GS1-01: Imlunestrant, an Oral Selective Estrogen Receptor Degrader (SERD), as Monotherapy & Combined with Abemaciclib, for Patients with ER+, HER2- Advanced Breast Cancer (ABC), Pretreated with Endocrine Therapy (ET): Results of the Phase 3 EMBER-3 trial

Komal Jhaveri, Patrick Neven, Monica Lis Casalnuovo, Sung-Bae Kim, Eriko Tokunaga, Philippe Aftimos, Cristina Saura, Joyce O'Shaughnessy, Nadia Harbeck, Lisa A. Carey, Giuseppe Curigliano, Antonio Llombart-Cussac, Elgene Lim, María de la Luz García Tinoco, Joohyuk Sohn, André Mattar, Qingyuan Zhang, Chiun-Sheng Huang, Chih-Chiang Hung, Jorge Luis Martinez Rodriguez, Manuel Ruiz Borrego, Rikiya Nakamura, Kamnesh R. Pradhan, Christoph Cramer von Laue, Emily Barrett, Shanshan Cao, Xuejing Aimee Wang, Lillian M. Smyth, François-Clément Bidard

Background: Imlunestrant is a next-generation, brain-penetrant, oral SERD and pure estrogen receptor (ER) antagonist that delivers continuous ER inhibition, including in ESR1-mutant cancers.

Methods: This phase-3, randomized, open-label trial (NCT04975308) enrolled patients (pts) with ER+, HER2- ABC that recurred or progressed on/after an aromatase inhibitor, alone or with a CDK4/6 inhibitor (CDK/6i). No other prior therapy for ABC was allowed. Pts were randomized 1:1:1 to imlunestrant (400 mg once daily [QD]), physician's choice standard-of-care (SOC) ET (fulvestrant or exemestane per label), or imlunestrant (400 mg QD) + abemaciclib (150 mg twice daily). Primary endpoints were investigator-assessed PFS of imlunestrant vs SOC in pts with ESR1 mutations (ESR1m) and all pts and of imlunestrant + abemaciclib vs imlunestrant in all concurrently randomized pts. Secondary endpoints included OS (tested if the corresponding PFS was statistically significant), PFS by BICR, ORR, and safety.

Results: Overall, 874 pts were randomized (imlunestrant, n=331; SOC, n=330; imlunestrant + abemaciclib, n=213), 60% received prior CDK4/6i (imlunestrant, 59%; SOC, 57%; imlunestrant + abemaciclib, 65%). A total of 256 pts had ESR1m (imlunestrant, n=138; SOC, n=118). Imlunestrant significantly improved PFS vs SOC in pts with ESR1m (HR, 0.62; 95% CI, 0.46-0.82; P<0.001; median PFS [mPFS] 5.5 vs 3.8 months). Imlunestrant did not significantly improve PFS in the overall population (n=661; HR, 0.87; 95% CI, 0.72-1.04; P=0.12). Imlunestrant + abemaciclib significantly improved PFS vs imlunestrant in all pts (n=426; HR, 0.57; 95% CI, 0.44-0.73; P<0.001; mPFS 9.4 vs 5.5 months), with benefit observed regardless of ESR1m or PI3K pathway mutation status and in CDK4/6i pretreated pts. Investigator and BICR assessments were consistent across all endpoints. In all pts with measurable disease, ORR was 12% for imlunestrant; 8% for SOC; and 27% for imlunestrant

+ abemaciclib. All OS analyses were immature and ongoing; favorable trends were observed for imlunestrant vs SOC in pts with ESR1m (31% events; HR, 0.55; 95% CI, 0.35-0.86; P<0.01 [not statistically significant]) and in all pts (23% events; HR, 0.69; 95% CI, 0.50-0.96; [not inferentially tested]). OS analyses were less mature for imlunestrant + abemaciclib vs imlunestrant (15% events; HR, 1.34; 95% CI, 0.81-2.21; P=0.25). In post-hoc analyses, imlunestrant had lower 12-month cumulative incidence of central nervous system progression vs SOC in pts with ESR1m (2% vs 7%; HR, 0.18; 95% CI, 0.04-0.90) and all pts (2% vs 3%; HR, 0.47; 95% CI, 0.16-1.38), though absolute numbers were small.

Common all-grade TEAEs with imlunestrant were fatigue (23% vs 13% SOC), diarrhea (21% vs 12%), and nausea (17% vs 13%), mostly grade 1. Notably, all-grade bradycardia (2% vs 0% SOC), photopsia (0% each), and dyslipidemia (7% vs 9%) were infrequent or not observed with imlunestrant. Common grade ≥3 TEAEs with imlunestrant were anemia (2% vs 3% SOC), and neutropenia (2% each). Common all-grade/grade ≥3 TEAEs with imlunestrant + abemaciclib were diarrhea (86%/8%), nausea (49%/2%), and neutropenia (48%/20%). Grade ≥3 TEAEs rates were 17% for imlunestrant, 21% for SOC and 49% for imlunestrant + abemaciclib. Discontinuation of imlunestrant and imlunestrant + abemaciclib due to AEs was low (4% and 6%, respectively). Conclusion: Imlunestrant significantly improved PFS vs SOC in pts with ESR1m, and imlunestrant + abemaciclib significantly improved PFS vs imlunestrant in all pts regardless of ESR1m status. Imlunestrant had a favorable safety profile alone and combined with abemaciclib, thus providing an all-oral targeted therapy option for ET-pretreated pts with ER+, HER2- ABC.

GS1-03: Pyrotinib or placebo in combination with trastuzumab and docetaxel for untreated HER2-positive metastatic breast cancer (mBC): prespecified final analysis of progression-free survival (PFS) of the phase 3 PHILA trial

Binghe Xu, Fei Ma, Min Yan, Wei Li, Quchang Ouyang, Zhongsheng Tong, Yuee Teng, Yongsheng Wang, Shusen Wang, Cuizhi Geng, Ting Luo, Jincai Zhong, Qingyuan Zhang, Qiang Liu, Xiaohua Zeng, Tao Sun, Qinguo Mo, Hu Liu, Ying Cheng, Jing Cheng, Xiaojia Wang, Jianyun Nie, Jin Yang, Xinhong Wu, Xinshuai Wang, Huiping Li, Changsheng Ye, Yang Fan, Jiaman Lin, Xiaoyu Zhu

Background: The interim analysis of the PHILA trial (NCT03863223) revealed that pyrotinib (an irreversible tyrosine kinase inhibitor targeting EGFR, HER2, and HER4) in combination with trastuzumab and docetaxel (PyroHT) significantly improved PFS compared to placebo in combination with trastuzumab and docetaxel (HT) in untreated HER2-positive mBC patients (Ma et al., BMJ, 2023). However, the overall survival (OS) data was immature at that time. Here, we present the prespecified final analysis of PFS, as well as long-term efficacy and safety outcomes from the PHILA trial following an additional 2-year of follow-up.
Methods: The PHILA study was a randomized, double-blind, multicenter, phase 3 trial

conducted at 40 centers in China. Eligible patients were randomly assigned in a 1:1 ratio to receive either oral pyrotinib (400 mg once daily) or placebo, both in combination with intravenous trastuzumab (8 mg/kg in the first cycle and 6 mg/kg in subsequent cycles) and docetaxel (75 mg/m2) on day 1 of each 21-day cycle. The primary endpoint was investigator-assessed PFS. The data cutoff date for this final analysis of PFS was April 30, 2024.

Results: Between May 2019 and January 2022, 590 eligible patients were randomized and received their allocated treatment (297 patients in the PyroHT group and 293 patients in the HT group). The median follow-up duration was 35.7 months for the PyroHT group and 34.3 months for the HT group. The benefit of investigator-assessed PFS associated with the PyroHT group, compared to the HT group, was sustained in this final analysis (22.1 months [95% CI 19.3–27.8] vs 10.5 months [95% CI 9.5–12.4], HR 0.44 [95% CI 0.36–0.53]; 1-sided P<0.0001), meeting the protocol-prespecified criteria for statistical significance. The PFS rates were 92.8% in the PyroHT group and 84.1% in the HT group at 6 months, 74.3% and 46.8% at 1 years, 47.6% and 20.2% at 2 years, and 39.7% and 9.9% at 3 years, respectively. Additionally, the benefits in PFS with PyroHT were observed across nearly all analyzed subgroups. As of the data cutoff, 59 patients (19.9%) in the PyroHT group and 87 patients (29.7%) in the HT group had died. The OS exhibited superiority in the PyroHT group compared to the HT group, with a HR of 0.64 (95% CI 0.46–0.89; 1-sided P=0.0038). The estimated Kaplan–Meier OS rates were 96.6% in the PyroHT group and 94.5% in the HT group at 1 year, 88.7% and 84.1% at 2 years, 80.9% and 72.4% at 3 years, and 74.5% and 64.3% at 4 years, respectively. The safety profiles in the updated analysis remained consistent with those reported in the previous interim analysis in terms of frequency, severity, and specificity. No new safety signals were identified. Grade ≥3 treatment-related adverse events were reported in 270 patients (90.9%) in the PyroHT group and 227 patients (77.5%) in the HT group, with decreased neutrophil count (63.0% vs 64.8%) and decreased white blood cell count (53.2% vs 50.9%) being the most frequent. Grade 3 diarrhea was predominantly observed during the first cycle and notably decreased in subsequent cycles, with no grade 4 or 5 diarrhea events reported. Treatment-related serious adverse events were experienced by 27.3% vs 7.5% of patients, and treatment-related deaths occurred in 0% vs 0.3% of patients in the PyroHT and HT groups, respectively.

Conclusion: After an extended follow-up period, the updated analysis demonstrates that PyroHT provides sustained longer PFS compared to HT, which translates into longer OS for PyroHT than HT in the first-line treatment of HER2-positive mBC. The safety profile of PyroHT remained manageable throughout the extended treatment duration. This updated analysis further reinforces PyroHT as a well-established and efficacious therapeutic strategy for this patient population.

GS1-04: HER2-Directed Antibody-Drug Conjugate SHR-A1811 in the Neoadjuvant Treatment of HER2-positive Early Breast Cancer: a Prospective, Randomized, Open-label, Phase 2 Trial

Junjie Li, Zhong-Hua Wang, Li Chen, Wen-Juan Zhang, Linxiaoxi Ma, Jiong Wu, Guang-Yu Liu, Yi-Feng Hou, Ke-Da Yu, Geng-Hong Di, Lei Fan, Yi-Zhou Jiang, Shu-Hao Jiang, Qian-Nan Liang, Yu Shen, Zhi-Ming Shao

Background: Standard neoadjuvant regimens for HER2 positive breast cancer include trastuzumab and pertuzumab combined with chemotherapy. No data has been reported for the efficacy and safety of HER2-direted Antibody-drug conjugate (ADC) monotherapy or combined with Tyrosin kinase inhibitor (TKI) in the neoadjuvant setting. We assessed the antitumor activity and safety of a novel ADC SHR-A1811 in neoadjuvant treatment of HER2+ breast cancer.

Methods: This open label, randomized, phase 2 study enrolled 265 HER2 positive patients, aged 18 years or older with stage II–III disease. Patients were randomly assigned (1:1:1) to receive nab-paclitaxel (100mg/m2 i.v. day 1, day 8, and day 21 in a 28-day per cycle) combined with carboplatin(AUC 1.5 i.v. day 1, day 8, and day 21 in a 28-day per cycle), trastuzumab(initial dose 8mg/kg, subsequent dose 6mg/kg i.v. every 3weeks), and pertuzumab (initial dose 840mg, subsequent dose 420mg i.v. every 3weeks) for 6 cycles (PCbHP), SHR-A1811 monotherapy (4.8mg/kg i.v. day 1 every 3weeks) for 8 cycles, or SHR-A1811 with pyrotinib (240mg orally once a day daily) for 8 cycles. SHR-A1811 is composed of anti-HER2 antibody trastuzumab, a cleavable linker, and the topoisomerase I inhibitor payload SHR169265 with a DAR of 5.7. Primary endpoints were pathological complete response (pCR) in all randomly assigned patients in the intention-to-treat population. This study is registered with ClinicalTrials.gov (NCT05582499).

