, 2022, and Jul 1, 2024, we recruited 65 patients, of whom 52 (80%) completed neoadjuvant therapy and received surgery as planned, and BluePrint results were available in 50 of them. Of the 50 patients, 32 (64%) were HER2-enriched subtype, 2 (4%) were luminal A, 9 (18%) were luminal B, and 7 (14%) were basal-like. Twenty-two (42.3%, 95% CI 29.0%-56.7%) of 52 patients had tpCR at the time of surgery. Eighteen (56.3%, 95% CI 37.9%-73.2%) of 32 patients with the HER2-enriched subtype and 4 (22.2%, 95%CI 7.3%-48.1%) of 18 patients with non-HER2-enriched subtypes achieved tpCR. Forty-five (86.5%, 95% CI 0.74-0.94) of 52 patients achieved objective response. The treatment related any grade adverse events was 91.2%, and 6 patients changed treatment regimen due to adverse events. And the most common grade 3 or 4 adverse events were diarrhea (12 [21.1%]), and neutrophil count decreased (3 [5.3%]).

Conclusion: The trial reached the pre-specified tpCR, had met the primary end point. Neoadjuvant pyrotinib, trastuzumab and nab-paclitaxel reached a high tpCR rate, with manageable toxicity, for patients with HER2-enriched subtype of HER2-positive breast cancer. Chemotherapy can be de-escalated in patients with HER2-enriched subtype breast cancer with BluePrint intrinsic subtyping.

P3-11-25: Use of the MammaTyper® Platform to Reclassify Breast Tumors by the Expression of HER2

Serafin Morales, Ana Velasco, Izaskun Rdanibia, Ariadna Gasol, Noemi Tuset

The molecular classification of breast cancer is essential for selecting the appropriate treatment. Most of the time, this classification is carried out by the immunohistochemical (IHC) status of hormonal receptors (estrogen and progesterone), HER2 protein and the Ki67 proliferation index.
MammaTyper® is a gene expression assay based on RT-qPCR, developed to provide enhanced sensitivity in testing these markers by determining the levels of their messenger RNA.
We analyzed the concordance between immunohistochemistry and MammaTyper® in the expression of hormonal receptors (estrogen and progesterone), Ki67, and HER2, with a particular focus on HER2 expression.
We examined a cohort of 30 cases, of which 27 were classified as HER2 +2. Among these, 19 were HER2 positive by FISH, 6 were luminal, and 5 were triple-negative. We found concordance in the expression of estrogen receptors (p: 0.001), with 83% agreement for negative receptors (10 out of 12) and 90% agreement for positive receptors.
Of the 19 cases considered HER2 positive by FISH, only 7 were confirmed by MammaTyper®, 15 were HER2 low and 5 ultralow. Additionally, none of the 11 HER2 negative cases were positive by MammaTyper®.
MammaTyper®reclassifies cases considered HER2 +2 by IHC and positive by FISH, identifying 36% (7 out of 19) as HER2 positive and 42% (8 out of 19) as HER2 low. Given

the critical role of accurately quantifying HER2 expression for selecting appropriate anti-HER2 treatments, this technique should be considered.

P3-11-26: A Phase II study of dalpiciclib combined with letrozole, pertuzumab and trastuzumab as neoadjuvant therapy in HR+/HER2+ breast cancer

Xinrui Liang, Ningning Zhang, Jing Wu, Xiaohua Zeng

Background: HR+/HER2+ breast cancer is a unique subtype of breast cancer. Between ER and HER2 crosstalk pathways may affect the sensitivity to both HER2-targeted and endocrine therapy in patients with HR+/HER2+ breast cancer. Current therapies for HER2-positive breast cancer have demonstrated limited efficacy in patients with HR+/HER2+ breast cancer. This Phase II trial aimed to assess the efficacy and safety of a neoadjuvant regimen combining trastuzumab, pertuzumab, dalpiciclib (a cyclin dependent kinase 4/6 inhibitor) and letrozole in patients with HR+/HER2+ breast cancer, alongside the exploration of efficacy biomarkers.

Methods: Patients were administered six 28-day cycles of dalpiciclib (150 mg once daily on days 1-21) and letrozole (2.5 mg once daily), plus six 21-day cycles of trastuzumab (8 mg/kg loading dose followed by 6 mg/kg maintenance dose on day 1), pertuzumab (840mg loading dose followed by 420mg maintenance dose on day 1), prior to surgery. The primary endpoint was total pathological complete response (tpCR, ypT0/is, ypN0) rate. Secondary endpoints were objective response rate (ORR), breast pathological complete response (bpCR; ypT0/is) rate, change in Ki-67 level from baseline to one cycle of treatment and to surgery, and safety. For biomarkers analysis, next-generation sequencing was performed on pre-treatment tissue and circulating tumor DNA (ctDNA) at various time points before surgery.

Results: A total of 29 patients have been enrolled from July 12, 2022 to July 4, 2024. Among these patients, 19 patients had completed the neoadjuvant treatment and surgery. The median age of these 19 patients was 52 years, with 57.9% being postmenopausal. Stage II and III accounted for 52.6% and 47.4%, respectively. Additionally, 89.5% of the patients had lymph node metastasis. The tpCR and bpCR rate were 42.1% (8 out of 19) and 52.6% (10 out of 19), respectively. The ORR was 84.2 %. Significant reductions in Ki-67 levels were noted after both one ($P < 0.05$) and six cycles of neoadjuvant therapy ($P < 0.05$). Grade 4 neutropenia was reported in one case, with no fatalities. The most common grade 3 adverse events were neutropenia (10 [71.4%]) and leukopenia (8 [57.1%]). NGS identified frequent mutations in TP53 (73.7%), PIK3CA (47.4%), and ARID1A (21.1%). Cell cycle pathway gene alterations correlated with a higher pCR rate (80% vs 25%, P=0.101). Ten (55.6%) patients had positive ctDNA at baseline, and ctDNA positivity decreased significantly post-neoadjuvant treatment ($P < 0.05$). Patients with positive ctDNA at baseline without

clearance post-treatment exhibited a trend towards a lower pCR rate.

Conclusions: This combination neoadjuvant regimen of dalpiciclib, letrozole, pertuzumab and trastuzumab demonstrated promising pathological responses and manageable safety in patients with HR+/HER2+ breast cancer. The predictive value of genetic alterations and ctDNA status for treatment efficacy warrants further investigation.

P3-11-27: Pathologic Complete Response and Residual Cancer Burden as Powerful Prognostic Markers in HER2-Positive Early Breast Cancer: A Comprehensive Real-World Study

Emad Shash, Nashwa Kordy, Ahmed Haggag, Salma Seddik, Ibrahim S Al Hussini, Tarek Hashem, Tamer M. Manie, Sherif N Taha, Abdelrahman M Essam, Maha Yahia, Mohamed Alorabi, Ameera H Radwan, Mohamed Kamal, Mohamed Mahmoud

Background: Pathologic complete response (pCR) following neoadjuvant therapy in HER2-positive early breast cancer (eBC) is recognized as a significant prognostic marker. This study aims to evaluate the impact of pCR and residual cancer burden (RCB) on survival outcomes in a real-world cohort of women with HER2-positive eBC.
Methods: A retrospective review was conducted on 385 newly diagnosed women with HER2-positive eBC who underwent neoadjuvant therapy between June 2016 and December 2022. Clinicopathological data were collected, including age, menopausal status, tumor grade, stage, ER/PR status, and neoadjuvant treatment regimens. Overall survival (OS) and event-free survival (EFS) were analyzed using Kaplan-Meier estimates, stratified by pCR and RCB status. Prognostic factors were identified using Cox proportional hazards modeling.

Results: Among the 385 patients, 55.1% achieved pCR. Those treated with trastuzumab plus pertuzumab exhibited a higher pCR rate (69%) compared to trastuzumab alone (53.8%). Five-year OS was 82.4%. Patients who achieved pCR had significantly improved OS (HR: 0.373, p = 0.005), while those who did not achieve pCR had a lower OS (HR: 2.676). Three-year EFS was 88.9%. Although not statistically significant, patients achieving pCR had better EFS (HR: 0.56, p = 0.087). Residual cancer burden analysis showed that patients with minimal residual disease (RCB-0) had significantly improved OS (HR: 0.178, p = 0.003) and EFS (HR: 0.300, p = 0.023) compared to those with higher RCB scores. When stratified by hormonal receptor status, hormone receptor-negative (HR-) patients who achieved pCR had improved OS (HR: 0.366, p = 0.006) and EFS (HR: 0.302, p = 0.017) compared to those who did not. Similar trends were noted in hormone receptor-positive (HR+) patients.

Conclusion: This real-world study demonstrates that achieving pathologic complete response (pCR) and having minimal residual cancer burden (RCB-0) are strongly associated

with improved survival outcomes in HER2-positive early breast cancer. These findings underscore the critical importance of pCR and RCB as prognostic markers in guiding neoadjuvant therapy and optimizing treatment strategies.

P3-11-28: HER2+ Breast Cancer: Loss of HER2 and Disease Prognosis After Neoadjuvant Treatment - A Pertuzumab effect?

Francisco Paralta Branco, Ana Ferreira, Isabel Pazos, Marta Freitas, Sónia Oliveira, Vanessa Patel, Joana Albuquerque, Rita Freitas, Manuela Martins, Nuno Coimbra, António Polónia, JL Passos-Coelho

Introduction: HER2 overexpression/amplification occurs in 15-20% of breast cancers (BC) and is associated with worse prognosis. The addition of anti-HER2 treatment to neoadjuvant chemotherapy significantly improves pathological complete response (pCR) rate. Changes in HER2 status after neoadjuvant treatment (NAT) may affect prognosis (Mittendorf EA, Cancer Res 2009; Guarneri V Ann Oncol 2013). Our group previously studied this topic in the era of trastuzumab (T) single treatment, finding that patients (pts) who did not achieve a pCR and had loss of HER2 expression/amplification during NAT had worse disease-free (DFS) and overall survival (OS) (Branco FP, Am J Transl Res 2019). The present study aimed to confirm these findings in a more recent and larger cohort.

Methods: A retrospective chart review and pathologic evaluation was conducted on all consecutive pts with HER2+ BC (defined as IHC 3+ or IHC 2+ with amplification by ISH) treated with NAT between Jan 2015 and Dec 2017 at 8 Portuguese hospitals.

Results: 304 female pts were included, with a median age of 42 years (range 24-82); 9 pts (3%) with stage I, 187 (62%) with stage II, 104 (34%) with stage III and 4 (1%) unknown. Hormone receptors were positive (>1% tumor cells) in 201 tumors (66%). The majority of pts (293, 96%) received NAT with anthracyclines and taxanes, while 11 (4%) received non-anthracycline NAT; all received anti-HER2 treatment with T and 250 (82%) also received pertuzumab (P) (dual blockade). pCR (ypT0/is ypN0) was achieved in 172 pts (57%), with increase in 5-year DFS (5yDFS) compared to pts with residual disease, 95% (SE 1.7%) versus 85% (SE 3.3%), respectively (p=0.02). With a median follow-up of 62 months, among the 132 pts (43%) with residual disease at surgery, in 79 (60%) the residual tumor remained HER2+, 32 (24%) lost HER2 overexpression/amplification, and 21 (16%) had insufficient residual tumor to allow HER2 determination. The 5yDFS was 79% (SE 4.9%) for pts with HER2+ residual tumors, 90% (SE 5.4%) for those who became HER2-negative, and 100% (SE 4.9%) for those with insufficient material. In the overall population, the 5yDFS was 79% (SE 5.5%) in pts who received neoadjuvant T alone and 93% (SE 1.6%) for T+P (p=0.004). Among pts with residual disease, the 5yDFS difference was even greater: 66% (SE 9.3%) with T versus 91% (SE 3.0%) with T+P (p=0.001). Among pts treated with T-only NAT whose tumors lost HER2, 2 out of 5 relapsed (5yDFS 60%, SE 21%) compared to 7 out

of 20 who remained HER2+ (5yDFS 64%, SE 11%). In contrast, pts treated with T+P NAT whose tumors lost HER2 only 1 out of 27 pts relapse (5yDFS 96%, SE 3.9%) compared to 8 of 59 with HER2+ residual tumors (5yDFS 85%, SE 4.9%). In multivariate survival analysis, among the subgroup of pts with residual disease, the inclusion of P in NAT was the only factor with a statistically significant impact on DFS (HR=0.21, p=0.005) after adjusting for age (above or below 50), estrogen receptor expression, grade, stage, dose-dense versus standard AC chemotherapy, and HER2 in residual tumor (positive or negative). A similar result was observed when stage was substituted by nodal status (positive or negative), with only P impacting DFS (HR=0.22, p=0.007).

Discussion: This real-world cohort study confirms the benefit of dual HER2 blockade in increasing pCR rate after NAT but also in improving 5yDFS. Contrary to our previous findings, loss of HER2 in residual tumor at surgery was not associated with worse DFS. The main difference between studies was the use of preop P. In this cohort, pts treated only with T maintained a trend towards worse prognosis with loss of HER2 overexpression/amplification, while the addition of P to NAT impacted positively the prognosis of HER2 BC despite HER2 loss. Pts with insufficient material in the surgical specimen for HER2 determination likely had a near pCR, which may explain why none relapsed. Future clinical trials in HER2+ BC should take into consideration HER2 status in the surgical specimen post NAT.

P3-11-29: Early change in lymphocyte count on neoadjuvant therapy (NAT) and treatment response in patients with HER2+ breast cancer (BC)

Colin Bergstrom, Ingrid Luo, Eran Kotler, Mina Satoyoshi, Candice Thompson, Christina Curtis, Summer Han, Jennifer L. Caswell-Jin

Introduction: While immune infiltration of the tumor after initiation of NAT has been shown to predict response in HER2+ BC, it is unknown if peripheral blood changes correlate with effective immune activation. This study aimed to evaluate the association between the change in lymphocyte count after the initial cycle of NAT and pathological complete response (pCR) among patients with HER2+ BC.

Methods: Patients with HER2+ BC who received NAT, had baseline absolute lymphocyte count (ALC) pre-therapy (within 90 days of diagnosis), and on-treatment (7-35 days after first dose) were identified from the Oncoshare database. Oncoshare merges data from the California Cancer Registry and electronic medical records of women diagnosed with BC between 2000-2022 from the Stanford Health Care Alliance, encompassing an academic hospital, a community hospital, and a community practice network. Data collected included demographic (age, race/ethnicity), laboratory (ALC values across therapy), clinical (stage, grade), and pathological (estrogen receptor (ER) and pCR status) variables. For the primary analysis, patients were excluded if the baseline ALC was < 0.5. ALC change was defined as

ALC after the first cycle of NAT divided by baseline ALC prior to NAT. Univariate (Mann Whitney U test) and multivariate (logistic regression) analyses between pCR and ALC change were performed. An exploratory analysis examined changes in the ALC trajectory across the entire treatment course between patients with and without pCR.

Results: The study included N=207 patients with HER2+ BC. The median diagnosis age was 51 (interquartile range[IQR] 43-61), 51% were non-Hispanic White, the majority had ER+ disease (69%) and received pertuzumab-based NAT (58%). pCR occurred in 47% of patients. One patient was excluded for sub-threshold baseline ALC (<0.5). Among all patients, the median ALC decreased from 1.8 (IQR 1.4-2.3) at baseline to 1.3 (IQR 1.0-1.9) on-treatment. Greater ALC reduction occurred in patients who ultimately achieved pCR: on-treatment ALC was 72% (SD 30%) of baseline in patients with pCR, as compared to 86% (SD 40%) in patients without (P=0.013). In multivariate analysis, ER status (P<0.001) and pertuzumab-based NAT (0.016) were associated with pCR, and a significant association persisted between pCR and ALC change (p=0.017) after adjusting for these factors. In the exploratory analysis, patients who underwent pCR not only experienced a greater early decline in their ALC, but a greater recovery toward the end of NAT.

Conclusion: In patients with HER2+ BC undergoing NAT, a significant association was found between an early ALC decline after first treatment and subsequent pCR. These results suggest that an effective immune response to NAT in HER2+ breast cancer may be detectable within a few weeks of initiation of therapy, opening new avenues to development of biomarkers of treatment response.

P3-11-30: Low Ki67 is associated with a lower pathological complete response rate after neoadjuvant therapy in HER2-positive breast cancer patients.

Brunna Silva, Mario Machado Lopes, Vladmir Claudio Cordeiro de Lima, Solange Moraes Sanches, Cynthia Aparecida Bueno de Toledo Osório, Marina de brot, Victor Gabriel Bertoli, Guilherme Rossato de Almeida, Carolina Campanholo Marques, Nathália Machado Soldi, José Reinaldo de Oliveira Junior, Mila Meyer Campos Kraychete, Marcelle Goldner Cesca

Introduction: The expression of the Ki67 protein assessed by immunohistochemistry (IHC) can estimate the cell proliferation rate and, therefore, be used as a prognostic biomarker to stratify breast cancer patients who harbor a high risk of disease relapse and can benefit more from chemotherapy. However, the prognostic and predictive value of Ki67 for HER2-positive breast cancer is not clearly understood. This study aimed to test the relationship between Ki67 expression and the pathological response in HER2-positive breast cancer. Materials and Methods: We included 260 patients with HER2-positive breast cancer treated with neoadjuvant chemotherapy plus anti-HER2 therapy at A. C. Camargo Cancer Center, Brazil, from January 2010 to December 2022. Information regarding demographics,

comorbidities, immunohistochemical features, treatment, clinical staging, and toxicity was collected from patients' electronic medical records. Ki67 expression information was collected from pathological reports and categorized as <30% or >30%. Descriptive statistics were used to summarize data. Multivariate analysis using Cox's regression models was performed to integrate factors associated with pathological complete response(pCR).

Results: The number of stage II and III patients was 154 (58.3%) and 93 (35.2%), respectively. Histological grade II and III were observed in 136 (51.5%) and 121 (45.8%) tumors. Ki67 >30% was seen in 185 (70%) tumors, and 172 (65.2%) had hormonal receptor expression. The median follow-up was 41 months (37.13-44.87). One-hundred and forty-four (55.4%) patients achieved pCR. The Ki67 <30% was significantly associated with a lower rate of pCR, 33 patients (42.3%) compared to 111 patients (61%) in the group with Ki67>30% (p=0.002). On the multivariate analysis, after adjustment for the use of neoadjuvant trastuzumab plus pertuzumab, use of neoadjuvant anthracyclines, and HER2 score + 3 on IHC (vs. HER2 amplified by FISH/ISH), Ki67 remained as an independent factor associated with pCR.

Conclusion: Tumors with Ki67 <30 were associated with a lower rate of pCR after completing neoadjuvant treatment. Ki67 was kept as an independent predictor for pCR regardless of the use of neoadjuvant antracycline or trastuzumab plus pertuzumab, and HER2 score as evaluated by IHC. In the future, PAM 50 or another multigenic test may better fit these patients into different prognostic subgroups and help to de-escalate treatment.

P3-12-01: Eribulin in HER2-negative breast cancer. Results of real world data (RWD) in the era of precision oncology.

Diego Martín Sánchez, Rocío Pérez Velasco, Nikhil Karani Karani, Elisenda Llabrés Valenti, Elisa Guadalupe Guadalupe, Pedro Delgado Garcés, Ana Gil-Torralvo, Alejandro Falcón Gonzalez, Manuel Ruiz Borrego, Javier Salvador-Bofill, Mónica Cejuela Solís

Background: Eribulin is a standard of care for HER2-negative metastatic breast cancer (MBC) regardless of hormone receptor expression. It is approved for use after progression to anthracyclines and taxanes based on the phase 3 EMBRACE trial. Despite its widespread use, there is a paucity of real-world data (RWD).

Methods: Patients with HER2-negative MBC treated with eribulin at Virgen del Rocio and Insular de Gran Canaria Hospital (Spain) between January 2016 and December 2022 were reviewed. IBM SPSS Statistic 27.0.1.0 was used for statistics.

Results: 211 patients were identified and retrospectively followed up until March 2024. Median age at diagnosis was 62 years. 66.4% were luminal phenotype and 53.1% showed high Ki67 expression (>30%). 18.3% were diagnosed with metastatic disease at debut.

Prior to eribulin treatment, 85.1% of patients had visceral disease, 55% liver involvement and 11% brain metastases. 6.2% of patients received eribulin as 1st line, 17.1% as 2nd line, 27.5% as 3rd line and 49.3% as 4th line or later. Progression-free survival (PFS) with eribulin was 4.76 months (95% CI, 4.06-5.47) and overall survival (OS) 10.75 months (9.37-12.12), median follow-up of 12 months. PFS was 5.53 months (4.60-6.46) in the luminal phenotype and 3 months (2.67-3.74) in the triple negative population. OS was 11.43 (9.79-13.06) and 9.31 (6.79-11.82), respectively. Overall response rate was assessed in 160 patients and was 43.12%. Median survival in this subgroup was 7.6 months. The presence of visceral disease and more than three lines of treatment before eribulin seems to decrease survival but did not reach statistical significance. 33.49% required dose reductions of eribulin. Most common toxicities were asthenia (73.7%), neutropenia (45.5%) and nausea (27.3%).

Conclusions: In our population, the efficacy and toxicity of eribulin are consistent with published data. The RWD complements the results of clinical trials by providing information on the efficacy and safety of treatments under conditions of routine clinical practice. This is the first phase of a multi-center RWD on the use of eribulin in the context of personalized medicine after the incorporation of targeted therapies.

P3-12-02: Ribociclib in Combination with Aromatase Inhibitors or Fulvestrant in Hormone Receptor (HR)-Positive, HER2-Negative Premenopausal Women with Metastatic Breast Cancer. Real World Data from a Resource-Restricted Country

Suhaib Khater, Hikmat Abdel-Razeq, Faris Tamimi, Baha' Sharaf, Mariam Al-Atrash, Sarah Abdel-Razeq, Mahmoud Abu-Nasser, Sarah Edaily, Hira Bani Hani, Hala Abu Jaish, Hanan Khalil, Tamer Al-Batsh, Anas Zayed, Yosra Al-Masri, Ahmad Khater, Osama Mahafdah

Background: Cyclin-dependent kinase (CDK) 4/6 inhibitors when combined with aromatase inhibitors (AI) or fulvestrant have revolutionized the treatment landscape of hormone receptor (HR)-positive, human epidermal growth factor receptor-2 (HER2)-negative metastatic breast cancer (MBC). Here we report real-world clinical outcomes and toxicity data in premenopausal patients treated at a single tertiary cancer center in a resource-restricted country; patients of which were not well represented in clinical trials that led to the approval of these drugs.

Methods: This is a retrospective analysis of individual patients' data. All consecutive premenopausal women with HR-positive and HER2-negative MBC, treated at our institution with ribociclib plus AI or fulvestrant, between July 2017 and December 2023 were reviewed. Progression-free survival (PFS) was defined as the time from treatment initiation with CDK4/6 inhibitor (all with ribociclib) until the first documented progression, death

from any cause, or last follow-up, whichever occurred first. The Overall survival (OS) was defined as the time from treatment initiation with ribociclib until the date of death from any cause or last follow-up.

Results: A total of 164 patients, median age 43 (27-54) years were enrolled; almost one-third (n=52, 31.7%) were below the age of 40. All patients had metastatic disease; de novo (n=83, 51.6%), or recurrent following a presentation as early-stage (n=81, 49.4%). Although bone metastasis was reported in 100 (61.0%) patients, bone-only metastasis was identified in 87 (53.0%), while visceral metastasis was reported in 60 (36.6%), including the lung (n=23, 14.0%) and liver (n=40, 24.4%). Majority of the tumors were high grade; G3 (n=50, 31.2%) or G2 (n=102,63.8%). Ribociclib combined with AI were used in 147 (91.3%) patients and with fulvestrant in only 14 (8.7%). Dose reduction was required in 43 (26.2%) patients, mostly because of neutropenia (n=34, 20.7%) and abnormal liver enzymes (n=17, 10.4%), while 18 (11.0%) discontinued treatment or switched to another CDK4/6 inhibitors, including 3 (1.8%) due to cardiac toxicities. Patients were followed up for a median of 41.0 (range 27-54) months. Overall response rate (ORR) was 64.6% and median PFS, irrespective of the line of therapy, was 35.0 months (95% CI, 30.6-42.2). PFS was longer in those with bone-only metastasis; 48.1 (95% CI, 35.0-59.1) versus 33.3 (95% CI, 29.0-40.2) months for patients with visceral metastasis (HR 0.45; 95% CI 0.25-0.83; P=0.011.), and for those with de novo MBC; 42.1 months (95% CI, 37.1-55.2) vs. 29.0 months (95% CI, 25.4-35.9) in patients with recurrent disease. In multivariate analysis, only timing of metastasis (de novo versus recurrent) had significant impact on PFS (HR, 2.82; 95% CI, 1.46-5.43; p=0.002). The median OS for the whole group was 56.8 (95% CI ,44.9%-NR).

Conclusions: Outside the stringent clinical trials settings, and in a resource-restricted country, treatment outcomes of ribociclib and AI or fulvestrant in premenopausal patients with MBC, in real-world settings, are comparable to those reported in major clinical trials, including the MONALEESA-7.

P3-12-03: Optimizing Treatment Sequence for Inoperable LABC: Long-Term Outcomes of Surgery First vs. Neoadjuvant Chemotherapy in a Real-World Setting

Yu Song, Bowen Liu, Yan Lin, Ying Xu, Xin Huang, Yidong Zhou, Qiang Sun

Background: Breast cancer is the most common cancer in Chinese women. Locally advanced breast cancer (LABC) is a subtype with a high incidence and poses a significant treatment challenge. Traditionally, inoperable LABC patients receive neoadjuvant chemotherapy (NAC) followed by surgery. However, not all patients benefit from NAC, raising questions about the need for a more precise definition of inoperability and the potential benefits of upfront surgery.

Objectives: This retrospective cohort study aimed to assess the feasibility and efficacy of upfront surgery compared to NAC as the initial treatment approach for inoperable LABC patients. The study also evaluated the impact of various factors on disease-free survival (DFS) and overall survival (OS).

Methods: The study included 243 patients diagnosed with inoperable LABC (excluding T3N1M0) at PUMCH between January 2017 and December 2018. Patients were divided into two groups: initial surgery (n=187) and NAC (n=56). Propensity score matching (PSM) was used to minimize selection bias. The primary endpoint was investigator-assessed DFS and OS. Secondary endpoints included confirmed objective response rate and subgroup analyses based on age, tumor stage, lymph node stage, molecular subtypes, and treatment response. Survival was estimated using the Kaplan-Meier method with log-rank tests for comparisons. Cox proportional hazards models were used for univariate analyses in different subgroups (Figure 1).

Results: The median follow-up was 60.9 months. The 5-year OS was 89.6% for the upfront surgery group and 81.9% for the NAC group (p=0.12). Similarly, the 5-year DFS was 73.0% and 67.1%, respectively (p=0.24). No significant difference in survival outcomes was observed between the two groups overall (Figure 2).
Subgroup analyses revealed that upfront surgery resulted in significantly better OS for patients younger than 60 years old (HR=0.32; 95% CI, 0.10 to 0.96; P=0.0429) and those with stage IIIA disease (HR=0.22; CI, 0.06 –0.86; P = 0.03). There was a trend towards better OS for patients with tumors smaller than 5cm receiving upfront surgery (HR=0.37; 95% CI 0.13 –1.03; p=0.056). NAC response also played a role, with patients experiencing progressive disease (PD) or stable disease (SD) after NAC having a significantly worse DFS (HR, 0.27; 95% CI, 0.09 to 0.79; P = 0.017) and OS (HR, 0.09; 95% CI, 0.02 to 0.48; P =0.004) compared to those who responded well to NAC (Figure 3).

Conclusion: This study suggests that upfront surgery may be a viable and potentially beneficial treatment option for a subset of inoperable LABC patients, particularly those younger than 60 years old, with stage IIIA disease, or smaller tumors. Additionally, the response to NAC can be a valuable factor in guiding treatment decisions. These findings highlight the need for a more nuanced approach to LABC treatment, considering patient characteristics and NAC response. Further research is warranted to refine the definition of inoperability and develop personalized treatment strategies for LABC patients.

P3-12-04: Aromatase Inhibitors versus tamoxifen for Elderly Breast Cancer Patients: A Retrospective Study on the Survival Outcomes

Jinyoung Byeon, Eunhye Kang, Ji-jung Jung, Changhoon Lee, Hyelim Kang, Min Jung Lee, Hong Kyu Kim, Han-Byoel, Wonshik Han, Hyeong-Gon Moon

Background: The use of aromatase inhibitor (AI) significantly reduced breast cancer recurrences in postmenopausal women with hormone receptor (HR)-positive breast cancer when compared to tamoxifen. However, there is limited data on the efficacy of AI in elderly patients. This study aimed to compare the outcomes of adjuvant AI versus tamoxifen in elderly breast cancer patients.

Methods: This retrospective cohort study used the clinical records of postmenopausal patients who underwent breast cancer surgery and adjuvant treatment at Seoul National University Hospital between January 2000 and December 2020. Postmenopausal women with HR-positive and human epidermal growth factor receptor 2 (HER2)-negative stage I to III breast cancer were included for analysis. Elderly patients were defined as patients aged 70 or older.

Results: Among a total 3,952 postmenopausal patients, 3,315 (83.9%) were age <70 and 637 (16.1%) were >=70. Patients aged <70 included 2,434 patients in the AI group and 881 patients in the tamoxifen group. The median age of the participants was 57 years [IQR, 53 to 62]. After a median follow-up of 95.2 months [IQR, 71.5 to 126.0], there was no significant differences in overall survival (OS), breast cancer-specific survival (BCSS), and distant metastasis-free survival (DMFS) between the AI and tamoxifen groups. However, a significant difference was observed in disease-free survival (DFS) between the two groups (Hazard ratio, 1.36; 95%CI, 1.09-1.68, p=0.005), with the tamoxifen group showing a higher risk of disease recurrence compared to the AI group. In the multivariate analysis, the tamoxifen group continued to demonstrate a higher risk of recurrence compared to the AI group in patients under the age of 70 (OR, 1.46; 95%CI, 1.13-1.87).
We identified a total of 637 breast cancer patients aged ≥70 during the study period who met the inclusion criteria. Among them, 505 patients were treated with AI and 132 with tamoxifen. The median age of patients was 74 years [IQR, 72 to 77]. After a median follow-up of 62.3 months [IQR, 47.2 to 80.7], there was no significant difference in OS, BCSS, DFS, and DMFS between the AI and tamoxifen groups. The 10-year BCSS and 10-year OS for patients treated with AI was 96.1% and 62.3%, respectively, suggesting most of the mortality was unrelated to their breast cancer.

Conclusion: These findings suggest that in elderly breast cancer patients aged ≥70, the use of AI did not provide survival benefit over tamoxifen. Most of the mortalities in these elderly patients were unrelated to breast cancer. Our data indicates that the choice of endocrine therapy in elderly patients can be tailored to each patient's comorbidity and quality of life with no meaningful difference in oncologic outcomes.

P3-12-05: Real-world use of sacituzumab govitecan (SG) in the management of metastatic triple-negative breast cancer (mTNBC) through a Canadian Patient Support Program (PSP)

Pierre-Luc Tanguay, Meng Wang, Winson Y. Cheung, A. Anna Cumaraswamy, Philip Q. Ding

Background: In the ASCENT trial, SG demonstrated significant survival improvements compared to single agent chemotherapy in previously treated mTNBC. Based on these findings, SG was approved by the FDA and Health Canada in 2021 for the treatment of adult patients with unresectable locally advanced or metastatic TNBC who have received ≥2 prior systemic therapies, at least one of them in the metastatic setting. Here, we report the first study to characterize the real-world use of SG in patients with previously treated mTNBC in Canada.

Methods: This was a cohort study of Canadian patients with unresectable locally advanced or metastatic TNBC who received at least one dose of SG between November 2021 and December 2023 via the Gilead Sciences Canada's Patient Support Program post-approval. Demographic and clinical data were collected as part of PSP enrollment. Patients were followed up until the end of treatment, defined as death, SG discontinuation or lost to follow up, whichever occurred the first. The Kaplan-Meier method was used to estimate treatment duration.

Results: A total of 453 patients were identified with a median age of 58 years and mean weight of 71 kg. 245 patients (54%) were primarily treated at a cancer centre and 208 patients (46%) were treated at private infusion Innomar Clinics location. Patients were enrolled in the PSP to receive SG in second-line (2L, 29%); 3L (43%) or 4L+ (28%). The median treatment duration was 4.2 months (95% CI 3.7-4.9). The median dose at treatment initiation was 10.0 mg/kg (IQR, 10.0-10.0) and 355 patients (78%) experienced at least one dose delay and 250 patients (55%) experienced at least one dose reduction. Treatment delay and dose reduction were due to any reason. Among the 323 patients who discontinued treatment, 197 (61%) discontinued due to physician decision in the context of change in patient condition or disease progression. Patients aged < 65 years at enrollment had a median treatment duration of 4.4 months (95% CI 3.7-5.1), whereas those aged ≥ 65 years had a median treatment duration of 3.8 months (95% CI 3.0-5.3). The median treatment duration of SG was 3.7 months (95% CI 3.0-5.3), 4.7 months (95% CI 3.9-5.6), and 3.5 months (95% CI 2.8-4.9) when used in 2L, 3L, and 4L+, respectively with a logrank

p=0.2.

Conclusions: This study reports real-world SG treatment patterns that are generally consistent with those of the ASCENT trial. These findings support the clinical benefit of SG demonstrated by existing clinical trial data. Potential limitations include the limited capacity of the PSP, the presence of unmeasured confounding, purposive sampling during PSP enrollment, and lack of data linkage.

P3-12-06: Locoregional and contralateral breast tumor events within 5 years after diagnosis of primary breast cancer in the Netherlands: a population-based study including 121,426 breast cancer patients

Sabine Siesling, Joyce Meijer, Marissa C. van Maaren, Linda de Munck, Linetta Koppert, Desirée van den Bongard

Background: Due to an increasing incidence, improving survival rates and changes in treatment patterns, a comprehensive overview of trends in breast tumor events (BTE) in breast cancer survivors is highly needed. In this study, contemporary trends in the occurrence of locoregional and contralateral BTE in patients with previous non-metastatic invasive breast cancer in the Netherlands were investigated.