Findings: 265 patients were randomly assigned, 90 to PCbHP, 87 to mono-SHR-A1811, 88 to SHR-A1811 plus pyrotinib. Baseline characteristics were well balanced between the treatment groups, about 45% were Hormone receptor (HR) positive, 70% were stage III. The pCR rate was 63% in mono-SHR-A1811 (44% in HR+ and 78% in HR-), 62% in SHR-A1811 plus pyrotinib (44% in HR+ and 76% in HR-) and 66% in PCbHP (54% in HR+ and 75% in HR-), with no statistical difference between each group. Grade 3 or higher adverse events occurred 45% in mono-SHR-A1811, 72% in SHR-A1811 plus pyrotinib and 34% in PCbHP. 1 patient occurred grade 2 interstitial lung disease in SHR-A1811, 9% patients occurred grade 3 diarrhea in SHR-A1811 plus pyrotinib, no treatment related death was occurred.

Interpretation: This is the first study to report the efficacy of third generation HER2-directed ADC in the neoadjuvant setting of HER2 positive breast cancer. SHR-A1811 exhibited promising antitumor activity and acceptable tolerability, with monotherapy pCR rate up to 63%.

GS1-06: PRO B - a superiority randomized controlled trial evaluating the effects of symptom monitoring in metastatic breast cancer patients

Maria Margarete Karsten, Pimrapat Gebert, Therese Pross, Anna M. Hage, Adam Dordevic, Susan Stephan, Friedrich Kühn, Lea Doppelbauer, Jens-Uwe Blohmer, Felix Fischer, Matthias Rose, Anna Pöhlmann, Bianca Materne, Morten Aagaard Petersen, Luis Pauler, Julia Ferencz, Simone Wesselmann, Clara Breidenbach, Ulrike Grittner, PRO B Investigators, Christoph Kowalski

Despite improved treatment options up to 30% of patients with breast cancer develop distant metastases. With their detection the treatment focus changes from cure to prolonging survival and maintaining the best possible quality of life (QoL). There is increasing evidence that the use of Patient Reported Outcomes (PRO) can help to achieve these goals. The PRO B study examined the impact of a weekly PRO monitoring combined with an automated alert system in advanced breast cancer patients within the routine care in the German health care system.

Methods: The PRO B trial, a multi-center, superiority, randomized controlled trial, enrolled 924 patients from 52 certified breast centers between 05/2021 and 06/2023. Patients were randomized in a 1:1 ratio, stratified by hormone receptor (HR) status and localization of metastases present at time of randomization. Patients in the intervention arm received a weekly questionnaire to their smartphone consisting of items selected from the EORTC CAT Core item banks for optimized assessment of QLQ-C30 domains. In case of deteriorating PRO values, an automated alert was sent to the treating breast center, which then contacted the patient within 48 hours to inquire about the reported symptoms and to intervene, if necessary. Patients in the control arm received PRO questionnaires every 3 months, but were not connected to the alert system. Primary endpoint was patient-reported fatigue at 6 months post-randomization. Secondary endpoints included physical functioning (PF), QoL, and subgroup-specific overall survival (OS). The comparison of PRO values between study arms was performed using linear mixed models with adjustment for baseline PRO and other confounders.

Results: 909 patients were included in the main analysis (456 in the intervention and 453 in the control arm. Mean age at randomization was 50.7 (range 19-81) in the intervention vs. 51.1 (range 25-83) years in the control arm. 726 (79.9%) patients had HR+ disease, 366 in the intervention vs. 360 in the control arm. 183 patients presented with HR- breast cancer, 90 in the intervention vs. 93 in the control arm. 178 patients self-reported an ECOG 0 (21.5% vs. 18.5%), 496 an ECOG 1 (53.7% vs. 57.8%) and 216 ECOG 2 or worse (24.8% vs. 23.7%) at baseline. Median follow-up time was 64 (IQR 37 – 100) and 52 (IQR 26 – 91) weeks in the intervention and control arms, respectively. During the study period a total of 39,817 questionnaires were sent, 36,845 to the intervention and 2,972 to the control arm. The return rate at 6 months was 80% vs. 61%, at 12 months 72% vs. 51%. Patients in the intervention arm reported a fatigue T-score of 57.6 (SD 9.5) at baseline vs. 60.2 (SD

9.0) for the control arm. After 6 months, the fatigue T-score in the intervention arm was significantly lower than in the control arm (54.5 vs. 59.9, mean difference = -5.4 [95%CI: -6.6 to -4.1], p<0.001) after adjustment for baseline fatigue score. Similar significant differences were observed at 3, 9, and 12 months between both arms. Moreover, the PF and QoL T-scores in the intervention arm were significantly better than those in the control arm over the study period. OS in the intervention arm was better than the control arm (OS rate at 12 months 88% vs. 85%, HR 0.71 [95%CI: 0.51 to 0.99], p=0.043). Additionally, similar results were observed in patients with visceral metastases (HR 0.46 [95%CI: 0.12 to 1.82]) and patients with HR+/Her2- (HR 0.71 [95%CI: 0.48 to 1.04]).

Conclusions: Our study provides further evidence that integrating alerts based on PRO monitoring into routine care of advanced breast cancer patients leads to improved symptom control and better functioning scores. Alert-based PRO monitoring significantly decreased levels of fatigue, improved physical functioning and overall quality of life. A benefit in overall survival was observed in the intervention as well as in a subgroup-specific analysis. Based on these findings PRO monitoring should become standard of care for advanced breast cancer patients.

GS1-08: Association between risk-reducing surgeries and survival in young BRCA carriers with breast cancer: results from an international cohort study

Matteo Lambertini, Amir Sonnenblick, Elisa Agostinetto, Raphaëlle Bas, Hee Jeong Kim, Maria Alice Franzoi, Rinat Bernstein Molho, Sabine Linn, Ava Kwong, Katarzyna Pogoda, Judith Balmana, Ann Smeets, Jyoti Bajpai, Halle C.F. Moore, Ann H. Partridge, Kelly-Anne Phillips, Angela Toss, Christine Rousset-Jablonski, Fedro A. Peccatori, Tiphaine Renaud, Alberta Ferrari, Shani Paluch-Shimon, Pablo Mando, Jeong Eon Lee, Robert Fruscio, Wanda Cui, Stephanie M. Wong, Claudio Vernieri, Kathryn J. Ruddy, Maria Vittoria Dieci, Alexios Matikas, Mariya Rozenblit, Deniz Can Guven, Minna Lee, Cynthia Villarreal-Garza, Shelley E. Hwang, Laura De Marchis, Fabio Puglisi, Zoe Kemp, Pedro A. Meireles, Anastasia Parokonnaya, Gustavo Werutsky, Maiko Okano, Hatem A. Azim Jr., Kleida Mati, Shoshana Rosenberg, Richard Gelber, Luca Boni, Eva Blondeaux

Background: In carriers of germline pathogenic/likely pathogenic variants (PVs) in *BRCA1* and/or *BRCA2* genes, cancer risk management strategies are widely recommended. While risk-reducing salpingo-oophorectomy (RRSO) has shown to improve overall survival (OS), bilateral risk-reducing mastectomy (RRM) reduces the risk of developing breast cancer (BC) but has no proven OS benefit. Very limited evidence exists on RRSO and/or RRM specifically in *BRCA* carriers with prior BC diagnosis at a young age.

Here we investigated the association between RRM and/or RRSO with survival outcomes in the largest global cohort of young *BRCA* carriers with BC.

Methods: The BRCA BCY Collaboration (NCT03673306) is an international, multicenter, hospital-based, retrospective cohort study including women harboring germline *BRCA1* and/or *BRCA2* PVs and diagnosed between January 2000 and December 2020 with stage I-III invasive BC at the age of 40 years or younger. Patients with no information on uptake or timing of RRM and/or RRSO, or their uptake before BC diagnosis and *BRCA* healthy carriers were excluded.

Primary endpoint was OS. Disease-free survival (DFS) and BC-free interval (BCFI) were secondary endpoints. Survival endpoints were computed from BC diagnosis.

To account for potential lead time bias, in the primary analysis Cox models were used to explore the association between RRM and RRSO both included as time-dependent covariates and survival outcomes. Stratification factors were year at BC diagnosis, region/country and nodal status; OS models were also adjusted by development of distant recurrences/second primary malignancies as time-dependent covariates. In addition, sensitivity analyses were performed including a 3-year landmark analysis and a subgroup analysis including only patients tested for *BRCA* before or within 6 months from BC diagnosis.

Results: From 109 centers in 5 continents, 5290 patients were included. Median age at BC diagnosis was 35 years (IQR 31-38). A total of 3361 (63.5%) patients were *BRCA1* carriers, 2708 (51.2%) had node-negative and 2421 (45.8%) hormone receptor-positive (HR+) BC.

A total of 2910 (55.0%) patients underwent RRM and 2782 (52.6%) RRSO. Median time from BC diagnosis to RRM was 0.8 years (IQR 0.5-2.7) and to RRSO was 3.0 years (IQR 1.3-6.8); median follow-up was 5.1 years (IQR 2.7-8.3) after RRM and 4.9 years (IQR 2.3-8.1) after RRSO.

At a median follow-up of 8.2 years (IQR, 4.7-12.8), 686 (13.0%) OS, 1923 (36.3%) DFS and 1751 (33.1%) BCFI events were observed.

RRM was associated with a significantly reduced risk of OS events (adjusted HR [aHR] 0.65, 95% CI 0.53-0.78). This association was observed irrespective of specific *BRCA* gene, age at BC diagnosis, tumor subtype, tumor size and nodal status. RRM was also associated with a significantly reduced risk of DFS (aHR 0.58, 95% CI 0.52-0.65) and BCFI (aHR 0.55, 95% CI 0.48-0.62) events.

RRSO was associated with a significantly reduced risk of OS events (aHR 0.58, 95% CI 0.48-0.71). This association was observed irrespective of age at BC diagnosis, tumor size and nodal status. A significant interaction was observed according to specific *BRCA* gene (*BRCA1* carriers: aHR 0.44, 95% CI 0.34-0.57; *BRCA2* carriers: aHR 0.85, 95% CI 0.64-1.15) and tumor subtype (triple-negative BC: aHR 0.44, 95% CI 0.33-0.58; HR+ BC: aHR 0.80, 95% CI 0.60-1.05). RRSO was also associated with a significantly reduced risk of DFS (aHR 0.68, 95% CI 0.61-0.77) and BCFI (aHR 0.65, 95% CI 0.57-0.74) events.

Sensitivity analyses provided consistent results.

Conclusions: In this unique international cohort of *BRCA* carriers with prior BC diagnosis at a young age, RRM and RRSO were both associated with a significant improvement in OS, DFS and BCFI. These findings are critical for improving the counseling of young *BRCA* carriers with BC on cancer risk management strategies.