Methods. In this nationwide population-based study, women ≥18 years diagnosed with primary non-metastatic invasive breast cancer between 2003-2008 and 2012-2016, treated with local surgery in the Netherlands, were selected. Data on patient-, tumor-, and treatment-related characteristics were retrieved from the Netherlands Cancer Registry. Data on BTE of breast cancer patients diagnosed between 2003 and 2008 were collected 5 years after primary diagnosis from all hospitals in the Netherlands in retrospect by checking all patient files. For patients diagnosed between 2012 and 2016, data on locoregional BTE were collected by linking the NCR to the Nationwide Pathology Archive (PALGA). Patients with suspected locoregional recurrence were selected through an algorithm based on diagnostic codes within the database and dates of occurrence. Descriptive statistics and Chi-squared tests were performed to compare both cohorts with regard to patient-, tumor-, and treatment-related characteristics and to identify potential differences over time. Five-year event rates were calculated per type of BTE (ipsilateral, regional, and contralateral), and stratified for age at primary diagnosis (<50, 50-69, or ≥70), primary tumor stage (stage I, II, or III), primary subtype based on hormone receptor status and human epidermal growth factor receptor 2 (HR+/HER2-, HR+/HER2+, HR-/HER2+, or HR-/HER2-), and primary tumor grade (grade I, II or III). An ipsilateral breast event was defined as an event in the same breast as the primary breast cancer, i.e. an in-breast recurrence or a second primary breast cancer. A regional event was defined as a regional lymph node metastasis on the same side as the primary breast cancer, where regional lymph nodes were defined as either axillary, periclavicular, or internal mammary lymph

node regions. A contralateral breast event was defined as an event in the contralateral breast as the primary breast cancer, which could be either in situ or invasive breast cancer. Findings. Of the 121,426 included breast cancer patients, at least one type of BTE was observed in 6,256 patients (5.2%), of which 422 patients (6.7%) had multiple events at the same time (occurring within 30 days). Five-year ipsilateral, regional and contralateral breast event rates decreased from 3.3%, 1.8% and 2.7% in 2003 to 2.0%, 1.3% and 2.0% in 2016, respectively. The largest decreases were shown in ipsilateral breast event rates for stage III (4.7% in 2003 to 1.7% in 2016) and grade III (5.5% in 2003 to 2.1% in 2016). Interpretation. Taking the change of way of notification into account, our study indicates a slight decrease in or at least stable event rates of ipsilateral, regional, and contralateral BTE in breast cancer patients with a primary diagnosis between 2003-2008 and 2012-2016 in the Netherlands. As breast cancer treatment has been personalised increasingly over the last decades, with de-escalation of local treatment and more options in systemic treatment, it is reassuring that BTE have not increased.

P3-12-07: SARELIFE study: Safety and efficacy of Sacituzumab Govitecan (SG) in pretreated metastatic triple negative breast cancer (mTNBC): a multicentric, real-life study

Elena Florio, Giovanna Catania, Elisa Gallerani, Giuliana D'Auria, Paola Tagliabue, Andrea Botticelli, Rita Chiari, Federica Villa, Alessandra Chirco, Monica Giordano, Mirco Pistelli, Francesco Verderame, Annalisa Bramati, Agnese Latorre, Simonetta Chiara Stani, Patrizia Vici, Icro Meattini, Beatrice Tedesco, Azzurra Irelli, Serena Madaro, Giusy Ricciardi, Laura Roazzi, Luigi Rossi, Luigia Stefania Stucci, Sara Zanelli, Barbara Tagliaferri, Lorenzo Ruggieri, Ottavia Amato, Anna Gambaro, Davide Dalu, Alessio Midali, Francesca Galli, Eliana Rulli, Nicla La Verde

Background: mTNBC is an aggressive subtype of breast cancer with poor prognosis, so treatment primarily aims to prolong patients (pts) survival and improve their quality of life. SG is a new antibody-drug conjugate that incorporates the anti-TROP2 antibody hRS7 conjugated to a topoisomerase-1 (TOP1) inhibitor payload, that increased overall survival (OS) in pretreated mTNBC. Based on the results of ASCENT pivotal study, SG was approved in Italy since August 2022 for mTNBC pts, pretreated with at least 2 previous lines of chemotherapy. To date, very fragmentary real-world data are available. In order to study safety and efficacy of SG outside of a registrative trial, the SARELIFE study was designed.

Patients and Methods: This is an observational, retrospective and prospective study, whose primary objective was to evaluate the safety of SG in a real-world population. The secondary objectives included: treatment adherence, safety of concomitant radiation therapy (RT) and drug-drug interactions (DDI), response rate according to RECIST v1.1 criteria, progression free survival (PFS) and OS. Treatment-related adverse events (AEs) were categorized and graded according to NCI-CTCAE v5.0. Data were analysed for safety, activity and survival

outcomes, and the results were reported using descriptive statistics.

Results: Since August 2023 to July 2024, 121 women were enrolled from 27 Italian centres. Median age was 59 years (range: 31-86). PS (ECOG) was 0-1 in 89.7% of pts; 12% had ≥ 2 comorbidities; 10.4% of pts were gBRCAmut carriers; 23.1% were metastatic at the diagnosis. Visceral metastases (mts) were present in 62.6% of pts, the commonest metastatic site was lung (40.9%), 12.2% had brain mts. Median number of prior treatment lines was 2 (range: 0-8): 29.3% of pts had received >2 prior lines of therapy, 26.7% had been treated with immunotherapy and 9.5% with PARP inhibitors.
For the safety analysis, 116 pts were considered: 68.1% experienced at least one AE of any grade. The most frequent were: neutropenia (51.9%, G3/G4: 24.1%), fatigue (45.6%, G3/G4: 3.8%), nausea (44.3%), diarrhoea (32.9%, G3: 5.1%), anaemia (27.8%, G3: 6.3%) and febrile neutropenia (6.3%, G4: 3.8%). 1 case of G3 pneumonitis was recorded. No G5 AEs observed. Median time to the onset of the first AE is 21 days. Dose reductions were needed for 43 pts. Median time to first dose reduction: 39 days (range 7 -161). 4 pts discontinued SG due to toxicities. UGT1A1 status was evaluated in 18 pts: 4 were (*28/*28), 6 were (*1/*28). In the (*28/*28) group only 1 case of G3 anaemia was reported. Interestingly, 21 pts received RT during SG treatment, including 10 concurrent treatments, but no additional AEs occurred. Data analyses on DDI are still ongoing.
With a median follow-up of 11.5 months, the median PFS was 5.9 months (95%CI: 4.5-6.8), while the median OS was 14.1 months (95%CI: 11-16.3) these data were consistent with those reported in the ASCENT study (mPFS: 5.6 months; mOS: 12.1 months). Best response was evaluable in 95 pts: 25.2% obtained partial response (PR), 1% complete response (CR), 40% stable disease (SD) and 31.5% progression disease (PD).

Conclusions: SARELIFE offers an interesting overview on the performance of SG in an unselected real-world mTNBC population. Of note, in our study was included also a small percentage of pts with PS (ECOG): 2, excluded in the ASCENT trial. No new safety signals were reported. Survival outcomes are surprisingly good. Concomitant RT appears safe, although few pts underwent to both treatments.

P3-12-08: Results of the cohort w/ central nervous system (CNS) metastasis in the real-world evidence observational study SACISUR, patients treated w/ Sacituzumab-Govitecan (SG) in triple neg metastatic breast cancer (mTNBC) clinical practice in the south

Alejandro Falcón-González, Llabrés-Valenti Elisenda, Urbano-Cubero Rocio, Morales-Estévez Cristina, Martín-Calero Braulio, Nieto-Ramírez Julio César, Díaz-Redondo Tamara, Casaut-Lora Estefanía, Chavarría-Piudo Natalia, Vargas-Prado Ana Milena, Morales-Pancorbo David, Zarcos-Pedrinaci Irene, González-Alba Alba, Estalella-Mendoza Sara, Godoy-Ortiz Ana, Valero-Arbizu María, González-Flores Encarna, Acosta-Sánchez Ariadna,

Vicente-Rubio Elena, De Toro-Salas Rubén, Cano-Jiménez Alicia, Alba-Conejo Emilio, Sánchez-Guisado Antonia, Rodríguez José Francisco, Cruz-Jurado Josefina, Gil-Torralvo Ana, De la Fuente-Domínguez Icíar, Rodríguez-García Jose Andrés, Cejuela-Solís Mónica, Torres-Zurita Alberto, Benavent-Viñuales Marta, Henao-Carrasco Fernando

Background: mTNBC patients will develop metastasis in CNS in between 25-46% along the course of the treatment. SG is a new antibody-drug conjugate against Trop-2 that has been approved for the treatment of mTNBC after progression on at least one previous line of chemotherapy (CTX) for advance disease. In the ASCENT trial, progression-free survival (PFS) and overall survival (OS) were longer with SG compared with CTX (5.6 vs 1.7 months PFS and 12.1 vs 6.7 months respectively). In this trial, 11.5% of patients (61/529) had metastasis in CNS but they were excluded of the final survival analysis.

Methods: We included 159 patients with mTNBC treated at least with 1 cycle of SG between 1 January 2022 and 31 December 2023. This study has been supported by SAOM (Andalusian Society of medical oncologist). The aim of this abstract is presenting the results in the cohort of metastasis in SNC. Results of all the patients will be presented in a different poster.
Statistical analysis was made by IBM SPSS statistics, including descriptive results of the population and survival analysis by Kaplan-Meier.

Results: We report the data of 22 female patients treated in 18 different hospitals of Andalucía, Canarias and Extremadura (Spain). These patients represent a 13.9% of total of 159 patients treated in our study. All of them were treated with radiotherapy previous to the use of SG.
The median age was 47 years (50 % premenopausal, 50% Her2low). 22.7% were de novo, stage I-III patients were treated with CTX in the early setting in 54.5% in neoadjuvant and 41.2% in the adjuvant setting. Pathological complete response was 9% in the case of neoadjuvant treated patients.
Medium previous line of therapy was 2.4 (2-4) with a medium of 4.1 cycles of SG. SG was received in second line in 68.2% patients, 22.7% patients in third line and 9.1% in fourth line. 18.2% received immunotherapy in first line.
With a median follow-up of 11.8 months, PFS was 2.27 months (95% CI, 1.36-3.17) (fig 1). The percentage of patients with an objective response was 13.6% (36.3% with clinical benefit rate).
The incidence of diverse adverse events were neutropenia 45.5% (G3-4 27.2%), diarrhea 36.8% (G3-4 9.1%), nauseas 21.1% (G3-4 5.3%) and ALT/AST elevation 30% (no G3-4). The use of GCSF were 18.2 % as primary prophylaxis and 18.2 % as secondary prophylaxis. None of the patients finished SG due to adverse events and 31.8% had at least one dose reduction.

Conclusions: SG has worse results in survival for patients with CNS metastasis. Despite these results, patients could be treated with this drug safely taking in account the bad prognosis of this situation.

P3-12-09: Evaluation of the Early Risk of Recurrence in HR+/HER2- Early Breast Cancer Patients – A Retrospective Study Based on the Chinese National Cancer Database

Qiao Li, Mingxia Jiang, Jiaxuan Liu, Mengqi Zhang, Binghe Xu

Background: Recent published studies have demonstrated the value of CDK4/6i in the adjuvant setting by significantly reducing the risk of recurrence (ROR) in high-risk and intermediate-risk patients (pts). However, the ROR and adjuvant treatment pattern has not been reported in China. This study explored the ROR of 3-year and 5-year in HR+HER2- eBC pts who were treated with standard of care in China within the last decade.

Methods: This study retrospectively analyzed the electronic medical record (EMR) of a random sample of the pts with HR+/HER2- eBC (stage I-III) that were diagnosed from Jan. 2013 to Dec. 2022 from the Chinese National Cancer Database, which is the largest oncology database in China. Pts received primary breast tumor surgery and adjuvant therapy were included into the analysis. while pts with concurrent malignant tumors other than BC were excluded. RFS was defined as time from surgery to recurrence. RFS analysis was performed using SAS v9.4 software with cutoff date of Dec 31, 2023. Hazard ratio (HR) and 95% confidence interval (CI) were derived from Cox proportional hazards regression models.

Results: A total 3295 of HR+/HER2- eBC pts from the database were included in the analysis. Median age at diagnosis was 49.0 years (range,22-80 years). Majority (98.4%) were women with 54.5% in premenopausal status. There were 728 pts (22.1%) , 1558 pts (47.3%) and 1009 pts (30.6%) in stage I, stage II and stage III respectively. 62% of pts had lymph node metastasis (LN+). 3006 pts (91.2%) received AET, which contained 96 pts (3.2%) who received CDK4/6i combination treatment. The analysis showed that with a median follow up of 20.8 months (range, 0.5-121.7 months), the 3-y and 5-y RFS rates were 87.3% (95% CI, 85.7-88.9%) and 77.5% (95% CI, 74.9-80.2%), respectively. The 3-y RFS rates in stage III, II and I were 75.1%, 91.2% and 95.2% respectively. Compared to stage I, the ROR of pts in stage III (HR 4.62, 95% CI 3.25-6.56) and stage II (HR 1.75, 95% CI 1.21-2.52) were significantly higher. More importantly, the ROR of pts eligible for NATALEE trial (NATA-Group) was higher than those not eligible for NATALEE trial (nonNATA-Group) (3-y RFS rate 83.9 % vs 95.3%; HR 3.02, 95% CI 2.17-4.19). NATALEE eligible pts were defined as pts in stage II and stage III who with LN positive, or LN negative with high-risk. The ROR of pts who received AET showed consistent trend with total population.
Conclusions
This analysis from the Chinese National Cancer Database indicates that the ROR for stage II

and III breast cancer within 5 years is relatively high in China. Pts eligible for the NATALEE trial exhibits a significantly higher ROR compared to lower risk pts who are not eligible for NATALEE trial and warrant the consideration for tolerable ET adjuvant treatment escalation.

P3-12-10: Utilizing Registry Data to Explore Treatment Patterns in HR+ HER2-Negative Metastatic Breast Cancer: Insights from Denmark and Norway

Anja Reithmeier, Alina Carmen Porojnicu, Morten Johnsen, Trude Ågesen, Johan Liseth Hansen

Background: Breast cancer (BC) represents the most common cancer in women worldwide [1] and within the metastatic setting (mBC) the treatment options are continually evolving [2]. Using the unique, nationwide, population-based registries in Denmark and Norway linked on individual level, we aimed to identify patients with BC and define treatment lines in the metastatic setting exemplified by forming a patient cohort of hormone receptor-positive and human epidermal growth factor receptor 2-negative (HR+/HER2) metastatic BC (mBC).
This registry-based study aims to link data from national registries in both Denmark and Norway to explore/provide real-world data on treatment pattern exemplified by patients treated in the metastatic setting.

Methods: This is a cohort study utilizing the BC registries in Denmark and Norway linked to information from hospital administered treatment from prescription databases and patient registers to describe the treatment pattern in a selected BC cohort.
The cohort included both de novo mBC patients (Stage IV) or recurrent BC (incident Stage I-III) patients between 2017-2021 for Denmark, and 2017-2022 for Norway. De novo mBC patients were identified by using the national cancer registries (ICD-10 code: C50) with confirmed metastatic disease. Recurrent patients included those who had incident stage I-III diagnosis between 2008-2021 and 2008-2022, for Denmark and Norway respectively, and that progressed to metastatic disease from 2017 and onwards. An algorithm to identify recurrence was built including information from patient registers, hospital treatments, and pathology reports (only in Denmark).
HR and HER2-status were collected from the Danish nationwide pathology register and Norwegian quality of care register for BC.

Results: We identified 449 and 597 patients with HR+/HER2- de novo mBC and 1373 and 1218 with HR+/HER2- recurrent mBC in Denmark and Norway, respectively. Hereof, n=1651 (90.6%) patients in Denmark, and n=1562 (86.1%) of patients in Norway received a 1L treatment. In Denmark the most common first line (1L) treatment was endocrine treatment monotherapy, n=603 (36.5%), followed by CDK 4/6 inhibitor + endocrine

combination therapy with n=512 (31.0%), and chemotherapy, n=423 (25.6%). In Norway, the most common 1L treatment was CDK 4/6 inhibitor + endocrine combination therapy with n=672 (43.0%), followed by endocrine treatment monotherapy n=549 (35.2%), and chemotherapy, n=252 (16.1%). The number of patients that received a second line treatment and beyond (≥2L) in Denmark was n=812 (48.3%), and in Norway was n=930 (59.0%). The number of patients who stayed on their 1L treatment until the end of follow-up was n=478 (28.4%) and n=273 (17.3%), and the number of patients who stayed on 1L until death was n=391 (23.3%) and n=373 (23.7%) in Denmark and Norway, respectively.

Conclusion: Endocrine treatment, either as monotherapy or combination therapy with CDK4/6 inhibitors are the predominant recommended treatment for patients with HR+/HER2- mBC in 1L in Norway and Denmark. Our results show that patients are generally treated according to these guidelines. Hence, the administrative Danish and Norwegian registers are well suited to study treatment lines among patients with HR+/HER2- mBC and to identify recurrent patients. This work enables further studies on treatment outcomes, comparative effectiveness, and healthcare costs.

P3-12-11: Effect of pretreatment lab abnormalities on the time-to-treatment discontinuation and overall survival on hormone receptor-positive metastatic breast cancer patients receiving targeted therapies

Jeffrey Franks, Andres Azuero, Kelly Kenzik, Nusrat Jahan, Mackenzie Fowler, Russell Griffin, Gabrielle Rocque

Background: Metastatic breast cancer (MBC) randomized controlled trials (RCTs) enroll healthier patients than the general population. However, given that over one quarter of women have a comorbidity at the time of their breast cancer diagnosis, RCTs may inadequately represent the patient population. Therefore, the purpose of this study was to estimate time-to-treatment discontinuation (TTD) and overall survival (OS) for patients with and without lab abnormalities receiving a targeted therapy for MBC.

Methods: This retrospective study used the nationwide, de-identified electronic health record-derived Flatiron Health database to include women with hormone receptor-positive, Human epidermal growth factor receptor 2- negative MBC with receipt of a cyclin dependent kinase (CDK) 4/6 inhibitor everolimus, or alpelisib between 2011 and 2020. Lab tests included platelet count, neutrophil count, lymphocyte count, hemoglobin, glucose, hemoglobin A1c, creatinine, Alanine transaminase, Aspartate transaminase, and bilirubin.

Abnormalities were defined by common exclusionary cut-offs in targeted therapy clinical trials. TTD was defined as time from treatment initiation to the first occurrence of either treatment change or death. The secondary outcome was OS defined as time from treatment initiation to death from any cause. Parametric accelerated failure time (AFT) models estimating the survival time ratio, predicted mean survival time differences, and 95% confidence intervals (CIs) were used for the association between lab abnormalities and TTD or OS. All models were adjusted for age at treatment initiation, race and ethnicity, site of metastasis, concurrent treatment, and line of therapy.

Results: Among patients with receipt of a CDK 4/6 inhibitor, patients with at least one lab abnormality had 33% (MR, .67; 95% CI, .59, .68) lower TTD than those with no lab abnormalities. On average, the predicted TTD for those with no lab abnormalities was 8 months longer than those with lab abnormalities. Similar differences in the CDK 4/6 cohort were observed in OS where those with at least one abnormality had 25% (MR, .75; 95% CI, .70, .81) lower OS than those with no lab abnormalities. In our sample of patients with receipt of everolimus, more modest differences were seen in TTD. After adjusting for covariates, patients with at least one lab abnormality had 10% (MR, .90; 95% CI, .83, .98) lower TTD than those with no lab abnormalities. Similarly, patients with receipt of Everolimus and at least one abnormality had 12% (MR, .88; 95% CI.76, .98) lower OS compared to those without an abnormality. Finally, among those with receipt of alpelisib, those with any lab abnormality had 25% (MR, .75; 95% CI, .64, .87) lower TTD than those without any abnormalities. On average, patients without any lab abnormalities had 1.5 months longer survival than those with abnormalities. For OS, patients with receipt of Alpelisib with lab abnormalities had 37% (MR, .63; 95% CI, .51, .78) lower survival than those without a lab abnormality.

Conclusion: Patients with lab abnormalities saw significantly lower TTD and OS than those without abnormalities. More real-world studies of patients with lab abnormalities are needed to empower oncologists when making treatment decisions in high-risk populations, to discuss prognosis and to inform RCT eligibility criteria.

P3-12-12: Real-World Efficacy and Outcomes of CDK4/6 Inhibitors in HR+ Metastatic Breast Cancer: A Retrospective Analysis from Russia

Anastasia Danilova, Daniil Stroyakovsky, Polina Shilo, Irina Nigmatullina, Ignat Profatilo, Nikolai Ryabishin, Valery Nyashin, Vera Vashenko, Dmitry Kanner

Background: The use of CDK4/6 inhibitors has transformed the treatment landscape of HR+ metastatic breast cancer, improving progression-free survival and, in some studies, overall survival. Most of the available data come from randomized clinical trials, but the importance of data from real-life settings cannot be understated. This is the largest data set to date on the use of CDK4/6 inhibitors in routine clinical care in Russia, describing the patient

population, efficacy of treatment, comparing CDK4/6 inhibitors head-to-head, and describing post-treatment outcomes.

Materials and Methods: We retrospectively evaluated all orders of CDK 4/6 inhibitors prescribed at Moscow 62 Oncology Center in Russia and identified 803 patients who received CDK4/6 inhibitors plus endocrine therapy for advanced HR+ breast cancer. We then performed survival analysis to identify differences between CDK4/6 subgroups using Kaplan-Meier curves, the log-rank test, and Cox regression. Differences were considered statistically significant when $p<0.05$.

Results: 803 patients were included in the final analysis with a median follow-up of 37 months. Patient characteristics are described in the table below:
Patient Characteristics (N=803)
Median age: 57 years
HistologyNOS: 58 (77.3%)Lobular: 137 (18.2%)Other: 34 (4.5%)
Tumour grade1: 21 (3.4%)2: 384 (62.3%)3: 34.3%
Her2 status0: 172 (22.9%)1: 522 (69.5%)2 (FISH -): 57 (7.6%)Her2 low: 77.1%
Mutational StatusBRCA1/2 (status known in 14.4% of patients): 9.5% (12 patients positive)PIK3CA (status known in 20.2% of patients): 34.6% (56 patients positive)
StagingDe novo metastatic: 41.1%Progression: 58.9%
Metastatic SitesBone metastases present: 546 (68.3%)Liver metastases present: 134 (16.8%)Lung metastases present: 221 (27.7%)Brain metastases present: 20 (2.5%)
Line of CDK4/6 Therapy (median): 1
CDK4/6 InhibitorsPalbociclib: 408 (50.9%)Ribociclib: 346 (43.2%)Abemaciclib: 47 (5.9%)
Endocrine TherapyAnastrozole/Letrozole: 495 (62.0%)Fulvestrant: 277 (34.7%)Exemestane: 26 (3.3%)
Treatment EffectComplete response: 27 (3.4%)Partial response: 194 (24.7%)Stable disease: 518 (65.9%)Progression: 46 (6.0%)
Reason for DiscontinuationProgression: 410 (80.7%)Toxicity: 40 (7.9%)Patient refusal: 15 (3.0%)Other: 8.5%
The main efficacy endpoints in the overall population were progression-free survival (PFS) of 27 months (95% CI [23.6-30.4]) and overall survival (OS) of 47 months (95% CI [42.6-53.4]). Median PFS2 was 7.1 months.
Post progression therapy
Chemotherapy 63%Endocrine 37%
The baseline characteristics of the different CDK4/6 inhibitor subgroups were well balanced without any adjustment. There were no statistically significant differences between CDK4/6 inhibitors: the median PFS was 24 months for Palbociclib (95% CI [19.3-28.4]), 30 months for Ribociclib (95% CI [24.7-35.3]), and 32 months for Abemaciclib (95% CI [18.4-45.7]), $p = 0.743$. The follow-up periods were different between subgroups, with less mature data for Abemaciclib and the most mature for Palbociclib. We adjusted for follow-up to address this, but there were still no statistically significant differences between

CDK4/6 inhibitors (p = 0.689). Multivariable Cox regression showed that the type of CDK4/6 drug is not an independent predictor of survival. There were no statistically significant differences between metastatic site subgroups:mPFS by site of metastasis Palbo vs Ribo
Bone only disease 27 months vs 30Bone metastases present 23 vs 25 monthsBone metastases absent 41 vs 44 monthsLiver metastases present 15 vs 14 monthsLiver metastases absent 28 vs 32 monthsLung metastases present 23 vs 29 monthsLung metastases absent 26 vs 30 monthsVisceral metastases present 20 vs 25 monthsVisceral metastases absent 30 vs 32 months
InterpretationThese are the largest real-world data presented from routine clinical practice in Russia. These data confirm the results of several randomized clinical trials, providing even more information on the use of CDK4/6 inhibitors. We performed an analysis comparing the two most widely used CDK4/6 inhibitors, showing similar efficacy outcomes. These data provide essential information for physicians and patients reflecting real-world use of CDK4/6 inhibitors, and further analyses are underway.

P3-12-13: Malignant phyllodes tumor of the breast

Tatiana Titova, Elena Artamonova, Alexander Petrovsky

Purpose: Malignant phyllodes tumor of the breast (MPTB) is a rare type of breast cancer, with an incidence of less than 1%

Methods: Data on patients with a malignant MPTB were treated in N.N. Blokhin NMRCO from July 2018 to July 2023

Results: 31 MPTB patients were included in this study. Median age was 46 years. Median follow-up was 26.3 months. 13 cases (41,9%) experienced local recurrence, 7 cases (22.6%) exhibited distant metastasis, and 8 cases (25.8%) resulted in death. MPTB patients more often had breast-conserving surgery (BCS) as a surgery (67,7%). In MPTB adjuvant radiotherapy was given in 25.8%. The observed PFS at 12 months was 69% and PFS at 24 months was 27%. The observed OS at 12 months was 90%. Among patients with initial margins < 1 cm, LRFS (P = 0.004) and DFS (P = 0.003) were improved in patients reoperated to achieve margins ≥ 1 cm. Surgical margin < 1 cm (HR = 1.567, 95%CI 1.137-2.793, p = 0.043) and age < 45 years (HR = 1.059, 95%CI 1.022-3.008, p = 0.047) were identified as independent risk factors for local recurrence-free survival.

Conclusions: Surgical margin < 1 cm and age < 45 years were identified as independent risk factors for local recurrence-free survival for MPTB.

P3-12-14: Real world data with standard (SD) and reduced dose (RD) sacituzumab-govitecan (SG) in metastatic triple negative (TNBC) and ER+/HER2- metastatic breast cancer (mBC)

Naji Mallat, Nicholas Stabellini, Alexis Bennett, Naji Mallat, Bahar Moftakhar, Cynthia Owusu, James Martin, Takae Mizukami, Amanda Amin, Corey Speers, Alberto J. Montero

Background: SG is a Trop-2–directed antibody-drug conjugate currently FDA approved for: (i) unresectable, locally advanced or metastatic TNBC following ≥ 2 prior systemic therapies; and (ii) pretreated HR+/HER2- mBC following endocrine-based therapy. In the ASCENT and TROPiCS phase 3 trials, SG was shown to be superior to chemotherapy of physician's choice with superior median progression free survival (PFS), overall survival (OS), as well as higher overall response rates (ORR). This activity, however, comes with increased toxicities, primarily diarrhea and neutropenia. Cancer drugs have long been administered to patients (pts) at the maximum tolerated dose, which is selected on the basis of evaluating increasing doses in small groups of pts for short periods of time. It is therefore likely that a slightly lower SG dose may have comparable efficacy and less toxicity than the FDA approved SG dose. This study aimed to assess treatment patterns and clinical outcomes in mBC pts who received SD versus RD of SG.

Methods: This retrospective single-institution cohort study utilized de-identified patient data obtained from chart reviews. We included mBC pts who received at least 1 cycle of SG between April 30, 2021 and April 30, 2024. SG treatment parameters and patient characteristics were obtained. PFS and OS estimates from the date of SG initiation to the date of the last follow-up were assessed using the Kaplan-Meier method. Differences of OS and PFS between SD and RD groups were examined by log-rank test.

Results: We analyzed 47 mBC pts (median age 63 at SG initiation; 36% non-White), with 24 receiving SG at an initial SD (10 mg/kg) and 23 receiving a RD (median 8 mg/kg). In the overall cohort, 70% had TNBC (19/24 SD vs. 14/23 RD, p=0.29), and 30% had HR+/HER2- mBC (9/24 SD vs. 5/23 RD, p=0.45). Moreover, the median number of distinct metastatic sites of disease was 3; 83% had baseline visceral metastases and 23% had brain metastases. In the overall cohort, pts had received a median of 2 prior metastatic lines of therapy, with SD pts having received more prior metastatic lines of therapy (3 vs 1, p<0.01). All SD TNBC pts had previously received neoadjuvant chemo-immunotherapy with the Keynote-522 regimen (11 vs 0; p<0.001). For the overall cohort, 8.5% had received prior trastuzumab deruxtecan; 100% of HR+/HER2- pts had received prior CDK4/6 inhibitors; 42.6% of TNBC pts had received prior PD-1 inhibitor therapy. The median treatment duration for SD and RD were similar (96 vs 100 days; p=0.62). For the entire cohort, the ORR was 21% (17% RD and 26% SD). Among TNBC and ER+/HER2- pts, the ORR was 39.1% (36% SD & 21% RD) and 35.7% (20% SD & 11% RD), respectively. At the last follow-up, 40.4% of pts were alive. From the start of SG, the median PFS was 3 months for SD (95% CI 2-10) and 3

months for RD (95% CI 1-8; p=0.9). Similarly, the median OS was not statistically different between SD and RD: 9 months ([95% CI 7-NA] vs. 13 months [95% CI 5-NA]; p=0.7). From the start of SG, the overall median OS was 9 months (95% CI 6-15). From the date of initial mBC diagnosis, the median OS was 64 months (95% CI 29-92).
For TNBC pts, the median PFS and OS in months for the SD and RD groups, from the date of first SG, were 3 ([95% CI 2-10] vs. 4 months [95% CI 2-NA]; p=0.4); and 10 ([95% CI 7-NA] vs. 25 months [95% CI 8-NA]; p=0.5) respectively. Myeloid growth factor use was significantly higher in the SD group (58% vs. 0; p=<0.01). More SD pts required hospitalization due to SG toxicity compared to RD (20.8% vs. 4.3; p=0.20).

Conclusions: In this small data set, the median SG treatment duration, PFS, and OS did not appear to differ between SD and RD groups. A prospective trial with RD SG is warranted.

P3-12-15: Oncologists' Prescribing Habits for Adjuvant Therapy in Luminal Breast Cancer: Insights from a Low Middle Income Setting

Emad Shash, Ibrahim Salem Al Hussini, Nashwa Kordy, Ahmed Haggag, Salma Seddik, Mohamed Alorabi, Maha Yahia

Background: In low- and middle-income settings where genomic profiling is often inaccessible, oncologists must rely on clinicopathological factors to make crucial decisions regarding adjuvant therapy in luminal breast cancer. This study provides an in-depth analysis of how demographic and tumor characteristics influence the selection between combined chemotherapy and hormonal therapy (CTH&HT) versus hormonal therapy alone (HT) in a resource-limited environment, focusing on patients treated at the Shefa Orman Comprehensive Cancer Center in Luxor, Egypt.

Methods: We performed a comprehensive retrospective analysis of 675 luminal breast cancer patients treated from June 2016 to December 2022. The study examined the influence of variables such as age, tumor size, nodal involvement, and comorbidities on therapy choices using Chi-square tests for categorical outcomes and logistic regression for continuous predictors.

Results: The analysis revealed significant age-dependent differences in therapy choices. Patients aged ≤45 years predominantly received CTH&HT, a trend that extended up to the age of 65, suggesting a preference for more aggressive treatment in the absence of genomic risk stratification. Tumor size and nodal involvement were also critical determinants, with larger tumors and higher nodal involvement favoring CTH&HT. Specifically, 82% of chemotherapy cases employed Anthracycline-based regimens. For hormonal therapy, Aromatase Inhibitors were used in 52.3% of cases, followed by Tamoxifen (24.3%) and combinations of LHRH agonists with either AIs or Tamoxifen (23.4%). Additionally, older

patients and those with multiple comorbidities were less likely to receive aggressive treatments, even when presenting with higher-risk clinicopathological factors.

Conclusions: This study highlights a heavy reliance on traditional clinical indicators for adjuvant therapy decisions in luminal breast cancer in the absence of genomic tools. The findings stress the importance of developing tailored treatment strategies that are sensitive to the constraints of local resources and the availability of diagnostic tools. Such strategies are essential to optimizing patient outcomes in global low-resource settings.

P3-12-16: MELODY: A prospective non-interventional multicenter cohort study to evaluate different imaging-guided methods for localization of malignant breast lesions (EUBREAST-4 / iBRA-NET, NCT 05559411)

Maggie Banys-Paluchowski, Nina Ditsch, Thorsten Kühn, James Harvey, Nuh Zafer Canturk, Neslihan Cabioglu, Tove Filtenborg Tvedskov, Lina Pankratjevaite, Maria Luisa Gasparri, Dawid Murawa, Jai Min Ryu, Oreste Davide Gentilini, Rosa Di Micco, Mah Muneer Khan, Aoife Lowery, Natalia Krawczyk, Steffi Hartmann, Isabel T. Rubio, Antonio J. Esgueva, Jana de Boniface, Andreas Karakatsanis, Rajiv V. Dave, Shelley Potter, Ashutosh Kothari, Walter Paul Weber, Güldeniz Karadeniz Cakmak, Markus Hahn, Michael Patrick Lux, Marjolein Smidt, Bahadir M. Gulluoglu, Michaelis Kontos, Florentina Peintinger, Lia Pamela Rebaza, Maria Antónia Vasconcelos, Mariana Correia, Sarah Nietz, Francois Malherbe, Severine Alran, Khaled Mohammad Abdelwahab, Veronica Yamila Fabiano, Svs Deo, Yazan Masannat, Katharina Jursik, Bilge Aktas Sezen, Meldoy Study Group

Background: In the last decades, the proportion of breast cancer patients receiving breast-conserving surgery has increased, reaching 70-80% in developed countries. In case of non-palpable lesions, surgical excision requires some form of breast localization. While wire-guided localization has long been considered gold standard, it carries several limitations, including logistical difficulties, the potential for displacement and patient discomfort, and re-excision rates reaching 21%. Other techniques (radioactive seed or radio-occult lesion localization, intraoperative ultrasound, magnetic, radiofrequency and radar localization) have been developed with the aim of overcoming these disadvantages. However, comparative data on the rates of successful lesion removal, negative margins and re-operations are limited. In the majority of studies, the patient's perspective with regard to discomfort and pain level has not been evaluated. The aim of MELODY (MEthods for LOcalization of Different types of breast lesions) is to evaluate different imaging-guided localization methods with regard to oncological safety, patient-reported outcomes, and surgeon and radiologist satisfaction.