GS1-09: OlympiA: A phase 3, multicenter, randomized, placebo-controlled trial of adjuvant olaparib after (neo)adjuvant chemotherapy in patients w/ germline BRCA1 & BRCA2 pathogenic variants & highrisk HER2-negative primary breast cancer:

Judy Garber, David Cameron, Christine Campbell, Greg Yothers, Maria Taboada, Sarra El-Abed, Priya Rastogi, Vicki Paterson, Jinyu Kang, Stephanie Zafonte, Liu Xiaochun, Giuseppe Viale, Tanja Spanic, Rita Schmutzler, Martine Piccart, Sibylle Loibl, Barbro Linderholm, Sunil R. Lakhani, Larissa Korde, Michael Gnant, Karen Gelmon, Sue Friedman, Tanner Freeman, Susan M. Domchek, Gursel Aktan, Richard D. Gelber, Charles E. Geyer, Jr., Andrew N.J. Tutt

Background The OlympiA trial (NCT02032823) compared 1 year of adjuvant oral poly(adenosine diphosphateribose) polymerase inhibitor olaparib (OL) to matching placebo (PL) in a randomized trial of 1836 patients (pts) with pathogenic or likely pathogenic variants in germline BRCA1 or BRCA2 (gBRCApv) and high-risk human epidermal growth factor receptor 2 (HER2)-negative primary breast cancer (BC) who had completed all (neo)adjuvant chemotherapy, surgery and radiation. The first pre-specified interim analysis (IA) demonstrated statistically significant improvements in invasive disease-free survival (IDFS) and distant disease-free survival (DDFS). The second IA demonstrated statistically significant improvement in OS and maintained improvement in IDFS and DDFS, irrespective of hormone receptor status, prior platinum administration, timing of prior chemotherapy or type of gBRCApv. No excess acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS) was observed. This updated analysis reports the results of the third pre-specified IA with median follow-up (MFU) of 6.1 years (maximum, 9.6 years). Methods Descriptive analyses are presented with longer-term follow-up comparing the primary endpoint IDFS, and key secondary endpoints DDFS and OS, across two arms: oral OL 300mg BID versus PL. Estimates of the hazard ratio (HR) based on the stratified Cox's Proportional Hazards Model and 95% confidence intervals (CI) are presented for each endpoint with event rates reported at the 6 year (yr) MFU. Safety analyses including adverse events of special interest (AESIs) and all deaths are highlighted. Results With longer follow-up, the benefit of OL in terms of IDFS, DDFS and OS was maintained with effect sizes similar to those reported in previous analyses. For IDFS, HR=0.65 (95% CI: 0.53, 0.78); 6-yr IDFS percents (OL vs PL): 79.6% vs 70.3% (diff. 9.4%; 95% CI, 5.1%, 12.7%). For DDFS, HR=0.65 (95% CI: 0.53, 0.81); 6-yr DDFS percents (OL vs PL): 83.5% vs 75.7% (diff. 7.8%; 95% CI, 3.8%, 11.5%). For OS, HR 0.72 (95% CI: 0.56, 0.93); 6-yr OS percents (OL vs PL): 87.5% vs 83.2% (diff. 4.4%; 95% CI, 0.9%, 6.7%). Total deaths/pts were 107/921 vs 143/915 in OL and PL, respectively. OL benefit was consistent across all key subgroups, including for pts with high-risk, hormonereceptor-positive disease. Fewer BRCA-associated cancers were reported with OL

vs PL: contralateral invasive BC (31 vs 40); contralateral non-invasive BC (3 vs 4), new primary ovarian cancer (3 vs 9), new primary fallopian tube cancer (1 vs 4). The percent of pts experiencing AESIs was lower with OL vs PL (6.3% vs 9.3%), comprising MDS or AML (OL, n=4; PL, n=6), pneumonitis (OL, n=9; PL, n=13), and fewer new primary cancers overall (OL, n=45; PL, n=68). Conclusions At 6.1 years MFU, one year of adjuvant OL after (neo)adjuvant chemotherapy continues to demonstrate meaningful improvements in IDFS, DDFS and OS in pts with gBRCApv and high-risk, HER2-negative primary BC, including all key subgroups, and with acceptable toxicity and no evidence of increased risk of MDS or AML. These data continue to highlight the importance of gBRCApv testing in high-risk, HER2-negative primary BC.

GS2-01: Exclusive endocrine therapy or radiation therapy in women aged 70+ years with luminal-like early breast cancer (EUROPA): preplanned interim analysis of a randomized phase 3 trial

Icro Meattini, Maria Carmen De Santis, Luca Visani, Marta Scorsetti, Alessandra Fozza, Bruno Meduri, Fiorenza De Rose, Elisabetta Bonzano, Agnese Prisco, Valeria Masiello, Eliana La Rocca, Ruggero Spoto, Carlotta Becherini, Gladys Blandino, Luca Moscetti, Riccardo Ray Colciago, Francesca Martella, Lorenzo Vinante, Sara Ramella, Marco Gatti, Sara Pedretti, Patrizia Vici, Nadia G. Di Muzio, Alice Pastorino, Maria Cristina Leonardi, Ivica Ratosa, Jure Verbancic, Riccardo A. Audisio, Etienne Brain, Saverio Caini, Marije Hamaker, Orit Kaidar-Person, Matteo Lambertini, Livia Marrazzo, Calogero Saieva, Tanja Spanic, Vratislav Strnad, Sally Wheelwright, Philip M. P. Poortmans, Lorenzo Livi, on behalf of the EUROPA trial Investigators

Background. Optimal therapy after breast conserving surgery (BCS) in older adults with low-risk early breast cancer (BC) is controversial. This study compares the effects of radiation therapy (RT) and endocrine therapy (ET) as exclusive treatments on health-related quality of life (HRQoL) and ipsilateral breast tumour recurrence (IBTR) rate in women aged ≥70 years with stage I luminal-like BC.
Methods. EUROPA (NCT04134598) is a phase 3, randomized, controlled trial. Women with early luminal-like BC (ER/PgR ≥10%, HER2 negative, Ki-67 index ≤20%, pT1ab N0/Nx, any grade or pT1c, grade 1-2), were 1:1 randomized after BCS to receive exclusive ET or exclusive RT. Central randomization was stratified by G8 health status (≤14 vs >14) and age at baseline (70–79 vs ≥80 years). The study coprimary endpoints are 2-year HRQoL as assessed by the global health status (GHS) scale of the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 and 5-year IBTR rate. Secondary endpoints are locoregional recurrence (LRR), contralateral BC (CBC), distant metastases (DM), BC specific- (BCSS), and overall-survival (OS) rates, adverse events, individual scale scores from QLQ-C30, QLQ-BR45, QLQ-ELD14 EORTC modules up to 5 years after treatment. We present the pre-planned interim HRQoL analysis results after at least 152 patients reached the 2-year HRQoL assessment. Data were analysed by intention to treat, using repeated mixed-effects methods.

Results. Between Feb 2021 and June 2024, 734 patients were enrolled and 731 randomly assigned to receive RT (n=365) or ET (n=366); 78.9% of the planned 926 patients from 21 centres. In the current interim analysis, the RT and ET arms included 104 and 103 patients, respectively. Age distribution was similar across treatment arms (74% aged 70-79 and 26% aged 80+ years); G8 scores were comparable (40% ≤14 and 60% scoring >14). At baseline, RT arm (n=104) had a mean GHS score of 71.9 (SD 19.05), while ET arm (n=99) had a mean score of 75.5 (SD 19.34). RT arm showed mean changes of -1.1 (24-month, SD 18.80) as compared to -10.0 (24-month, SD 25.80) of ET arm. Significant factors influencing GHS score changes were treatment type (p=0.045) and baseline GHS value (p<0.0001). Concerning adjusted mean GHS score reductions, for RT arm the mean changes were -3.77 (3-month; p=0.0452), -0.59 (6-month; p=0.7420), -4.33 (12-month; p=0.0333), and -3.40 (24-month; p=0.1314). For ET arm, mean changes were -6.45 (3-month; p=0.0015), -5.38 (6-month; p=0.0043), -6.60 (12-month; p=0.0025), and -9.79 (24-month; p<0.0001). The adjusted mean differences between RT and ET arms at 24 months showed a significant difference of 6.39 favouring RT arm (95%CI 0.14 to 12.65; p=0.0453). ET resulted in a more significant decline at 24 months in most of the functional and symptom scales of the QLQ-C30 questionnaire compared to RT. No IBTR, LRR, or DM events were reported in either group. CBC events occurred in 2 RT arm patients (1.9%) and 1 ET arm patient (1%). Deaths were 4 (3.8%) in RT arm and 2 (1.9%) in ET arm, none BC-related.
Conclusions. ET patients had significantly reduced HRQoL over 24 months compared to RT patients. These findings will help shared decision-making while awaiting final study results.

GS2-02: Impact of Tamoxifen Only after Breast Conservation Surgery for "Good Risk" Duct Carcinoma in Situ: Results from the NRG Oncology/RTOG 9804 and ECOG-ACRIN E5194 Trial

Jean Wright, Jennifer Moughan, Habib Rahbar, Amit B Shah, Christopher Comstock, Lesly A Jarvis, Judy A Tjoe, Isabelle Germain, Sunil S Badve, Eric Strom, Abram Recht, Diane C Ling, Laura A Vallow, Joseph J Stephenson, Adam Currey, Eleanor M Walker, Harold Reiter, Michael L. Steinberg, Lori J Pierce, Kathryn Winter, Joseph Sparano, Nancy E Davidson, Antonio C. Wolff, Robert J Gray, and Beryl McCormick

Background The NRG/RTOG 9804 and ECOG-ACRIN E5194 studies sub-classified duct carcinoma in situ (DCIS) into different risk groups after breast conservation surgery (BCS) based on size, DCIS grade, and margin width. NRG/RTOG 9804 randomized patients with “good risk” DCIS (size ≤2.5 cm, grade 1-2, margin ≥3mm) to whole breast radiation (RT) or none, and ECOG-ACRIN E5194 had 2 cohorts, one observing patients with the same “good risk” characteristics after BCS without RT. In both trials, the use of tamoxifen) was optional but tracked. This ancillary analysis of both trials was undertaken to assess the role of tamoxifen alone on ipsilateral breast recurrence (IBR) in this “good risk” group not receiving RT. Methods A combined database from the non-RT arm of NRG/RTOG 9804 and the “good risk” cohort from ECOG-ACRIN E5194 was created and distributions of patient and DCIS characteristics by tamoxifen use (yes vs. no) were compared using the Chi-square

test. IBR, invasive IBR, DCIS IBR and contralateral breast event (CBE) were estimated by the cumulative incidence method and distributions between tamoxifen use were compared using Gray's test. A 2-sided significance level of 0.05 was used. Univariate and multivariable Fine-Gray regression was used to analyze the effects of factors, in addition to tamoxifen use, that may be associated with endpoints. Results 878 patients were analyzed, 317 patients from NRG/RTOG 9804, and 561 from ECOG-ACRIN E5194. Median age was 59, margin width was ≥3mm or negative by re-excision in 97.8%, size was ≤5mm in 48.1%, and grade was 1-2 in 87.5%. The use of tamoxifen in the combined no-RT group was 43.1% (65.6% in NRG/RTOG 9804 and 30.3% in ECOG-ACRIN E5194). Median follow up of all patients was 14.85 years. There were 117 IBR, 65 invasive and 52 DCIS. There was a statistically significant association for reduced IBR with tamoxifen use (p=0.001); estimated 15-year IBR (95% CI) with tamoxifen is 11.4% (7.9%, 15.5%) and without is 19.0% (15.3%, 22.9%). Further analysis showed the reduction to be significantly associated with tamoxifen use for invasive IBR (p=0.0048) but not for DCIS IBR (p=0.089). No associations were seen for CBE. On univariable analysis, pathologic size (≤ 5 mm vs. > 10 mm) was significantly associated with IBR (p=0.0001) as was DCIS grade (1 vs 2, p=0.042). On multivariable analysis for IBR, DCIS grade fell out of the model and after adjusting for pathologic size, tamoxifen use remained statistically significantly associated with reduced IBR. On multivariable analysis for invasive IBR, size fell out of the model and adjusting for grade, tamoxifen use remained statistically significantly associated with reduced invasive IBR. Patients who received tamoxifen were 44% less likely to have any IBR (HR =

0.56, 95% CI: 0.38, 0.84; p=0.0044), and 51% less likely to have invasive IBR (HR=0.49, 95% CI: 0.28, 0.84; p=0.0092), as compared to patients with no tamoxifen. Conclusions For women with "good risk" DCIS who opt for BCS without RT, the use of tamoxifen is significantly associated with a reduction in IBR overall and specifically invasive IBR, not DCIS IBR.

GS2-03: Does postmastectomy radiotherapy in 'intermediate-risk' breast cancer impact overall survival? 10 year results of the BIG 2-04 MRC SUPREMO randomised trial: on behalf of the SUPREMO trial investigators

Ian Kunkler, Nicola Russell, Niall Anderson, Fidelis Muturi, Geertjan van Tienhoven, David Cameron, John Bartlett, Karen Taylor, Tammy Piper, Mike Dixon, Galina Velikova, Edwin Aird, Boon Chua, Coen Hurkmans, Karen Venables, Linda Williams, Jeremy Thomas, Marjory Maclennan, Richard Sainsbury, Susan Cleator, Eldo Verghese, Yexiong Li, Shulian Wang, Peter Canney

Background The NRG/RTOG 9804 and ECOG-ACRIN E5194 studies sub-classified duct carcinoma in situ (DCIS) into different risk groups after breast conservation surgery (BCS) based on size, DCIS grade, and margin width. NRG/RTOG 9804 randomized patients with "good risk" DCIS (size ≤2.5 cm, grade 1-2, margin ≥3mm) to whole breast radiation (RT) or none, and ECOG-ACRIN E5194 had 2 cohorts, one observing patients with the same "good

risk" characteristics after BCS without RT. In both trials, the use of tamoxifen) was optional but tracked. This ancillary analysis of both trials was undertaken to assess the role of tamoxifen alone on ipsilateral breast recurrence (IBR) in this "good risk" group not receiving RT. Methods A combined database from the non-RT arm of NRG/RTOG 9804 and the "good risk" cohort from ECOG-ACRIN E5194 was created and distributions of patient and DCIS characteristics by tamoxifen use (yes vs. no) were compared using the Chi-square test. IBR, invasive IBR, DCIS IBR and contralateral breast event (CBE) were estimated by the cumulative incidence method and distributions between tamoxifen use were compared using Gray's test. A 2-sided significance level of 0.05 was used. Univariate and multivariable Fine-Gray regression was used to analyze the effects of factors, in addition to tamoxifen use, that may be associated with endpoints. Results 878 patients were analyzed, 317 patients from NRG/RTOG 9804, and 561 from ECOG-ACRIN E5194. Median age was 59, margin width was ≥3mm or negative by re-excision in 97.8%, size was ≤5mm in 48.1%, and grade was 1-2 in 87.5%. The use of tamoxifen in the combined no-RT group was 43.1% (65.6% in NRG/RTOG 9804 and 30.3% in ECOG-ACRIN E5194). Median follow up of all patients was 14.85 years. There were 117 IBR, 65 invasive and 52 DCIS. There was a statistically significant association for reduced IBR with tamoxifen use (p=0.001); estimated 15-year IBR (95% CI) with tamoxifen is 11.4% (7.9%, 15.5%) and without is 19.0% (15.3%, 22.9%). Further analysis showed the reduction to be significantly associated with tamoxifen use for invasive IBR (p=0.0048) but not for DCIS IBR (p=0.089). No associations were seen for CBE. On univariable analysis, pathologic size (≤ 5 mm vs. > 10 mm) was significantly associated with IBR (p=0.0001) as was DCIS grade (1 vs 2, p=0.042). On multivariable analysis for IBR, DCIS grade fell out of the model and after adjusting for pathologic size, tamoxifen use remained statistically significantly associated with reduced IBR. On multivariable analysis for invasive IBR, size fell out of the model and adjusting for grade, tamoxifen use remained statistically significantly associated with reduced invasive IBR. Patients who received tamoxifen were 44% less likely to have any IBR (HR =

0.56, 95% CI: 0.38, 0.84; p=0.0044), and 51% less likely to have invasive IBR (HR=0.49, 95% CI: 0.28, 0.84; p=0.0092), as compared to patients with no tamoxifen. Conclusions For women with "good risk" DCIS who opt for BCS without RT, the use of tamoxifen is significantly associated with a reduction in IBR overall and specifically invasive IBR, not DCIS IBR.

GS2-05: Early Oncologic Outcomes Following Active Monitoring or Surgery (+/- Radiation) for Low Risk DCIS: the Comparing an Operation to Monitoring, with or without Endocrine Therapy (COMET) Study (AFT-25)

Eun-Sil Hwang, Terry Hyslop, Thomas Lynch, Marc D Ryser, Anna Weiss, Anna Wolf, Kelsey Norris, Meredith Witten, Lars Grimm, Stuart Schnitt, Sunil Badve, Rachel Factor, Elizabeth Frank, Deborah Collyar, Desiree Basila, Donna Pinto, Mark A Watson, Robert West, Louise Davies, Jenny Donovan, Ayako Shimada, Yutong Li, Yan Li, Antonia V Bennett, Shoshana

Rosenberg, Jeff Marks, Eric Winer, Marc Boisvert, Armando Giuliano, Kelsey Larson, Kathleen Yost, Priscilla McAuliffe, Lisa Carey, Alastair Thompson, Ann H Partridge

Background: Over 50,000 women in the United States will be diagnosed with ductal carcinoma in situ (DCIS) this year alone. Almost all of these diagnoses will be made in completely asymptomatic individuals with a highly variable risk of progression to invasive cancer. In some low-risk malignancies, “watchful waiting,” is offered as a treatment option. Such an approach is likely reasonable for some DCIS and could reduce the harms of treatment while helping to identify those most likely to benefit from more aggressive therapy. To date, this approach has not been tested in a clinical trial setting. Methods: The COMET study (Comparing an Operation to Monitoring, with or without Endocrine Therapy for low risk DCIS; AFT-25) is a large pragmatic randomized non-inferiority trial that compares oncologic outcomes between patients randomized to guideline concordant care (GCC; surgery +/- radiation therapy) or active monitoring (AM). The study population were women seeking treatment for DCIS at one of the Alliance Clinical Trial sites. Eligible participants were age>40 with low-intermediate grade estrogen and/or progesterone receptor positive, HER2 receptor negative (if HER2 tested) DCIS on core biopsy without microinvasive or invasive cancer. The choice for endocrine therapy was offered in both groups. Participants in the AM group had surgical intervention only upon diagnosis of invasive progression. All study endpoints were collected prospectively. Results: This is the first planned interim Intention-to-Treat (ITT) analysis of the COMET trial primary endpoints at a median follow up of XX months. We will present patient characteristics for the 997 participants who enrolled in the study and were randomized to either GCC or AM. The primary endpoint to be presented is whether the ipsilateral invasive cancer rate for AM is non-inferior to that for GCC. Characteristics of invasive cancer events in the two groups will be compared. Secondary endpoints (rates of mastectomy, radiation, chemotherapy) and survival endpoints between groups will also be presented. Conclusion: These data will provide the first randomized trial evidence of whether an active monitoring strategy is a safe alternative for women with low-risk DCIS. Longer-term data could support practice changing guidance as to how DCIS is managed and treated and will have future implications for treatment guidelines for these excellent prognosis patients.

GS2-06: Patient Reported Outcomes Following Active Monitoring or Surgery (+/- Radiation) for Low Risk DCIS in the Comparing an Operation to Monitoring, with or without Endocrine Therapy (COMET) Study (AFT-25)

Ann Partridge, Terry Hyslop, Shoshana Rosenberg, Antonia Bennett, Sarah Drier, Mattias Jonsson, Ayako Shimada, Yutong Li, Yan Li, Thomas Lynch, Elizabeth Frank, Deborah Collyar, Desiree Basila, Donna Pinto, Anna Weiss, Anna Wolf, Kelsey Norris, Meredith Witten, Marc Boisvert, Armando Giuliano, Kelsey Larson, Kathleen Yost, Priscilla McAuliffe, Amy Krie, Nina Tamirisa, Sonja Darai, Lisa Carey, Alastair Thompson, Shelley Hwang

Background: Data comparing patient-reported outcomes (PROs) comparing management strategies for low-risk ductal carcinoma in situ (DCIS) are lacking. Comparing an Operation to Monitoring, with or without Endocrine Therapy (COMET), for low-risk DCIS is a prospective randomized controlled trial that evaluated the effects of active monitoring (AM) compared to breast surgery (lumpectomy followed by radiation vs. unilateral mastectomy vs. bilateral mastectomy) on PROs including quality of life (QOL), anxiety, depression and specific symptoms. Methods: We compared PROs among patients who completed questionnaires at baseline prior to randomization, at 6 months and 1 year after randomization, then annually in years 2-5. Patients completed validated measures that assessed QOL, anxiety and depression and breast cancer treatment-related symptoms using the SF-36, EQ-5D-5L, a modified 19-item version of the Breast Cancer Prevention Trial (BCPT) Symptom Checklist, the Breast-Q, four items from the Quality of Life in Adult Cancer Survivors (QLACS), the State Trait Anxiety Inventory (STAI) scale and the Center for Epidemiologic Studies Depression Scale (CES-D-10), as well as the Breast Cancer Pain and Brief Pain Inventory. Results: We will present patient characteristics for the 997 patients who enrolled in the study and PRO questionnaire completion rates overall and within relevant subgroups to assess response bias. The analysis of differences by randomized group will include differences in the SF-36, STAI and CES-D, as well as the Breast Cancer Pain, Brief Pain Inventory and BCPT symptoms. We will also assess group differences over time and within specific subgroups (e.g., by age). Conclusion: In this analysis of PROs after active monitoring or surgical +/- radiation management for low-risk DCIS, quality of life, anxiety, depression and symptom patterns (severity, recovery, decline etc.) likely differed between the two groups; how they differed will be presented and whether these differences persisted over time.