Methods: The EUBREAST and the iBRA-NET have initiated the MELODY study to assess breast localization techniques and devices from several perspectives (NCT05559411, http://melody.eubreast.com). MELODY is a prospective intergroup cohort study which

enrolls female and male patients requiring breast-conserving surgery and image-guided localization for invasive breast cancer or DCIS. Multiple or bilateral lesions and neoadjuvant chemotherapy are allowed. Primary outcomes are: 1) Intended target lesion and/or marker removal, independent of margin status on final histopathology, and 2) Negative resection margin rates at first surgery. Secondary outcomes are, among others: rates of second surgery and secondary mastectomy, Resection Ratio (defined as actual resection volume divided by the calculated optimum specimen volume), duration of surgery, marker dislocation rates, rates of marker placement or localization failure, comparison of patient-reported outcomes, rates of "lost markers" and diagnostician/radiologist's and surgeon's satisfaction as well as the health economic evaluation of the different techniques. Target accrual: 7,416 patients. Enrollment started in January 2023. The study is being conducted in 30 countries and is supported by the Oncoplastic Breast Consortium (OPBC), AWOgyn, AGO-B and SENATURK. Financial support was provided by Endomag, Merit Medical, Sirius Medical and Hologic.

P3-12-17: NCT05074290 Phase I/II study of Pharmacokinetics and Safety of Epidiferphane and Taxanes in Breast Cancer Patients

Coy Heldermon, Shu Wang, Danielle Ogden, Debra Lyon, Brent Reynolds, Karen Daily

Patients with breast cancer are commonly treated with taxane class chemotherapy agents such as paclitaxel, Nab-paclitaxel or docetaxel. Some very common side effects of taxanes, such as anemia and peripheral neuropathy, result in dose reductions, dose delays and early discontinuation (collectively called relative dose intensity) of these chemotherapy agents in 15-80 % of patients on these drugs. This reduction in relative dose intensity (RDI) results in worse clinical outcomes such as survival. Pre-clinical studies in mouse models given chemotherapy regimens containing paclitaxelhave shown that Epidiferphane (EDP) delays tumor progression, and reduces both neuropathy and anemia.This is an Investigational New Drug Study that will investigate Epidiferphane in patients with breast cancer receiving a taxane-containing chemotherapy regimen in a Phase I/II trial. In phase I, we are evaluating the safety and pharmacokinetics of two EDP dose levels when given with taxane containing chemotherapy regimens to neoadjuvant and metastatic breast cancer patients. In phase II, we will assess the safety and efficacy at reducing neuropathy and anemia and improving tumor response and patient quality of life in breast cancer patients of adding EDP to taxane containing chemotherapy regimens.We will be assessing the correlation of neuropathy and anemia with the level of neurofilament light chain, VEGFA, Nrf2, NF-κB and IL18. This correlation will determine if EDP is having a similar effect to that seen in the mice and if these markers may be useful in predicting and targeting toxicity.Our intervention will determine pharmacokinetics of and test a novel therapy for safety and effectiveness at improving response to chemotherapy, improve quality of life, and reducing cytopenias and peripheral neuropathy in patients. If effective, this therapy will: improve treatment regimens by making current chemotherapy regimens more effective, less toxic, and impact

survival - ie allowing full dose chemotherapy without the side effects of neuropathy, anemia, and other cytopenias.

P3-12-18: NEOMET: A phase II randomized trial to evaluate the impact of “targeted” nutritional support and exercise on modulation of metabolic and immune-related markers in early breast cancer (eBC) patients candidate to neoadjuvant therapy (NAT)

Ida Taglialatela, Benedetta Conte, Gaia Griguolo, Davide Soldato, Francesca D'Avanzo, Valentina Rossi, Beatrice Ruffilli, Francesca Vezzoli, Alice Coassolo, Fabrizio Condorelli, Erika Del Grosso, Carmelo Bengala, Carmen Branni, Jacopo Gennari, Maria Sole Rossato, Germano Tarantino, Marcello Manfredi, Veronica Martini, Simone Gobbato, Letizia Matera, Nicolo Sala, Luca Boni, Lucia Del Mastro, Valentina Guarneri, Alessandra Gennari

Background: Metabolic reprogramming is a well-known hallmark of cancer. In breast cancer several metabolic pathways (including fatty acid metabolism) are frequently dysregulated and contribute to enhanced proliferation and resistance to treatments. Metabolomics is an “omics” approach that allows identification of metabolic host-related factors potentially correlated with treatment outcomes. Recent evidence from the SenNeoad trial showed that untargeted metabolic analysis can identify a metabolomic signature associated with a higher probability of achieving pCR after NAT. Among 445 small molecules analyzed, 61 were differentially expressed in patients with pCR vs residual disease (RD) ($p<0.05$); patients with RD showed lower levels of fatty acids, such as 9-hexadecenoic acid ($p <0.001$) and doconexent ($p<0.001$).
Trial Design: NEOMET is an exploratory randomized prospective multicenter study whose primary aim is to evaluate if plasma metabolomic signatures can be modified by lifestyle interventions including dietary supplements and physical exercise in eBC patients candidate to NAT. Eligible patients will be randomized to one of four groups: a) NAT according to molecular subtype; b) NAT plus nutritional supplementation; c) NAT plus supervised physical exercise; d) NAT plus nutritional supplementation plus supervised physical exercise. Nutritional supplementation will consist of two main long-chain polyunsaturated fatty acids omega-3 (n-3 Lc-PUFA), EPA (eicosapentaenoic acid) and DHA (docosahexaenoic acid), plus a source of palmitoleic acid (hexadecenoic acid).
The primary objectives are: 1) to explore the impact of lifestyle interventions on the modulation of metabolomic signatures in eBC patients candidate to NAT; 2) to assess the Omega-3 Index at baseline and before surgery. Secondary objectives are: to estimate the effect of combined lifestyle intervention on patient metabolic profile and body composition; to correlate immune and metabolic-related gene-expression signatures evaluated on baseline tumor tissue with metabolic profiles identified on plasma and response to NAT; to evaluate potential pharmacokinetic interactions between nutritional supplementation and NAT; to assess pCR rate in different treatment arms; to analyse the impact of the different interventions on Quality of Life (QoL).
Due to the explorative intent of the study no formal sample size calculation is provided. A

total of 160 consecutive patients will be enrolled into the four arms of the study, with an allocation ratio equal to 1:1:1:1 (40 pts/arm). It can be estimated that the accrual will be completed in 20 months. Data collection, molecular assessments and data analysis with final scientific output are expected to extend the study duration to a total of 26 months.
Planned analysis will include: conversion rate from poor to good metabolomic prognostic signature from baseline to end of NAT; change in Omega-3 Index and body composition; correlation between metabolic and immune-related gene-expression signatures and response to therapy (pCR vs RD).
Clinical Trial Identification: not yet assigned
Funding: Support and funding for the study has been provided by MUR-PRIN 2022 and Pharmanutra S.p.A.
Date of registration: June 2024.
First patient enrolled: September 2024

P3-12-19: NRG-BR008: A phase III randomized trial of radiotherapy optimization for low-risk HER2-positive breast cancer (HERO)

Melissa P. Mitchell, Lior Z. Braunstein, Hanna Bandos, William M. Sikov, Atif J. Khan, Peter Y. Chen, Patricia A. Ganz, Reshma Jagsi, Julia R. White, Reena S. Cecchini, Hyejoo Kang, Shannon L. Puhalla, Kelly L. Bolton, Eileen P. Connolly, Erica M. Stringer-Reasor, Kimberly R. Gergelis, Thomas B. Julian, Eleftherios P. Mamounas, Norman Wolmark

Background: Breast radiotherapy (RT) is the standard of care for patients with early-stage breast cancer (BC) who undergo breast-conserving surgery (BCS). However, the magnitude of benefit of RT is less clear in BCS patients with low-risk disease who receive effective systemic therapy. Among patients with early-stage HER2-positive (HER2+) BC, 10-year locoregional recurrence has been reported as low as 1.5% following BCS, adjuvant chemotherapy and HER2-targeted therapy, and RT. Given these exceedingly favorable outcomes, with the addition of HER2-directed therapy, we seek to evaluate the feasibility of omitting RT among patients with early-stage HER2+ BC following BCS and appropriate systemic therapy.

Methods: This is a phase III randomized trial for patients ≥40 years with early-stage, node-negative, HER2+ (IHC/FISH) BC treated with BCS with negative margins and sentinel lymph node biopsy or axillary dissection. Patients undergoing primary surgery must have pathologic T1 (≤2 cm) N0 disease, whereas patients receiving neoadjuvant therapy must have clinical T1-2 (with radiographically T≤3.0 cm) N0 disease and exhibit a pathologic complete response (ypT0N0) at surgery. All patients must receive cytotoxic chemotherapy and HER2-targeted therapy, either in the adjuvant or neoadjuvant setting. Stratification is by age (<60; ≥60), tumor size (≤1 cm; >1 cm), estrogen-receptor status (positive; negative), and systemic therapy sequencing (adjuvant v neoadjuvant). Patients will be randomized to standard breast RT in addition to continuation of trastuzumab to complete one year of treatment (Arm 1), or trastuzumab alone (Arm 2). Endocrine therapy will be recommended

for patients with hormone-receptor positive tumors. The primary endpoint is the recurrence-free interval (RFI). Secondary endpoints include time to ipsilateral breast recurrence, locoregional recurrence, disease-free survival, and overall survival, in addition to the 7-year ipsilateral breast recurrence rate among those not receiving RT. A health-related quality of life sub-study will assess differences in patient-reported breast pain and worry. We estimate a 7-year RFI of 97.5% with RT and allow for a clinically acceptable decrement of 3.63% without RT (7-year RFI of 93.87%; HR 2.5) to establish omission of RT as non-inferior. NRG-BR008 aims to enroll 1,300 patients over 4.5 years, yielding 80% power to detect the non-inferiority of RT omission with a one-sided α=0.05. We expect to observe the required 38 RFI events within 6 years of additional follow-up.
The NRG-BR008/HERO trial opened to accrual in March 2023.
Accrual is 32/1,300 as of July 9, 2024.
NCT #: NCT05705401.
Support: U10CA180868, -180822, UG1CA189867, U24CA196067.

P3-12-20: NRG-BR009: A phase III trial evaluating addition of adjuvant chemotherapy to Ovarian Function Suppression + Endocrine Therapy in premenopausal women with pN0-1, HR+/HER2- breast cancer (BC) and Oncotype Recurrence Score (RS) ≤25 (OFSET)

Shannon L. Puhalla, Gong Tang, Sandra M. Swain, Patricia A. Ganz, N. Lynn Henry, Reena S. Cecchini, Sonya A. Reid, Priya Rastogi, Charles E. Geyer, Jr., Julia R. White, Amy S. Clark, Tufia C. Haddad, Gregory A. Vidal, Norman Wolmark, Eleftherios P. Mamounas

Background: The TAILORx and RxPONDER trials demonstrated that RS identifies many postmenopausal pts with node-neg and node-pos BC and RS ≤25, who do not benefit from addition of ACT to endocrine therapy (ET). Both trials also showed that certain subsets of premenopausal pts (node-neg/high clinical risk/RS 16-20, node-neg/RS 21-25, and node-pos/RS ≤25) benefited from adding ACT to ET. Most premenopausal pts in these trials did not receive ovarian function suppression (OFS) as part of their ET regimen. Given the observed benefit from OFS in high-risk premenopausal pts with HR+/HER2- BC in the SOFT/TEXT trials, many questioned whether all or part of the observed ACT benefit in the TAILORx/RxPONDER trials may have been the result of chemotherapy-induced OFS. To address this question, we developed OFSET, a phase III, multicenter clinical trial comparing OFS+ET v ACT+OFS+ET.

Methods: We hypothesize that addition of ACT to OFS+ET is superior to OFS+ET in improving invasive breast cancer-free survival (IBCFS) among premenopausal, early-stage BC pts with HR+/HER2- tumors, and a 21-gene RS between 16-25 (for pN0 pts) and 0-25 (for pN1 pts). Secondary objectives include invasive disease-free survival, overall survival, distant recurrence-free interval, breast cancer-free interval, and health-related quality of life (HRQOL). Pts must be node-neg with RS 16-20 (plus high clinical risk), or RS 21-25, or

have 1-3 positive nodes with RS ≤25. Stratification is by nodal status/RS status (pN0 RS 16-25 v pN1 RS 0-15 and pN1 RS 16-25), intent to receive CDK4/6 inhibitor (yes; no), and age (18-39 v ≥40). Pts are randomized after surgery to either OFS+ET or ACT+OFS+ET. ET is an aromatase inhibitor (AI). Choice is per investigator discretion; tamoxifen is allowed if AI is not tolerated or if OFS is incomplete. Radiotherapy will be administered per investigator discretion per protocol guidelines. The HRQOL substudy will assess differences in severe menopausal symptoms, measured by the FACT ESS-19 score between arms, as well as increased pain severity (PROMIS). Blood and tumor specimens will be collected for future research.
Accrual of 3,960 pts is anticipated to be completed in 7 yrs, 7 mos. Per NSABP B-28 and RxPONDER data, 5-yr IBCFS of pN1 pts on the ACT+OFS+ET arm is estimated at 92.3%. Based on TAILORx data, 5-yr IBCFS of pN0 pts on the ACT arm is ~95%. Assuming 56% of pts to be pN0 and 44% pN1, and a 0.5% annual loss-to-follow-up rate, the definitive analyses to detect a hazard ratio: 0.75 with ACT+OFS+ET v OFS+ET, with one-sided α of 0.025 and 80% power, will require 380 IBCFS events, expected to occur ~11 yrs after study initiation. OFSET was activated August 2023.
Accrual is 69/3,960 (as of July 3, 2024).
NCT #: NCT05879926.
Support: U10CA180868, -80822, UG1CA189867, U24CA196067.

P3-12-21: NeoTAILOR: A phase II biomarker-directed approach to guide neoadjuvant therapy for patients with clinical stage II/III ER+, HER2-negative breast cancer

Nusayba Bagegni, Tracy Summa, Mary Halim, Isabella Grigsby, Emily Podany, Jingqin (Rosy) Luo, Fouad Boulos, Debbie L. Bennett, Katherine Glover-Collins, John A. Olson, Katherine N. Weilbaecher, Cynthia X. Ma

Background: Although aromatase inhibitors are the mainstay of therapy (tx) in postmenopausal women with early-stage ER-positive (ER+), HER2-negative (HER2-) breast cancer (BC), optimal tx strategies remain to be elucidated in high-risk, early-stage BC, particularly in Black women who have historically been underrepresented in BC clinical trials. Hormone-receptor expression remains the single predictive biomarker guiding endocrine therapy (ET) use, yet ET response remains heterogeneous and ~20-30% of patients (pts) will relapse. Molecular heterogeneity of BC, including molecular BC subtype (via PAM50), likely contributes to the observed differential responses to standard neoadjuvant (neo) ET and chemotherapy (chemo). Several studies have also demonstrated that proliferative changes by Ki67 expression post short-course neo ET (Ki67post) serves as an early pharmacodynamic marker of ET response, correlates with long-term outcomes and thus may guide personalized therapeutic decision-making. Routine genomic assays traditionally utilized in the adjuvant setting have helped identify pts who may be spared chemo toxicity, but are less prognostic in Black women, and significant racial disparity in survival exists. Few studies have had sufficient data on intrinsic subtype and recurrence

outcomes in Black women. An adaptive strategy utilizing dynamic Ki67 changes post neo ET may help to identify pts who will achieve excellent clinical response to neo ET, and others who will require tx escalation in a rapid setting. Prospectively integrating genomic signatures into the neo tx selection paradigm may permit a personalized biomarker-directed approach to better tailor optimal tx strategy to improve clinical response.

Methods: NeoTAILOR (NCT05837455) is a phase 2 clinical trial investigating the use of clinical genomic signatures to guide neo tx for postmenopausal women with clinical stage II/III ER+, HER2- BC using a dynamic Ki67 response-adaptive strategy, with a 33% minority enrollment goal to permit analysis of outcomes in a racially diverse patient population. Eligible pts (n=81) will undergo baseline (BL) breast MRI and tumor/blood collection, followed by a 28-day cycle of anastrozole (ana) (+/- 14 days, C1), during which BC risk category will be determined based on BL tumor Ki67 and study-funded Prosigna(R) PAM50 subtype. Pts with protocol-defined low-risk disease (Luminal A subtype or BL Ki67 ≤10%) will continue to receive 5 additional 28-day cycles of ana (C2-6). Pts who are considered to have high-risk BC (non-Luminal A or non-diagnostic subtype) will undergo breast tumor tissue collection at Week 4 for Ki67post assessment. If Ki67post ≤10% (high-risk endocrine-sensitive (ETsens) group), pts will continue to receive 5 additional 28-day cycles of ana (C2-6), while pts with Ki67post >10% (high-risk endocrine-resistant (ETres) group) will receive escalated tx with SOC chemo (combination anthracycline- and/or taxane-based). All pts will then undergo breast MRI followed by surgery. Adjuvant tx will be at the treating physician's discretion. The primary endpoint is to determine the objective response rate (ORR) by breast MRI in the pooled protocol-defined low-risk plus high-risk ETsens group. Key secondary endpoints include: breast conserving surgery rate, change in need for oncoplastic breast reduction surgery, ORR in the high-risk ETsens and ETres groups. Exploratory endpoints include delineating mechanisms of ET response and resistance by race. A sample size of 77 evaluable pts will be needed to obtain 23 pts with protocol-defined high-risk ETsens BC to test a desired ORR of 75% against a null ORR of 50%, by 1-sided 1-sample proportion test (alpha=5%, 80% power). If responses are observed in ≥16 pts among 23 ORR evaluable pts, the trial claims preliminary efficacy. The study is actively enrolling pts at Siteman Cancer Center.

P3-12-22: Neoadjuvant Therapy with Pyrotinib, Subcutaneous Trastuzumab, and Capecitabine for HER2-Positive Early Breast Cancer: A Prospective, Single-Arm, Multicenter Trial

Lina Zhang, JinFang Zhu, ZhuMing Yin, YongSheng Jia, Min Zhang, WeiPeng Zhao, XiaoLong Qian, XiaoJing Guo, Hong Lu, Lin Gu

Background: Neoadjuvant therapy has become a standard approach for HER2-positive early breast cancer, improving surgical outcomes, pathological complete response (pCR) rates, and survival. Previous studies have demonstrated the efficacy and safety of pyrotinib, an

oral, highly selective tyrosine kinase inhibitor, combined with trastuzumab and chemotherapy in this setting. However, these regimens primarily relied on intravenous administration, which can impact patient quality of life and increase treatment burden. This prospective trial is the first to investigate a fully non-intravenous neoadjuvant regimen consisting of oral pyrotinib, SC trastuzumab, and oral capecitabine in low- to intermediate-risk HER2-positive early breast cancer patients, aiming to evaluate its efficacy and safety.

Methods: This prospective, single-arm, multicenter trial (NCT06483386) will enroll 109 women with low- to intermediate-risk HER2-positive early breast cancer (clinical stage I-II, T1c-2N0-1M0) from May 2024 to June 2026. Eligible patients are aged ≥18 years, have no prior treatment, an ECOG performance status of 0-1, and at least one measurable lesion. HER2 positivity is defined as immunohistochemistry (IHC) 3+ or IHC 2+/fluorescence in situ hybridization (FISH) positive, regardless of hormone receptor status. Patients will receive 6 cycles of neoadjuvant therapy consisting of oral pyrotinib (400 mg daily), SC trastuzumab (600 mg on Day 1 every 3 weeks), and oral capecitabine (1000 mg/m2 twice daily for 14 days followed by a 7-day break). Treatment response will be assessed according to RECIST 1.1 criteria, and subsequent management will be determined by the investigator. The primary endpoint is pCR rate, with secondary endpoints including event-free survival (EFS), overall response rate (ORR), disease control rate (DCR), breast-conserving rate, and safety.

Conclusions: This prospective, single-arm, multicenter trial will provide valuable insight into the efficacy and safety of a novel, fully non-intravenous neoadjuvant regimen combining pyrotinib, SC trastuzumab, and capecitabine for low- to intermediate-risk HER2-positive early breast cancer patients. If proven effective and well-tolerated, this regimen may offer a more convenient and less burdensome treatment option for this patient population, potentially improving quality of life and treatment adherence.

P3-12-23: PATIENT ENGAGEMENT IN RESEARCH: CINDERELLA TRIAL AND LESSONS LEARNT FROM SCREENING FAILURES

André Pfob, Rosa Di Micco, Silvia Paola Corona, Eduard-Alexandru Bonci, Veronica Zuber, Sara Baleri, Giovanni Cisternino, Francesca Calabretto, Mario Rampa, Manuela Morgante, Vitalba Scaduto, Angelica Critelli, Nicole Rotmensz, Maciej Bobowicz, Jörg Heil, Pawel Kabata, Orit Kaidar-Person, Maria-Joao Cardoso, Oreste Davide Gentilini

Background: CINDERELLA is a randomised controlled multicentre clinical trial initiated with the aim of addressing the need for a more patient-centred care, enhancing shared decision-making, satisfaction, and health-related quality of life in breast cancer patients eligible for locoregional treatment. The project focuses on increasing patient awareness and engagement throughout their breast cancer journey, by providing easily accessible, always available, tailored, written and visual information. Despite its patient-centric design, the

trial recorded a significant number of screening failures in its initial year of enrolment. Our objective is to explore the reasons behind screening failures among patients recruited during the initial phase of the trial, aiming to provide valuable insights that can enhance future recruitment efforts or the design of new trials. To achieve this objective, we propose an unplanned analysis conducted in two phases: first, a pilot phase involving data collection from a single recruiting centre, followed by analysis and evaluation by the Trial Scientific Committee; subsequently, based on the findings from the initial phase, a second observational phase involving all recruiting centres.
TRIAL DESIGN: Data regarding screening failures in the randomised controlled CINDERELLA trial (ClinicalTrials.gov ID NCT05196269) from IRCCS San Raffaele Hospital (Milan, Italy) were compiled into a prospective database from October 1st, 2023, to July 3rd, 2024. Reasons for refusal to participate in the trial were categorised into 3 distinct groups as follows:
- Emotional distress: defined as potential patient anxiety arising from "too much information", namely learning more about surgery techniques, potential surgical complications, or visualization of postoperative images;
- Time constraints: defined as time constraints and necessary commitment to understand the project's details, complete informed consent forms and multiple questionnaires;
- Long distance (and other contingent-logistic issues): defined as long distance or other logistical challenges in reaching the hospital, which limit the patient's ability to attend subsequent follow-up appointments for postoperative photographs.
ENDPOINT: The primary endpoint of this analysis is to identify the reasons behind screening failures and potentially propose new strategies for better inclusivity, diversity, and equity by decreasing the number of patients who decline participation in this and other future trials, despite fulfilling inclusion/exclusion criteria.
CURRENT STATUS: During the enrolment period, 144 patients were screened at IRCCS San Raffaele Hospital. Among them, 43 patients (29.8%) declined participation. Reasons for refusal included: emotional distress in 21 cases (14,6%), time constraints in 14 cases (9.72%), and distance from the hospital in 8 cases (5,55%). The mean age of these patients was 57. Out of the 43 who declined, 34 underwent breast conservation (79%) while 9 underwent mastectomy with reconstruction (21%). Breast cancer staging revealed stage I in 36 patients and stage II-III in 7 patients.
FUTURE PLANS: To date, 489 patients have been recruited in the CINDERELLA trial. After examining results of this single-centre preliminary analysis, the Trial Scientific Committee proposed a study protocol amendment to start prospective data collection on the reasons behind screening failures. In this second analysis across all study sites, patients who decline to participate in the trial will be asked to complete a paper questionnaire detailing their reasons for refusal. Data collection for this second phase is scheduled to begin in September 2024.
FUNDING. European Union grant HORIZON-HLTH-2021-DISEASE-04-04 Agreement No. 101057389

P3-12-24: PREMO CNS: PREsentation, Management and Outcomes of patients with CNS disease secondary to breast cancer in England

Talvinder Bhogal, Kukatharmini Tharmaratnam, Christopher Cheyne, Gary Leeming, Marta Garcia-Finana, Carlo Palmieri

Background: Breast cancer is the second most common primary tumour to metastasise to the brain. Improvements in the systemic treatment of extracranial metastatic disease have resulted in patients surviving longer with their metastatic disease, which appears to be contributing to the increase in the incidence of cerebral metastases. There is a need to better understand the number of patients affected, their outcomes and treatments in the context of current modern oncological treatment. Finally, it is recognised that inequality can exist with regard to treatment. This study aims to document the burden treatment and survival from CNS disease secondary to breast cancer in England utilising national cancer registry data.

Study Design Methods: The study is a retrospective, cohort study using population-based registry data from The National Cancer Registration and Analysis Service (NCRAS) which is managed by NHS Digital (NHS England). Individual data on approx. 28,000 consecutive patients with CNS disease treated between 1995 and 2023 within the English Healthcare System will be utilized. Datasets utilised include: Hospital episode statistics (HES), Hospital Admitted Patient Care Activity (HESAPC), Systemic Anti-Cancer Therapy (SACT) and Radiotherapy Data Set (RTDS). Eligibility criteria: Inclusion Criteria Male or female, aged >16 years, Histologically and/or cytologically confirmed breast cancer with CNS involvement, as defined as having one or more of the following: a) Metastases to the brain parenchyma; b) Metastases to the leptomeninges c) Paraneoplastic Neurological Disorders. There were no formal exclusion criteria. This data release was approved by NHS Digital (ODR2021_030).

Study Objectives: The primary objectives are to audit the overall survival from the initial diagnosis of CNS involvement secondary to breast cancer in English centres. With Secondary objectives will include to audit (1) the number of cases of metastatic breast cancer (MBC) involving the CNS presenting per year. (2) the current practice in regarding the diagnosis and management of CNS disease and (3) the outcomes of patients treated for CNS involvement secondary to breast cancer. Dara will be analysed by breast cancer subtype as well as overtime, by geographical location and by deprivation index.

P3-12-25: PRSONAL - Population-based Randomized Study Of a Novel breast cancer risk ALgorithm and stratified screening

Stig Bojesen, Pia R Kamstrup, Bodil Ørkild, Berit Andersen, Ilse Vejborg, Antonis Antoniou, Janne Bigaard

Purpose: To measure short-term safety and efficacy of personalized versus standard biennial mammography screening among 50-67-year aged women.
Method: Randomized clinical trial of 962 consenting Danish women aged 50-67 years attending regular screening mammography. At recruitment all women fill in questionnaires on personal risk factor information, quality of life, anxiety and breast cancer worry. Height, weight and BIRADS density are also measured. Women in the intervention have blood sampled for measuring polygenic risk score for breast cancer.The control group will continue with standard biennial mammography, while women in the intervention arm will be grouped in categories based on their absolute 10-year breast cancer risk using the BOADICEA model. Risk categorization will be communicated on-line together with a suggested future screening program for each group: low risk (mammography every 4th year), intermediate risk (mammography every 2nd year), elevated risk (mammography every year), and high risk (MR mammography every year). Women could call the project telephone for questions.

Outcomes: Primary outcome is the acceptance of prolonged screening interval among low-risk women in the intervention group. Secondary outcomes consist of anxiety, breast cancer worry and quality of life. Tertiary outcomes include health care staff time spent on consultations after communication and suggested screening program.

Status: Recruitment began Feb. 1st 2024 and by June 30th, 851 women had been randomized. Of the 216 women who have received risk estimates, there were 109, 85, 17 and 5 in the low, intermediate, elevated and high risk group, respectively. This distribution was not different from the expected 46%, 44%, 8.5% and 1.5%, respectively (p=0.08). The automated on-line risk communication lead to 10 seconds telephone call per woman.

Conclusion: Recruitment, collection of risk factor information, real-time calculation of risk and automated communication of risk is possible and seems acceptable to the women in this randomized trial of personalized versus standard biennial mammography screening.

P3-12-26: Partial breast re-irradiation using ultra hypofractionation: A Phase 2 multi- institutional study

Danielle Rodin, Fadwa Abdel Rahman, Michelle Audoin, Aisling Barry, Jean-Marc Bourque, Keelan Byrne, Michelle Chan, Hanbo Chen, Eileen Connolly, Marc David, Jane De Rocchis, Frances Duane, Elizabeth Evans, Naamit Gerber, Guilherme Gondim, Revathy Krishnamurthy, Zhihui Liu, Tom Purdie, Valerie Theberge, Timothy Whelan, Martina Wood, Michael Yassa, Eileen Rakovitch, Anne Koch

Background: Most patients with breast cancer are treated with breast conserving surgery (BCS) followed by adjuvant radiation (RT) to reduce the risk of recurrence in the same

breast (local recurrence (LR)) and to maximize long-term breast preservation. Although these treatments are quite effective, a growing number of individuals who receive them are at risk of LR or develop a second primary breast cancer, which is traditionally treated with mastectomy. However, mastectomy has been associated with deleterious effects on quality of life. Advances in screening now allow many LRs to be detected as localized, small tumours amenable to further BCS.
BCS followed by reirradiation with partial breast irradiation (rPBI) has recently been found to be a safe treatment option in women with prior breast RT, but the optimal fractionation is unknown. For women with early-stage breast cancer receiving upfront treatment, a shorter 1-week course of breast RT (ultra-hypofractionation) has been found to be equivalent to longer fractionation schedules. However, this data cannot be directly applied to LR due to the higher cumulative RT doses and to tissue changes from previous treatment. The safety and efficacy of ultra-hypofractionated rPBI for LR are the focus of the proposed study. We hypothesize that ultra-hypofractionated rPBI following BCS for LR or new primary breast cancer in the previously irradiated breast will be associated with acceptable toxicity at 1 year (<13% grade >3 toxicity).

Methods: This study is a phase II, prospective, multi-center, international trial of ultra-hypofractionated rPBI following repeat BCS for LR or new primary breast cancer in the previously irradiated breast. rPBI will be delivered at a dose of 26 Gy in 5 daily fractions over a period of 1-week (excluding weekends and statutory holidays). Boost RT is not permitted. The primary endpoint is the risk of grade >3 adverse events (AEs) occurring at 1-year from rPBI completion (CTCAE v5.0). Secondary endpoints include local, regional and distant recurrence, invasive breast cancer-free survival, mastectomy-free survival, overall survival, financial toxicity, and patient-reported satisfaction. To achieve 80% power with a Type I error rate of 0.05 and 3% lost to follow up or unevaluable, 171 patients will be accrued.
Eligible patients are status post BCS for ductal carcinoma in situ or invasive cancer <3 cm in greatest diameter (invasive and non-invasive components) with negative margins (no tumor on ink) who are clinically node negative and who completed treatment >5 years earlier for breast cancer in the ipsilateral breast treated with BCS and adjuvant whole or partial breast RT. Patients with grade >2 late skin toxicity from prior radiation are excluded, as are those with T4 or multicentric disease or the presence of an extensive intraductal component. Final eligibility is determined at the time of RT planning based on ability to clearly define the surgical cavity. The RT planning target volume must be <50% of the whole breast.
The study is open to accrual 7 sites in Canada, the US, and Jordan, with an additional 9 international centers in the process of opening; 17 patients have been enrolled and treated as of 10-07-2024. Patients will be followed for a total of 5 years. Clinical trial information: NCT05592938. Supported by the Canadian Cancer Society and the Princess Margaret Cancer Foundation.

P3-12-27: Phase 1 Analysis from the PYNNACLE Phase 1/2 Study of Rezatapopt in the Subgroup of Patients with Advanced Breast Cancer Harboring a TP53 Y220C Mutation

Ecaterina Dumbrava, Shivaani Kummar, Melissa Johnson, Kim Le Duke, Yajuan G Qin, Marc Fellous, Alison M Schram

Background: Mutations in the TP53 gene occur in ~51% of breast cancers and result in loss of p53 tumor suppressor function and tumor progression. Reactivation of wild-type p53 is an attractive therapeutic approach for breast cancers with a TP53 mutation including the more aggressive triple-negative breast cancer (TNBC), where treatment options are limited. Rezatapopt (also known as PC14586) is an investigational first-in-class, p53 reactivator that selectively binds to the mutated p53 Y220C protein and stabilizes the structure in wild-type conformation, thereby restoring p53 wild-type activity. PYNNACLE (NCT04585750) is a Phase 1/2 clinical trial of rezatapopt in patients with locally advanced or metastatic solid tumors harboring the TP53 Y220C mutation. In Phase 1, rezatapopt demonstrated favorable safety and anti-tumor activity in heavily pre-treated patients (n=67 treated at the efficacious dose range of 1150 mg once daily [QD] to 1500 mg twice daily [BID]). This subgroup analysis assessed rezatapopt in patients with advanced breast cancer treated across the efficacious dose range.

Methods: Patients with locally advanced or metastatic breast cancer with a TP53 Y220C mutation were eligible to receive rezatapopt orally on a continuous schedule across the efficacious dose range (1150 mg QD to 1500 mg BID). Safety and preliminary efficacy, as evaluated by the investigator using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1, were assessed. Tumor next-generation sequencing was used to determine TP53 Y220C, BRCA, PIK3CA, and KRAS tumor mutation status.

Results: As of September 5, 2023, nine patients with breast cancer (HR+/HER2- n=3; HR+/HER2+ n=1; HR-/HER2+ n=1; TNBC n=4) received rezatapopt in the PYNNACLE Phase 1 trial. The median age was 53 years (range 32–65 years) and Eastern Cooperative Oncology Group (ECOG) performance score was 0 (n=3) or 1 (n=6). One patient had a somatic BRCA2 mutation, no patient had a BRCA1 mutation, two patients had a PIK3CA mutation, and all patients were KRAS wild-type. The median number of prior lines of systemic therapy was 4 (range 2–9). Of the eight patients who had measurable disease at baseline, three (37.5%) achieved a confirmed partial response (PR), four had stable disease (SD), and one had progressive disease (PD) as the best objective response. Reductions in target lesions were reported in all patients, with a maximum reduction in tumor volume from baseline ranging from -2.4% to -55.2%. The most frequent treatment-related adverse events in patients with breast cancer were consistent with the overall Phase 1 PYNNACLE population with solid tumors treated at the efficacious dose range (n=67), and included nausea (51%), vomiting (43%), and increased blood creatinine (27%), which were mostly

grade 1/2. Administration of rezatapopt with food led to an improvement in gastrointestinal adverse events including nausea and vomiting.