GS2-07: No axillary surgery versus axillary sentinel lymph node biopsy in patients with early invasive breast cancer and breast-conserving surgery: Final primary results of the Intergroup-Sentinel-Mamma (INSEMA) trial

Toralf Reimer, Angrit Stachs, Kristina Veselinovic, Thorsten Kuhn, Jorg Heil, Silke Polata, Frederik Marme, Thomas Muller, Guido Hildebrandt, David Krug, Beyhan Ataseven, Roland Reitsamer, Andrea Stefek, Carsten Denkert, Inga Bekes, Dirk Michael Zahm, Marc Thill, Michael Golatta, Johannes Holtschmidt, Michael Knauer, Valentina Nekljudova, Sibylle Loibl, Bernd Gerber on behalf of the INSEMA investigators

Background: Axillary nodal status is an important prognostic factor in breast cancer (BC), guiding (neo)adjuvant systemic treatment and postoperative radiotherapy. As axillary surgery does not significantly affect BC mortality itself, it is considered as a staging procedure in clinically node-negative patients. The replacement of axillary lymph node dissection (ALND) by sentinel lymph node biopsy (SLNB) two decades ago and later omitting completion ALND (cALND) according to the ACOSOG Z0011 criteria led to surgical de-escalation. The Intergroup-Sentinel-Mamma (INSEMA) trial (NCT02466737) aims to investigate whether surgical axillary staging as part of breast-conserving therapy (BCT) for

early BC can be avoided without compromising oncological safety.
Study Design:
The INSEMA trial was conducted between September 2015 and April 2019 in Germany and Austria. This prospective, randomized trial compares no axillary surgery with standard SLNB in pts with early invasive BC (tumor size ≤ 5 cm; c/iT1–2 c/iN0) scheduled for BCT, including postoperative whole-breast irradiation. The primary objective is to assess whether no axillary surgery is non-inferior to SLNB regarding invasive disease-free survival (iDFS). Clinical non-inferiority is a hazard ratio (HR) below 1.271 when comparing the non-SLNB with the SLNB group. The randomization was carried out in 4:1 allocation (SLNB vs. no SLNB) because pN1a(sn) pts in the SLNB arm underwent a second randomization to either SLNB alone or cALND (key secondary outcome). The primary analysis is based on the per-protocol (PP) set. Adjusting for 1:4 randomization, 5230 pts (PP set) are needed. Assuming a 5% exclusion rate from the PP set, about 5505 pts must be randomized.
Results:
5502 eligible pts were randomized to no SLNB (n=1101) vs. SLNB (n=4401). The drop-out rate was 6.3%, leading to an intent-to-treat (ITT) population of N=5154. After excluding 296 patients (n=252 without postoperative radiotherapy), 4858 patients (no SLNB: n=962, SLNB: n=3896) were included in the PP set. The median follow-up (FU) is 73.6 months (IQR 61.3-86.4).
Patient and tumor characteristics are well-balanced between treatment arms. The median age at diagnosis was 62.0 years (range 24.0–89.0). Most pts presented with low-risk BC (78.6% pT1 stage, 98.5% hormone receptor-positive, 3.6% HER2-positive, and 3.6% G3 tumors). Significantly more pts received adjuvant chemotherapy in the SLNB arm (13.2% vs 10.7% in the no SLNB arm).
The primary analysis in the PP established non-inferiority in iDFS between study arms with a HR=0.91 (95% CI: 0.73-1.14) for no SLNB to SLNB. The estimated 5-year iDFS rates are 91.9% (89.9%-93.5%) in the non-SLNB arm and 91.7% (90.8%-92.6%) in the SLNB arm. The first iDFS events (n=525, overall 10.8%) for no SLNB vs. SLNB consist of invasive locoregional recurrences (1.9% vs. 1.4%), including axillary recurrences (1.0% vs. 0.3%), invasive contralateral BCs (1.0% vs. 0.6%), distant metastases (2.7% vs. 2.7%), secondary malignancies (3.3% vs. 3.9%), and deaths (1.4% vs. 2.4%). The estimated 5-year overall survival (OS) rates are 98.2% (97.1%-98.9%) in the non-SLNB arm and 96.9% (96.3%-97.5%) in the SLNB arm.

Conclusion: The INSEMA trial, enrolling 5500 pts, demonstrated that the omission of SLNB in clinically node-negative BC pts undergoing BCT resulted in a statistically significant non-inferior iDFS meeting the primary endpoint. INSEMA demonstrates oncological safety in all aspects when the axillary SLNB is omitted in cN0 patients with an early BC planned for primary BCT. This practice-changing concept is suitable for patients presenting with low-grade (G1/G2), hormone receptor-positive/HER2-negative invasive BC with tumor size up to 5 cm.

GS2-09: Overweight, obesity and prognosis in 206,904 women in the Early Breast Cancer Trialists' Collaborative Group (EBCTCG) database

Hongchao Pan, Richard Gray, Richard Peto, Jeremy Braybrooke, David Dodwell, Robert Hills, Rosie Bradley, Hellen Gelband, Hui Liu, Paul McGale, Carolyn Taylor, Mike Clarke, Wolfgang Janni, Marianne Ewertz, Pamela J Goodwin, Joseph Sparano, Kathy I Pritchard, Jonas Bergh, Sandra M Swain, for the Early Breast Cancer Trialists™ Collaborative Group (EBCTCG)

Background: Analyses of the 2014 EBCTCG database suggested that, in early-stage breast cancer, obesity was strongly independently associated with breast cancer mortality only in pre/peri-menopausal oestrogen-receptor-positive (ER+) disease (Pan et al ASCO 2014). Based on the far larger 2024 EBCTCG database, however, we can now test that unexpected finding and better characterise any relevance of patient characteristics to the association of body mass index (BMI) with distant recurrence and mortality.
Methods: We analysed patient-level data on time to distant recurrence and death from the 206,904 women with early-stage breast cancer (entered during 1978-2017 into 147 randomised trials) in the 2024 EBCTCG database who had BMI at entry (within two years of diagnosis) recorded as 15-50 kg/m2 and with complete information on age, ER status, tumour diameter, nodal status, and randomly allocated treatment. Information on menopausal status, tumour grade, and HER2 status was available for most participants. Cox regression was used to estimate the associations of BMI with rates of distant recurrence and breast cancer mortality, calculating hazard rate ratios (RRs) per 5 kg/m2 increase of BMI or comparing 3 BMI groups (obese: BMI 30-50 [mean 34.7]; overweight: BMI 25 to <30 [mean 27.3]; lean: BMI 15 to <25 [mean 22.2] kg/m2).
Results: Of the 206,904 women, 60% were postmenopausal at trial entry and 77% had ER+ disease. Their mean BMI was 27.1 (SD 5.6) kg/m2 and 26.0% (53,872) were obese (BMI ≥30 kg/m2). The prevalence of obesity increased from 19% in the early 1980s to 27% in the early 2010s. The overall adjusted rate ratio (RR) of first distant recurrence (ignoring any local or contralateral recurrences) was 1.06 (95% CI 1.05-1.07, p<0.0001) per 5 kg/m2 increase in BMI. The RR for overweight versus lean women was 1.07 (CI 1.04-1.10, p<0.0001), and that for obese versus lean women was 1.17 (95% CI 1.14-1.20, p<0.0001). This approximately log-linear association between BMI and the rate of distant recurrence was seen irrespective of patient or tumour characteristics, type of adjuvant systemic therapy, year of diagnosis, or time since diagnosis. In the 82,464 pre-menopausal women the RR per 5 kg/m2 increase of BMI was 1.08 (1.07-1.10, p<0.0001), and in the 124,440 post-menopausal women it was 1.05 (1.03-1.06, p<0.0001; heterogeneity between RRs p=0.0004). There was little heterogeneity between the RRs in ER+ and ER-poor disease. In the 159,119 women with ER+ disease the RR per 5 kg/m2 increase of BMI was 1.06 (1.05-1.08, p<0.0001), and in the 47,785 with ER-poor disease it was 1.06 (1.04-1.08, p<0.0001). The associations of BMI with breast cancer mortality mirrored those with distant recurrence.
Conclusion: Overweight and obesity are associated with increased distant recurrence and breast cancer mortality in all types of patients with early-stage breast cancer, but the risk associated with a substantial (e.g. 5 kg/m2) difference in BMI is only moderate.

Nevertheless, randomised assessment of the effects among overweight or obese women with early breast cancer of weight-loss interventions (perhaps utilising a GLP-1 receptor agonist) could usefully be added, using a factorial design, to some current and future adjuvant treatment trials addressing unrelated questions.

GS2-10: A long-term image-derived AI risk model for primary prevention of breast cancer

Mikael Eriksson, Kamila Czene, Christopher Scott, Shawn Stoddard, Hugh Smith, Per Hall, Celine Vachon

Background: Image-derived artificial intelligence (AI) risk models have shown promise in short-term risk assessment for improving breast cancer screening. No image-derived long-term AI risk model for primary prevention has been developed and externally validated.
Methods: We performed a two-site case-cohort study of women aged 30-90 in a population-based screening study including two screening settings in Olmsted County, Minnesota (U.S.) and the KARMA cohort (Sweden) with women recruited between 2009-2017. Median follow-up was 10 years. An image-derived AI-risk model was developed in an independent Swedish population and we report on the validation in the Olmsted/KARMA studies. Absolute 10-year risks were calculated at study entry. Time-dependent Area Under the receiver operating characteristics Curve (AUC(t)) and the ratio of expected versus observed events (E/O) were estimated. Comparison with the clinical Tyrer-Cuzick v8 model was performed in KARMA using clinical guidelines. Analyses were performed for risk of all breast cancer and restricted to invasive cancer alone.
Results: The Olmsted/KARMA case-cohorts included 8,721 women with mean age 54.4 years (SD 10.6) in the subcohort and 1,633 incident breast cancer cases with mean age 57.0 years (SD 10.6). The image-derived AI 10-year average risk was estimated as 3.85% in Olmsted and 3.16% in KARMA. The E/O ratio was 1.01 (95% CI 0.95-1.06) in Olmsted and 0.98 (95%CI 0.90-1.07) in KARMA. The 10-year AUC(t) was 0.71 (95%CI 0.68-0.73) in Mayo and 0.72 (95%CI 0.69-0.77) in KARMA. Using the National Institute for Health and Care Excellence (NICE) guidelines, considering women at 8% as high risk, 32% of breast cancers could be subject to preventive strategies in the 9.7% of women at high 10-year risk based on the AI risk model. The corresponding numbers were 7.2% and 2.2% for Tyrer-Cuzick. Results were similar when restricted to invasive cancers only.
Conclusions: The 10-year image-derived AI-risk model showed good discriminatory performance and calibration in the two case-cohorts and, showed a significantly higher discriminatory performance than the clinical Tyrer-Cuzick v8 risk model in KARMA. The image-derived AI-risk model has the potential for clinical use in primary prevention and targets up to one third of breast cancers.

GS2-11: APOBEC3 mutagenesis induces resistance-promoting genomic alterations in breast cancer

Avantika Gupta, Andrea Gazzo, Pier Selenica, Anton Safonov, Fresia Pareja, Edaise M. da Silva, David N. Brown, Yingjie Zhu, Juber Patel, Juan Blanco-Heredia, Bojana Stefanovska, Michael A. Carpenter, Xin Pei, Denise Frosina, Achim A. Jungbluth, Marc Ladanyi, Giuseppe Curigliano, Britta Weigelt, Nadeem Riaz, Simon N. Powell, Pedram Razavi, Reuben S. Harris, Jorge S. Reis-Filho, Antonio Marra, Sarat Chandarlapaty