Conclusions: In this Phase 1 PYNNACLE trial, rezatapopt demonstrated promising preliminary single-agent efficacy in heavily pre-treated patients with advanced breast cancer, including TNBC, harboring a TP53 Y220C mutation. Rezatapopt had a favorable safety profile in the efficacious dose range with improvements in gastrointestinal adverse events observed when administered with food. The PYNNACLE tumor-agnostic registrational Phase 2 trial, which includes a breast cancer cohort, will assess rezatapopt as monotherapy at the recommended Phase 2 dose of 2000 mg QD with food in patients with TP53 Y220C-mutated and KRAS wild-type advanced solid tumors.

P3-12-28: Phase 1b study of EZH1/2 inhibitor valemetostat in combination with trastuzumab deruxtecan in subjects with HER2 low/ultra-low/null metastatic breast cancer

Toshiaki Iwase, Senthil Damodaran, Angela Marx, Funda Meric-Bernstam, Debu Tripathy, Carlos Hernando Barcenas, Jangsoon Lee, Naoto T Ueno

Background: Low HER2-expressing breast cancers have traditionally been classified as HER2-negative and treated as TNBC or hormone receptor (HR)-positive. Trastuzumab deruxtecan (T-DXd), an antibody-drug conjugate composed of an anti-HER2 antibody conjugated to topoisomerase I payload, is approved for clinical use in HER2-low (IHC 1+ or IHC 2+/ISH negative) metastatic breast cancer (MBC). In the DAISY (NCT04132960) and DESTINY-Breast06 (NCT04494425) studies, meaningful clinical response and survival benefit were observed with T-DXd in HER2 IHC 0 MBC. Valemetostat is an oral, selective dual inhibitor of enhancer of zeste homolog 1 and 2 (EZH1/2, methyltransferases that specifically methylate histone H3 lysine 27. It is approved for patients with relapsed or refractory adult T-cell leukemia/lymphoma in Japan. EZH2-mediated PP2A inactivation has been shown to confer resistance to HER2-targeted therapy. Additionally, valemetostat has been shown to upregulate Schlafen11 (SLFN11), a putative DNA/RNA helicase that regulates the sensitivity to DNA-damaging agents such as topoisomerase I inhibitors. Accordingly, this study examines the safety and anti-tumor activity of valemetostat in combination with T-DXd in subjects with HER2 low/ultra-low/null MBC.
Trial Design
This is a single-arm, phase-1b study to evaluate the safety and clinical activity of T-DXd in combination with valemetostat in patients with HER2 low/ultra-low/null MBC. The dosing for T-DXd is 5.4 mg/kg Q3W administered intravenously as indicated for current clinical use. Valemetostat will be evaluated in up to five doses (50mg, 75mg, 100 mg, 150 mg, and 200 mg) with a starting dose (level 1) at 100 mg QD. The dose-limiting toxicity (DLT) evaluation period will be the first 2 treatment cycles (42 days).
Eligibility criteria

Pathologically confirmed HER2 low/ultra-low/null breast cancer
ECOG performance status ≤1
Measurable disease (for dose-expansion cohort)
Received at least one line of chemotherapy in the metastatic setting
Progressed and would no longer benefit from endocrine therapy (HR-positive)
Normal organ and marrow function
Exclusion: symptomatic brain metastases, interstitial lung disease, cord compression, prior treatment with any anti-HER2 therapy

Specific aims: To evaluate the safety and determine the maximum tolerated dose (MTD)/recommended dose for expansion (RDE) of valemetostat in combination with T-DXd.
To evaluate the objective response rate (ORR) of valemetostat at the RDE in combination with T-DXd
To determine the duration of response, clinical benefit rate, progression-free survival, and overall survival of valemetostat at the RDE in combination with T-DXd.
To evaluate the pharmacokinetics and pharmacodynamic markers of valemetostat and T-DXd combination
To evaluate the immunogenicity of T-DXd when co-administered with valemetostat

Statistical methods: Approximately 15 evaluable patients will be enrolled for the dose-escalation portion based on the Bayesian optimal interval design with a target DLT rate of 25%. Patients enrolled and treated in cohorts of 3. The expansion will be performed at the RDE using the 2-stage Bayesian optimal dose-expansion design. In the first stage, 13 evaluable patients (including those treated at the RDE in the dose-escalation part) will be enrolled. If <5 patients respond in the first stage, the study will be stopped for futility. If ≥5 responses are observed, 13 additional evaluable patients will be enrolled. If 11 or more responses are observed among 26 patients, the treatment will be considered promising. This two-stage design yields 78% power under the alternative hypothesis of ORR = 50% (null ORR = 30%) while controlling the one-sided type I error at 10%.

P3-12-29: Phase 1b/2 Study of Naxitamab (Danyelza), Gemcitabine and Ex Vivo Expanded Allogenic Universal Donor, TGFβi Natural Killer (NK) cells in Advanced GD2-expressing Breast Cancers (DiG NKs)

Margaret Gatti-Mays, Marcelo de Souza Fernandes Pereira, Sumithira Vasu, Lynn O'Donnell, Marcos DeLima, Zihai Li, Daniel Stover, Robert Wesolowski, Sagar Sardesai, Gilbert Bader, Mathew Cherian, Kai Johnson, Ashley Pariser Davenport, Dionisia Quiroga, Nicole Williams, Joanne Kim, Dean Lee

Background: Intrinsic resistance to immunotherapy observed in breast cancer is attributed to low neoantigen levels, defective antigen presentation, low mutational burden, reduced

programmed death ligand 1 (PD-L1) expression and the presence of immunosuppressive signals like transforming growth factor-beta (TGFβ) in the tumor microenvironment (TME). These collectively attenuate the effector functions of T cells and natural killer cells (NK cells). NK cells are an important component of innate immunity.

We designed a clinical trial to evaluate the stepwise addition of (1) gemcitabine, (2) an off-the-shelf, TGFβ imprinted, IL-21 expanded allogenic universal donor NK cells (TGFβi NKs), and (3) naxitamab (FDA-approved humanized IgG1 monoclonal antibody targeting the tumor-associated antigen GD2) to overcome intrinsic resistance to immunotherapy in breast cancer. While generally TGFβ dampens the NK cell response in the TME, chronic stimulation of donor cells ex vivo with TGFβ during the expansion process produces TGFβi NKs which exhibit high cytotoxicity and resistance to suppression by TGFβ. Furthermore, the anti-tumor activity of monoclonal antibodies, like naxitamab, is enhanced by NK cells. Given high GD2 expression in aggressive breast cancer subtypes, there is a strong rationale for evaluating an anti-GD2 antibody along with NK cells in breast cancer. Finally, systemic chemotherapies like gemcitabine exhibit both cytotoxic effects as well as immunomodulatory effects including lymphodepletion and improved NK cell recruitment through upregulation of NKG2DL. In our preclinical assessment of this combination in an MDA-MB-231 mouse model, we found longer survival and no evidence of toxicity with gemcitabine + anti-GD2 antibody + TGFβi NKs.

Methods: In this phase Ib/II trial, the safety and efficacy of the doublet (gemcitabine + TGFβi NKs) and the triplet (gemcitabine + TGFβi NKs + naxitamab) is being assessed. . Patients with advanced/metastatic, HER2 negative, breast cancer that is measurable and have received ≥1 line in the metastatic setting are eligible for the trial. Patients must be ≥ 18 years old with a good functional status and adequate organ and bone marrow function. Key exclusion criteria include symptomatic/recently treated brain metastases (defined as < 6 months), leptomeningeal disease, cardiomyopathy, history of myocarditis, or immunocompromised status.
Patients receive gemcitabine 800mg/m2 on days 1, 8. 15 of a 28-day cycle. TGFβi NKs 3x107 cells are given on day 16 of each cycle and NK cell persistence is assessed on day 21. Naxitamab 2.4mg/kg (max 150mg/day per prescribing information) is given on day 1, 4, and 8 per the current recommend phase 2 dose along with GM-CSF. Dose limiting toxicities are evaluated in a modified 3+3 design. Clinical response is evaluated every 8 weeks. Co-primary objectives are response rate (ORR) per RECISTv1.1 and safety. Exploratory analyses include changes in immune cells and cytokines in the peripheral blood. While GD2 expression is not required for eligibility, we will assess clinical and immune outcomes by GD2 expression of archival tissue. Other exploratory outcomes including progression free survival and ORR per iRECIST. If there is adequate safety of the combination, subsequent patients will be enrolled to determine initial clinical efficacy of the combination using a Simon-two step design.
We plan to recruit up to 39 evaluable patients, with an accrual ceiling set at 45 patients.

This study is open and enrolling at The Ohio State University Comprehensive Cancer Center (NCT06026657, Columbus OH).

P3-12-30: Phase I trial of pegylated liposomal doxorubicin chemotherapy in combination with CD40 agonist and Flt3 ligand in metastatic HER2 negative breast cancer

Sangeetha Reddy, Cesar Santa-Maria, Virginia Kaklamani, Joyce O'Shaughnessy, Nisha Unni, Navid Sadeghi, Samira Syed, Joshua Gruber, Yisheng Fang, Isaac Chan, Namrata Peswani, Shahbano Shakeel, Meredith Carter, Kelly Kyle, Dawn Klemow, Nan Chen, Rita Nanda, Heather McArthur, Suzanne Conzen, Carlos L. Arteaga

Background: Only a subset of patients with metastatic breast cancer respond to FDA approved immune checkpoint blockade, and few have durable responses. Data suggest that breast cancers have defects in antigen presentation and that antigen presenting dendritic cells (DCs) are required for response to T cell directed immunotherapies such as immune checkpoint blockade. CD40 agonists activate antigen presenting cells, including DCs and B cells, and repolarize macrophages to an anti-tumor phenotype. Flt3 ligand is a growth factor that increases differentiation and expansion of DCs. We recently demonstrated in pre-clinical breast cancer models that the combination of liposomal doxorubicin chemotherapy, a CD40 agonist, and a Flt3 ligand improves outcomes compared to chemotherapy alone. Methods: This is a single arm phase I pilot study of the combination of liposomal doxorubicin, CDX-1140 (CD40 agonist monoclonal antibody), and CDX-301 (recombinant Flt3 ligand) in patients with metastatic or unresectable locally advanced HER2 negative breast cancer. Patients are randomized to 2 lead-in arms in 2:1 ratio (triplet therapy or liposomal doxorubicin only) for one cycle prior to receiving triplet therapy with tumor biopsies done before and after the lead-in treatment. A recent protocol amendment expanded eligibility from triple negative breast cancer (TNBC) to also include hormone receptor positive (HR+) breast cancer and closed a lead-in cohort of immunotherapy only. CDX-301 will be given for two cycles; liposomal-doxorubicin and CDX-1140 will be continued until disease progression or clinically limiting toxicities. Primary endpoint is determination of a recommended phase II dose of CDX-1140 based on treatment-related adverse events and dose-limiting toxicities. Secondary endpoints include anti-tumor immune response after triplet therapy and after liposomal doxorubicin alone, median progression-free survival, overall response rate, duration of response, and clinical benefit rate. Key eligibility criteria are unresectable stage III or stage IV HER2 negative breast cancer, for TNBC up to 3 prior therapies for metastatic disease allowed, for HR+ disease prior cyclin dependent kinase 4/6 inhibitors required and up to 3 prior lines of chemotherapy and/or antibody drug conjugates for metastatic disease allowed, measurable disease by RECIST 1.1 criteria, consent for pre- and on-treatment biopsies of tumor lesions, no prior treatment with an anti-CD40 antibody or a Flt3 ligand, no anthracycline treatment in the metastatic setting, no prior progression while on anthracycline-based therapy or within 6 months of completing (neo)adjuvant anthracycline-based therapy, and no history

of non-infectious pneumonitis or current pneumonitis. This trial will enroll up to 30 evaluable patients across multiple sites (NCT05029999) and is currently open at University of Texas Southwestern Simmons Cancer Center, Texas Oncology, University of Chicago, University of Texas San Antonio, and Johns Hopkins.

P4-01-01: An Innovative Approach to Alleviating Fatigue in Metastatic Breast Cancer Patients

Eliza Brufsky, Margaret Rosenzweig, Jill Brufsky, Arisha Patel, Jian Zhan, Danxiu Ren, Adam Brufsky

Background: Fatigue is debilitating for patients with metastatic breast cancer (MBC), impacting quality of life (QoL), pain, sleep, depression, and anxiety. Slow, whole-body vibration in the 0.01-0.3 Hz range may increase parasympathetic tone. Vibration at 100 Hz may activate the posterior insula, associated with increased attention to interception as seen in many meditative practices. This proof-of-concept study explores the potential of Apollo (Pittsburgh, PA), a wearable vibration delivery device, to mitigate fatigue in MBC patients.

Methods: In an 8-week single-arm trial, 27 women with MBC scoring $^{3}4$ on a Likert scale of 0-10 for fatigue self-applied the Apollo bracelet to the wrist or ankle. After informed consent and teaching, the device was used per manufacturer's instructions to deliver vibration on a user-determined schedule and intensity. Fatigue and QoL were measured at baseline, 4 weeks, and 8 weeks. Measures of efficacy included Patient-Reported Outcomes Measurement Information System (PROMIS) – fatigue, PROMIS – pain interference, PROMIS – sleep disturbance, Functional Assessment of Chronic Illness Therapy (FACIT) – Fatigue, Functional Assessment of Cancer Therapy – General (FACT-G), and Hospital Anxiety and Depression Scale (HADS). A repeated measures ANOVA was conducted at 4 weeks and 8 weeks.

Results: Of 27 patients enrolled, 23 completed the study and 4 withdrew (unrelated hospitalization (2), inconvenience of wearing the device (2)). The mean usage time of Apollo was 6575 minutes (range 216-26715). PROMIS-fatigue scale improved from 13.96 at baseline to 10.95 at 8 weeks ($p<0.001$). FACIT-fatigue score improved from 17.07 to 24.58 at 8 weeks ($p<0.001$). PROMIS-pain interference scale decreased from 10.04 to 7.19 at 8 weeks ($p=0.005$), and PROMIS-sleep disturbance declined from 11.44 to 9.29 ($p=0.014$). HADS-depression scores declined from 5.93 to 4.67 at 8 weeks, ($p=0.046$) while HADS-anxiety did not show a significant change ($p=0.160$).

Conclusions: MBC-related fatigue is challenging to treat and adversely affects QoL. Therapeutic vibration via Apollo may be a non-invasive way to alleviate fatigue and related outcomes in MBC. Placebo-controlled randomized trials are needed to confirm its efficacy.

P4-01-02: QUALITY OF LIFE IN BREAST CANCER PATIENTS UNDERGOING NEOADJUVANT CHEMOTHERAPY IN A BRAZILIAN CANCER CENTER: THE IMPACT ON YOUNG WOMEN

Fabiana Makdissi, Isabela Rodrigues Neves, Silvana Soares Dos Santos, Solange Moraes Sanches

Introduction: Quality of life/QoL is a subjective concept assessed from the patient's perspective, which encompasses physical, social and emotional functions of individuals. In recent decades, this concept has become an important outcome measure in breast cancer/BC patients, as it is the most frequent malignant neoplasm in women worldwide and due to the evolution in treatments, enabling an increase in the cure and survival rates of these patients.
Objectives: To evaluate the quality of life of patients undergoing neoadjuvant chemotherapy at a Brazilian Cancer Center.
Methods: Prospective cohort study carried out between 2022 and 2023 at A.C. Camargo Cancer Center. The study included 149 participants with non-metastatic breast cancer undergoing chemoradiotherapy; all of them signed an informed consent form approved by the local Research Ethics Committee. The study participants filled in assessment instruments, the "Psychosocial Well-being/PWB", "Sexual Well-being/SWB" and "Breast Satisfaction/BS" scales, translated into Portuguese, from the BREAST_Q Portfolio (https://qportfolio.org/breast-q/). Data was collected at M0 (pre-CT), M1 (halfway through the protocol) and M2 (end of CT). For the analysis of the scale scores, we considered $p < 0.05$. Results: Of the 149 women included, around 74.% were between 45-59 years of age; almost 70.0% were married or had a partner; 72.0% reported having some religion and 82.6% had at least a university degree. As for BC, almost half were Stage II (47.0%), of which 59.7% were T2 and 41.6% had a positive axilla (N+); 94.0% were invasive ductal carcinoma; 50.3% had B luminal tumors and 42.2% were triple negative. The median score on the "PWB" scale fell from 80 to 60 over the course of treatment ($p<0.05$); on the "SWB" scale, the reduction was from 62.5 to 45 ($p<0.05$). On the "BS" scale, there was a reduction from 81 to 68, but $p>0.05$. We checked whether education, marital status, religion and immunophenotype had an impact on the various scales, but all the analyses showed $p>0.05$. For the "SWB" scale, age was not significant either. For the "PWB" scale, there was a significant reduction for all ages ($p<0.05$); the greatest impact on QoL was between 45-59 years, with a 19-point reduction in the score over the course of treatment. In addition, we noted that on this scale, the final median score after treatment remained higher among women aged 60+ compared to younger women, up to 44 years old ($p<0.05$). The same happened with the "BS" scale. Discussion and Conclusion: In this study, we were able to observe the impact of CT on the QoL of women with BC. The reduction was already noticeable in the first assessment after starting treatment (M1), and became more pronounced at the end of treatment (M2). Chemotherapy treatment is responsible for changes in a woman's external image, but it is also responsible for transforming the perception of her internal image, i.e. the image a woman has of herself, which is subjective and corresponds to her identity. These bodily changes remind women of their illness,

affecting their sense of femininity and self-esteem. This has been demonstrated especially in younger women, who seem to be more affected by image-related symptoms. The impact on quality of life can even reduce the effectiveness of self-care and symptom management. Thus, identifying early on and taking on board the subjective and individual aspects of each woman will enable personalized care for the needs of the cancer journey.

P4-01-03: Beyond Aesthetics: Cold Cap Hair Preservation Correlates with Lower Chemotherapy Symptom Burden in Patients with Breast Cancer

Talar Telvizian, Kathryn J Fleck, Meghan Ely, Aarti l. Shevade, Zonera A. Ali, Arezoo Ghaneie, U. Margaretha Wallon

Introduction: Hair loss is one of the most feared treatment side effects for women starting chemotherapy. Treatment-induced alopecia creates feelings of increased social stigma and isolation, emotional states correlated with poorer overall disease prognosis. Supporting quality of life during cancer treatment, including successful hair preservation via scalp cooling, has been shown to correlate with higher ratings of health-related well-being. Currently, the only option for reducing hair loss during chemotherapy is scalp cooling with devices like the Paxman and Dignicap, which are usually well-tolerated. This study aims to investigate the difference in reported symptoms and total symptom burden in women with breast cancer receiving scalp cooling interventions and matched controls during chemotherapy.

Methods: In this ongoing IRB-approved study at Lankenau Medical Center, 25 patients have chosen to use scalp cooling during breast cancer treatment. These patients were matched by age and chemotherapy regimen to those who did not use scalp cooling. Our patient base typically has a high proportion of African Americans given that our medical center is located adjacent to West Philadelphia, a community with a 90 - 95% African American population. However, only 8% of patients in the cold cap group were African American compared to 36% of African American patients in the control group. With a high up-front co-pay, many patients of all races forego this supportive care. The average age was approximately 50 in both groups. At treatment visits participants completed the Modified Rotterdam Symptom Checklist; a self-report questionnaire rating 29 chemotherapy side effects on a scale of zero to three. Data from the first 50 patients was analyzed in GraphPad Prism 8.4.3 for relationships between factors and the patient's total symptom burden, calculated as the total symptom checklist score at each visit. Wilcoxon matched pairs signed rank test (CI 95%) was used to assess the difference between total symptom burden in cold cap users and their matched controls.

Results: Most patients who chose scalp cooling were younger and predominantly Caucasian. The total symptom burden was significantly lower ($p<0.0002$) among patients using scalp cooling compared to the matched controls. Of individual symptoms, there was a moderate reduction in reported tiredness even though the Paxman-using patients reported a

moderately significantly higher level of difficulty sleeping. Patients using scalp cooling reported a significant reduction in appetite compared to their controls but had no significant weight loss. There was no significant difference in sexual interest between the two groups.

Discussion and Conclusion: Cold cap systems have benefits beyond just aesthetics, use of scalp cooling interventions provide significant improvement in patient's symptom ratings. Maintaining hair can contribute to a patient's sense of normalcy and self-esteem during a challenging time which can positively impact their overall quality of life and well-being. Even though scalp cooling had a positive effect by decreasing the overall symptom burden, individual symptoms that can be associated with emotionally related symptoms such as appetite, sleep, and sexual interest were not necessarily improved by the use of scalp cooling. The current co-pay system prevents many of our patients from the West Philadelphia community from taking advantage of this supportive car. We are currently in the process of reducing the economic barrier to access to scalp cooling to increase the diversity of the cohort and include other hair textures, a factor known to affect the efficiency of scalp cooling.

P4-01-04: Adaptation of the EORTC Quality of Life Breast Cancer Module for male Breast Cancer – Results of the Phase I-II module

Vesna Bjelic-Radisic, Fatima Cardoso, Joachim Weis, Evelien Bleiker, David Cameron, Galina Velikova, Katarzyna Pogoda, Samantha Serpentini, Kevin Punie, Rinat Yerushalmi, Erika Matos, Birgit Carly, Luisa Zoe Probst, Sina Schafer, Nora Nevries, Ivana Bozovic-Spasojevic, Nicola Russell, Adelheid Roelstraete, Sofie Tombeur, Joanna Vermeij, Ruddy Kathryn, Juan Ignatio Arraras, Carolina De la Pinta, Omar Shamieh, Yuichiro Kikawa, Edward Chow, Tom Bootsma, Ibrahim Sallam, Fatjona Kraja, Andrew Bottomley

Background: Approximately 1% of all new cases of breast cancer (BC) cases occur in men. Treatment and symptom management for male BC patients are largely based on strategies developed for women. While the impact of BC diagnosis and treatment on the quality of life (QoL) in women with BC is well documented, there is a paucity of comprehensive, prospective data on QoL in men treated for BC. Due to absence of a validated QoL questionnaire, QoL in male BC patients has recently been assessed using the EORTC QLQ-C30 and the breast module QLQ-BR23 with female-specific items replaced by male-specific items from the EORTC QoL prostate module (EORTC QLQ-PR25). The development of the first validated worldwide questionnaire for male BC is sponsored by the EORTC QoL Group and is conducted in collaboration with the EORTC BCG and the International Male BC Program (a collaboration of EORTC-BCG, TBCRC, within the BIG and NABCG networks). The trial design was presented at SABCS 2000 (abstract OT-14-01). This report presents the results from phase 1 and 2 of the EORTC module development study to assess QoL in male BC patients.

Methods: Phase I and II of the EORTC module development study focused on identifying QoL issues relevant to male BC and translating these issues into a questionnaire for a comprehensive QoL assessment. The development process included a systematic literature review, interviews with patients and healthcare professionals (HCPs) and consultations with experts in oncology and QoL. According to the recommendations of the EORTC module development manual, an issue was included to the issue list if it had a patient and/or HCP relevance rating ≥ 2 (on a scale of 1 to 4) and there was a patient and/or HCP priority rating ≥ 30 %. The relevant issues were translated into items with the help of the EORTC item library and the experts, resulting in a preliminary questionnaire. This questionnaire has been reviewed by the EORTC Quality of Life Department translation unit and will be tested in the phase III.

Results: The mixed methods approach (systematic literature search, questionnaires review, investigator brochures, focus group, research group meetings) identified 86 issues that appear to be related to QoL in male BC patients. An issue list was created and used for interviews with patients and HCPs, who rated each issue according to relevance for male BC patients (using a four-point EORTC response format: not at all, a little, quite a bit, very much) and priority (yes/no response format). Interviews were conducted with male patients (N=64) with histologically confirmed diagnosis of BC from a total of eleven centres. A total of 29 HCPs from seven centres representing different specialities participated in this study. Centres were located in northern, southern and eastern Europe, USA, Egypt, and Asia. Of the initial 86 issues, 27 (rated by patients) and 46 (rated by HCPs) fulfilled both inclusion criteria. Additionally, 24 issues are covered by the BR-45 (updated BR-23 module Phase III) and/or the PR-25, and 25 are new issues not covered by these modules. In phase II, these issues were translated into items and a preliminary Phase II module/questionnaire with 68 items to assess QoL in male BC patients was created and will be presented at SABCS 2024.

Conclusion: The results of the phases I-II highlight that the current practice of using combining parts of the EORTC QLG breast module and prostate module does not sufficiently cover all the relevant QoL issues for male BC patients. Ten items commonly used in the assessment may not add value, and 25 potentially valuable new items are not included in existing modules. Therefore, a new, male BC dedicated QoL questionnaire should be developed. A preliminary phase II questionnaire will be tested in phase III of the EORTC module development.

Note. This document represents preliminary findings of the module development and is subject to revision; subsequent modifications of the module in the next stages may reflect significant changes.

P4-01-05: Impact of treatment for early-stage breast cancer on patient quality of life: a large single-institution experience in Brazil

Adriana Kahn, José Roberto Rossari, Arthur Pille, Juliana Sena de Souza, Kim RM Blenman, Maryam Lustberg

Background: Early-stage breast cancer local and systemic treatments may affect patients' quality of life (QoL) in many aspects. Depending on age, role, culture and beliefs, QoL may be impacted differently among women. The purpose of this study is to describe and compare QoL scores before and after initial treatment of patients with early-stage breast cancer from a single institution in Brazil.

Methods: Between 2019 and 2023, patients with stage 0-III breast cancer treated at Hospital Moinhos de Vento, Brazil, were included. QoL data were collected using two questionnaires of The European Organisation for Research and Treatment of Cancer (EORTC): the Cancer Quality of Life Questionnaire (EORTC QLQ-C30); and the Breast Cancer-Specific Quality of Life Questionnaire (EORTC QLQ-BR23). Functional and symptom scales were dichotomized according to patient responses. The associations between age groups (<60y [younger] vs. ≥60y [older]) and QoL scales were defined to include only patients who completed all the QoL questionnaires at each comparison segment (baseline, 6m and 1y). Both the Bhapkar test and the Wilcoxon signed-rank test were conducted, depending on the nature of the variable. Bonferroni correction was applied to adjust p-values due to multiple tests. The level of statistical significance was set at 5%.

Results: 745 patients completed QoL questionnaires at baseline. Answers were collected at follow up (FUp) of 6m (708 pts, 95%) and 1y (633 pts, 85%) post-diagnosis. At baseline, most patients were <60 years-old (419 pts, 56.2%) with a postmenopausal status (397 pts, 73%), and were treated for invasive disease (664 pts, 89%). Mastectomy was performed in 262 patients (35%), and breast-conserving surgery in 417 (56%). By the time of the 6m FUp, 305 patients had radiotherapy (41%), 316 chemotherapy (42%) and 306 endocrine therapy (41%). Regarding baseline vs. 6m FUp (296 pts): Emotional functioning at 6m improved from baseline for both younger ($p<0.0001$) and older women ($p=0.0011$). Physical functioning worsened for younger patients ($p=0.0097$) and future perspective improved for both young ($p<0.0001$) and older women ($p=0.024$). For older women, the function score increased significantly ($p<0.0001$). Regarding baseline vs. 1y FUp (185 pts): emotional functioning ($p <0.0001$), sexual enjoyment ($p=0.003$) and future perspective ($p<0.0001$) improved in younger women. Function score improved in older women ($p<0.0001$). Regarding 6m FUp vs. 1y FUp (236 pts): physical functioning continued to improve in older women ($p=0.013$). Breast-related symptoms worsened for the whole group of patients ($p=0.037$), but the difference was not statistically significant for age groups ($p=0.375$).

Conclusions: Treatment of early-stage breast cancer affects younger and older women in different ways and domains of QoL. In this single-institutional dataset, emotional functioning and future perspectives tended to improve over time for younger and older women. For younger women, physical functioning tended to worsen, and sexual enjoyment tended to improve. These results may aid in development of strategies to mitigate specific needs of patients based on their age groups.

P4-01-06: Evaluation of the results of fully implantable catheters for chemotherapy (cervical and brachial region) in cancer patients

Marina Toledo, Afonso Celso Pinto Nazário, Fabio José Bonafé Sotelo, Renato Manzioni

Introduction: Totally implantable venous devices (DVTIs) or ports, are essential for patients with malignant neoplasia who require chemotherapy and other long-term parenteral treatments. Because they were totally implantable, they enabled better quality of life, longer durability, lower infection rate and other complications when compared to other devices. Implantation through the internal jugular vein has been the preferred route of insertion, however it has been debated in recent years due to its association with severe complications such as pneumothorax, hemothorax, puncture of the subclavian artery and carotid artery. An alternative to avoid these complications is the use of totally implantable venous devices for peripheral insertion in the arm, less invasive procedure and with better aesthetic results.

Methods: It is a prospective study in which 36 patients with neoplastic disease from the vascular surgery outpatient clinic of the Ipiranga Hospital - UGA II (public) and Santa Catarina – Paulista Hospital (private), submitted to port implantation through cervical or brachial access, according to medical indications and patient preference. These patients were followed up from June 2018 to December 2023, and the primary outcomes were: time of the procedures, complications and discomfort of the patient in the intraoperative period, 10 days, 1 month and 6 months after the procedure. The satisfaction assessment was performed at the end of the study based on the application of a specific questionnaire.

Results: In all cases the procedure was successfully completed and the proper functioning of the catheters was confirmed. Complications observed in patients with brachial access (nineteen cases) included three cases of local bruise, one case of asymptomatic thrombophlebitis, one case of subcutaneous infection and one case of pain when stretching the arm. All of these complications were resolved without the need for surgical procedures. There was one case of extrusion due to a probable allergic reaction to the chemotherapy drug requiring early removal of the port. In patients with cervical access (seventeen cases), two cases of malfunctioning catheters were observed, one of which required early removal of the port, and another case of subcutaneous pocket infection unresponsive to clinical treatment, with early removal of the port also performed. Most patients preferred catheter implantation in the arm, but cervical access was more practical due to the larger venous caliber in this topography and greater availability of appropriate material. Of the thirty-

three patients who maintained the port for 6 months and underwent the quality of life questionnaire (fifteen patients with cervical access and eighteen patients with brachial access), thirty-two would recommend to another person. Conclusion: The implantation of the port through the brachial and cervical access did not present serious complications, and the patients demonstrated high general satisfaction.

Keywords: Catheters; Fully implantable; Chemotherapy; Brachial; Port

P4-01-07: The contribution of Acceptedance, awareness of illness, social contexts and economic status to mental health among women with breast cancer

Davide Dalu, Valentina Biscaldi, Maria Silvia Cona, Anna Gambaro, Lorenzo Ruggieri, Ottavia Amato, Cinzia Fasola, Sabrina Ferrario, Cristina Marrazzo, Nicla La Verde

Background: In 2023 the Lancet Commission evaluated the three main asymmetries in relation to cancer and gender differences: decisional processes, awareness of illness and economic domains. It highlighted the necessity of considering a complex frame, in which women live with cancer and beyond it, and fill the role of caregivers for family members and friends, job employers and members of a social community. METHODS: In the attempt to contribute to fill this gap, the aim of the study was to explore a) acceptance and awareness of illness, social contexts (family and relationships), economic difficulties, anxious/depressive symptoms, and mental health in cancer patients (pts) undergoing active therapy with breast cancer (BC); b) the relationship of acceptance and awareness of illness, social contexts, and economic difficulties with anxious/depressive symptoms and positive mental health among BC pts. A monocentric cross-sectional study was conducted. Pts were enrolled during the first session of a psychological support path. Patients' cancer diagnosis and stage, as well as presence of family and friendships, and economic difficulties were explored. The Revised Illness Perception Questionnaire (IPQ-R), Hospital and Depression Anxiety Scale (HADS), Benefit Finding short form (BF-SF) and Mental Health Continuum Short-Form (MHC-SF) were administered. Descriptive, parametric and non-parametric statistics, and regression models were conducted.RESULTS: Out of the 70 BC pts (median age =54.5, mean=54.5, SD=11), 78.8% of them had a localized cancer and 21.2% a metastatic/advanced one. As concern socio-demographic characteristics, 65.7% of the BC pts was married or cohabiting, 72.7% reported having structured friendships, 17.1% economic difficulties, and 7.1% of them reported housing difficulties. Participants reported moderate levels of beliefs, showing positive awareness of illness. As for HADS, pts mean score exceeded anxiety and depression clinical cutoff (depressive symptoms mean score=8.29, SD=4.39, and anxiety symptoms mean score=9.06, SD=4.78). Overall, pts reported moderate values of acceptance of illness at BF-SF, and moderate values of mental health at MHC-SF, scoring higher in psychological than in hedonic and social well-being, with 28.6% of BC pts flourishing, 25.7% languishing and of 45.7% of pts with moderate mental health. Finally, multiple linear regression showed that acceptance of illness and

perceived illness control promoted high mental health ($F=3.82$, $p<.05$). No significant contribution emerged for cancer stage, perceived consequences of illness, having a family, structured friendships and absence of economic difficulties. On the opposite, when depressive and anxiety symptoms were tested, multiple linear regression founded that low illness control and perceived consequences of illness was associated with high levels of anxiety and depressive symptoms ($F=2.84$, $p<.05$). No significant contribution emerged for cancer stage, low acceptance of illness, family and friendships contexts, and economic difficulties.

Conclusions : Findings supported the literature highlighting that acceptance and perceived control of illness promote better quality of life in BC pts, fostering mental health and defending from anxiety and depressive symptoms. In line with scientific litterature in heallth psychology, it is, nevertheless, interesting notice that in this group of participants cancer stage, the presence of a partner and solid friendships, and no economic difficulties did not emerge as a predictor of well-being and mental health. Tailored interventions for BC women should consider psychological needs and individuals' potentials, and social opportunities for the empowerment or maintenance of a good quality of life.

P4-01-08: PYNK at 20: From SABCS Inspiration to Multisite Clinical, Research, and Educational Program for Young Women with Breast Cancer

Sandy Vuong, Katarzyna Jerzak, Brooke Macdonald, Yonina Juni, Alexandra Landsberg, Karen Fergus, Judith Weinroth, Ellen Warner

Introduction: The last session of the 2004 San Antonio Breast Cancer Symposium focused on the unique biological, fertility, and psychosocial issues faced by women diagnosed with breast cancer at age 40 or younger (YWBC). Attendees EW and JW, for whom this was a startling eye-opener, returned to Sunnybrook Health Sciences Centre in Toronto determined to create an interdisciplinary program for YWBC. Their vision was to ensure these patients received: 1) State-of-the-art clinical care, 2) A continuum of support for themselves and their families, and 3) Educational resources. Additional priorities would be: 4) Clinical and translational research focused on YWBC, and 5) YWBC-focused education of health care professionals. Today's PYNK program - its origins and operations (including challenges and successes) - are described in this presentation.

Methods: From January 2005 through January 2008 the program infrastructure was built. Steps included: Review of the literature on unmet needs of and existing programs for YWBC; Monthly meetings of a multidisciplinary executive from medical, radiation, and surgical oncology, nursing, social work, psychology plus 2 young breast cancer survivors; Presentations to skeptical colleagues and to "management" who liked the concept but could not offer financial support; Establishment of a seamless fertility preservation referral process; Fundraising to pay a part-time nurse for the 1st year; Creation of a prospective

research database, serial patient questionnaires, and a mechanism for storing baseline blood; and Selection of a name for the program: PYNK.

Results: Since the enrollment of the first patient in Feb. 2008, there have been 40 to 50 newly diagnosed patients per year who remain in the program until discharged from our centre. Within 2 years a full-time nurse navigator became necessary. Since Jan. 2023 the navigator role has been taken over by a Physician Assistant (SV). Program objectives: 1 & 2) The navigator, along with the social worker (BM), meets the patient +/- accompanying family shortly after the 1st visit post-diagnosis, helps facilitate referrals/appointments, provides intensive support through active treatment, and medical/psychosocial support as needed thereafter. The navigator and social worker also co-lead 2 monthly support groups, one for non-metastatic and one for metastatic patients. A child life specialist is available when necessary for home visits to children. 3) In addition to brochures, books, and educational events, an online multimedia virtual library focusing on YWBC issues is maintained. 4) Consenting patients were enrolled in the prospective clinical database including family history, lifestyle factors, and serial psychological measures until 2015 when PYNK became one of the biggest contributors to the pan-Canadian RUBY (Reducing the bUrden of Breast cancer in Young women) prospective cohort. We have also enabled our patients to join pivotal trials such as the Dana Farber's Young Women's Breast Cancer Study and the Breast International Group's POSITIVE study (NCT02308085). 5) Trainees of all levels and health disciplines rotate through PYNK clinics. In addition, we host formal CME events.

Conclusions/Discussion: Since 2008, PYNK has helped hundreds of YWBC and their families manage their complex medical and psychosocial issues. PYNK research has resulted in numerous presentations and publications. Trainees learn unique skills and perspectives about YWBC management. In 2023 PYNK expanded to 2 additional donor-funded sites in the Greater Toronto Area. PYNK has not only been a model for other YWBC programs internationally but has sparked the creation of special programs for young patients in other disease sites. The greatest strength of PYNK has been the continuous input of the YWBC themselves on its executive.

P4-01-09: REAL-LIFE OUTCOMES OF A 10-YEAR ONCOFERTILITY PROGRAM IN EARLY BREAST CANCER PATIENTS

Bernardo Pereira, Duarte Machado, Hugo Nunes, Teresa Santos, Alexandra Santos, Teresinha Simões, Ana Marujo, Iris Bravo, Beatriz Mira, Emanuel Gouveia, Patricia Pereira, Catarina Cardoso, Susana Esteves, Catarina Relvas, Madalena Machado, Margarida Pereira, António Moreira, Fátima Vaz, Margarida Brito

Introduction: Fertility preservation (FP) is a critical aspect of care for young breast cancer (BC) patients. Guidelines on FP from cancer societies recommend that patients in their

reproductive years should receive fertility counselling and, if interested, should be timely referred to a FP specialist.
There is, however, limited information on real-life follow-up of BC patients who underwent FP.
We aimed to assess the outcomes of an Oncofertility program in young women with early breast cancer (EBC) proposed for curative treatment with chemotherapy (CT).

Methods: Retrospective analysis of EBC patients under 40 years proposed for FP before curative CT in an EBC clinic of a tertiary cancer center from January 2012 to December 2021. FP procedures were carried out in 3 different fertility units.
Collected data covered patient demographics, BC characteristics, genetic risk, treatment, survival outcomes and FP methods and complications, number of oocytes retrieved, oocyte utilization, pregnancies, live births, ongoing pregnancies, miscarriages and elective terminations.
Disease-free survival (DFS) and overall survival (OS) were estimated by Kaplan Meyer method.

Results: In the study period 88 women were referred to FP and 70 (80%) accepted to proceed with FP after specialist appointment. Median follow-up time was 6.9 years. Median age was 32 years (interquartile range [IQR] 29-36). Before diagnosis 38% of women had been pregnant and 30% had children. Patient BC was staged as II in 55% and III in 24% of cases and 48% had node positive disease. Hormone receptor expression was found in 77% of tumors, HER2 in 25% and 16% were “triple negative”.
Genetic testing was done in 93% of patients and germline pathogenic variants were identified in 16%, including BRCA in 13%.
Neoadjuvant CT was performed in 67% of patients and adjuvant CT in 32%. CT protocol included anthracyclines in 87% of treatments. Median time from FP specialist referral to CT start was 3.7 weeks (IQR 3.0-5.5).
The methods used for FP were oocyte (91%) (median number of oocytes retrieved: 10 [IQR 6-16.3]), both oocyte and embryo (2%) and ovarian tissue (4%) cryopreservation. There were complications in 2 patients (3%): ovarian hyperstimulation syndrome and hemorrhagic corpus luteum.
Adjuvant endocrine therapy (ET) was administered to 76% of patients. Interruption to attempt pregnancy happened in 40% with a median ET exposure time of 4 years (IQR 2.8-5.4).
After FP, 38 pregnancies occurred in 24 patients (34%). We observed 18 live births (47%), 11 miscarriages (29%), 4 elective terminations (11%) and 5 pregnancies are ongoing (13%). Artificial reproductive technologies were used in 29% of pregnancies, all with oocytes retrieved pre-CT. Median time to pregnancy was 4.3 years (IQR 2.9-6.5).
Oocyte utilization rate was 19% (13 patients). Among oocyte users 11 pregnancies (29% of all pregnancies) occurred in 10 women (77%). We observed 6 live births (55%), 4 miscarriages (36%) and 1 pregnancy is ongoing (10%).
Overall, FP was performed in 7 patients to achieve one pregnancy via cryopreserved

material and in 12 patients to achieve a live birth.
DFS and OS at 5 years was 82.1% and 92.0%, respectively.

Conclusion: In our cohort FP outcomes were encouraging.
FP appeared to be effective and complications were rare and manageable, with no worrisome trends regarding DFS or OS.
Clinician awareness and ongoing research in FP will provide more opportunities for BC patients to achieve their reproductive goals.

P4-01-10: Sexual well-being and its association with breast surgery indications: an exploratory study

Nynke Willers, Paul Enzlin, Patrick Neven, Sileny. N. Han

Purpose: Although breast surgery can have a negative impact on a woman's body image, we are not aware of studies measuring the impact of surgery for benign breast disease on sexuality or body image. There are studies on the impact of breast surgery on sexuality and body image for breast cancer (BC) survivors. We want to know if breast surgery has an impact on sexual wellbeing after breast surgery and/or if other BC specific treatments weigh on the decline in sexual functioning after breast surgery. Therefore, we compared sexual functioning in patients who underwent breast surgery for invasive BC versus patient who underwent breast surgery for a benign, prophylactic or premalignant indication.

Methods: Between October 2021 and January 2024, we recruited female patients older than 18 years with a history of breast surgery (self-report) via: 1) consultation site of the breast clinic of the University Hospitals Leuven; 2) social media platforms of Think Pink vzw (https://www.think-pink.be/nl); and 3) patients support groups. After giving eConsent, participants completed an online survey, which included validated questionnaires: Female Sexual Function Index (FSFI), Female Sexual Distress Scale (FSDS-R), World Health Organization – Five Well-being Index (WHO-5), and Dyadic Adjustment Scale (DAS).

Results: We recruited 86 participants who underwent surgery for invasive BC (n=74; mean age: 50,1y; age range: 25-69y) and non-invasive indication (n=12; mean age: 45,5y; age range: 21-72y). Both groups had a comparable outcome for DAS (BC – group mean score: 117,9 versus non-BC group mean score: 119,9) indicating a good partner relation in both groups and WHO-5 (BC-group: 51,17 versus non BC-group: 61,45) indicating a good well-being in both groups (using the cutoff score of 50).
Combing the cutoff score of the FSFI (i.e., <25) and the FSDS-R (i.e., >11), we found that in the BC-group 41/74 (55,4%) had a sexual dysfunction compared to 2/12 (16,7%) in the non BC-group. When considering the use of endocrine therapy, we noticed that a sexual disfunction was present in 52,4% of BC survivors who never took endocrine therapy, in

55,9% of those still taking endocrine therapy and in 60,0% of those who stopped endocrine therapy.
We found poorer sexual function after breast surgery in the invasive BC group (mean total FSFI score: 18.83) compared to the non-BC group (mean total FSFI score: 23,47). While participants with invasive BC who never took endocrine therapy (n=21) had a mean FSFI-score of 21,4, those still taking endocrine therapy (n=43) had a mean FSFI-score of 17,67 and those who stopped endocrine therapy (n=10) had a mean FSFI-score of 15,51.
We found more sexual distress after breast surgery in the invasive BC group (mean FSDS-R score: 24,0) compared to the non-BC group (mean FSDS-R = 10,9). While participants with invasive BC who never took endocrine therapy (n=21) had a mean FSDR-R-score of 18,14, those still taking endocrine therapy (n=43) had a mean FSDS-R-score of 24,65 and those who stopped endocrine therapy had a mean FSDS-R score of 34,89.

Conclusions: This study shows that a higher percentage of women who underwent breast surgery due to a malignancy (52.4%) reported a sexual dysfunction compared to the non-BC group (16,7%).
Moreover, women using endocrine therapy reported lower sexual function and higher sexual distress compared to women who never used endocrine therapy. Women who stopped endocrine therapy reported the lowest scores on sexual function and the highest scores on sexual distress.
These results highlight the importance of addressing sexual side effects during BC treatment and follow-up.

P4-01-11: Patient-reported outcomes assessment using mobile applications in the HR+/Her2- breast cancer adjuvant setting.

Federico Waisberg, Alexis Ostinelli, Sergio Rivero, Laura Lapuchesky, Diego Enrico, Alejandro Frydman, Andrés Rodriguez, Carlos Palmés, Claudio Paletta, Matías Chacón, Jorge Nadal, Victoria Costanzo, Adrián Nervo

Introduction: Adjuvant treatments for HR+/Her2- breast cancer include various options such as tamoxifen, aromatase inhibitors, CDK4/6 inhibitors, and ovarian suppression. These agents are associated with specific adverse events, which may impair quality of life and treatment adherence. Numerous studies have shown that adverse events are often underreported in clinical records. This study aimed to evaluate the adherence to online questionnaires for patient-reported outcomes (PROs) using a mobile application based on the Spanish version of the PRO-CTCAE tool.

Methods: An online questionnaire was designed using 39 questions from the Spanish version of the PRO-CTCAE tool. Patients were instructed to complete the questionnaire after the first month of adjuvant treatment and then every six months, with email reminders. The questionnaire was available for completion at the patient's request. The primary objective was to evaluate adherence to online questionnaires, with the expectation that at least 73%

of a sample size of 42 patients would answer two questionnaires after one year of follow-up. Secondary objectives included evaluating the incidence of self-reported adverse events across different treatment types. Fisher tests and longitudinal-analysis models using generalized estimating equations were performed to evaluate the incidence of adverse events throughout the patients' follow-up. A p-value of <0.05 was defined for statistical significance. This pilot experience only included patients from an Argentinean private center, Instituto Alexander Fleming.

Results: Forty-two patients were included between December 2022 and June 2023, and a total of 123 questionnaires were recorded. The median age was 51.5 years (range 32-73), 59.5% were premenopausal, 14.3% received ovarian suppression, and 16.7% received abemaciclib. 95.2% of patients were followed up for more than one year. The median number of completed questionnaires was three (IQR 1-5). Additionally, 85.7% (95% CI: 71-97%) and 66.6% (95% CI: 50-80%) of the cohort answered one and two questionnaires, respectively. The most reported adverse events were decreased libido (81%), headache (78.6%), and insomnia (78.6%). Treatment with tamoxifen was associated with higher intensity of specific adverse events, including decreased libido (p=0.021) and insomnia (p=0.049). Higher intensity of diarrhea was more frequently reported among patients receiving abemaciclib (p=0.024). Longitudinal analysis showed that the incidence and intensity of hot flushes increased during the first year of follow-up (p=0.024).

Conclusions: This study represents the first experience of PRO assessment using online and mobile applications in Argentina. Strategies tailored to our population are required to promote adherence to online questionnaires, which may include WhatsApp text messages and patient education materials. As expected, this study allowed the recognition of certain treatment-related adverse events that are often overlooked during medical visits.

P4-01-12: Advanced Breast Cancer, Comorbidities, and Overall Survival: An Integrated Review

Abbey Kaler, Veronica Brady, Zayd Razouki, Carina Katigbak

Purpose: Patients living with advanced breast cancer (ABC) and comorbidities are at a greater risk for decreased overall survival. The survivorship needs of ABC patients are an emerging science and little is known about how to best treat ABC patients living with one or more comorbidities. Understanding the impacts of comorbid diagnoses in addition to a diagnosis of ABC may influence treatment and long-term survival. Therefore, the purpose of this review was to determine the state of the science regarding the impact of comorbidities on overall survival among patients with ABC.

Methods: Following PRISMA reporting guidelines, we conducted a comprehensive search of MEDLINE Ovid, EMBASE, and Web of Science databases using defined inclusion and exclusion criteria. The Joanna Briggs Institute Critical Appraisal Tool was used to evaluate article quality. The process of member checking was completed. Covidence electronic software was utilized to manage and streamline data review and extraction.
Results: A total of 876 articles were identified and imported into Covidence electronic software. 172 duplicated citations were removed; 704 studies title and abstracts were manually screened. A total of 691 studies were excluded as they did not meet the review's inclusion criteria. Thirteen full text articles were reviewed for inclusion and exclusion criteria. Ultimately, seven articles were included in the review. Study designs included retrospective chart reviews (n=4), prospective chart reviews (n=2), and a longitudinal cohort study (n=1). The sample sizes ranged from 100 patients (n=1), 250 patients (n=2), 500 patients (n=3), and 1000 patients (n=1). All studies (n=7) were conducted in large medical centers. Three studies were completed in the United States of America, two in Mexico, one in the Netherlands, and one in Germany. Data collection time frames ranged from four to 25 years. Articles were published in the past two decades. Patient setting characteristics included patients with ABC admitted to the hospital, patients with ABC receiving palliative chemotherapy, those living four years after an ABC diagnosis, those with ABC and brain metastasis, and those diagnosed with denovo ABC. Results of included studies are reported in the context of Sarfati's "Cancer and Comorbidity Construct" framework. None of the included studies were grounded to a theoretical framework. A frequency count of comorbidities reported in included studies was preformed: previous cancer (1), hyperuricemia (1), endocrine/other metabolic disorders (1), primary chronic polyarthritis (1), depression/psychosis (2), lung disease (3), dyslipidemia (4), cardiovascular disease (5), obesity (5), and diabetes (6).

Conclusion: There remains limited literature available on the comorbidities experienced by patients living with ABC. Further quantitative and qualitative studies are needed with the inclusion of men, rural communities, and minority populations to explore the impact of comorbidities on outcomes among persons with ABC. The long-term goal of this work is to develop comorbidity management guidelines specific to the oncology and ABC population to positively impact their overall survival.
Keywords: advanced breast cancer, metastasis, comorbidity, overall survival.

P4-01-13: Are we tired of talking about sleep? Insomnia amongst breast cancer patients

Emily Scott, Amani Chowdhury, Amy Guppy, Andreas Makris

Background: Sleep disturbance is one of the most common symptoms experienced by cancer patients at all stages of the disease and treatment.1 Studies indicate that up to 61% of these patients face sleep difficulties, which negatively impacts fatigue, mood, pain sensitivity, cognitive function, and physical activity.2,3 A systematic review found that

addressing insomnia in breast cancer patients can reduce depressive symptoms and anxiety, improve therapy adherence, and enhance quality of life.3
Significant disruption to sleep, of more than 3 months duration is classified as insomnia. In 2023, the European Society for Medical Oncology released guidelines for assessing and managing insomnia in adult cancer patients.4 They recognise insomnia is often underdiagnosed and poorly treated in this population. The Insomnia Severity Index, validated for cancer patients, is recommended for screening all cancer patients, with a further detailed evaluation for those scoring 15 or higher.
Cognitive behavioural therapy (CBT) is the recommended standard of care for treating insomnia. While hypnotics are the most widely used treatment for insomnia, they are associated with side effects and adverse effects with long-term use. Melatonin can be considered when there is circadian rhythm disruption. Some evidence suggests exercise, either alone or as a supplementary measure, can provide benefits.

Methods: We conducted a study using a custom-designed survey to gather information from patients about their sleeping patterns, duration of insomnia, and management they have undertaken. Following the survey, we carried out a service evaluation to assess the knowledge of breast oncology staff regarding the assessment and management of sleep disturbance at our centre.

Results: From our patient cohort, 63% had metastatic breast cancer, and all were female. The median age was 58 years (range 37-79). Among the respondents, 52% reported sleep disturbance, with the majority (22 out of 27) experiencing symptoms for over three months. Of those with insomnia, 30% expressed a desire to discuss treatment options, while 63% were either unsure or did not want to discuss treatment with their oncology team. Patients with insomnia reported higher incidences of fatigue (81%), poor concentration (52%), and mood disturbance (37%) compared to those without insomnia. Among those with insomnia, 86% had not been offered treatment, and the remaining 14% had been offered treatment by their General Practitioner. No reasons were provided for their reluctance to discuss insomnia with their oncology team.
Our staff survey revealed staff felt moderately comfortable discussing insomnia with patients (mean Likert score of 2.7/5, mode 2/5). Only 15.8% were aware of validated screening tools, and 11% felt comfortable managing insomnia (mean Likert score of 2.8/5, mode 3/5). Additionally, 26.3% were aware of insomnia management options available at our centre. The preferred treatment options among the staff included mindfulness therapy, drug therapy (excluding melatonin), and exercise.

Conclusions: The analysis corroborates previous studies indicating that insomnia is prevalent among breast cancer patients and is associated with other symptoms such as fatigue, mood disturbances, and poor concentration. Our cohort expressed unease in discussing insomnia with their oncology team, and all treatment offers were made by primary care providers. Our staff lacked awareness of validated assessment tools for insomnia and ESMO guidelines. To address this gap, it is crucial to enhance staff education

and direct patients to the available resources at our centre.

P4-01-14: The impact of early breast cancer on psychological resilience, distress levels and perception of health, a longitudinal study

Anuska Budisavljevic, Renata Kelemenic Drazin, Marina Letica Crepulja

Background: Confronting early breast cancer (EBC) diagnosis, along with complex and challenging treatment procedures is an extremely stressful experience. Psychological resilience (PR) is the ability to maintain or restore normal functioning while facing adversity. The aim of this study was to explore the impact of EBC on PR, distress, and perception of health throughout the first year of EBC diagnosis.

Study design: The longitudinal case-control study was conducted at the GH Pula, Croatia and approved by the Ethics Committee. Study included 50 patients newly-diagnosed with EBC and 67 healthy women with screening mammogram graded 1 or 2 using a Breast Imaging-Reporting&Data System.
Levels of distress, perception of health, and PR were assessed using the Depression, Anxiety, and Stress scale (DASS-21); the SF 36-Item Health Survey 1.0 (SF-36), and the Connor-Davidson RISC-25 scale (CD-RISC-25). Differences between variables were examined using the t-test and Chi-Square test, for interval and categorial variables. We made adjustment for age by using age as covariate. The significance level was set at $p < 0.05$. The first measurement was conducted within four weeks after EBC diagnosis and the second after 12 months.

Results: Participant age ranges were 27–70 (mean = 57.94, SD = 10.24) years and 40–70 (mean = 57.01, SD = 9.62) years in the EBC and control group, respectively (t = -0.501, df =

115, p = 0.618). The groups were well balanced considering all the demographic characteristics. In the EBC group 70% of participants had stage I, 24 % stage II, and 6% stage III EBC. Around 36% of EBC patients were premenopausal. Breast conserving surgery was obtained in 84% of patients. Regarding systemic treatment, 66% were treated with adjuvant/neoadjuvant chemotherapy, 90% were treated with antihormonal therapy, and 12% with antiHER2 therapy.
First measurement showed that EBC group had significantly higher CD-RISC-25 scores than the control group, indicating higher levels of PR (t(df) 2.530, $p < 0.05$). Also, patients in the EBC group had lower scores on the single SF-36 item evaluating perceived change in general health compared to 1 year prior than those in the control group (t (df) 3.835, $p < 0.01$) while no significant differences in the four domains of physical and emotional health perception were detected between the EBC and control group.
After one year of follow up EBC group showed lower scores on SF-36 subscale of physical functioning (t(df)2,472, $p < 0.05$), while at the same time they perceived better general health compared to 1 year prior than the control group (t(df) -4,656, $p < 0.01$). Moreover, participants from EBC group achieved higher results on the CD-RISC-25 scale than healthy control (t(df) -2.801, $p < 0.01$). Furthermore, when comparing the first and second measurement for EBC group, 12 months after being diagnosed the EBC group showed lower scores for depression (t(df) 2,744, $p < 0.01$) and stress (t(df) 2,158, $p < 0.05$), better social functioning (t(df) -2,169, $p < 0.05$), and better perception of general health compared to 1 year prior (t(df) -7,713, $p < 0.01$).

Conclusion: To the best of our knowledge, this is the only longitudinal study comparing PR levels in EBC patients and healthy controls and we found EBC patients to be more resilient even though EBC group underwent first year of EBC treatment. This altogether suggests that being diagnosed with EBC might induce effective adaptation to stress, leading to higher PR and consequently better perception of change in general health in EBC patients compared to healthy controls.

P4-01-15: Treatment tolerability and adherence in people living with metastatic and non-metastatic breast cancer: Findings from the Cancer Experience Registry

Erica Fortune, Kara Doughtie, Joanne Buzaglo, Aude Roborel de Climens, France Ginchereau-Sowell, Anubha Shukla, Melissa F. Miller

Background: Treatment adherence, an essential component of effective cancer care, can be affected by treatment tolerability. The widely accepted definition of tolerability, based on how well patients tolerate adverse events, does not fully address patient perspective and their quality of life. This study aims to further understand breast cancer patients' perceptions of treatment tolerability by metastatic status and association with adherence.

Methods: A total of 244 participants (242 women, 2 men) with a primary diagnosis of breast cancer enrolled in the Cancer Experience Registry, an online survey research study, between November 2023 and June 2024. For tolerability, participants were asked to rate the level of importance (1=Not at all to 5=Very much) for 11 factors when deciding if a treatment (past or current) is tolerable or not. For adherence, participants indicated if they ever deviated from their cancer care plan and rated the contribution of 8 factors to their non-adherence (1=Not at all to 5=Very much). Chi-square analysis was utilized to assess group differences among tolerability items based on metastatic status and adherence.

Results: The sample was 84% Non-Hispanic (NH) White, 9% NH Black. Participants varied in age (range: 28-88; mean=63 yrs; SD=12), time since diagnosis (range: 2-41; median=9 yrs), and socioeconomic status (13% household income <$40K); 34% currently receiving cancer treatment, with 72% in remission, 17% metastatic, and 18% with history of recurrence. In the full sample, the three most important factors determining whether a treatment was tolerable (as reported by participants who rated these factors as Somewhat to Very much important) were: ability to slow disease progression (99%), symptom relief (96%), and side effects of treatment (95%). Conversely, the least endorsed factors were related to treatment administration: frequency of treatment (71%), home vs. in-clinic (64%), and oral vs. injectable (60%). When looking at top factors by metastatic status, the top three remain unchanged for those who are metastatic (n=41). For those who are non-metastatic (n=200), while ability to slow disease progression and symptom relief remain important, potential cure was deemed more important than side effects; 98% of non-metastatic patients rated this as Somewhat to Very much important compared to 75% of ever metastatic patients (X^2=28.8, p<.001). A total of 56 individuals (23% of total sample; 10 of these ever metastatic) indicated they had not always adhered to their treatment plan. The most frequently endorsed reasons (as reported by participants who rated these factors as Somewhat to Very much contributing to non-adherence) included avoiding side effects (80%), interference with day-to-day activities (67%), and interference with personal life (62%). Those who reported non-adherence were significantly more likely to report high importance on the following tolerability items: cost/affordability of treatment (X^2=5.77, p<.05), impact of treatment on daily life (X^2=5.88, p<.05), and impact on emotional well-being (X^2=6.06, p<.05).

Conclusion: Slowing disease progression, symptom relief, and side effects of treatment are among the most important factors for breast cancer patients when determining tolerability of treatment. Curative potential is also highly rated for non-metastatic patients. Non-adherence was specifically associated with some tolerability factors including financial cost of treatment, treatment impact on daily life, and emotional well-being. There are multiple drivers of treatment intolerance and multiple reasons for treatment non-adherence in breast cancer. Individual priorities, preferences, and expectations are important to consider to maximize treatment acceptability and adherence.

P4-01-16: Comprehensive Genomic Characterization of ILC Organoids: A BCRF Legacy Project Initiative

Jagmohan Hooda, Jian Chen, Daniel D. Brown, Rohit Bhargava, David N Brown, Pier Selenica, Kaitlyn Gill, Hunter Green, Britta Weigelt, Adrian Lee, Steffi Oesterreich

Background: Invasive lobular carcinoma (ILC) is a distinct histologic type of breast cancer with unique features. The lack of well-characterized ILC organoid models has limited research and therapy development. We aim to establish a well-characterized ILC organoid biobank under the BCRF Legacy Project, creating a valuable resource for ILC research.

Methods: We performed whole-genome (WGS) and RNA-sequencing (seq) on patient FFPE tumor tissues. ILC organoids are subjected to whole-exome (WES), bulk RNA-seq, single cell (sc)RNA-seq, scATAC-seq, and MSK-IMPACT targeted sequencing. STR profiling confirmed specimen relatedness. Data were analyzed using validated bioinformatics tools. Immunofluorescence (IF) analysis of E-cadherin and p120 was performed.

Results: After establishing a total of 9 ILC organoids, WES was performed on all 9 organoids while WGS was performed on 2 patient samples corresponding to 2 of these organoids. WGS analysis of bilateral ILCs (TP19-M179), corresponding to LIO-046 organoid, revealed that both tumors shared a CDH1 p.L333Wfs23 frameshift mutation coupled with loss-of-heterozygosity (LOH), concurrent 1q gain and 16q loss, and dominant aging/clock mutational signatures. The left ILC was found to have fewer copy number alterations and somatic mutations than the right ILC. LIO-046 organoid was generated from right breast tumor tissue. Organoid IPM-BO-084 was generated from left ovarian metastasis of a mixed ILC (TP20-M130). Based on WGS analysis, the primary invasive carcinoma and ovarian metastases were found to be characterized by a somatic BRCA2 p.Q2157Ifs18 mutation associated with LOH, and displayed genomic features of homologous recombination deficiency (HRD). The levels of chromosomal instability were higher in ovarian metastases compared to the primary lesion. WES analysis of ILC organoid models identified genetic alterations affecting CDH1, which correlated with IF data where frameshift or nonsense mutations were associated with loss of E-cadherin and cytoplasmic p120 expression.

Conclusions: We successfully established long-term ILC organoids. Our comprehensive genomic analysis of ILC organoids and patient samples underscores the genomic heterogeneity of ILC. Advanced sequencing techniques provide a framework for understanding ILC's molecular landscape. As we expand our biobank, these organoids and their data will be invaluable for developing targeted therapies and advancing ILC research. We are committed to making the genomic data and organoid models available to the research community. Our future goal is to foster collaboration and accelerate advancements in ILC research through this shared resource.

P4-01-17: Uncovering of NRAGE/JNK and PI3K/AKT pathways through serial WGS of breast cancer patients

Byeongju Kang, In Hee Lee, Soo Jung Lee, Jeeyeon Lee, Ho Yong Park, Ji-Young Park, Nora Jee-Young Park, Eun Ae Kim, Seolhwa Jeong, Jieun Kang, Yee Soo Chae

Purpose: Cancer genomic sequencing has fundamentally advanced our understanding of the basic biology of this disease, and more recently, has offered method to guide and evaluate treatment in clinic. We performed whole-genome sequencing (WGS) on three consecutive tissue and blood samples from breast cancer patients: diagnosis, post-neoadjuvant chemotherapy, recurrence after curative resection.

Methods: We performed WGS to compared the genetic profiles of the primary, surgical and recurrent samples (tissue and blood) to determine: (1) how closely related the genetics are among the primary , post- neoadjuvant chemotherapy, and the recurrent tumors, (2) whether there are variations in mutational processes among the primary, post- neoadjuvant chemotherapy, and recurrent tumor. WGS was performed on three patients for whom both tissue and blood were available at diagnosis, at surgery after neoadjuvant chemotherapy and at a recurrence.

Results: As a result of somatic protein coding variant analysis, PIK3CA mutation was confirmed at the time of diagnosis tissue in all cases. Mutations were found at p.E545K in patient 14, p.R916C in patient 18, and p.R916C in patient 3. Among these, patients 14 and 18 had PIK3CA mutations even at the time of recurrence. In patient 14, the same PIK3CA mutation was found in 3 consecutive samples, but in patient 18, it changed from p.R916C at diagnosis to p.G480E at relapse. Furthermore, functional enrichment analysis identified a common NRAGE signaling system in the cfDNA. The NRAG pathway was found in the blood at diagnosis, surgery, and recurrence in all three patients.

Conclusion: This study was a proof-of-concept study, in which we hypothesized that NRAGE/JNK and PI3K/AKT signaling pathways are involved in breast cancer recurrence and treatment response through WGS of consecutive samples. Further research is ongoing with larger numbers of patients.

P4-01-18: NEDD9 expression as an indicator for pathological complete response (pCR) in early-stage HER2-positive breast cancer patients undergoing neoadjuvant therapy

Bei Jiang, Elena Pugacheva, Stell Patadji Santiago, Sijin Wen, Jordan Hill, Michelle Hartzell, Hiba Khan, Maria Hafez

Background: Neural Precursor Cell Expressed Developmentally Downregulated Protein (NEDD9) is a scaffolding protein implicated in various oncogenic signaling pathways, contributing to cancer progression and metastasis. Our preclinical study has highlighted the crucial role of NEDD9 in the tumorigenesis of HER2-positive breast cancer. This study aims to assess the potential of NEDD9 expression as an indicator for pathological complete response (pCR) in early-stage HER2-positive breast cancer patients undergoing neoadjuvant therapy, especially those with low estrogen receptor (ER) expression (ER <10%).

Methods: NEDD9 expression was assessed by tissue microarray in a cohort of 134 early-stage HER2-positive breast cancer patients. The correlations of NEDD9 expression with clinical/biological characteristics, treatment, and pCR rate were analyzed by Fisher's exact test.

Results: Significant associations were found between NEDD9 expression and tumor stage (cT) (p=0.018), clinical stage (Cstage) (p=0.035), lymph node surgery (p=0.001), adjuvant radiotherapy (p=0.017), and Ki67 index (p=0.002). In the overall HER2-positive cohort who received neoadjuvant chemotherapy (n=67), no significant association was found between NEDD9 expression and pCR (p=0.554). However, in the subgroup of ER low (<10%) HER2-positive patients (n=27), high NEDD9 expression was significantly associated with an increased pCR rate of 93.8% compared to 27.3% in those with low NEDD9 expression (p=0.0006). NEDD9 expression did not correlate with pCR rate in the ER/PR-positive subgroup.

Conclusions: Consistent with our previous preclinical study, high NEDD9 expression is significantly associated with aggressive tumor characteristics such as advanced tumor stage and high proliferation rates in early-stage HER2-positive breast cancer. High NEDD9 expression is significantly associated with a higher pCR rate in early-stage HER2-positive breast cancer patients with low ER expression (<10%). This suggests that NEDD9 could serve as a predictive marker for pCR in this specific patient population. Further research is ongoing to explore the mechanisms underlying this association and the potential therapeutic implications of targeting NEDD9 in HER2-positive breast cancer.

P4-01-19: Clinical impact of MRD detection via ctDNA tumor-agnostic assay in early-stage breast cancer patients: a real-world experience

Caterina Gianni, Eleonora Nicolo', Marla Lipsyc-Sharf, Brian DiCarlo, Eleni Andreopoulou, Ashley Schreier, Jeannine Donahue, Letizia Pontolillo, Laura S. Muñoz-Arcos, Mara Serena Serafini, Elisabetta Molteni, Nadia Bayou, Kelly Eng, Amanda Kaylan Strickland, Marko Velimirovic, Lorenzo Gerratana, Andrew A. Davis, Arielle Medford, Olivier Elemento, Aditya Bardia, Ugo De Giorgi, Carolina Reduzzi, Massimo Cristofanilli

Background: Detecting minimal residual disease (MRD) in the adjuvant setting can help identify patients (pts) with early breast cancer (EBC) at a higher risk of recurrence. Circulating tumor DNA (ctDNA)-based MRD detection is strongly associated with recurrence. Typically, MRD tests require prior knowledge of the tissue genetic alterations. However, obtaining tissue samples can be challenging. This multi-institution retrospective analysis investigates the impact of a plasma-only genetic and epigenetic ctDNA testing on the care of pts with EBC.

Methods: Our retrospective study included 73 pts with stage I-III EBC who had MRD testing after curative-intent treatment between 09/2022 - 06/2024 at Weill Cornell Medicine (New York) and University of California Los Angeles (Los Angeles, CA). ctDNA evaluation was performed using the Guardant Reveal® (GR) tissue-free assay (Guardant Health, Redwood City, CA), a next-generation sequencing panel. ctDNA presence was determined by a custom bioinformatics classifier identifying tumor-derived variants and epigenetic methylation profiles. All tests were ordered in the real-world clinical setting, and data were gathered through a retrospective review of electronic medical records with appropriate IRB approval. A descriptive analysis was performed.