Background: Large-scale genomic profiling has cataloged the prevalence of single base substitution (SBS) mutational signatures associated with the activity of Apolipoprotein B mRNA-editing enzyme catalytic polypeptide-like 3 (APOBEC3) cytidine deaminases in breast cancer (BC). These mutational signatures are enriched in metastatic BC (mBC) compared to early tumors indicating an association with poor prognosis and a potential function in therapy resistance and disease progression. We sought out to investigate whether APOBEC3 mutational signatures can serve as biomarkers for poor treatment outcomes and if APOBEC3 mutagenesis-driven genomic instability can induce therapy resistance in mBC.
Methods: We analyzed SBS mutational signatures in 3,880 BC samples with paired tumor-normal sequencing by the MSK-IMPACT assay using the SigMA algorithm. We utilized the detailed clinical annotation to assess the clinical characteristics of APOBEC3-dominant tumors including survival analyses on endocrine and targeted therapies. We generated cellular models of BC to investigate the molecular drivers of APOBEC3 mutagenesis and its function in promoting therapeutic resistance. We performed whole genome sequencing (WGS) of BC models and paired primary/metastatic patient samples to identify broader genomic alterations mediated by APOBEC3 activity.
Results: Building on published results, we found that APOBEC3 mutational signatures were highly prevalent in all subtypes of BC and enriched in metastatic hormone receptor-positive (HR+) and triple-negative breast cancers (TNBC) compared to unmatched primary tumors ($p < 0.0001$ for HR+/HER2-, $p < 0.01$ for HR+/HER2+ and TNBC). APOBEC3 mutational signatures were independently associated with shorter progression-free survival on antiestrogen plus CDK4/6 inhibitor combination therapy in patients with HR+ mBC (HR 1.5, 95% CI 1.2 - 1.8, $p < 0.001$). Expression of APOBEC3A (A3A) and APOBEC3B (A3B) enzymes generated APOBEC3-associated alterations including single nucleotide variants, copy number alterations (CNAs), and clustered mutations in a deamination-dependent manner, and promoted resistance acquisition of estrogen receptor-positive (ER+) BC cells to agents including an ER degrader and CDK4/6 inhibitors. In HER2+ cells, endogenous A3A-driven APOBEC3 activity was also necessary for faster resistance development against anti-HER2 therapies. WGS analyses of resistant models identified CNA events such as loss of heterozygosity in chromosome 13 exclusively in APOBEC3-positive cells. Upon exposure to the CDK4/6 inhibitor abemaciclib, these cells acquired APOBEC3-context truncating mutations in RB1 tumor suppressor gene, a well-characterized mechanism of resistance. Detailed analyses of WGS of five paired patient samples also highlighted acquired resistance-linked alterations such as PIK3CA E54XK mutations in APOBEC3-dominant

tumors, which were corroborated in paired pre/post-treatment samples in our clinical cohort. The acquisition of APOBEC3-context alterations in APOBEC3-dominant samples highlights the causality of APOBEC3 mutagenesis in driving resistance-promoting changes. Lastly, comparison of mutational signatures in the paired cohort demonstrated pre-existence of APOBEC3 signatures in 75% of pre-treatment samples that became APOBEC3-dominant post-treatment illustrating that APOBEC3 mutagenesis can be active during early stages of BC.
Conclusions: Our work reveals that APOBEC3 mutational signatures predict poor treatment outcomes of HR+ mBC. We demonstrate that APOBEC3 mutagenesis, primarily through the enzymatic activity of A3A and A3B, drives resistance to endocrine and targeted therapies by causing APOBEC3-context resistance-associated changes. We further show that the presence of APOBEC3 mutagenesis can be detected before therapy exposure and may therefore represent a valuable biomarker and therapeutic target.

GS3-01: Circulating tumor DNA surveillance in ZEST, a randomized, phase 3, double-blind study of niraparib or placebo in patients w/ triple-negative breast cancer or HER2+ BRCA-mutated breast cancer with molecular residual disease after definitive therapy

Nicholas Turner, Isabel Pimentel, David Cescon, Hiroji Iwata, Wolfgang Janni, Aleksandra Lacko, Sibylle Loibl, Hope Rugo, Gianfilippo Bertelli, Hiroshi Ishiguro, Sumainizah Sukor, Tytti Ahola, Christian Kurzeder, Erin Hofstatter, Laura Austin, Fotini Kouri, Magdalena Zajac, Cheynna Crowley, Yufei Wang, Jon Chung, Angela Silvestro, Melinda Telli

Background: Circulating tumor DNA (ctDNA) testing in plasma offers the opportunity to identify early breast cancer (BC) recurrence in patients (pts) who, despite completion of definitive therapy, have molecular residual disease (MRD). ZEST is a randomized, phase 3, double-blind trial evaluating whether niraparib can enhance disease-free survival in pts with BC and ctDNA detection (ctDNA+) without evidence of radiographic recurrence after completion of curative intent therapy. Methods: Pts with stage I–III triple negative breast cancer (TNBC) or BRCA-mutated HER2− BC were eligible. A personalized, tumor-informed ctDNA assay (Signatera) was designed based on whole-exome sequencing of tumor tissue and matched normal blood. Testing for ctDNA-based MRD began any time after the end of definitive treatment (EODT); pts with HR+ disease were allowed concurrent endocrine therapy (stable regimen). Upon ctDNA+, radiographic staging was performed. Those without evidence of metastatic disease were randomized (1:1) to niraparib (200 or 300 mg/day, depending on weight and platelet count) or placebo (PBO). Imaging was performed every 12 weeks. The primary endpoint was safety of niraparib; disease-free survival (measured as time from randomization to recurrence or death from any cause) was also assessed.

Results: As of May 8, 2024, a total of 2746 pts were prescreened; 1901 pts had ≥1 ctDNA test result (ctDNA+, 147 [8%]). Of the 1901 pts, median age was 52 (range, 22–88) years;

1683 pts (89%) had TNBC (ctDNA+, 135), and 218 (11%) had BRCA-mutated HR+ disease (ctDNA+, 12); 620 (33%) pts received neoadjuvant therapy, 643 (34%) received adjuvant therapy, and 593 (31%) received both neoadjuvant and adjuvant therapy. Due to low rates of ctDNA+, study enrollment was terminated early. ctDNA+ was 5.2% on first test of pts with ≥1 test, and 4.4% on second or subsequent test of pts with ≥2 tests. Of pts with ctDNA+ (n=147), 66% had ctDNA+ on the first test, 91% on the first or second test, and 59% were ≤6 months from EODT. Compared with pts with ctDNA undetected, pts with ctDNA+ tended to have positive lymph nodes, T3/T4 tumor size, stage III disease, residual disease after neoadjuvant therapy, and received both neoadjuvant and adjuvant therapy. Of the 147 pts with ctDNA+, 72 (49%) had radiographic recurrence upon initial staging before randomization. The rate of radiographic recurrence was 52% (51/98) at first ctDNA+ test and 44% (21/48) at second or later ctDNA+ test. Of pts with ctDNA+, 40 were enrolled and randomized (niraparib, 18; PBO, 22); 36 pts (90%) had TNBC, and 4 pts (10%) had BRCA-mutated HR+ disease. At data cutoff, 6 pts in the niraparib arm and 4 pts in the PBO arm remained on study without radiographic recurrence. Median disease-free

survival was 11.4 (95% CI, 5.7–18.2) months for niraparib vs 5.4 (95% CI, 2.8–9.3) months for PBO (hazard ratio, 0.64; 95% CI, 0.30–1.39). No new safety signals were observed for niraparib. Conclusions: The ZEST study was terminated early because of infeasibility of completing enrollment due to a low rate of ctDNA+ and a high rate of metastatic disease at the time of ctDNA+. Although ctDNA testing began any time after EODT, ctDNA+ occurred most frequently on the first test and ≤6 months from EODT. Pts, predominantly those with TNBC, had a high rate of radiographic recurrence at time of ctDNA+, consistent with early recurrence typical of TNBC. These findings have implications for future trial design, emphasizing the importance of early ctDNA testing, and careful selection of criteria defining risk of recurrence. Updated survival data and on-treatment ctDNA dynamics will be presented.

GS3-03: Impact of Anthracyclines in High Genomic Risk Node-Negative HR+/HER2- Breast Cancer

Nan Chen, Jincong Q Freeman, Sudha Yarlagadda, Aishwarya Atmakuri, Kevin Kalinsky, Lajos Pusztai, Dezheng Huo, Rita Nanda, Frederick M Howard

Background: The Anthracyclines in Early Breast Cancer (ABC) trials demonstrated no clear improvement in invasive disease-free survival with the addition of anthracycline to a taxanecontaining chemotherapy for patients with hormone receptor-positive (HR+) breast cancer. Thus, an anthracycline-free regimen is often administered for lower risk patients with HR+/HER2- disease. However, the benefit of anthracyclines for patients with high Oncotype DX recurrence score (RS) has not been studied, despite the widespread use of RS to guide the use of adjuvant therapy for HR+ patients with 0-3 positive nodes. Methods: We analyzed data from patients who received taxane + anthracycline/cyclophosphamide and similar regimens (T-AC) or taxane + cyclophosphamide (TC) chemotherapy in the TAILORx trial (NCT00310180), which enrolled patients with stage I/II, node-negative, HR+/HER2-

negative breast cancer. Patients with an RS between 11 and 25 were randomized to endocrine therapy or endocrine therapy plus chemotherapy of physicians' choice, whereas patients with an RS > 26 received chemotherapy of physician's choice. Distant recurrence-free interval (DRFI), recurrencefree interval (RFI), distant recurrence-free survival (DRFS), recurrence-free survival (RFS), and overall survival (OS) were compared using adjusted hazard ratios (aHR) controlling for age, RS, grade, tumor size, and estrogen/progesterone receptor status. Outcomes were stratified by RS > 31 and < 31. Inverse probability of treatment weighting was used to estimate adjusted 5-year event rates for these outcomes, controlling for differences in the above covariates. Restricted cubic spline regression was used to estimate aHR for receipt of TAC (versus TC) for these endpoints as a function of RS. Results: Of 2,528 cases that met eligibility, 437 were treated with T-AC and 2091 received TC. Treatment regimens in the T-AC group included anthracycline + cyclophosphamide (dose dense or standard) followed by taxane (n = 298, 68%), concurrent anthracycline, cyclophosphamide, and docetaxel (n = 59, 14%), and other anthracycline + taxane combinations (n = 80, 18%). All patients in the TC group received treatment with any taxane with cyclophosphamide. 32% had an RS >26 (n = 816) and 20% had an RS > 31 (n = 501). The mean age was 55 and median follow-up time was 7.3 years. Patients treated with T-AC had a higher RS (mean 30 vs 23), larger tumors (mean 20 mm vs 18 mm), and were more likely high grade (38% high grade vs 25%) than those treated with TC. In patients with an RS > 31 after adjusting for covariates, receipt of T-AC was associated with improved outcomes at 5 years, DRFI adjusted rate 97.5% with T-AC vs 89.4% with TC (aHR 0.27, p = 0.01), DRFS adjusted rate 96.5% with TAC vs 88.3% with TC (aHR 0.45, p = 0.03), RFI adjusted 5- year rate 95.7% with T-AC vs 87.7% with TC (aHR 0.31, p < 0.01), RFS adjusted 5-year rate 94.6% with T-AC vs 86.6% with TC; aHR 0.45, p = 0.02), and a trend towards improved OS at 5 years (adjusted rate 97.7% with T-AC vs 92.5% with TC; aHR 0.58, p = 0.22). Among cases with an RS < 31, receipt of T-AC was not associated with improved DRFI (aHR 1.12, p = 0.73), DRFS (aHR 1.09, p = 0.75), or other outcomes. Spline regression estimated the effect of T-AC over TC on DRFI at RS 20 to be aHR 0.84, (95% CI 0.30 – 1.39), at RS 30 aHR 0.63, (95% CI 0.14 – 1.12), at RS 40 aHR 0.54, (95% CI 0.18 – 0.90), and at RS 50 aHR 0.47, (95% CI 0.10 – 0.84) indicating increasing anthracycline benefit as RS increased. Conclusions: Patients with early-stage, HR+/HER2-negative breast cancer and high RS values (> 31) may benefit from adjuvant taxane and anthracycline-containing therapy more than from TC. Genomic RS testing may predict anthracycline benefit more accurately than other factors such as nodal status.