Results: By 06/2024, 73 EBC pts had plasma-only ctDNA testing for MRD monitoring post-surgery. At diagnosis 22% were stage I, 53% were stage II and 21% of pts were stage III. Tumor subtypes included HR+/HER2- (44; 60%), HR-/HER2- (11; 15%), HER2+ (17; 24%), 1 case was unknown. Fifty-five pts (75%) had received neo/adjuvant chemotherapy. Among these, 10 pts had pathological complete response. At the time of the analysis, 49 pts were still receiving adjuvant therapy. The median recurrence free survival (RFS) since surgery was 22.5 months (interquartile range [IQR] 13.3-36.8). With a median follow-up of 2.2 years (IQR, 1.6-3.2) since diagnosis, 6 pts had a distant recurrence. Among them, 3 were HR+/HER2-, 2 were HR-/HER2- and 1 was HER2+ EBC. From 09/2022 to 06/2024, 124 GR tests were performed, with a median of one test (IQR 1-2) per patient. Thirty-nine pts (53%) had one GR test, while 47% had ≥2 tests. The median time between subsequent tests was 119 days (IQR, 93-200). 16 tests (13%) were positive, with 10 pts having at least one GR+ result over a median time of 7 months (IQR 2.7-12.1) from first testing to last follow-up. The first GR test was ordered after a median time from surgery of 13.8 months (IQR 7.0-50.5). Five out of 6 relapses were preceded by MRD+ testing, except for one patient that developed a solitary brain lesion. Pts with ctDNA+ had a primary EBC stage II or III (7 and 2, respectively, 1 unknown). In 7/10 pts, after a first ctDNA+ result, an imaging scan was planned with detection of distant asymptomatic disease recurrence in 3 cases. In 3/10 patients, a follow-up test after 3 months led to further scans and detection of 2 additional relapses. At the time of the analysis 5 patients MRD+ were free of detectable metastases (clinically or radiologically). Overall, ctDNA detection was the only prognostic factor for RFS ($p < .001$). These data estimate a negative predictive value of 98.4% and a positive predictive value of 50% for this GR test, with a related sensitivity and specificity of 83.3% and 92.5%, respectively.

Conclusions: Our analysis suggests the utility of a tissue-free ctDNA assay in diagnosing minimal residual disease. This could have clinical implications by enabling earlier diagnosis and possibly intervention to delay or prevent metastatic recurrence. We confirm prior studies showing high specificity for recurrence detection with multi-omic plasma-only MRD testing. Sensitivity limitations may be due to the small sample size and short follow-up. These findings warrant further study in larger cohorts and future clinical trials.

P4-01-20: Impact of neoadjuvant chemotherapy on PD-L1 status in patients with high-risk early-stage triple-negative breast cancer

Ariadna Roqué-Lloveras, Emma Polonio-Alcalá, Helena Pla-Juher, Roser Fort-Culillas, Clàudia Montañés-Ferrer, Ferran Pérez-Bueno, Xavier Pozo-Ariza, Glòria Oliveras, Teresa Puig, Gemma Viñas

Triple negative breast cancer (TNBC) stands out as one of the most lethal breast cancer subtypes, primarily due to the lack of targeted therapies, being chemotherapy the standard treatment. Thus, the development of new targeted therapies for this aggressive subtype are required, given its high rates of tumor recurrence and metastasis. Immunotherapy is emerging as a promising therapeutic approach for TNBC, driven by its greater genomic instability, higher mutation rate, and increased production of neoantigens, all of which contribute to heightened immunogenicity. Therefore, the main objective of this study is to analyze the PD-L1 status in paired tumor samples from high-risk TNBC patients undergoing neoadjuvant chemotherapy (NACT).
The retrospective study included a total of 25 patients diagnosed with early-stage TNBC who were treated at the Catalan Institute of Oncology of Girona between 2010 and 2019. Clinicopathological variables and tumor characteristics were collected from clinical records. For each participant, paired pre- and post-NACT samples (core biopsy and tumor from the surgical specimen after NACT, respectively) were obtained from Institutional Tumor Biobank. The expression of PD-L1 was assessed by immunohistochemistry.
The median age of the participants was 47 years, 79% of the tumors were classified as invasive ductal carcinomas and 62% had positive node involvement at baseline. Moreover, 79.4% of the patients received both anthracyclines and taxanes as neoadjuvant chemotherapy, followed by surgery and 75.9% also received adjuvant radiotherapy. At the time of data cut-off, 48.3% of participants were alive, with a median follow-up of 59 months. At baseline, 92% (23/25) of our population exhibited PD-L1-negative (<1%). Following NACT, 52% (13/25) of these patients positivized PD-L1 status (≥1%), being statistically significant the association between PD-L1 status and NACT (p=0.002). Additionally, the patient cohort whose tumors positivized PD-L1 after NACT showed higher median progression-free survival (PFS) (44.3 m vs. 21.0 m) and overall survival (OS) (56.5 m. vs. 34.1 m.), with time to progression (TTP) not reached (NA vs. 21.0 m), compared to the cohort that remained PD-L1 negative. However, the differences between the two cohorts were not statistically significant.
In conclusion, in patients with early-stage TNBC and PD-L1 negative tumors, NACT can

induce the positivization of PD-L1 status. This conversion may correlate with improved response to NACT and better clinical outcomes. Furthermore, PD-L1 positivization suggests potential suitability for immunotherapy in these high-risk patients. Nevertheless, further studies involving a larger cohort of patients are necessary to validate these findings in a more robust manner.

P4-01-21: The clinical significance of disialoganglioside GD2 synthases in breast cancer

Niamh O'Neill, Amber Li, Kefah Mokbel, Jia Tong, Lin Ye, Wen G. Jiang, Tracey A. Martin

Introduction: Disialoganglioside GD2 is a glycosphingolipid found in the plasma membrane, consisting of a hydrophobic ceramide linked to a hydrophilic sialic acid-containing glycan chain. Its synthesis involves sequential glycosylation and sialylation steps facilitated by multiple enzymes. Recent studies have identified GD2 as being overexpressed in certain cancers and cancer cells, potentially influencing their survival, motility, and invasive properties. This study aimed to investigate the clinical significance of GD2 synthases in breast cancer by examining their clinical, pathological, and prognostic associations.
Materials and Methods: A cohort of human breast cancer and background tissues were assessed for expression of a group of disialoganglioside GD2 synthases using q-PCR and statistically analysed using Mann Whitney U tests for comparisons, ROC, logistic regression Kaplan-Meier and Baysian methods for survival analyses. The relationship between the expression of the enzymes and patient's responses to drug therapies were also explored.
Results: We tested eight key enzymes involved in GD2 synthesis and explored them as a coherent group of synthesis regulators. Excessive expression of B4GalT5 and, notably, ST8Sia1, two enzymes involved in GD2 synthesis, significantly influenced patients' clinical outcomes ($p=0.023$ and $p=0.006$, respectively). When treatment response was assessed from the public database (TCGA), patients with high levels of B4GalNT1 in breast cancer did not respond to chemotherapies ($p<0.00001$) but showed response to endocrine and anti-Her2 therapies. This association was more pronounced in Luminal-B subtypes patients but had little connection with ER or Her2 alone. Conversely, patients with high levels of B3GalT4 were more sensitive to endocrine therapies ($p=0.001$) but showed no connection with chemotherapies. Further analysis using a combination of the three synthases provided a significantly effective prognostic indicator for patient survival, identifying two distinct divisions for the synthases as favourable and non-favourable for survival ($p=0.0009$, HR=2.02 (95%CI 1.33-3.08), a finding further supported by Bayesian analysis. The combination indicator, when stratified by ER, Her2 and TNBC subgrouping, revealed that the signature identified from the synthases is strongly associated with hormone status and the molecular subtype.

Conclusions: These data indicate that GD2 synthases have potential as a significant indicators for prognosis and therapeutic responses in human breast cancer, particularly in

association with hormone receptor status. Further work is warranted to unpick the potential mechanism/s underlying this phenomenon.

P4-01-22: Serum Thymidine Kinase as a Biomarker for Response Beyond Progression in First-line CDK 4/6 Inhibitors: Insights from the Randomized Phase II MAINTAIN Trial

Ruth Sacks, Codruta Chiuzan, Melissa K. Accordino, Elizabeth Sakach, Amy Williams, Prabhjot S. Mundi, Claire Sathe, Meghna S. Trivedi, Naomi Sender, Yelena Novik, Amy Tiersten, George Raptis, Lea N. Baer, Sun Y. Oh, Amelia B. Zelnak, Kari B. Wisinski, Eleni Andreopoulou, Williams J. Gradishar, Erica Stringer-Reasor, Sonya A. Reid, Anne O'Dea, Ruth O'Regan, Katherine D. Crew, Dawn L. Hershman, Kevin Kalinsky

Background: There are multiple therapeutic strategies for patients (pts) with hormone receptor positive (HR+), HER2 negative (HER2-) metastatic breast cancer (MBC) following progression on a first-line cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) and endocrine therapy (ET). There is an unmet need for predictive and prognostic biomarkers to identify HR+, HER2- MBC pts likely to benefit from continued CDK4/6i therapy beyond progression. Thymidine kinase (TK), an enzyme involved in DNA synthesis, represents a promising biomarker due to the association of elevated serum TK activity (sTKa) with greater tumor cell division and poorer clinical outcomes. We investigated sTKa as a potential biomarker of response to continued CDK4/6i therapy beyond progression in the MAINTAIN trial.

Methods: MAINTAIN was the first randomized controlled trial to demonstrate a significant progression-free survival (PFS) benefit for HR+, HER2- MBC patients who switched ET (fulvestrant or exemestane) and received the CDK4/6i ribociclib compared to ET plus placebo after progressing on prior CDK4/6i and ET. We evaluated the association between sTKa and PFS. In this exploratory analysis, sTKa levels were analyzed from blood samples collected at baseline and cycle 2 day 1 (C2D1) by Biovica using the Divitum® TKa assay. Patients were categorized into low (<250 Divitum® unit of Activity [DuA]) and high (≥250 DuA) sTKa groups for PFS analysis. The cut-off point of 250 DuA is a clinically validated and FDA 510(k) cleared reference value for prognosis in HR+ MBC. Log-rank test and Cox regression models were used to assess the association between sTKa levels and PFS as well as calculate hazard ratios (HR) and 95% confidence intervals (CI). The database was locked on Jan 4, 2022.

Results: Of the 119 MAINTAIN participants, 90 had samples available for analysis. Forty (44%) in the placebo+ET group and 50 (56%) in the ribociclib+ET group. Eighty-one pts had baseline sTKa, 73 had C2D1 sTKa, and 69 had sTKa at both timepoints. Fifty-three percent (43/81) of pts had high baseline TKa and 37% (27/73) of pts had high C2D1 TKa. Pts with low baseline sTKa exhibited a non-significant trend towards improved PFS compared to those with high baseline sTKa (median PFS [mPFS] 5.6 vs 3.0 mo; HR 0.73,

95% CI 0.45-1.18, p=0.198). In contrast, pts with low C2D1 sTKa demonstrated a statistically significant PFS benefit compared to those with high C2D1 sTKa (mPFS 5.7 vs 2.7 mo; HR 0.30, 95% CI 0.17-0.52, p<0.001). Notably, the mPFS in the ribociclib+ET group was 10.9 mo for pts with low C2D1 sTKa compared to 2.7 mo for those with high C2D1 sTKa (HR 0.15, 95% CI 0.06-0.37, p<0.001). The placebo+ET group did not show a statistically significant PFS benefit for those with low C2D1 sTKa versus high C2D1 sTKa (mPFS 4.8 vs 2.5 mo; HR 0.51, 95% CI 0.23-1.13, p=0.098). Among 69 pts evaluated for sTKa dynamics, the longest PFS was seen in 13 pts (19%) who transitioned from high baseline to low C2D1 sTKa (mPFS 8.2 mo; 95% CI 5.6-16.6). Twenty-one (30%) pts who maintained high sTka levels from baseline to C2D1 had the shortest PFS (mPFS 2.7 mo; 95% CI 2.1-3.0).

Conclusions: In the phase II MAINTAIN trial, sTKa was a predictive biomarker for response to switching ET + continuing CDK4/6i in HR+, HER2- MBC pts following progression on CDK4/6i and ET. Low (<250 DuA) C2D1 sTKa levels predicted a positive treatment response, especially among those receiving ribociclib+ET. sTKa dynamics from baseline to C2D1 were prognostic, providing insights into PFS outcomes. Our analysis supports C2D1 as a critical timepoint for sTKa in assessing continued benefit of CDK4/6i and risk of progression. Further research in a larger trial evaluating sTKa dynamics and clinical outcomes is warranted.

P4-01-23: Potential prognostic Value of HER2/CEP17 FISH ratio in HER2-positive non-metastatic breast cancer

Fangchao Zheng, Feng Du, Zixuan Yang, Xue Wan, Jian Yue, Yun Ling, Peng Yuan

Background: HER2-positive breast cancer (BC) requires anti-HER2 therapy. We aimed to determine whether the expression of the HER2/centromeric probe for chromosome 17 (CEP17) ratio is associated with prognosis in patients with HER2-positive non-metastatic BC.
Methods: 267 HER2-positive BC were enrolled between January 2010 and December 2011. Stabilized inverse probability treatment weighting (sIPTW) was used to balance baseline characteristics. Real-world disease-free survival (DFS) and overall survival (OS) was analyzed.
Results: The median follow-up time was 10.3 years (interquartile range: 9.4-10.8 years). HER2/CEP17 ratio of > 7.0 was defined as the HER2 ultra-positive group; a HER2/CEP17 ratio of ≤ 7.0 was defined as the HER2 normal-positive group. After sIPTW adjustment, no differences were observed in DFS and OS when anti-HER2 therapy was unclear, and so was in the patients who did not receive trastuzumab (all p > 0.05). Interestingly, HER2 ultra-positive group had a worse DFS than the normal-positive group (hazard ratio [HR] = 2.72, p = 0.02), but there was no difference in OS (p = 0.30) in patients receiving trastuzumab. The multivariate Cox models also showed that the HER2 ultra-positive have worse DFS than HER2 normal-positive patients (HR = 3.71; p < 0.01).
Conclusion: For non-metastatic HER2-positive BC with or without trastuzumab treatment,

the HER2/CEP17 ratio did not predict the survival time. However, our study supports that HER2 ultra-positive group had a worse DFS than the normal-positive group among non-metastatic HER2-positive BC patients receiving trastuzumab; therefore, this could be a potential predictor of DFS in these patients.

P4-01-24: Common determinants of CDK4/6 inhibitor-based therapy in metastatic HR+/HER2- breast cancer

Erik Knudsen, Agnieszka K. Witkiewicz, Jianxin Wang, Emily Schultz, Thomas N. O'Connor, Ellis Levine

CDK4/6 inhibitors in combination with endocrine therapy are widely used to treat HR+/HER2- metastatic breast cancer. Generally, CDK4/6 inhibitors lead to a doubling of progression-free survival compared to single agent endocrine therapy. Despite a known mechanism of action, features that define the duration of response to CDK4/6 inhibitors with either aromatase inhibitors or fulvestrant remain lacking. Over 300 patients receiving standard-of-care CDK4/6 inhibitor combination therapy for metastatic disease were enrolled in an ongoing observational study (NCT04526587) and an IRB-approved retrospective analysis. Clinical, pathological, and gene expression data were employed to define determinants for the duration of progression-free survival (PFS). Visceral disease (HR 1.55, p=0.0013), prior endocrine therapy (HR 2.34, p<0.001), and the type of endocrine therapy (HR 2.16, p<0.001) were associated with duration of progression-free survival. Multiple gene expression signatures associated with prognosis of HR+/HER2- breast cancer were evaluated for association with PFS with variable statistical significance.
Random survival forest was applied to combined prognostic signatures and clinical variables to identify independent features associated PFS. The resultant final model resulted in robust association with PFS (HR: 6.9, p<e-10) using all samples, as well as selectively in a validation subset (HR: 2.2, p<e-04). This tool was effective at predicting intrinsic resistance in metastatic and neoadjuvant samples. Additionally, the mortality predicted by this model tracked with the median PFS observed in PALOMA-2/3 and PEARL studies. Interrogating significant genes across all studies indicate common enrichment of genes associated with cell cycle and estrogen receptor signaling. These findings indicate that there are common features from real-world use of CDK4/6 inhibitors and clinical studies that could be used to infer time-to progression.

P4-01-25: THE ROLE OF SERUM THYMIDINE KINASA 1 ACTIVITY (TK1) AS A PROGNOSTIC FACTOR Y LUMINAL HER2 NEGATIVE BREAST CANCER

Serafin Morales, Izaskun Urdanibia, Ana Velasco, Noemi Tuset, Ariadna Gasol

TKI plays an important role in DNA synthesis and cellular proliferation so has been studied a prognostic marker and as an early indicator of response in luminal HER2 negative.

We analyze the function of TK1 in a cohort of 30 cases with early luminal HER2 negative breast cancer. Serum sampled were collected at baseline and after surgical resection. The median level of TK1 was 704 DuA (172 -1759) in the baseline and 903 (299 – 1977) after surgical resection. This association is not significative but in patients with high risk ONCOTYPE (>25 in 10 cases) the median level of TK1 was superior in this point, 1154 DuA vs 800 p:0,02.
We also analyze the dynamics change of TK1 in a series of 55 metastatic luminal HER2 breast cancer to compare the level of TK1 in the initial treatment with standart ET plus iCDK 4/6 and patients with durable response of this treatment. The median level of TK1 for initial treatment was 1315 DuA (215 – 18751) and for durable response 416 Dua (147 – 1004). In 27 patients we had 2 TK1 samples, at the beginning and 3-6 months after treatment. The median value in the initial sample was 512 (215 – 18751) and the second sample was 622 (182 – 1320). 12 patients had in progression at the time of the analysis, of which 10 had an increase in TK1 levels while in the 15 patients who remained in response, only 3 had an increase in TK1 levels.
The kinase activity has an important role in the evolution of HER2-negative luminal breast cancer. In early breast cancer there is an increase in cases with high-risk genomic testing, which are cases that intrinsically carry a worse prognosis. In advanced breast cancer, the decrease in its expression is associated with a good response.

The expression of kinase activity should be considered in large prospective studies to validate its role as a prognostic biomarker.

P4-01-26: The Xpert® Breast Cancer Insight test predicts distant recurrence and overall survival in estrogen receptor-positive, HER2-negative early breast cancer: A validation study in ABCSG Trial 8

Martin Filipits, Viktoria Gruber, Christian F. Singer, Florian Fitzal, Zsuzsanna Bago-Horvath, Richard Greil, Marija Balic, Peter Regitnig, Nancy Toro-Bauer, Wolfgang Hulla, Daniel Egle, Daneida Lizarraga, Alice Baker, Rajesh Kaldate, Malini Satya, Jodi Weidler, Michael Bates, Scott Campbell, Dominik Hlauschek, Peter Dubsky, Michael Gnant

Purpose: To validate the clinical performance of the Xpert® Breast Cancer Insight (BC Insight) (IUO*) test in patients of the prospectively randomized Trial ABCSG 08. BC Insight is a prognostic signature designed to be run in local pathology laboratories on the GeneXpert in-vitro diagnostic platform in a closed-cartridge RT-qPCR format with a turnaround time of approximately 3 hours using formalin-fixed, paraffin-embedded (FFPE) samples.
Patients and Methods: We studied the BC Insight test in 1278 surgical FFPE specimens from postmenopausal women with estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative primary breast cancer with 0–3 involved lymph nodes who received at least 5 years of endocrine therapy. Time to distant recurrence (DR) and

overall survival (OS) were analyzed using Cox models.
Results: The BC Insight test categorized 764 of 1089 (70.2%) evaluable patients as “low risk”. The Xpert BC Insight Risk Score (XRS) was highly prognostic for prediction of DR (hazard ratio (HR) 1.93, 95% confidence interval (CI) 1.58 to 2.35, P<0.0001; C-index 0.73) and OS (HR 1.45, 95% CI 1.26 to 1.67, P<0.0001; C-index 0.65). At 10 years of follow-up, 95.3% of Xpert BC Insight Risk Category (XRC) low-risk patients were metastasis-free and 89.6% were alive, compared with 85.6% and 77.1% of XRC high-risk patients, respectively (absolute DR risk difference 9.7%, P<0.0001; absolute risk of death difference 12.5%, P<0.0001). Furthermore, XRS was highly prognostic in node-negative patients (HR for DR 1.59, 95% CI 1.25 to 2.03, P=0.0003, C-index 0.70; HR for death 1.26, 95% CI 1.06 to 1.50, P=0.0077, C-index 0.62), and in patients with 1–3 involved lymph nodes (HR for DR 3.01, 95% CI 2.01 to 4.52, P<0.0001, C-index 0.77; HR for death 2.07, 95% CI 1.54 to 2.79, P<0.0001, C-index 0.71).
Conclusions: XRS and XRC are highly prognostic for 10-year DR in postmenopausal women with ER-positive, HER2-negative primary breast cancer treated with endocrine therapy. Furthermore, the BC Insight test accurately predicted OS in these patients, particularly in patients with 1–3 involved lymph nodes.
*For Investigational Use Only. The performance characteristics of this product have not been established.

P4-01-27: Detection, isolation, and genetic characterization of circulating tumor cells from the cerebrospinal fluid of breast cancer patients with leptomeningeal metastasis

André Franken, Martin Schramm, Barbara Alberter, Jens Warfsmann, Bernhard Polzer, Franziska Meier-Stiegen, Natalia Krawczyk, Michael Sabel, Marion Rapp, Eugen Ruckhäberle, Tanja Fehm, Hans Neubauer

The gold standard to diagnose leptomeningeal metastasis (LM) is to identify malignant cells in the cerebrospinal fluid (CSF) or in a leptomeningeal biopsy. Using conventional cytology its sensitivity remains low with approximately 50% and 85% for the first and the second lumbar puncture, respectively. While rare cell capture technologies like the CellSearch system reach higher sensitivity than conventional cytology, they have limitations, including capturing only cells with sufficient EpCAM antigen expression, limited antibody customization, and high costs. Once diagnosed with LMs, to date most patients are still treated with untargeted therapies with limited effectiveness and significant side effects.
To address this, we developed a workflow using Sievewell 370 K microwell chips. Each chip contains 370,000 hexagonal microwells (20 µm in diameter, 25 µm deep) with two 2 µm pores at the bottom. On the chip, individual cells are separated, identified with cytokeratin antibodies, and isolated as single cells via micromanipulation for molecular analysis. 15 CSF samples from 9 LM-patients were analyzed on the microwell chips and by conventional cytology in parallel. The isolated cells’ DNA was amplified by whole genome amplification and sequenced by low pass whole genome sequencing and panel sequencing on single cell

level and compared to extracranial tissue biopsies.
On-chip immunostaining achieved less than 5% cell loss and over 95% single cell isolation for the MCF7 breast cancer cell line. For 10 of the 15 CSF samples, concordant results were obtained by analysis on the microwell chips and conventional cytology: 1 sample was tumor cell-negative, 9 samples were tumor cell-positive. In the other 5 samples, tumor cells were detected by analysis on the microwell chip with either inconclusive (3 samples) or negative (2 samples) results obtained by cytological analysis. With the microwell chips, 5 to 10,000 (mean 1,218; median 116) CSF-CTCs were found per mL CSF. The detection of chromosomal aberrations confirmed the malignant origin of detected tumor cells, including those from samples that were tumor cell-negative in conventional cytology. A high level of clonality was observed among the tumor cells in the CSF of each patient, yet these CSF tumor cells often exhibited an aberration pattern with distinct differences compared to the corresponding extracranial metastases or primary tumors. In addition to mutations shared by corresponding tissue biopsies, panel sequencing revealed private mutations of CSF-CTCs in resistance related genes and tumor driver genes.
In conclusion, the microwell-based CSF-CTC detection appears superior to conventional cytology. The high level of clonality indicates a very close evolutionary relationship within the CSF-CTCs and a monoclonal origin of LMs. Private mutations in resistance related genes and tumor driver genes could impact drug susceptibility and therapy resistance. Therefore, the CSF-based liquid biopsy should be considered for genetic profiling of LMs, potentially improving diagnosis, treatment monitoring, and targeted therapy selection.

P4-01-28: The role of ctDNA clearance in the adjuvant setting in triple negative breast cancer patients with residual tumors after neoadjuvant chemotherapy in the TRICIA trial.

Mark Basik, Adriana Aguilar-Mahecha, Talia Roseshter, Anna Klemantovich, Luca Cavallone, Josiane Lafleur, Cathy Lan, Jean Francois Boileau, Manuela Pelmus, Rosanna Pezo, Muriel Brackstone, Terry Ng, Suzan McNamara

Triple negative breast cancer patients with incomplete response to neoadjuvant chemotherapy (NAC) have a poor prognosis. The CREATE-X clinical trial showed that the addition of adjuvant capecitabine resulted in a 42% decrease in disease relapse (Hazard Ratio 0.58). The TRICIA trial is a multicentre trial for TNBC patients with residual disease after NAC, in which plasma was collected after NAC pre-operatively (T1), immediately after surgery (T2, median 1.1 months), 3 months (T3, median 3.8 months) and at least 6 months after surgery (T4, median 8.7 months). The median follow up of these patients is 32 months. We assayed for circulating tumor DNA (ctDNA) in these samples using a tumor-informed academic digital droplet PCR approach (Cavallone L et al, Sci Reports 2019). We recently reported that the lack of ctDNAdetection in plasma collected at the post-NAC pre-operative timepoint is highly prognostic with 95% of patients with undetectable ctDNA at this T1 time point not presenting distant disease relapse. We now focus on the ctDNA clearance during the post-surgical period in 42 patients who had detectable ctDNA after surgery (T2) and a

blood collection at T4. 32 of these patients received capecitabine while 10 did not (before the CREATE-X report). This is the largest series of TNBC patients with residual disease at surgery with serial ctDNA measurements before (T2), during (T3) and immediately after capecitabine treatment (T4). In the 10 non-capecitabine patients, only 1 cleared and that patient did not show relapse. Of 32 patients receiving adjuvant capecitabine, 13 cleared their ctDNA by the T4 time point (42%, similar to the benefit of capecitabine in the CREATE-X study), significantly higher than in the cohort without capecitabine (p=0.03). Only one of these patients (8%) showed disease relapse. This patient had detectable ctDNA 8 months after T4 and relapsed 33 months after surgery. Four of these 13 with ctDNA clearance had become negative by the T3 time point, while the remainder still had detectable ctDNA at the T3 time point. The relapse-free survival for patients on capecitabine who cleared their ctDNA at T4 was 86% while that for those who did not was 55%, with a HR of 0.16 (95% CI 0.04-.66, p=0.05). These results show that ctDNA clearance in the short-term post-operative period has prognostic value and that the addition of capecitabine increases ctDNA clearance throughout the immediate adjuvant period. The clearance of ctDNA after surgery in these high-risk TNBC patients may be predictive of response to adjuvant capecitabine.

P4-01-29: Identification of Urinary microRNA as Potential Biomarkers in Breast Cancer Patients

Yuka Inoue, Nami Yamashita, Natsue Uehiro, Atsushi Satomura, Hiroki Yamaguchi, Sakura Maezono, Mariko Palfalvi, Yoriko Ando, Yumi Nishiyama, Mika Mizunuma, Yuki Ichikawa, Yukinori Ozaki, Tetsuyo Maeda, Takayuki Kobayashi, Tomo Osako, Takehiko Sakai, Takayuki Ueno

Backgrounds and Aims: MicroRNAs (miRNAs) are small functional nucleic acids consisting of 20-25 nucleotides. They maintain homeostasis in the body by balancing regulatory functions within cells, while abnormalities in their expression levels have been associated with various diseases, including the transformation of cells into cancer. Over 2000 miRNAs have been identified in humans, and it is known that there are specific expression patterns of miRNAs depending on the type of cancer. miRNAs are encapsulated in exosomes and circulate in the blood, with some being excreted into the urine. Therefore, urinary miRNAs are garnering attention as potential biomarkers in cancer diagnostics. Yasui and colleagues have developed a method for analyzing exosomal miRNAs in urine using a zinc oxide nanowire device, successfully achieving comprehensive analysis of miRNAs from urine. Urinary miRNAs are expected to be applied as non-invasive diagnostic biomarkers for early cancer detection, assessment of treatment efficacy, and monitoring post-treatment for recurrence. In SABCS 2023, we reported that 28 differentially expressed miRNAs (DEMs), defined as miRNAs with adjusted p-values < 0.05 and Log2FC > 0.5, were identified between the primary breast cancer group and the control group, suggesting their potential as biomarkers. In this presentation, we advanced our research by analyzing the time-course in these miRNAs along with treatment to their clinical significance.
Patients: Patients who were diagnosed with breast cancer from October 2021 to May 2022

in our hospital were recruited. The eligibility included female, 20 years or older, no prior treatment for breast cancer. The protocol was approved by the institutional review board and informed consent was obtained from all patients.

Methods: Samples were collected before starting the treatment, after surgery, and 3 to 6 months after surgery. Small RNA seq was performed using a NextSeq 550 System (Illumina, San Diego, CA, USA), and urinary miRNA profiles were obtained and analyzed. Differential expression analysis was conducted using DESeq2 between breast cancer group and the control group, to identify DEMs. The analysis of time-course in DEMs was performed by calculating p-values using the Wilcoxon rank sum test, followed by multiple comparison correction using the Benjamini-Hochberg method.

Results: Two hundred patients with stage 0-III primary breast cancer treated in our hospital (breast cancer group) and 105 healthy volunteers (control group) were included in the study. Among the 200 cases in the primary breast cancer group, the initial treatment was surgery for 170 cases and chemotherapy for 30 cases. Comparing the primary breast cancer group with the control group, 15 of the 28 identified DEMs were elevated in the primary breast cancer group compared to the control group, while 13 were decreased. When examining the time-course in the 170 cases which the initial treatment was surgery, it was found that among upregulated 15 DEMs, miR-22-3p, miR-374a-5p, miR-450b-5p, miR-500a-5p/500b-5p, miR-57b-5p, and miR-92b-3b significantly decreased after surgery. On the other hand, we found variable alteration of downregulated 13 DEMs after surgery. miR-125a-3p, miR-151a-5p/151b, miR-30a-3p, miR-331-3p, and miR-574-5p significantly increased after surgery, while miR-12136 and miR-619-5p significantly decreased. Similar trend was also observed in the 30 cases where the initial treatment was chemotherapy.

Conclusions: We identified urinary miRNAs that could serve as biomarkers for breast cancer. Notably, the upregulated 15 DEMs showed declining trend after surgery or chemotherapy.

P4-01-30: Proteogenomic profiles of HER2-positive breast cancer and response to neoadjuvant anti-HER2 treatment

Kang Wang, Luca Finn Gaessler, Ioannis Zerdes, Yajing Zhu, Emmanouil Sifakis, Dimitrios Salgkamis, Luuk Harbers, Nicola Crosetto, Jonas Bergh, Thomas Hatschek, Henrik J. Johansson, Alexios Matikas, Janne Lehtiö, Theodoros Foukakis

Background: The prospective and randomized PREDIX HER2 (n=202) compared neoadjuvant treatments of docetaxel, trastuzumab, and pertuzumab (DHP) against trastuzumab emtansine (T-DM1) in HER2-positive breast cancer, demonstrating similar pathologic complete response (pCR) rates and disease-free survival between the two

groups (Hatschek, JAMA Oncology 2021). In this study, we aimed to elucidate the proteogenomic (PG) characteristics of pre-treatment HER2-positive breast cancer biopsies from the PREDIX HER2 trial, and identified predictive biomarkers for DHP or T-DM1.

Methods: We performed high quality shallow whole-genome sequencing (CUTseq), RNA-sequencing (RNA-seq), and mass spectrometry-based (MS) proteomics profiles of pre-treatment core biopsies. Imputed and normalized protein abundance data were used as an input for differential protein abundance analysis using DEqMS. Correlations between mRNA expression (trimmed mean of M-values (TMM) normalized transcript per million reads (TPM)), somatic copy number alterations (SCNA) and normalized protein abundance for each gene-protein pair were measured using Spearman correlation (rho), and a false discovery rate (FDR) lower than 0.05 was considered statistically significant. Furthermore, we assessed the association of biomarkers with pathologic complete response (pCR) in each treatment arm using logistic regression, and evaluated their predictive value by adding the interaction term between biomarker and treatment arm.

Results: In total, we identified 9,550 proteins (median (interquartile range): 7,424 (6,655-7,884)), of which 7099 proteins were finally quantified in each of the 137 tumors (70 samples from DHP and 67 samples from T-DM1 arm). We conducted differential protein abundance analysis adjusting for estrogen receptor (ER) status between responders (pCR) and non-responders (i.e., residual disease (RD)) within DHP and T-DM1 arm, respectively. We identified 112 upregulated (e.g., ERBB2, GRB7, CDK12, HLA-B) and 83 downregulated proteins (e.g., MAST4, FBN1, COX11) (nominal P values<0.05, log2 fold-change>0.5) within patients who attained pCR from DHP arm compared to counterparts without reaching pCR. Furthermore, GSEA demonstrated that proliferation (E2F, MYC) and inflammation and immune (IL2-STAT5, inflammatory response, IFN-γ response) pathways were enriched in pCR cases, whereas the epithelial–mesenchymal transition (EMT) pathway was enriched in RD patients. Similarly, we revealed 103 upregulated (e.g., ERBB2, ZNF652, MAPK11, CD3E) and 107 downregulated (e.g., ECM2, COL2A1, PDCD2L) proteins that were enriched in EMT and immune pathways (IFN-γ and IFN-α response, IL6-JAK-STAT3) in T-DM1 arm. We identified significant cis-correlations (rho > 0, FDR < 0.05) for 4706 (71.8%) SCNA–mRNA and 603 (9.2%) SCNA–protein pairs, while trans-effects (FDR < 0.05, for at least 50 genes) were identified in 4,636 (70.8%) and 493 (7.5%) genes at the transcriptional and translational level, respectively. We prioritized 43 putative drivers based on correlated SCNA-mRNA-protein genes, which were located on 1q32.2, 6q21, 8p11.23, 8q23.3, 11q13.3 and 17q12. Amplification of 8p11.23 (ERLIN2, RAB11FIP1) (Pfor interaction=0.02) was associated with pCR in the T-DM1 arm (odds ratio (OR)=1.95, p=0.1), but exhibited a trend towards RD in the DHP arm (OR=0.67, P=0.2). Interestingly, 36 pseudo-HER2+ cases were clustered with 9 HER2-low tumors that were re-evaluated using the 2018 ASCO guidelines, based on protein level of HER2 and its adjacent genes PNMT, MIEN1, GRB7. Patients with pseudo-HER2+ subtype were less likely to attain pCR compared to those with HER2-

positive breast cancer (DHP arm, OR=0.16, p=0.001; T-DM1 arm, OR=0.27, p=0.03).