GS3-04: (Neo)adjuvant nab-PAC weekly vs sb-PAC q2w, followed by EC q2w, in genomically or clinically high-risk HR+/HER- early breast cancer according to ET-response: final survival results from the WSG ADAPT-HR+/HER2- chemotherapy-trial

Sherko Kuemmel, Gluz, O; Nitz U; von Schumann, R; Braun, M; Luedtke-Heckenkamp, K; Darsow, M; Forstbauer, H; Polata, S; Grischke, EM; Uleer, C; Aktas, B; Hoffmann, O;

Schumacher, C; zu Eulenburg, C; Kates, R; Burmeister, S; Graeser, M; Wuerstlein, R; Baehner, R; Christgen, M; Kreipe, H; and Harbeck, NBackground
In high-risk hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) early breast cancer (EBC), nanoparticle albumin-bound (nab)-paclitaxel (PAC) showed promising efficacy versus solvent-based (sb)-PAC in neoadjuvant trials. However, the optimal chemotherapy regimen and impact of pCR on survival in HR+/HER2- EBC are still unclear. In the WSG ADAPT HR+/HER2- chemotherapy trial, we saw a significantly higher pathological complete response (pCR) in the neoadjuvant cohort. Here, we present final survival results from the chemotherapy part of the ADAPT HR+/HER2- trial utilizing clinical risk or Oncotype DX® recurrence score (RS) and endocrine therapy (ET) response (by post-endocrine Ki-67 after 2-4 weeks of induction standard ET) for therapy stratification.
Methods
Within the WSG-ADAPT trial (NCT01779206), high-risk HR+/HER2- EBC patients were randomized to (neo)adjuvant 4 x sb-PAC 175 mg/m2 q2w or 8 x nab-PAC 125 mg/m2 q1w, followed by 4 x EC (90 mg/m2 / 600 mg) q2w.
Inclusion criteria for the chemotherapy trial comprised: (i) c/pN0-1, RS 12-25, and post-ET Ki-67 >10 %; (ii) cN0-1 with RS >25. Patients with cN2-3 or G3, baseline Ki-67 >40 %, and tumor size >1 cm were allowed to be included without RS and/or ET response-testing. 2,242 patients were required to test superiority of 8 x nab-PAC weekly vs. 4 x PAC q2w regarding iDFS after 317 invasive events or 5 years of completed follow-up.
Results
2,233 patients were randomized (1,129 / 1,104), median age was 51.0/ 51.0, clinical (in neoadjuvant chemotherapy-treated patients) or pathological N2-3 status was 19.5 % vs. 18.3 %, RS >25 occurred in 48.2 % vs. 50.7 % of the patients, and G3 tumors in 56.1 % vs. 57.5 %; ET-responders were 22 % in each treatment arm. Survival results: There was a trend for nab-Pac towards a better 5y-iDFS (85.7% versus 82.9%) compared to sb-Pac (p-value 0.054) (primary endpoint). DFS (5y 84.9 vs. 81.7%, p=.035) and RFS (5y 86.9% vs. 84.0%, p-value 0.041) showed a significant advantage with nab-Pac. Interestingly, preplanned subgroup analysis showed a benefit for nab-Pac in patients with a RS <=25, which mainly corresponds to ET non-responders (5y-iDFS nab-Pac 89.5% vs. sb-Pac 84.5%, p-value: 0.011), but not for RS>25 (5y 82.9 vs. 82.7%) . Current analysis showed no significant advantage with regard to the dDFS (5y 87.1 vs. 84.8%, p=0.13) and OS (5y 94.0 vs. 92.9%; p-value 0.387).
No new safety signals were observed so far. Details will be presented at the meeting.
Conclusions
WSG ADAPT HR+/HER2- is the largest prospective study so far, which compared two taxane-based dose-dense regimens in patients selected by RS and endocrine response. nab-Pac seems to be superior to sb-PAC in particular in patients with endocrine-non-responsive tumors.
These results will help to further optimize chemotherapy in the different prognostic subgroups of high-risk HR+/HER2- EBC.

GS3-05: NSABP B-59/GBG-96-GeparDouze: A randomized double-blind phase III clinical trial of neoadjuvant chemotherapy with atezolizumab or placebo followed by adjuvant atezolizumab or placebo in patients with Stage II and III triple-negative breast cancer

Charles Geyer, Gong Tang, Valentina Nekljudova, Priya Rastogi, Mattea Reinisch, Joshua Acosta, Andreas Schneeweiss, Christie Hilton, Sabine Seiler, Carsten Denkert, Rohit Bhargava, Patricia Cortazar, Fernando Moreno, Jay Andersen, Stephani Christensen, Peter Klare, Sujatha Murali, Serafín Morales, Jens Huober, Jean-François Boileau, Christian Jackisch, Álvaro Rodríguez-Lescure, Dominique Boudreau, Dirk-Michael Zahm, Claus A. Hanusch, Peter J. Polewski, Kerstin Lüdtke-Heckenkamp, Saima Hassan, João Mouta, Eleftherios P. Mamounas, Norman Wolmark, and Sibylle Loibl

Background:Sequential neoadjuvant chemotherapy (NAC) regimens of taxanes with carboplatin followed by anthracyclines with cyclophosphamide (AC/EC) result in pathological complete responses (pCR) in 55-60% of patients with Stage II/III triple-negative breast cancer (TNBC) who enjoy a favorable prognosis. However, those with residual invasive disease (RID) following NAC have an increased risk of recurrence even with adjuvant capecitabine. Immune checkpoint inhibitors have demonstrated improved outcomes in patients with PD-L1-positive metastatic breast cancer and increased pCR when added to NAC for Stage II/III TNBC, irrespective of PD-L1 status. This trial evaluated the efficacy and safety of adding atezolizumab to NAC followed by atezolizumab as adjuvant therapy to complete 1 year of therapy in Stage II/III TNBC. The required number of events was confirmed on 09/16/2024 to establish the data cut-off for conduct of the planned definitive analysis of the primary endpoint, event-free survival (EFS), along with secondary endpoints of pCR, overall survival (OS), and safety with results available for presentation at SABCS 2024.

Methods Design: This is a phase III, double-blind, placebo-controlled trial evaluating neoadjuvant atezolizumab with NAC followed by adjuvant atezolizumab in Stage II/III TNBC. Patients were stratified by region (North America; Europe), tumor size (1.1-3.0 cm; >3.0 cm), AC/EC schedule (q2w; q3w), and nodal status (positive; negative), then randomized 1:1 to receive atezolizumab/placebo 1200 mg IV every 3 wks concurrently with both sequential regimens of weekly paclitaxel 80 mg/m2 IV for 12 doses with every 3-wk carboplatin AUC of 5 IV for 4 doses followed by AC/EC every 2-3 wks (per investigator discretion) for 4 cycles. Following surgery, patients resumed atezolizumab/placebo 1200 mg IV every 3 wks as adjuvant therapy to complete 1 year. Radiotherapy based on local standards was co-administered with atezolizumab/placebo. Patients with RID were allowed to receive adjuvant/post-operative capecitabine or olaparib per investigator discretion. Atezolizumab/placebo could be co-administered with capecitabine but not with olaparib.
Eligibility criteria: Centrally confirmed ER-negative, PR-negative, HER2-negative invasive breast cancer by ASCO/CAP guidelines. The primary tumor must be stage T2 or T3 if cN0 or

cN1 with negative biopsy or T1c, T2, or T3 if cN1 with positive biopsy or cN2 or cN3. LVEF >55% and no significant cardiac history.
Statistical methods: The study was designed to detect a hazard ratio of 0.7 between atezolizumab and placebo for the primary endpoint of EFS with a 2-sided alpha of 0.05. Secondary endpoints include pCR breast/nodes, distant disease-free survival, OS, safety, and toxicity. Exploratory endpoints include brain metastases-free survival.
Results: 1,550 patients were randomized from December 2017–May 2021. Patient characteristics included age <60 in 79%, primary tumors >3 cm in 41%, clinically node-positive in 41%, and PD-L1 positive in 36%. With a median follow-up of 44 months, the pre-specified number of EFS events for definitive analysis was reached for top-level analyses to be completed by mid-November 2024 and available for presentation at SABCS 2024.
NCT #: NCT03281954
Support: Genentech/Roche

GS3-06: Neoadjuvant camrelizumab plus chemotherapy (chemo) for early or locally advanced triple-negative breast cancer (TNBC): a randomized, double-blind, phase 3 trial

Zhi-Ming Shao and Co-Author(s): Li Chen, Hui Li, Hao Zhang, Huawei Yang, Jun Qian, Zhihua Li, Yu Ren, Shu Wang, Peifen Fu, Hongjian Yang, Yunjiang Liu, Jing Sun, Jianyun Nie, Ruiwen Lei, Yongzhong Yao, Anqin Zhang, Shouman Wang, Xiaopeng Ma, Zhong Ouyang, Hongwei Yang, Song-Yang Wu, Shuo-Wen Cao, Kun Wang, Aimei Jiang, Quchang Ouyang, Da Pang, Limin Wei, Xiaoming Zha, Yu Shen, Xiangwen Qu, Fei Wu, Xiaoyu Zhu, Zhong-Hua Wang, Lei Fan & the CamRelief Study Group

Background: For early or locally advanced TNBC, preferred neoadjuvant strategies include a four-drug chemotherapy regimen containing anthracyclines, cyclophosphamide, taxanes, and platinum. Accumulating evidence suggests that blockade of the PD-1/PD-L1 pathway may enhance the efficacy of conventional neoadjuvant chemotherapy. Camrelizumab is an anti-PD-1 antibody that has demonstrated antitumor activity in advanced or metastatic TNBC. Herein, we conducted a double-blind, randomized phase 3 trial (NCT04613674) to evaluate the efficacy and safety of neoadjuvant camrelizumab plus chemo in early or locally advanced TNBC.
Methods: Patients with previously untreated, invasive stage II (T2N0-1M0/T3N0M0) or III (T2N2-3M0/T3N1-3M0) TNBC were randomized (1:1) to receive neoadjuvant camrelizumab (200 mg, Q2W) or placebo plus chemo (nab-paclitaxel [100 mg/m2, D1, D8, D15, Q4W] + carboplatin [AUC 1.5, D1, D8, D15, Q4W] for 16 weeks, followed by dose-dense epirubicin [90 mg/m2, Q2W] + cyclophosphamide [500 mg/m2, Q2W] for 8 weeks). Randomization was stratified by tumor clinical stage (stage II vs III) and PD-L1 expression (combined positive score [CPS] <10 vs ≥10). After surgery, patients allocated to the camrelizumab group received camrelizumab (200 mg, Q2W) for up to a year (from first dose). The primary endpoint was pathological complete response (pCR; ypT0/is ypN0).

Secondary endpoints included event-free survival (EFS), disease-free survival (DFS), distant disease-free survival (DDFS), and pre-surgery objective response rate (ORR; per RECIST v1.1).
Results: As of data cutoff (Sep.30, 2023), 441 patients were randomized and treated (camrelizumab, n=222; placebo, n=219). Median follow-up was 14.4 mo. Overall, median age was 48.2 years; 35.8% of patients had stage III disease at baseline, and 70.5% presented with nodal involvement (N3 disease, 9.1%). pCR rate was 56.8% (95% CI 50.0-63.4) with camrelizumab + chemo and 44.7% (95% CI 38.0-51.6) with placebo + chemo (rate difference, 12.2% [95% CI 3.3 to 21.2]; 1-sided p=0.0038). The benefit in pCR with camrelizumab + chemo was observed regardless of PD-L1 expression, nodal status or disease stage at baseline. Specifically, among patients with poor prognostic factors, the pCR rate with camrelizumab + chemo vs placebo + chemo was 57.8% (89/154) vs 42.7% (67/157) for node-positive disease (rate difference, 15.1% [95% CI 4.1 to 26.1]), and 49.4% (39/79) vs 38.0% (30/79) for stage III disease (rate difference, 11.4% [95% CI -4.0 to 26.8]). Pre-surgery ORR reached 87.4% (95% CI 82.3 to 91.5) with camrelizumab + chemo and 82.6% (95% CI 77.0 to 87.4) with placebo + chemo. EFS (HR, 0.80 [95% CI 0.46-1.42]), DFS (HR 0.58 [95% CI 0.27 to 1.24]) and DDFS (HR 0.62 [95% CI 0.29-1.33]) were immature, with a trend favoring the camrelizumab + chemo group. Across stages, TRAEs of grade ≥3 occurred in 90.1% of patients in the camrelizumab + chemo group vs 82.6% in the placebo + chemo group; all events with incidence ≥10% were hematological toxicities.
Conclusions: Addition of camrelizumab to platinum-containing intensive neoadjuvant chemotherapy significantly improved pCR rate in early or locally advanced TNBC, with a manageable safety profile. Early survival data also favored the camrelizumab + chemo group.