Conclusion: This study underscores the importance of PG analysis in predicting the treatment response to chemotherapy, dual blockade or antibody drug conjugate in HER2-positive breast cancer.

P4-02-01: Clinical and biological markers to improve the identification of frailty in patients with early breast cancer

Emanuela Risi, Anna Picca, Matteo Benelli, Chiara Biagioni, Giuseppe Colloca, Domenico Fusco, Erica Moretti, Valeria Emma Palmieri, Luca Livraghi, Luca Malorni, Francesca Del Monte, Riccardo Calvani, Giuseppe Mottino, Emanuele Marzetti, Laura Biganzoli

Background: Aging is associated with deficits accumulation and increased vulnerability to adverse outcomes, ultimately resulting in frailty. Comprehensive geriatric assessment (CGA) is considered the gold standard to assess aging. Using the information gathered as part of the CGA in elderly breast cancer (BC) patients (pts), our group has designed a 43 item-frailty index (43-FI). Over the last few years, the analysis of cellular senescence through senescence-associated secretory phenotype (SASP) has been suggested as alternative biomarker of aging. In this study, we identified a panel of 23 SASP-related factors(RF) that was correlated with the 43-FI, and both with prognosis, resulting in new indicators for aging assessment.

Methods: 164 pts aged ≥65 years, with early BC included in 3 onco-geriatric trials, were evaluated by the means of a CGA. Geriatric assessments and blood sampling were performed after breast surgery, and before the initiation of systemic treatment (adjuvant endocrine therapy or chemotherapy). Serum samples were available for 140 pts, and were analyzed to identify the 23 SASP-RF. Pts were classified as fit, vulnerable or frail according to the Balducci criteria (Balducci-c) and the 43-FI. The 23 SASP-RF were correlated with the 43-FI and with survival. For each SASP-RF, Area Under the Receiver Operating Characteristic Curve (AUC-ROC) analysis on the fit and frail pts was perfomed to identify the best performing markers (AUC > 0.65) and optimal cut-points. Marker-specific optimal cut points were then used to classify vulnerable pts into high- and low-risk groups. A senescence score (SenS) was developed by training a Random Forest model on fit and frail pts considering the best-performing SASP-RF, defined as those showing relative importance > 5%. The SenS was used to classify vulnerable pts into high- and low-risk groups. Overall survival (OS) was computed from study entry to death from any cause.

Results: The 43-FI identified 20% of pts as fit, 71% as vulnerable, and 9% as frail. Vulnerable and frail pts were older than fit (77 and 78 yrs respectively vs 73 yrs), and had less aggressive tumors (62% and 60% of vulnerable and frail pts had Ki67 < 20%; 71% and

80% had G1-2). Hormone receptor-positive HER2-negative tumors were predominant in all three categories. Chemotherapy was administered more often to fit (63%) than vulnerable (33%) and frail (7%) pts. 43-FI and Balducci-c provide markedly concordant classification of pts (frail pts identified by Balducci-c had higher 43-FI score, overall percent agreement= 47%). The 43-FI identified pts with different prognosis: median(m)-OS was 5.5 months (mo) in frail vs 13 mo in fit (HR=4.39, 1.88-10.23 95% CI, p=0.001), and 9.8 mo in vulnerable pts. This association was independent from age. A total of 8 SASP-RF were found associated with the 43-FI, including GDF15, ICAM1, TIMP1, HUIL9, HUGCSF, HUMIP1A, HUMIP1B, HU TNFA. Among these, GDF15 was the best associated with frailty (AUC=0.88, fit vs. vulnerable p=0.001; Fit vs. Frail p=0.001; Vulnerable vs. Frail p=0.038). Applying GDF15 optimal cut-point to the vulnerable cohort, we find that higher levels of GDF15 were correlated with worse prognosis (mOS 11.6 mo low-GDF15 vs 7.8 mo high-GDF15, HR 2.23, 1.29-3.85 95% CI, p=0.003). The SenS model, including 7 SASP-related markers (GDF15, TIMP1, ICAM 1, HU IL9, HU MIP1A, HU MIP 1B, TNF a), was positively associated with prognosis (mOS 10.9 mo low-SenS vs 9.3 mo high-SenS, HR 1.97, 1.14-3.41 95% CI, p=0.013).

Conclusions: Our findings suggest that the 43-FI may serve as a potential clinical marker of aging in pts with early BC. GDF15 and SenS, could be used to dissect the heterogeneity of vulnerable pts, identifying subgroups with different prognoses within this cohort. Further analyses in a wider population are needed to confirm these results.

P4-02-02: Hospitalizations and emergency visits for Ontario breast cancer patients undergoing neoadjuvant chemotherapy with pembrolizumab: A population-based analysis

Gary Ko, Eitan Amir, Matthew Castelo, Andrea Covelli, Antoine Eskander, Vivianne Freitas, C. Anne Koch, Qing Li, Ning Liu, Jenine Ramruthan, Emma Reel, Amanda Roberts, Toni Zhong, Tulin D. Cil

Background: Immunotherapy-containing chemotherapy regimens are increasingly used for the neoadjuvant treatment of triple negative breast cancer (BC). However, these regimens can be associated with immune-related adverse events, which may lead to increased hospitalizations and emergency department (ED) visits. The objective of this study was to assess the rate of hospitalization and ED visits for BC patients undergoing neoadjuvant chemotherapy (NAC) with and without immunotherapy in Ontario, Canada.

Methods: Breast cancer patients who underwent NAC and surgery between April 1, 2022 and August 31, 2023 were included. Neoadjuvant chemotherapy regimens were classified into three groups containing either pembrolizumab, an anti-HER2 drug, or chemotherapy alone. The proportion of patients who had ED visits or were hospitalized during the neoadjuvant period (first date of chemotherapy to the day of surgery) and the post-

operative period (day of surgery to 30 days after surgery) were calculated. Rates and 95% CI of ED visits and hospitalizations during each time period per patient per year were analyzed.

Results: The study cohort consisted of 1301 newly diagnosed BC patients who had systemic therapy before surgery with a median age of 52 (44 - 62); 94.7% of patients had no previous comorbidities. A total of 229 patients (17.6%) received a regimen with pembrolizumab, 532 (41%) had an anti-Her 2 agent, and 540 (41.4%) had chemotherapy alone. The proportion of patients on pembrolizumab who had one or more ED visits during the neoadjuvant period was significantly higher (54.6%) than patients on anti-HER2 (42.3%) or chemotherapy alone (40.0%; $p < 0.001$). The rate of ED visits was also higher for the pembrolizumab cohort at 2.81 visits per patient per year (95% CI: 2.52-3.15) compared to anti-HER2(1.95 [95% CI: 1.77-2.15]) or chemotherapy alone groups (1.74 [95% CI 1.57-1.93]). However, there was no significant difference in ED visits in the post-operative period between the groups (pembrolizumab: 18.3%, anti-HER2: 14.5%, chemotherapy alone: 14.4%, $p=0.33$). The rate of ED visits in the post-operative period was also similar: pembrolizumab: 2.67 visits per patient per year (95% CI: 2.04 – 3.51), anti-HER2: 2.10 (95% CI: 1.72 – 2.77), chemotherapy alone: 2.35 (95% CI 1.95 – 2.85). Hospitalization was more frequent among patients receiving pembrolizumab pre-operatively (pembrolizumab: 32.3%, anti-Her2: 15.2%, chemotherapy alone: 11.1%; $p < 0.01$), but there were no significant differences in hospitalization after surgery.

Conclusion : Breast cancer patients undergoing neoadjuvant therapy including pembrolizumab had higher rates of ED visits and hospitalizations before surgery compared to those receiving anti-HER2 therapy or chemotherapy alone. However, differences in these outcomes were not seen in the post-operative period. This study provides confirmatory population-level data regarding the integration of immunotherapy into NAC. Further work to understand the etiology and mitigate unanticipated health care utilization for BC patients undergoing NAC is needed.

P4-02-03: Transparency for patient assistance and compassionate use programs for high-cost intravenous and oral therapies in breast cancer patients at an NCI-designated cancer center

Jina Yun, Lynn Symonds, Hannah Linden

Background: Financial toxicity (FT) is a growing concern for cancer patients and affects overall survival, treatment adherence and quality of life. 1 Approaches to address FT include incorporating cost information into treatment decision making, which relies on accurate cost information as well as transparency into the process and timeline for treatment initiation. 1 Objectives: the primary objective is to identify the rates of patient assistance program (PAP) approval for oral anticancer medications (OAMs) and approvals

for compassionate use high-cost intravenous (IV) therapies in breast cancer patients. The OAMs and high-cost IV therapies of interest include palbociclib, ribociclib, abemaciclib, fam-trastuzumab deruxtecan, trastuzumab, pertuzumab, pembrolizumab, goserelin, leuprolide, liposomal doxorubicin, and sacituzumab govitecan. The secondary objectives include characterization of insurance approval, copay information, time to manufacturer PAP or EAP approval, clinical decision making (switching or discontinuing therapeutic agents) due to lack of PAP or EAP approval for OAMs and high-cost IV therapies in breast cancer patients.

Methods: A retrospective chart review was conducted at Fred Hutchinson Cancer Center (FHCC) for breast cancer patients referred to the Patient Assistance (PA) team for OAMs and high-cost IV therapies of interest within the study period of 1/1/2023 to 6/31/2024. Data was collected for therapy of interest, insurance type, insurance approval, copay information (if available), date of PAP initiation and determination, other patient assistance, off-label indication, and clinical decisions made based on PAP denial.

Results: For OAMs, 79 referrals to the PA team for 74 distinct patients were evaluated. For high-cost IV therapies, 17 referrals to the PA team for 15 distinct patients were evaluated. For OAMs, 48 were approved by insurance and 8 were not. Copay information was available for 49 patients and the median copay was $2520 (range $0 to $15,680). The median time from PA initiation to notification of PA determination was 19 days (range 0 to 200 days). Patients referred to the PA teams were insured by a Medicare Part D plan (53.2%), Medicaid (2.5%), private insurance (21.5%), or had no insurance (8.9%). Most patients identified as white (83.5%) with English as their primary language (88.6%). Of the 8 patients denied PA, one patient declined therapy, one patient switched to another agent in that class. For high-cost IV therapies, 1 out of 15 patients pursued PA due to insurance denial while 8 out of 15 patients pursued PA as they had no insurance. The median time from PA initiation to notification of PA determination was 17 days (range 4 to 221 days).

Conclusion: Mitigation of financial toxicity should include transparency and metrics for time to drug approval for patients. Our review showed that the median time to patient assistance approval for OAMs and high-cost IV therapies was 19 and 17 days, respectively, and this can be in addition to the time to initial insurance denial or determination. This review also identifies patients with Medicare as a population that may benefit from upfront financial navigation to expedite paperwork around the drug approval and acquisition process, as their median copay was $2520. The scope of this review should be broadened across all OAMs and high-cost IV therapies to provide patients and clinicians clear expectations and opportunities for patients and clinicians to identify and participate in quality improvement efforts and patient advocacy with manufacturer programs. References: Khan HM, Ramsey S, Shankaran V. Financial toxicity in cancer care: implications for clinical care and potential practice solutions. J Clin Oncol 2023; 41: 3051-3058.

P4-02-04: Development of ASSESS, a breast cancer decision support tool using SEER data and treatment benefit estimates from randomized adjuvant therapy trials.

Michal Marczyk, Joanna Tobiasz, Mariya Rozenblit, Robert J. Volk, Balázs Győrffy, Lajos Pusztai, Sharon H. Giordano

Background: Shared decision-making about adjuvant therapies requires accurate and personalized predictions of prognosis and treatment benefit. Multiple independent clinical characteristics influence the prognosis, and the most accurate individualized prediction can only be made by integrating these variables into a statistically valid multivariate model. The absolute improvements from each additional layer of systemic adjuvant therapy are also difficult to estimate. Our goal was to develop a multivariate prognostic model for breast cancer that also predicts absolute improvements in outcomes with various systemic adjuvant treatment modalities.

Methods: SEER incidence data including 394,503 breast cancer patients diagnosed in the years 1975-2020 were used to develop four distinct subtype-specific baseline (no-adjuvant chemotherapy) Fine-Gray subdistribution hazard prognosis models for overall survival. Multivariable fractional polynomials were used to model the non-linear effect of continuous variables on with a custom method for searching for best data transformations. Baseline model validation was done using 4,485 patients without chemotherapy from TCGA, Metabric, and GSE96058 cohorts. Hazard ratios (HR) from randomized adjuvant therapy trials were taken from the literature, 18 treatment regimens were grouped into 6 categories: (i) CMF, AC, and EC; (ii) CEF, TC, (iii) AC->T, FEC+Docetaxel, FEC+Paclitaxel, TAC, ddAC->T, A->T->C, AC->Docetaxel; (iv) AC_T+Olaparib, AC_T+Pembrolizumab; (v) TCH, ACTH, AC->T+Trastuzumab; (vi) TCHP. The final prognostic prediction included adjusting the baseline model with pooled HRs corresponding to each of the 6 treatment categories. Adjuvant chemotherapy validation in hormone receptor (ER) positive/HER2 negative patients was performed on data from the PACCT-1 clinical trial (NCT00310180) obtained from the NCTN/NCORP Data Archive (Request ID – 1843). The models were evaluated for overall survival in terms of calibration (a ratio between predicted and observed survival with 95% confidence intervals) and predictive ability (area under ROC curve (AUC) for alive/dead classification) 5 years after diagnosis.

Results: The baseline model built on 4 explanatory variables (age, tumor size, tumor stage, and number of positive lymph nodes) on SEER data showed good calibration in all BC subtypes: 1.02 (1.02;1.03) for ER+/HER2-, 1.03 (1.02;1.04) for ER+/HER2+, 1.04 (1.02;1.06) for ER-/HER2+, and 1.07 (1.05;1.08) for TNBC. Similar results were obtained on the independent PACCT-1 dataset: 1.05 (1.02;1.09) for ER+/HER2-, 1.10 (0.93;1.29) for ER+/HER2+, 1.18 (0.85;1.63) for ER-/HER2+, and 1.19 (1.06;1.34) for TNBC. Visual inspection of the calibration curves did not show major deviations from the diagonal, demonstrating good model performance for patients with varying survival. The model efficiently predicted whether the patient would still be alive after 5 years, giving an AUC

equal to 0.760 for ER+/HER2-, 0.762 for ER+/HER2+, 0.751 for ER-/HER2+, and 0.747 for TNBC subtypes. Similar results were obtained on the PACCT-1 dataset: 0.722 for ER+/HER2-, 0.750 for ER+/HER2+, 0.547 for ER-/HER2+, and 0.728 for TNBC subtypes. The chemotherapy model also gave an accurate survival estimate (1 (0.95;1.05) for CMF or AC, 1 (0.96;1.05) for TC, and 1.01 (0.91;1.11) for AC->T) and a prediction of vital status (AUC equal to 0.636 for CMF or AC, 0.619 for TC, and 0.648 for AC->T).

Conclusions: We developed and successfully validated a multivariable risk prediction model to estimate patient-specific survival and incremental benefits from systemic adjuvant therapies. The model is being used to develop ASSESS, a web-based decision support tool that can be used to inform shared decision-making.

P4-02-05: Real-world treatment patterns of neoadjuvant chemotherapy delays in operable breast cancer

Margaux Wooster, David DeStephano, Melissa Beauchemin, Shikun Wang, Jason Wright, Chin Hur, Dawn L. Hershman, Melissa K. Accordino

Background: Delays in initiation of neoadjuvant chemotherapy (NACT) after breast cancer (BC) diagnosis are associated with worse outcomes including increased risk of death. Previous studies have shown that Black patients are more likely to receive NACT compared to White patients. Currently there are limited studies that have evaluated delays in NACT initiation (NACTi), which could contribute to worse survival. Our previous work using the National Cancer Database showed that patients who were Black, Hispanic, non-commercially insured, or treated at an academic facility were more likely to be delayed. We used an electronic medical record (EMR) based database to evaluate incidence and predictors of delays of NACTi among high clinical risk patients in the real-world setting.

Methods: We conducted a retrospective cohort study using the ConcertAI Patient 360TM Database, an EMR-based breast cancer dataset comprised of both structured and curated data derived from over 900 US oncologic community and academic entities and linked with ASCO CancerLinQ data. Eligibility included age ≥18 years, diagnosis of cT2-4 or cN1+, M0 BC between 1/1/2010 – 12/31/2022, treated with NACT within 180 days of BC diagnosis. Patients who received neoadjuvant endocrine therapy were excluded. Time to chemotherapy (TTC) in days was recorded. Multivariable logistic regression, adjusted for demographic, socioeconomic and tumor characteristics, was used to identify characteristics associated with delays > 60 days from diagnosis to NACTi. Multiple imputation was used for missing data.

Results: We identified 2107 eligible patients, 213 (10.1%) of which experienced a delay greater than 60 days from diagnosis. Of the entire cohort, 70.8% were White, and 18.8% were Black; across all racial categories, 30.4% were Hispanic. Median age at diagnosis was

53 years (range 22-85) and median TTC was 31 days (range 0-178). By tumor type, 35.1% (n=740) were hormone receptor positive/HER2-negative, 35.7% (n=752) were HER2-postive, and 29.2% (n=615) were triple negative BC; 11.4%, 9.2%, and 9.8% (p = 0.4) had a delay in NACTi, respectively. In a multivariable analysis across all tumor types, patients who were Black (OR 2.31 95%CI 1.46-3.63, p <0.001) or Hispanic (OR 2.20 95%CI 1.23-3.94, p 0.011) were more likely to be delayed compared to White and non-Hispanic patients, respectively. Patients with Medicaid were more likely to be delayed compared to those with commercial insurance (OR 2.0 95%CI 1.30-3.07, p 0.002). Patients treated at community facilities were less likely to be delayed (OR 0.50 91%CI 0.34-0.74, p <0.001) compared to those treated at academic facilities.

Conclusions: Among patients with operable breast cancer who received NACT in this real-world EMR-based database using both structured and curated data, patients who were Black, Hispanic, had Medicaid insurance, or received treatment at an academic facility had a significant increase in odds of a delay in NACTi. These racial, socioeconomic, and access disparities warrant targeted interventions to ensure equitable care.

P4-02-06: Assessing the True Cost of Breast Cancer Screening: Chargemaster, Payer, and Cash Price Discrepancies for Mammography

Mason Alford-Holloway, Austin Triana, Katherine Baker, Samyukta Mullangi

Introduction: Patients in the United States (US) often lack information about the price of breast cancer screening services across hospitals and payers. Recent legislation in the US, including the 2021 Hospital Price Transparency Final Rule, requires hospitals to publish standard chargemaster rates, payer-specific negotiated prices, and discounted cash prices for all services, creating a unique opportunity to understand variation in hospital pricing. While uninsured or underinsured patients may be exposed to high chargemaster rates for screening services, those who are able to pay upfront in cash or have negotiated rates through insurance face significantly discounted prices. More research is needed to better understand the relationship between the distinct screening prices facing patients in the United States.

Methods: We extracted standard chargemaster prices, payer-specific negotiated prices, and self-pay cash prices for screening mammography (CPT code 77067) from machine-readable files published by ten top US hospitals. For each hospital, we compared the standard chargemaster rate for screening mammography with the average payer negotiated price and determined the chargemaster-payer price ratio. Additionally, we compared the standard chargemaster rates and discounted cash prices for screening mammography, and determined the chargemaster-cash price ratio for each hospital.

Results: Across ten top US hospitals, the average chargemaster rate for screening mammography was $855. The average cash price for the same service was $305, with an average chargemaster-cash price ratio of 3.7. The average payer-negotiated price for screening mammography was $411, and chargemaster rates were greater than payer-negotiated prices by an average factor of 2.2. The average cash price for breast cancer screening was 74.2% of the average payer negotiated rate for the same service. We observed wide variation across institutions for chargemaster rates, payer-negotiated rates, and discounted cash prices for screening mammography, with interquartile ranges of $198, $292, and $203, respectively.

Conclusion: Across ten top US hospitals, the chargemaster price for screening mammography was greater than the average payer negotiated rates and discounted cash price for the same service by a factor of 2.2 and 3.7, respectively. This price discrepancy has important consequences for individuals seeking essential breast cancer screening services, with uninsured patients facing prohibitive costs. As curable breast cancers go undetected, the burden on the healthcare system escalates. Policies should aim to improve price transparency, equity, and access to lifesaving breast cancer screening for the most vulnerable populations in the United States.

P4-02-07: Uptake of Ovarian Function Suppression Over Time and Endocrine Therapy Adherence Among Premenopausal Women with Breast Cancer

Dawn Hershman, Ling Chen, Melissa Accordino, Claire Sathe, N. Lynn Henry, Jason D Wright

Purpose: About 50,000 women under the age of 50 are diagnosed each year with invasive breast cancer. In 2017 the SOFT and TEXT trials demonstrated that endocrine therapy (ET) in combination with ovarian function suppression or ablation (referred to as OFS) improves disease-free survival by about 35% in premenopausal women with hormone receptor-positive breast cancer compared to tamoxifen without OFS. However, the addition of OFS increases the frequency of adverse events and symptoms resulting in reluctance to initiate this treatment. Factors influencing the rates of uptake are unknown.

Methods: We used the MarketScan health care claims database to identify women <50 years of age, diagnosed with breast cancer between the years of 2008-2022 using a standard algorithm. Patients with a prior history of a gynecologic cancer or prior oophorectomy were excluded. The analysis was limited to patients with insurance coverage one year prior and one year following first diagnostic claim. Non-adherence to ET was defined as proportion of days covered (PDC) < 80%. Logistic regression was used to determine factors associated with OFS in the overall cohort and then stratified by chemotherapy use and age category.

Results: We identified 36,670 women who met inclusion criteria, of whom 4,344 (11.8%) received OFS. Among the 18,409 women who underwent chemotherapy, 19.3% received OFS. OFS use increased over time from rates as low as 6.6% prior to 2016, up to 24.8% in 2021 (OR= 3.80 (3.19-4.52)). Oophorectomy remained constant at 5% and therefore the increases in OFS resulted from increased use of GNRH agonists. Among women who underwent chemotherapy, OFS rates increased over time from 9.4% in 2008 to 45.9% in 2022, OR=6.19 (5.05-7.59). Higher rates of OFS use were associated with younger age (22.4% for 18-34 yo vs. 8.7% for 45-49 yo; OR=2.42, 95% CI 2.13-2.76) and chemotherapy use (OR=4.89 (4.50-5.33)), By 2021, about 50% of women undergoing chemotherapy under the age of 45 underwent OFS. Among women who initiated OFS, only 30.8% underwent bone mineral density testing within the first year. Among women who initiated OFS, 39.8% were on antidepressant medications within the first year compared to 33.0% among those who did not initiate OFS ($p<0.001$); however, new initiation of antidepressant medications did not differ between group (12.6% vs 12.7%). Non-adherence to endocrine therapy in the first year was higher among women undergoing OFS compared to those on endocrine therapy alone (19.2 vs 16.9%, $p=0.001$).

Conclusion: Use of OFS has dramatically increased over time, with a quarter of all premenopausal women, and half of women <45 who underwent chemotherapy, receiving OFS by 2021. It is important to understand how clinicians are selecting patients for the addition of OFS, in order to optimize ET and reduce breast cancer recurrence. Of concern, in just the first year, OFS was associated with higher ET non-adherence rates. Efforts to improve adherence should focus on these high-risk pre-menopausal women to better understand how overall adherence and care quality is affected overtime.

P4-02-08: Comparative budget impact of CDK 4/6 inhibitors at a Mexican public healthcare institution

Karla Alicia Centelles-Lopez, Jose Antonio de Anda-Romero, Arturo Quintanilla-Guzman, Luis Miguel Celis-Guzmán, Isabel Alicia Loya-Aguilar, Laura Torrecillas-Torres

Background: Metastatic or advanced breast cancer (ABC) management has experienced significant improvements since the advent of CDK 4/6 inhibitors (iCDK4/6). Abemaciclib, palbociclib, and ribociclib are iCDK 4/6 medications approved for use in the Mexican public healthcare system to treat HR+ HER2-ABC in postmenopausal women as first and second line treatments. All competitors have equal cost per pack but portray different survival and economic evidence. ISSSTE, a Mexican public healthcare institution caring for government officials, introduced palbociclib and ribociclib to treat these patients. Currently, the number of patients treated with each of these therapies is similar at ISSSTE. Therefore, it is important to understand the economic implications of this decision.

Objective: To compare the economic impact of having palbociclib and ribociclib available instead of palbociclib as the only available iCDK4/6 at a Mexican public healthcare institution.

Methods: We conducted a budget impact analysis (BIA) with a 5-year horizon using MS Excel to compare the current scenario (i.e., palbociclib + ribociclib) to a hypothetical scenario considering palblociclib as the only available iCDK 4/6. Target population were postmenopausal women with HR+/HER2- ABC without previous treatment for advanced disease treated at ISSSTE. The BIA accounted for the historical and projected market shares and costs for drug acquisition. Market shares of current scenario were based on historical data from two previous years and assumed a static participation of 50% ribociclib and 50% palbociclib, from the year 3 onwards. Market share of hypothetical scenario assumed a 100% use of palbociclib. Number of eligible patients were estimated based on epidemiological and population data. The analysis considered the cost of medication and assumed dose reductions for every comparator. Dose reductions were based on MONALEESA-2 and PALOMA-2; a sensitivity analysis was also performed using consumption data. Unit costs were obtained from the latest available published data and were reported in 2024 Mexican Pesos. Model outputs included annual and cumulative budget impact (absolute and as a percentage of the Institution's budget in medicines).

Results: The average annual cost per patient treated with ribociclib was $64,430.87 MXN (-20.9%) less costly than that of palbociclib. On average, 122 patients are diagnosed with ABC every year. As a result, current scenario with ribociclib and palbociclib has resulted in estimated savings of $8,955,710 MXN since its introduction two years ago. In a 5-year timeframe, savings could reach $40,512,962 MXN if market share is maintained. On average, the Institute could save up to $8.1 million MXN annually (0.0005% of 2022 ISSSTE medicines budget).

Discussion: Ribociclib's presentation allows patients to decrease dose using the same pack; this is translated into savings to the institutional budget. Despite portraying equal cost per pack, on average, patients treated with ribociclib consume a smaller number of packs than palbociclib patients due to dose reductions. Our analysis estimated that at current market shares, the Institution could save $40.5 million MXN in a 5-year time horizon; until today, the use of ribociclib has allowed to save $9.0 million MXN. Due to its cost-saving profile, the use of ribociclib in a larger proportion of patients could bring further savings to the institution.

Conclusion: Our analysis demonstrated that current scenario could save $40.5 million MXN in a 5-year timeframe. As compared to other iCDK 4/6, ribociclib is a cost-saving strategy that could maximize institutional resources. Additionally, it has shown a statistically and

clinically significant impact on overall survival and quality of life for HR+ HER2- ABC patients.

P4-02-09: Community Socio-geographic Distress Predicts Metastatic Breast Cancer at Diagnosis and Delays in Treatment Initiation

Priyanka Parmar, Jessica Lin, Fardeen Bhimani, Noor Habboosh, Andreina Giron, Rajika Jindani, Andrew Miller, Yu Chen, David Entenberg, Maja Oktay, Anjuli Gupta, Jessica Pastoriza, Maureen McEvoy, Sheldon Feldman

Background: Detection of breast cancer at later stages results in higher mortality rates and stark contrasts in 5-year survival: 99% for localized early-stage, 84% for regional stage, and 27% for metastatic-stage disease. Despite advancements in screening and treatment, late-stage diagnoses persist due to various factors. In the US, the proportion of women diagnosed with breast cancer at later stages is higher among those of lower socioeconomic status and among Black women. Socioeconomic factors such as income, education level, and insurance coverage have individually been studied and shown to contribute to delayed diagnoses and poorer outcomes. However, more nuanced measures beyond these traditional proxies are needed to better understand a patient's socio-geographic environment and its cumulative effect on patient health. The Distressed Communities Index (DCI) is a validated socio-geographic measure of economic deprivation derived from the American Community Survey, providing a comprehensive assessment of economic distress at the zip code level. It incorporates factors such as the percentage of people without a high school diploma, unemployment rates, housing vacancy rates, poverty rates, median income, and changes in employment and business within a community. A high DCI score, typically greater than 3, identifies a distressed community. This study aims to determine whether higher community-level socioeconomic distress is predictive of metastatic-stage breast cancer at diagnosis, delays in treatment, and decreased 5-year survival.

Methods: A retrospective study was conducted among women aged 18 years or older who were either diagnosed and/or treated with first primary invasive breast cancer between 2012-2022 at Montefiore/Einstein Comprehensive Cancer Center. The study population was extracted by the tumor registry, and each patient's zip code was linked to the corresponding DCI score. Multinominal logistic regression, adjusting for age, race, ethnicity, and insurance status was used to evaluate the association between breast cancer stage at diagnosis (localized, regional, and metastatic stage) and DCI score. Additionally, an ANCOVA analysis was conducted to compare time to treatment between patients from high versus low DCI areas, controlling for stage.

Results: This study included 3,102 localized (N0), 1,042 regional (N1-3), and 122 metastatic stage (M1) breast cancer cases. After adjusting for age, race, ethnicity, and insurance status, women from zip codes with high DCI scores were twice as likely to be diagnosed with

metastatic disease compared to those from lower DCI areas (OR= 2.02, 95% CI 1.19-3.45, p = 0.009). Additionally, patients from higher DCI zip codes experienced significant delays in initiating treatment in neoadjuvant chemo (33 vs 49 days, p=0.024), adjuvant chemo (85 vs 105 days, p = 0.01), surgery (56 vs 76 days, p < 0.001), and radiation therapy (119 vs 169 days, p = <0.001), compared to those from lower DCI areas. Furthermore, the 5-year survival rates showed a decreasing trend among patients from higher DCI zip codes compared to lower DCI groups: 86.5% vs. 87.2% in localized, 75.4% vs. 82.0% in regional, and 22.1% vs. 30.8% in distant-stage cancer.

Conclusion: Patients residing in higher-distressed communities exhibited a twofold higher likelihood of being diagnosed with metastatic breast cancer and experienced delays in treatment initiation compared to those from lower-distressed communities. These results underscore the influence of socio-geographic factors on breast cancer disparities, emphasizing the need for tailored interventions to enhance outcomes in underserved populations. Leveraging the DCI database enables identification of high-risk zip codes, facilitating targeted screening initiatives aimed at mitigating disparities in breast cancer outcomes.

P4-02-10: Validating Navya Earthshot: An AI Driven Point of Care Solution for Guideline Adherent Treatment Planning in a Decentralized Cancer Care Model.

Umesh Mahantshetty, Nancy Feldman, Dolorosa Fernandes, Shalaka Joshi, Shilpa Kandipalli, Raviteja Miriyala, Srinivasan Padmanabhan, Motepalli Panduranga Kumari, Vani Parmar, Rima Pathak, Shona Nag, Guru Raghavendra Naik, Shveta Sharma, Rakesh Vyas, Tabassum Wadasadawala, Rajendra Badwe

Background: Adherence to breast cancer guidelines is associated with increased overall survival and disease-free survival globally (Ricci-Cabello et. al., BMC Health Serv Res. 2020;20(1):920). In resource-constrained settings, approximately 30% of patients receive undertreatment that is not evidence-based, or overtreatment that is potentially harmful (C.S Pramesh et al., J Clin Oncol 38: 2020). Despite significant investment in physical infrastructure for decentralized cancer care—with the goal of tertiary hub centers providing support to multiple non-specialized spoke centers—shortage of oncologists in resource constrained settings creates a knowledge gap at the point of care, which may be partially filled with digital AI solutions.
Navya is a clinically validated digital AI solution for cancer patients in use since 2014 which matches patient-specific evidence and guidelines to generate treatment options for a cancer patient vetted via asynchronous expert review (Nita Nair et. al., Cancer Res (2015) 75). Navya Earthshot is a new, provider facing solution for cancer treatment planning for non-specialized providers at the point of care, and is built as a search interface on Navya's validated domain model supporting subspecialized expert opinions in oncology (Tiffany A

Traina et. al, J Clin Oncol 39, 2021). Navya earthshot was customized to analyze the NCG guidelines for this use case.

Methods: In this multicenter, prospective validation in India, patients with a complete diagnostic workup and confirmed diagnosis of breast, oral and lung cancer at a decision point of treatment planning between January and June 2024 at participating centers were included. All decision points (curative and palliative; surgery, radiation and systemic therapies) addressed by India's standard of care National Cancer Grid (NCG) guidelines were included. At each decision point, Navya Earthshot first prompted a clinical navigator to complete a case specific short set of questions; then matched input case data with NCG guidelines, and output evidence based treatment plans at the point of care. Navya Earthshot output was given to providers at each of the participating centers, and scored as concordant or discordant by the tumor board/treating oncologists, as well as by a group of domain experts experienced in analyzing NCG guidelines. Results for the breast cancer cohort are presented below.

Results: 643 breast cancer patients met eligibility criteria at participating sites, which included 5 centers in the state of Andhra Pradesh, 1 center in Assam, 2 centers in Maharashtra, and a national organization of experts supporting care of underprivileged patients in several cancer hospitals across India. 70 patients (11%) were excluded from analysis due to the presence of rare histologies and bilateral cancers not covered by the NCG guidelines. Patients were well represented with respect to age (<45 years (35%) and >45years (65%), and early stage (45%) and advanced stage (54%). In 96% (553/573) of cases, Navya Earthshot output was concordant with the NCG guidelines as assessed by the domain experts, and validated by the tumor board/treating oncologists. Of these, in 93/553 cases (17%), treating oncologists/tumor board added additional treatment related guidance beyond NCG concordant Navya Earthshot. These cases did not require any further subspecialized expert review. The remaining 4% (20/573) cases were referred to a tertiary center for treatment planning.

Conclusion: A point of care solution used by clinical navigators that outputs guideline concordant treatment plans for consideration by treating providers can improve capacity in resource constrained settings that lack subspecialized organ specific multidisciplinary expertise. Navya Earthshot can enhance adherence to guideline driven care across spoke centers without overreliance on tertiary hub centers influencing treatment outcomes at scale.

P4-02-11: Outcomes of Susan G. Komen's "Navigating People with Metastatic Breast Cancer" Patient Navigation Training Course

Kelley Moultry, Nate Adams, Amber Linthakhan, Jacquelyn Pearson, Samantha Scott, Alyncia Mason, Stephanie McCoy, Janet Okamoto, Julie McMahon

Background: Susan G. Komen's Patient Care Center patient navigators (PNs) reported a need for additional training to meet the unique needs of individuals with metastatic breast cancer (MBC) and a landscape analysis revealed a lack of systematic work done to understand the navigational needs of those with MBC and efforts to equip PNs to specifically address them. Komen's Patient Navigation Training Program provides interactive, virtual training to equip trainees to provide high-quality services addressing the needs of underserved communities. To build a training to fill this identified gap, a study was conducted to identify the needs of people with MBC and the training requirements of their PNs, leading to a targeted training course, "Navigating People with Metastatic Breast Cancer".
Focus groups with MBC patients and PNs identified key themes, including health care experiences, diagnosis challenges, professional and system obstacles, insurance issues, health inequities, coping mechanisms, ideal PN traits, and support needs. People with MBC emphasized the importance of access to PNs, while PNs expressed a need for training to address these challenges, underscoring the need for comprehensive PN training focused on MBC.

Methods: Focus group findings were used to develop the course learning objectives: 1) Highlight strategies and resources PNs can use to support the unique needs of those living with MBC, 2) Define MBC and identify barriers people with MBC may face, 3) Provide tools for PNs to better support people with MBC, and 4) Connect PNs to ongoing MBC training opportunities for continued learning and professional peer support. Komen's Patient Care Center PNs and experts validated content alignment with learning objectives through a survey instrument. Instructional design incorporated interactive, scenario-based learning approaches, including a self-assessment to tailor additional training to each learner's needs. The free course is available in Komen's online learning system, where demographic information and pre- and post-program survey instruments assess content, method of content delivery, and intent to apply content, using a Likert scale.

Results: From May to June 2024, 28 learners completed the course. Participant demographics included 21% Black/African American, 36% White, and 29% Hispanic/Latino (14% preferred not to answer). Common roles were PN (26%) and social worker (14%), with 11% having prior navigation training or certification.
All participants reported increased confidence in describing and navigating barriers and meeting the needs of people with MBC (100%), identified opportunities for continued learning to meet the needs of people with MBC (100%), and most participants intended to use the information professionally (96%). All respondents reported the information was

useful and relevant (100%), presented in an understandable way (100%) and that the level of interaction was helpful (100%).

Conclusion: The course was developed to fill a PN workforce reported need for training to address the unique needs of people living with MBC, informed by focus groups with people living with MBC and PNs who support them. The course attracted a diverse group of learners, including PNs and social workers, with significant representation from Black, White, and Hispanic/Latino communities. The virtual format proved accessible and effective in improving the learners' capacity to meet the needs of people living with MBC and met the need for interactive learning delivered virtually. Participants reported substantial improvements in confidence and ability to navigate MBC-related barriers. The training was universally rated as useful, relevant, and easy to understand, with a high level of engagement. These positive outcomes underscore the program's success in equipping PNs with the necessary skills and knowledge to better support individuals with MBC, addressing a crucial gap in patient navigation training.

P4-02-12: Incidence and Survival Trends in Young Women (Aged 20-49) with Breast Cancer: SEER analysis.

Nikhila Aimalla, Lekha Yadukumar, Rachel Gabor, Meghana Kesireddy

Background: Breast cancer (BC) is the most common cancer worldwide, classified based on the hormone receptor (HRc) and human epidermal growth factor receptor (HER2) status into 3 sub-types: HRc+ & HER2-, HER2+, and HRc- & HER2-. Its incidence, especially in advanced stages, is rising among young women, leading to it being the primary cause of cancer-related deaths for those aged 20 to 49.

Methods: A retrospective study using the Surveillance, Epidemiology, and End Results (SEER) database analyzed women aged 20 to 49 diagnosed with BC from 2010 to 2020. Cox proportional regression analysis was used to assess the impact of various variables on overall survival (OS) across the three BC subtypes.

Results: A total of 123,690 women aged 20-49 were diagnosed with BC: 81,006 (65.5%) HRc+ &HER2-, 25,253 (20.5%) HER2+, and 17,431 (14%) HRc- & HER2-. Incidence was higher in ages 40-49 (75.4%) than in 30-39 (21.9%) and 20-29 years (2.7%). Incidence was higher in 2015-2020 (55.85%) than in 2010-2015 (44.2%). Most were caucasian (72.7%), earned < 75,000$ (53.6%), lived in urban areas (92.3%), and were married (64.8%).
The study examined OS hazard ratios (HRs) across all three BC subtypes. OS HRs for ages 20-29 and 30-39 years indicated poorer survival than ages 40-49 across all subtypes, except for ages 20-29 in HRc- & HER2-, likely due to aggressive biology and advanced stage in the very young population. For ages 20-29 (vs. 40-49), the HRs were 2.4 for HRc+ & HER2-, 1.36 for HER2+, and 1.1* for HRc- & HER2-. For ages 30-39 (vs. 40-49), the HRs were 1.74 for HRc+ & HER2-, 1.11 for HER2+, and 1.08 for HRc- & HER2-.

Although the incidence rose in 2015-2020 across all subtypes, OS was worse for HRc+ & HER2- from 2010-2014 compared to 2015-2020, likely due to newer treatments, with no significant OS difference in the other two subtypes. Specifically, the OS hazard ratios for 2010-2014 (vs. 2015-2020) were 1.08 for HRc+ & HER2-, 1.07* for HER2+, and 1.06* for HRc- & HER2-.
Higher-income, Asian race, urban residence, marriage, receipt of radiation, and surgery were linked to better OS in all subtypes. Higher-income ($75,000+ vs. < $75,000) was associated with OS HRs of 0.69 for HRc+ & HER2-, 0.64 for HER2+, and 0.81 for HRc- & HER2-. Compared to White patients, Asians or Natives had lower OS HRs of 0.82 for HRc+ & HER2-, 0.86 for HER2+, and 0.88 for HRc- & HER2-, while Black patients had higher OS hazard ratios of 2.17, 1.94, and 1.47, respectively. Rural residence was linked to higher OS HRs of 1.31 for HRc+ & HER2-, 1.34 for HER2+, and 1.01 for HRc- & HER2-. Being married improved OS with HRs of 0.61 for HRc+ & HER2-, 0.57 for HER2+, and 0.7 for HRc- & HER2-. Surgery shows substantial protective effects across all subtypes (HRs of 0.1 for HRc+ & HER2-, 0.14 for HER2+, and 0.22 for HRc- & HER2-), radiation also correlates with improved outcomes (HRs of 0.81 for HRc+ & HER2-, 0.83 for HER2+, and 0.93 for HRc- & HER2-). Chemotherapy improved OS, except in HRc+ & HER2-, where it is reserved for high-risk cases (HRs of 2.25 for HRc+ & HER2-, 0.63 for HER2+, and 0.84 for HRc- & HER2-).
The advanced cancer stage was associated with poor OS in all subtypes.
(* indicates not statistically significant.)

Conclusion: Our study highlights trends in young women with BC, emphasizing the necessity for tailored interventions to improve outcomes.

P4-02-13: The global failure of mammography screening accessibility – a systematic literature review

Carlos Barrios, Shani Paluch-Shimon, Elvira Mueller, Kurt Neeser, Melina Arnold, Pavel Napalkov, Evandro de Azambuja

Background: Breast cancer is the most diagnosed cancer among women and a leading cause of cancer mortality worldwide. In high-resource healthcare settings, screening mammography combined with early treatment has consistently shown a reduction in breast cancer mortality. However, globally, most breast cancers are diagnosed based on clinical symptoms because screening programs are not available, or the participation rate seems to be low. Understanding and addressing the barriers women face in accessing breast cancer care, from screening to treatment, is crucial for improving patients' clinical outcomes.
Objective: This systematic literature review (SLR) aims to estimate the number of women affected by barriers to breast cancer screening mammography worldwide.

Methods: This SLR followed PRISMA guidelines (registered on PROSPERO; CRD42023423823) and included a comprehensive search in bibliographic databases and

grey literature. The number of women potentially eligible and participating in screening mammography was estimated from the UN population data and considering region-specific information on screening guidelines and programs. Extrapolations were made for countries without data, using gross national income level per capita and linear regression for missing values.

Results: A total of 20,434 citations were identified, resulting in 256 extracted sources that fulfilled the inclusion criteria focusing on quantitative data about the number of patients hindered by barriers from participating in breast cancer screening. The review identified living in rural areas, low education level, advanced age, low frequency of gynecologic visits, and concerns about radiation as important barriers to breast cancer screening. The estimated proportions of women aged 50 to 75 eligible for breast cancer screening programs but not participating in screening mammography varied considerably between regions, from 95% in Asia, 93% in Africa, and 52% in Latin America to 45% and 20% in Europe and North America, respectively. The total number of women not participating in mammography screening worldwide amounts to approximately 700 million, or 79% of all breast cancer screening eligible population.

Conclusion: This comprehensive SLR identified major access barriers to breast cancer screening for women worldwide. These hurdles are particularly prevalent in low-resource healthcare settings. Our estimates suggest that globally, most women eligible for screening based on their age do not participate in screening mammography programs, either because there is no screening program in place or because existing programs have low uptake rates for various reasons. This finding supports the need for the urgent dissemination and implementation of the WHO Global Breast Cancer Initiative 2023 guidelines, which focus on establishing early-detection programs to promote favorable stage shifting (earlier tumor stage at diagnosis) to achieve a reduction in breast cancer mortality, especially in low- and medium-income countries.

P4-02-14: A Multi-Practice Quality Initiative Focused on HER2+ and HER2low Metastatic Breast Cancer

Mike Gart, Rushir Choski, Fred Kudrik, Vikram Gorantla, Anupama Vasudevan, Teena Sura, Anna Rui, Doug Kanovsky, Dawn Brenneman, Prateesh Varughese, Brandon WangSimon Blanc

Background: Given the results of both DESTINY-03 and DESTINY-04 trials and the practice changing nature of such studies, Integra Connect (IC) PrecisionQ partnered with several oncology practices, including Regional Cancer Care Associates (RCCA), University of Pittsburgh Medical Center (UPMC), and South Carolina Oncology Associates (SCOA) to conduct a quality initiative to evaluate treatment against the standard of care, identify any potential gaps in care, and address those gaps. We aim to show the improvement in

treatment of HER2low breast cancer patients following chemotherapy in the metastatic setting (HER2low eligible) and HER2 positive (HER2+) breast cancer patients on second line of therapy or greater (LOT 2+).
Methodology: Using the IntegraConnect PrecisionQ de-identified database, a baseline cohort of patients were evaluated and determined as HER2low eligible on or after 6/1/2022 through 9/30/2023 (RCCA – 70, UPMC – 85, SCOA – 28) and HER2+ who started LOT2+ on or after 1/1/2022 through 9/30/2023 (RCCA – 94, UPMC – 92, SCOA – 25). Results of the initial analysis were shared with practice leaders and were also shared among oncologists at the practices. Following those interventions, over the next 6 months, the following number of patients were analyzed by practice to determine whether an improvement occurred among HER2low eligible patients (RCCA – 18, UPMC – 18, SCOA – 13) and HER2+ patients who started LOT2+ (RCCA – 23, UPMC – 25, SCOA – 11). Descriptive analyses were performed, and proportions were compared using a chi-squared test.
Results: The HERlow eligible patients treated with fam-trastuzumab deruxtecan-nxki increased from 51% to 61% at RCCA, from 33% to 56% at UPMC, and 18% to 39% at SCOA. Across all three practices, HERlow eligible patients treated with fam-trastuzumab deruxtecan-nxki increased from 38% to 53% ($p = .05$). The HER2+ LOT 2+ patients treated with fam-trastuzumab deruxtecan-nxki increased from 42% to 74% at RCCA, from 49% to 60% at UPMC, and 16% to 46% at SCOA. Across all three practices, HER2+ LOT2+ patients treated with fam-trastuzumab deruxtecan-nxki increased from 42% to 63% ($P < 0.01$).
Conclusion: This multi-practice quality initiative helped to improve treatment against standard of care in both HER2low and HER2+ breast cancer patients eligible for fam-trastuzumab deruxtecan-nxki across multiple oncology practices. This suggests even after considerable time passes following a new standard of care being established, oncology practices stand to benefit from assessing current treatment practices to ensure patients are receiving the highest standard of care.

P4-02-15: Potential Drug-Drug Interactions and Related Safety Considerations in Patients with Metastatic Breast Cancer Treated with Ribociclib

Claire Sathe, Rohit Raghunathan, Melissa Accordino, Jason Wright, Dawn Hershman

Background: Ribociclib, a cyclin dependent kinase 4/6 inhibitor (CDK4/6i), is part of the preferred first-line treatment of hormone receptor-positive (HR+) metastatic breast cancer (MBC). Polypharmacy is common among all BC survivors, and concomitant medication use is an under-researched safety issue for the growing number of patients on ribociclib. All CDK4/6i are metabolized through CYP3A4 and thus have potential for drug-drug interactions (DDI) when prescribed concurrently with CYP3A4 inhibitors (toxicity) and inducers (reduced efficacy). Furthermore, ribociclib use is associated with QTc interval prolongation, and requires electrocardiogram (ECG) monitoring and avoidance of antiarrhythmics and other agents with QTc prolongation potential.

Methods: We used the MarketScan health care claims database to identify patients who were prescribed ribociclib from 3/2017 (FDA approval) until 12/2022. We identified medications with DDI potential based on FDA labeling and categorized them as follows: CYP3A4 inhibitors (strong or moderate); CYP3A4 inducers (strong or moderate); antiarrhythmics; and QTc prolonging medications. We examined claims for medications with potential for DDI with ribociclib between each patient's first and last claim for ribociclib, or, if only one ribociclib claim was found, in the 180-day period after that claim. We also assessed whether an ECG was obtained within 60 days prior to initiating ribociclib (baseline ECG), and whether 2 ECGs were obtained within 60 days after starting treatment, based on Current Procedural Terminology (CPT) and ICD-10 procedure codes. These timeframes are longer than the FDA label recommendations for ECG monitoring to account for delays between claims and treatment initiation.

Results: We identified a total of 1,010 patients who were prescribed ribociclib between 3/2017 and 12/2022 (97.7% female; 63.4% <60 yo; 58.3% commercially insured, 14.6% Medicare, 27.4% Medicaid). Of these, 323 patients (32.0%) were prescribed a medication with potential for DDI with ribociclib while treated with ribociclib based on claim data. Specifically, 11 patients (2.1%) were prescribed a CYP3A4 inhibitor, 7 (0.7%) a CYP3A4 inducer, 6 (0.6%) an antiarrhythmic, and 289 (28.6%) a QTc prolonging medication. Among all medications with potential for DDI with ribociclib, the most commonly co-prescribed agents were ondansetron (80.8% of claims) and hydroxychloroquine (4.5% of claims), both of which have QTc prolonging potential, followed by the antiarrhythmic sotalol (2.4% of claims), methadone (2.4% of claims), which has QTc prolonging potential, and verapamil (2.1% of claims), an antiarrhythmic and CYP3A4 inhibitor. Of our total study population, 590 (58.4%) did not have a procedure code for a baseline ECG before their first ribociclib order. In addition, 595 (58.9%) were missing procedure codes for two additional ECGs after ribociclib initiation. There was no statistically significant difference between the cohort of patients co-prescribed a medication with DDI potential vs those who were not in terms of baseline ECG prevalence (42.5% vs 41.2%, p=0.7) or post-treatment initiation ECG prevalence (45.1% vs 39.4%, p=0.09).

Conclusions: Concomitant use of medications with DDI potential is common among patients with MBC treated with ribociclib. The antiemetic ondansetron is the most commonly co-prescribed medication with DDI potential as both agents are associated with QTc prolongation. Of concern, safety recommendations regarding ECG monitoring are inconsistently followed. As indications for ribociclib may expand to the adjuvant setting based on recent trial data, future research should identify strategies to improve patient safety, which may involve pharmacist-led interventions and improved dissemination of safety guidelines.

P4-02-16: Genetic Spectrum and Prevalence of Hereditary Breast and Ovarian Cancer Genes in Ceará's Families, Brazil: A Retrospective Study on Germline Mutations and Regional Variants

Valbert Oliveira Costa Filho, Mariana Macambira Noronha, Pedro Robson Costa Passo, Duílio Reis da Rocha Filho, Leonardo Saraiva Pontes, Victor Queirós Calheiros Campelo Maia, Ormando Rodrigues Campos Junior, Cristiane de carvalho Coutinho Farias, Georgia Fiuza Alencar Araripe, Virginia Moreira Braga, Ingrid Hariman Fonseca da Cunha, Carla Dias, Antônio Bitu dos Santos Filho, Leonardo Atem, Milena Viana de Holanda, Aline Carvalho Rocha, Cárilla Carrascoza Caramuru, Lorena Alves Oliveira da Silva, Paulo Zattar Ribeiro, Ana Lucíola Borges Pinheiro, Eric Lima Freitas Mota, Gabriel Sampaio Feitosa, Ígor Giordan Duarte Jorge, Izaberen Sampaio Estevam, Letícia Pinheiro Amorim, Paulo Eduardo de Oliveira, Kevin Lucas Silva Ribeiro, Carlos Alberto Barbosa Neto, Emmanuel Filizola Cavalcante, Paulo Henrique Walter Aguiar, Gina Zully Carhuancho Flores, Flávio Henrique Cantanhêde Ximenes, Natália Couto Monteiro Feitosa, Everardo Leite Gonçalves, Josmara Ximenes Andrade Furtado, Leandro Jonata de Carvalho Oliveira, Gabriela Carvalho Pinheiro, Marclesson Santos Alves, Francisco Pimentel Cavalcante, Danielle Calheiros Campelo Maia

Introduction: Approximately 10% of all neoplasms are influenced by germline mutations in pathogenic or likely pathogenic (P/LP) genes, with a majority of these mutations impacting the development of Hereditary Breast and Ovarian Cancer (HBOC) syndrome. The most common genes involved in HBOC are related to homologous recombination (HR) DNA repair, such as BRCA1, BRCA2, PALB2, CHEK2, ATM, RAD51, and BRIP1. In breast cancer, other genes like PTEN, TP53, CDH1, NF1, STK11, MUTYH, and BARD1 also play a crucial role in developing this neoplasm. Furthermore, the specific type of gene variation is important for understanding the spectrum and phenotype of hereditary cancer itself. Most studies on germline mutations and lifetime cancer risk have been conducted in developed countries. Therefore, the regional impact of specific variants in low and middle-income countries remains under investigation. Thus, we present the spectrum of germline mutations observed in Ceará, a northeastern state of Brazil. Methodology: This retrospective, cross-sectional study was conducted between 2018 and 2024 with patients from a private oncology clinic in Brazil, who met clinical criteria for Hereditary Predisposition Syndromes, specifically Hereditary Breast and Ovarian Cancer, according to the National Comprehensive Cancer Network (NCCN) guidelines. Molecular analyses were performed using a commercial multi-gene cancer panel with next-generation sequencing (NGS) capture panels, which included 27 to 84 genes depending on clinical suspension. These panels were validated for copy number variation and were designed to cover at least each exon and 20 base pairs of the intronic sequences adjacent to the exons. The primary endpoint was the prevalence of Hereditary Breast Cancer genes (BRCA1, BRCA2, PALB2, CHEK2, ATM, RAD51, BRIP1, PTEN, TP53, CDH1, NF1, STK11, MUTYH, and BARD1) in this population and the specific variants of the genes involved. Results: From 1055 patients analyzed, 141 (13.4%) individuals harbored a P/LP variant with 92 (8.7%) families harboring genes associated with an increased risk of HBOC syndrome. The most frequently mutated gene was BRCA1 (34.8%), followed by BRCA2 (15.2%), CHEK2 (14.1%), PALB2

(11.9%) ATM (8.7%), MUTYH (6.5%), RAD51 (4.3%), TP53 (3.3%) and NF1 (1.1%). In BRCA1, c.5074+2T>C (31.3%) was the most common variant, followed by C.5266dup (25.0%) and c.1961dup (12.5%). In BRCA2, the most common variant was c.4808del (35.7%), followed by c.9382 C>T (21.4%), c.2167delA (14.2%), and c.6024dup (14.2%). Within CHEK2, the most common variant was c.846+1G>C (69.2%), followed by c.349A>G (23.1%), and c.593-1 G>T (7.7%). Deletion (Exons 1-10) (27.3%) was the most common variation in PALB2, followed by c.1042C>, c.1240C>T (9.1%). In ATM, was c.1236 (25.0%), c.640del (25.0%) and Deletion (Exons 27-29) (25.0%). In MUTYH cases, it was c.536A>G (50.0%) and c.1187G>A (33.3%). In RAD51D was, c.694 C>T (50.0%). A TP53 founder pathogenic variant (R337H) accounted for 33% of all TP53 P/LP. Conclusion: These findings highlight the genetic diversity in HBOC syndrome and emphasize that regionality plays a crucial role in the distribution and prevalence of specific P/LP variants. Also, this study underscores the importance of conducting germline studies in under-represented populations to understand the landscape of HBOC syndrome better and develop unique prevention strategies. However, further research is needed to explore the underlying factors driving these regional differences and to understand the clinical implications of specific variants identified in this research.

P4-02-17: Toward Universal Germline Genetic Testing for Patients with Breast Cancer, Perspectives from a Recourse-Restricted Country

Sarah Abdel-Razeq, Faris Tamimi, Hira Bani Hani, Baha Sharaf, Suhaib Khater, Mohammad Sammour, Marwa Sh Abrahim, Tamer Al-Batsh, Hanan Khalil, Hikmat Abdel-Razeq

Introduction: Breast cancer continues to be the most common cancer diagnosed among women worldwide. Median age at diagnosis tends to be significantly lower in low-resource countries compared to Western societies. Almost half of breast cancer patients, in countries like ours, are diagnosed at age 50 years or younger. Pathogenic germline variants (PGVs) in cancer-predisposing genes, mostly in BRCA1 and BRCA2 have been linked to the etiology of more than 10% of breast cancers. Identification of individuals with PGVs may reduce cancer burden by informing treatment decisions in patients themselves, whereas at-risk relatives may benefit from intensive screening and risk-reducing strategies.
Universal germline genetic testing (GGT) via multigene panels (MGP) is currently recommended for patients with ovarian, pancreatic, and metastatic prostate cancers. However, many international professional societies have established guidelines recommending GGT for high-risk patients with breast cancer. Such guidelines are somewhat complicated for most health care worker to follow; a fact that may contribute to the lower-than-expected referral rates for GGT in such patients. Age at which GGT for patients with breast cancer is recommended keep changing; moving from 40 to 45 and 50 and lately was moved to age 65 years by the American Society of Clinical Oncology (ASCO) most recent guidelines. Complexity of current guidelines may create barriers to GGT.
Methods: Medical records consecutive patients newly diagnosed and treated for breast cancer at our institution were reviewed. Patients with indication for GGT testing as per the

latest ASCO guidelines were identified based on age , breast pathology and family history. Number and percentage of patients who are not eligible for GGT will be determined.
Results: During the study period a total of 1570 patients were diagnosed with breast cancer, median age 51 (22-96) years, majority 1352 (86.1%) were Jordanian while the rest (n= 218, 13.9%) were non-Jordanian Arabs. Based on age criteria (i.e. patients aged ≤ 65 years), a total of 1346 (85.7%) were eligible for testing. Among the others 224 (14.3%), medical records were reviewed for indications, other than age at diagnosis, for GGT. Another 134 (8.5%) were found eligible for testing because of personal or family history of breast and other cancers (n=121, 7.7%), having triple-negative disease (n=9, 0.57%) and male gender (n=4, 0.25%). In total, 1480 (94.3%) patients are eligible for GGT as per the most recent ASCO guidelines, leaving only 90 (5.7%) who are not candidates for testing as per current guidelines. Among the 1570 patients, 1134 (72.2%) were referred for the genetic counselling clinic and were tested.
Conclusions: Applying a universal germline genetic testing for newly diagnosed breast cancer, regardless of their age, disease characteristics, family or personal history of breast or other cancers, would increase the pool of eligible testing by few percentage points; the burden of which can be justified given its impact on improving referral rate.

P4-02-18: Change in MRI Background Contrast Enhancement (BPE), Fibroglandular Volume, and Hormones with Bazedoxifene and Conjugated Estrogens

Carol Fabian, Onalisa Winblad, Adrian Zelenchuk, Amy L. Kreutzjans, Krystal Pittman, Christy Altman, Kandy R. Powers, Lauren Nye, Mary McCarthy, Dinesh Pal Mudaaranthakam, Bruce F. Kimler

Background: The proportion of MRI fibroglandular tissue exhibiting contrast is termed background parenchymal enhancement (BPE). American College of Radiology (ACR) BPE criteria are minimal, <25%; mild, 25-50%; moderate, 50-75%; and marked, >75%. Postmenopausal women have a low proportion of MRIs with moderate and marked BPE, but those with BPE of ≥ 50% have an elevated cancer risk. In cross-sectional studies, women taking combined estrogen + progestin hormone replacement are more likely to have a high BPE; while women taking tamoxifen are less likely. We explored use of abbreviated MRI BPE as a response biomarker in a feasibility study of 6 months of the SERM bazedoxifene plus conjugated estrogens (BZA+CE) vs waitlist control in high-risk postmenopausal women with vasomotor symptoms.
Methods: Inclusion criteria were age 45-64, no periods for ≥2 months, vasomotor symptoms, and ≥ 2x population risk for breast cancer. Following consent, women underwent phlebotomy, 3D mammography, and abbreviated breast MRI and were randomized to BZA +CE or waitlist with repeat procedures at 6 months. Women randomized to waitlist were offered the option of BZA+CE at 6 months. 11 women were enrolled in STUDY00145121 of BZA 20mg + CE 0.45 mg as Duavee™ vs waitlist between 5-2020 and 8-2020 which closed with the temporary withdrawal of Duavee™. 16 women

were enrolled on its replacement, STUDY00146761, between 2-2021 and 9-2023 which used imported BZA and commercial CE in the same doses as Duavee™. Following study completion all baseline and 6-month MRIs were re-assessed by a single radiologist blinded to treatment assignment. This research assessment altered ACR criteria reads by changing minimal to 5-25% BPE and adding a 5th category of almost none (<5%). Mammographic fibroglandular volume (FGV) was assessed by Volpara™ fully automated software. Baseline and 6-month serum samples were assayed together for estrogen and progesterone. Results: 27 women were randomized, 15 to BZA+CE and 12 to waitlist. Five randomized to waitlist did not have 6- month reassessment due to dissatisfaction with randomized arm (1) or unavailability of Duavee™ at 6 months in STUDY00145121 (4). Two withdrew from BZA+CE due to muscle cramps and colon cancer. Twenty are evaluable for change in FGV and MRI, and 19 for change in hormones. Using the ACR 4 category assessment with clinical interpretations, 16/20 (75%) were in the lowest BPE category (<25%) at baseline. However, with our 5-category research assessment and a single reader, only 4/20 (20%) were in the lowest (<5% BPE) category. For the 13 evaluable women randomized to BZA+CE, the median relative change in FGV was -3%. Change in MRI category was 6 decreased, 2 increased, and 5 no change despite a median relative increase in estradiol of 80% and little change in progesterone. For the 7 evaluable women randomized to waitlist, the median relative change in FGV was +3%. Change in MRI category was 2 decreased, 1 increased, and 4 no change. Baseline or directional change in MRI category was not associated with baseline or directional change in FGV or estradiol. Hot Flash Score in the BZA+CE arm was reduced from a median of 16 to 0 but unchanged in waitlist. Conclusions: A no-treatment control arm in women with vasomotor symptoms is feasible if BZA+CE can be supplied after the 6-month randomized period. Use of categorical MRI BPE as a response biomarker for prevention is limited by low level of enhancement at baseline. A fully quantitative measure should be explored. MRI BPE change after BZA+ CE appears independent of change in serum estradiol or mammographic FGV in this pilot assessment.

P4-02-19: Development and Validation of a Genetic Risk Prediction Model for Breast Cancer: The Prognostic Role of SNAI1 and CDH1 in Treatment Response and Patient Survival

Chieh-Ni Kao, Chi-Wen Luo, Shu-Jyuan Chang, Sin-Hua Moi, Fang-Ming Chen, Ming-Feng Hou

Background: Breast cancer is a highly heterogeneous disease characterized by varied molecular profiles, leading to diverse clinical treatment responses. Effective and specific classification and diagnosis are critical for optimizing breast cancer treatment. This study aims to establish a genetic risk prediction model for breast cancer patients, focusing on malignant manifestations and treatment response.

Methods: This study extracted and transformed mRNA data from 27 target genes from 486 breast cancer patients into a data matrix. A hierarchical clustering-based risk prediction algorithm was developed to identify the most influential risk molecules and protective factors. The top 10 important genes identified were SNAI1, HDAC1, DNMT3A, WHSC1, PRDM15, PRMT2, CDH1, PRDM7, HDAC3, and PRMT8. Validation was further conducted using immunohistochemistry and scoring on samples from 74 patients.

Results: The genetic risk prediction model identified SNAI1 as the most significant risk molecule and CDH1 as the primary protective factor. Pearson's analysis indicated a negative correlation between SNAI1 and CDH1. Kaplan-Meier analysis showed that SNAI1 is a poor prognostic indicator for overall survival in lymphatic invasion (LN+), chemotherapy alone (CT), chemotherapy plus radiotherapy (CT plus RT), and breast-conserving surgery (BCS). Univariate analysis highlighted SNAI1 as a prognostic indicator, while multivariable analysis confirmed that SNAI1 and CDH1 are significant independent prognostic indicators for overall survival in breast cancer after adjusting for clinical parameters. SNAI1 demonstrated excellent discrimination in CT, CT plus RT, and BCS subgroups and acceptable discrimination in overall and radical treatment groups.

Conclusion: This study proposes a genetic risk prediction platform to identify potential risk factors. Clinical specimen validation showed that SNAI1 has a significant diagnostic effect on lymphatic invasion, patient survival, and chemotherapy prognosis in breast cancer patients. These findings provide a valuable biomarker prediction model for effective diagnosis, monitoring, and treatment. The ultimate goal is to prolong patient survival while avoiding over-treatment and unnecessary medical expenses.

P4-02-20: Investigating Age-Dependent Breast Cancer Dynamics in a Mouse Model

Yun Zhang, Jyotsna Godavarthi, Abie Williams-Villalobo, Bin Liu

Breast cancer incidence increases with age, but the relationship between age and breast cancer survival remains controversial. Additionally, while younger and older patients exhibit distinct molecular profiles, the intrinsic age-related molecular events in breast cancer are yet to be fully understood. To address this gap, we investigated the age-dependence of breast cancer in a controlled setting, aiming to uncover key signaling pathways. In this study, we utilized a breast cancer mouse model we previously published, which is highly relevant to human breast cancer. This model features the conditional p53wm-R245W allele that allows Cre recombinase-mediated conversion of wild-type p53 into the p53R245W mutant (corresponding to human p53R248W, one of the most common mutations in breast cancer). Female p53wm-R245w/+ mice received mammary intraductal injections of adenovirus expressing Cre (Ad-Cre) at 2 months or 10 months of age (referred to as the 2-month and 10-month groups, respectively) and were monitored for tumor

development. Twenty-six percent of the 2-month group and 34% of the 10-month group developed mammary tumors, most of which were adenocarcinomas. The average latency for tumor onset was 15 months post-injection (p.i.) in the 2-month group and 18 months p.i. in the 10-month group. Interestingly, tumors from the 2-month group grew significantly faster but had a lower rate of lung metastasis (43% vs 82%) compared to those in the 10-month group. In addition, molecular analysis revealed significant differences between the two groups. The mRNA levels of estrogen and progesterone receptors and the erythroblastic oncogene B indicated distinct breast cancer molecular subtype distributions: luminal A/normal-like subtypes dominated in the 2-month group, while triple-negative subtypes were more prevalent in the 10-month group. Notably, tumors from the 2-month group exhibited a higher frequency of p53 loss of heterozygosity (LOH) compared to the 10-month group (37.5% vs 9.09%). To further explore the molecular mechanisms driving age-related differences in breast cancer, we performed RNA sequencing on tumors and mammary gland controls. We identified 6,799 differentially expressed genes in the 2-month group and 6,502 in the 10-month group. Ingenuity Pathway Analysis revealed that the two groups were associated with distinct signaling pathways, such as EIF2 signalling in the 2-month group and Notch signaling in the 10-month group. Additionally, Interferon gamma signaling and Th1 responses were strongly correlated with reduced tumor growth rates, while pro-metastatic pathways, such as IL-4 and FAK signaling and Phagosome Formation, may contribute to the increased metastatic potential of slow-growing tumors in our model. Further investigation is needed to elucidate the role of these pathways in the age-dependence of breast cancer. Our findings may ultimately lead to improved diagnosis and personalized therapeutic targets to extend the lives of breast cancer patients.

P4-02-21: Disparities among patients evaluated in dedicated high-risk breast cancer clinic

Helen Yuan, Erin Biggs, Joshua King, Adam Salup, Jessica Baudier, Erica Doubleday, Peggy Jo Alker, Raina Saxena, Melanie Sheen, Caitlin Taylor

Background: Annual screening mammogram is recommended for all women aged 40 years and older, as early detection of breast cancer leads to increased overall survival and better outcomes. During mammography, various risk factors such as age, BMI, and family history influence the risk of breast cancer. These data points, along with breast density classification, are used to calculate a Tyrer-Cuzick (TC) score, which estimates both the ten year and lifetime risk of breast cancer as a percentage. If the TC lifetime risk score percentage is ≥20%, the patient is considered to be at high risk for breast cancer and qualifies to be seen in high-risk breast cancer clinic to discuss additional recommendations beyond the annual screening mammogram. These recommendations include annual breast MRI, consideration of risk reduction strategies and genetic counseling. While previous studies have established that breast density and BMI are risk factors in developing breast cancer, few have explored the characteristics and trends among high-risk breast cancer patients. We hypothesize that patterns may exist among race, breast density, breast imaging