GS3-08: In situ detection of individual classical MHC-I gene products in breast cancer identifies gene- and subtype-specific biased antigen presentation loss

Paula Gonzalez-Ericsson, Susan R. Opalenik, Violeta Sanchez, Amy Palubinsky, Melinda Sanders, Laura Kennedy, Elizabeth Philips, Justin M. Balko

Background: Tumor-specific HLA-ABC expression is required for cytotoxic T-cell elimination of cancer cells expressing tumor associated- or neo-antigens. Moreover, the success of MHC-I-targeted cancer vaccines typically hinge on the carriage of specific types (e.g. HLA-A2) in the patient as well as type-specific antigen presentation in the tumor itself. In contrast to specific type carriage, the retention of protein expression of individual HLA genes (e.g. A/B/C) is not assessed in situ in tumor cells, despite the widely recognized knowledge that cancers downregulate or eliminate antigen presentation via multifaceted mechanisms to avoid adaptive immunity. Unfortunately, the highly polymorphic nature of the genes encoding these proteins coupled with quaternary-structure changes after formalin-fixation, complicate detection by immunohistochemistry. Moreover, only a few commercially available antibodies recommended for IHC have been characterized to

determine their recognition of specific HLA-ABC alleles.
Results: In this study, we determined allele and type-specificity for 15 commercially available antibodies for immunohistochemical use by staining HLA-ABC-null K562 cells transduced with 16 specific common HLA-A, B and C alleles. We identified and validated EMR8-5, EPR22172 and HC-10 as true pan-HLA-ABC antibodies and EPR1394Y, 2A11G7, EPR26121-73 as specific HLA-A, B, and C antibodies, respectively, to facilitate the investigation of HLA-ABC loss in situ. We applied this novel approach to a series of early-stage HER2-negative breast cancers (n=175) and DCIS (n=24) as a proof of utility. HLA-A, B and/or C expression on <15% of tumor cells was defined as loss, 15-75% as partial loss and >75% as fully conserved expression. Samples from hormone receptor-positive (HR+) breast cancer patients showed a higher rate of total HLA-A, B and/or C loss, any combination, than triple-negative breast cancer (TNBC) patient samples (73% vs 50% Fishers test p=0.0027, n=89 vs 77), driven by loss of HLA-A and/or B (total HLA-A loss 69% vs 30% p=0.0001 and total HLA-B loss 59% vs 34% p=0.0048). In contrast, samples from TNBC patients showed a higher rate of conserved expression for each single molecule and combined HLA-ABC (total conserved HLA-ABC 2% vs 16% in HR+HER2- vs TNBC p=0.0009). Among cases with HLA-A, B and/or C expression, most showed partial loss of at least one molecule, partial expression/loss was often observed within matching discrete spatial areas for HLA-A, B and/or C. Samples from patients with DCIS showed a pattern of HLA-A, B and/or C loss more similar to HR+HER2- invasive cancer regardless of HR status, both showing prominent AB loss and no cases with single molecule C loss. DCIS presented lower rates of HLA-C loss, any combination, than invasive carcinoma (8% vs 32% p=0.0165) regardless of subtype. Of note, the pan-HLA-ABC clones were insufficient to identify single or double molecule loss. All samples showed HLA-ABC expression on surrounding non-tumor tissue; however, we observed lack of staining on tumor and non-tumor cells in 5 samples with HLA-C specific EPR26121-73 antibody that were excluded from the analysis.
Discussion: We demonstrate the novel finding that up to 70% of early HR+ breast cancers lack any detectable HLA-A expression, compared to 30% of early triple-negative breast cancers. HLA-A and B loss are early events present in DCIS while HLA-C loss was more common in invasive carcinoma. Moreover, HLA-C expression was the most conserved across breast cancer subtypes. We also report an unprecedented level of individual gene product expression loss across breast cancers, which would not be detectable using poorly validated or pan-MHC-I antibodies in situ. These findings have clear implications on the success of checkpoint inhibitors and vaccine strategies in this setting, and hint at 'para-genomic' mechanisms of MHC-I gene-specific silencing in cancer-specific contexts, enabling the discovery of novel tumor evolution principles.

GS3-09: Multimodal integration of real world clinical and genomic data for the prediction of CDK4/6 inhibitors outcomes in patients with HR+/HER2- metastatic breast cancer.

Enrico Moiso, Emanuela Ferraro, Luc Cabel, Anton Safonov, Joshua Z. Drago, Sherry Shen, Mehnaj Ahmed, Julia Ah-Reum An, Komal L. Jhaveri, Larry Norton, Mark E Robson, Shanu Modi, Sarat Chandarlapaty, Pedram Razavi

Introduction: Addition of CDK4/6 inhibitors (CDK4/6i) to endocrine therapy (ET) have led to marked improvement of outcomes in patients (pts) with HR+/HER2− metastatic breast cancer (MBC). However, the responses vary significantly with a subset of patients experiencing early therapeutic resistance. In view of many potential alternative therapeutic approaches for these patients, we sought to develop machine learning (ML) models based on clinical and genomic characteristics at the time of metastatic recurrence, to predict outcomes on 1st line CDK4/6i+ET in pts with HR+/HER2- MBC.

Methods: We identified 535 pts with HR+/HER2- MBC who received 1st line CDK4/6i+ ET between 12/2013 and 10/2023 from MSK translational database for whom MSK-IMPACT targeted tumor sequencing was performed on samples collected pre-treatment or within 2 months of the start of CDK4/6i. The models were trained on pts with complete clinical and genomic data (n=370) with 10-fold cross validation and tested on the hold-out set (n=165). OncoCast-MPM ML framework and Gradient Boosting Machine (GBM) algorithm was used to generate 3 models to predict CDK4/6i progression-free survival (PFS) based on clinicopathological features (CF), genomic features (GF) and integrating CF and GF (CGF). The Kaplan-Meier estimator with log-rank test and Cox proportional hazard models were used to assess differences in PFS, and to calculate hazard ratios (HRs) between risk groups.

Results: The median PFS (mPFS) of the full cohort was 17.8 m (95% CI: 16.1-19.7), with 67% of pts having an event. The mPFS of the training and hold-out set cohorts were 17.3 m (95% CI: 15.2.1-19.6), and 18.3 (95% CI: 16.1-23.5) with 68% and with 65% of pts having an event, respectively. The model trained on CF identified 2 risk groups (RGs): good RG (n=221), with a mPFS of 23.2m (95% CI: 18.3-28.5), and poor RG (n=149), with a mPFS of 11.6m (95% CI: 8.78-13.71). The model trained on GF identified 2 RGs: good RG (n=209), with a mPFS of 28.1m (95% CI: 21.9-31.7), and poor RG (n=161), with a mPFS of 9.7m (95% CI: 8.4-11.9). The CGF integrated model identified 3 RGs: good RG (n=113), with a mPFS of 31.3m (95% CI: 24.9-44.4), intermediate RG (n=156), with a mPFS of 18.5m (95% CI: 15.2-21.9), and poor RG (n= 101), with a mPFS of 7.9 m (95% CI: 5.4-10). The HRs between the good and poor RGs were 1.95 (95% CI: 1.5-2.5; p= 2.6e-7), 2.4 (95% CI: 1.9-3.1; p= 2.0e-11) and 4.2 (95% CI: 3.0-5.9; p= 2.8e-16) for the CF, GF and CGF models, respectively, highlighting the superior stratification power achieved by integrated clinico-genomic features. Interestingly the top 10 key features used by the multimodal model represent the union of the top 5 clinical and molecular features of the unimodal models. These features, in order of importance were tumor mutational burden (TMB), fraction of genome altered

(FGA), TP53 alteration, fraction of genome with loss of heterozygosity (LOH), presence of liver metastasis,

adjuvant treatment free interval < 1 year, primary tumor grade III, presence of visceral metastasis, primary tumor PR negativity and whole genome doubling. The results of the CGF model on the hold-out test set confirmed the presence of 3 RGs with similar HR to those identified in the training set, with no statistically significant difference in results between the training and tests sets.

Conclusions: The multimodal machine learning model integrating both clinical and genomic features, provided superior stratification and predictive power for outcomes on 1st line CDK4/6i combination compared to unimodal models. Precise risk stratification of HR+/HER2- MBC patients at the time of metastatic recurrence is key for devising therapeutic and monitoring strategies and trial design.

GS3-10: Paired DNA and RNA analysis of CALGB 40603 (Alliance) reveals insights into the molecular and prognostic landscape of stage II-III triple-negative breast cancer

Brooke Felsheim, Aranzazu Fernandez Martinez, Cheng Fan, Adam Pfefferle, Michele Hayward, Katherine Hoadley, Naim Rashid, Sara Tolaney, George Somlo, Lisa Carey, William Sikov, Charles Perou

Background: Heterogeneity within triple-negative breast cancer (TNBC) makes it challenging to target therapeutically. Despite recent advances in the standard of care treatment of stage II-III TNBC, which now includes multiple chemotherapeutic agents plus an immune checkpoint inhibitor, the cure rate for these patients remains suboptimal. There is still a critical need for improved molecular characterization of TNBC and the development of accurate prognostic tools to assist in making treatment escalation and de-escalation decisions. Here, we present an analysis of the DNA and RNA landscape in a set of patients treated on a clinical trial and validation of molecular and prognostic features using three additional data sets.
Methods: CALGB 40603 (Alliance) is a randomized phase II trial that evaluated the impact of adding carboplatin and/or bevacizumab to standard anthracycline/taxane neoadjuvant chemotherapy in stage II-III TNBC. Targeted panel DNA sequencing of pre-treatment tumor samples from 238 patients enrolled in this study was performed and analyzed alongside matched pre-treatment RNAseq data. These results were then combined with clinical outcomes data to develop a prognostic multi-variable elastic net model of overall survival. We subsequently evaluated this model on samples from 380 stage II-III TNBC patients from three independent publicly available datasets.
Results: Similar to other TNBC data sets, DNAseq results of 40603 identified TP53 (86%) as the most frequent somatically mutated gene, followed by MT-ND5 (16%), MT-ND4 (12%), CSMD3 (8%), and PIK3CA (7%). BRCA1 (germline 8%, somatic 4%), BRCA2 (germline 2%, somatic 0.4%), and PALB2 (germline 1%) gene mutations were also detected, and when

combined into a single “homologous recombination deficiency” category totaled 15%. The DNA copy number landscape of TNBC was very similar across the four data sets, and largely mirrored the landscape seen for basal-like breast cancer characterized in TCGA. Importantly, only one somatically mutated gene (PIK3R2), and no DNA copy number altered regions, were associated with pathologic complete response or survival at a false discovery rate < 0.05. We next sought to use these multi-platform data to train a prognostic Cox elastic net regression model using CALGB 40603 data and a diverse set of features, including tumor stage, 804 RNA expression signatures, 727 genes with somatic mutations, and 534 chromosomal segment-level copy number alterations. This yielded a 31-feature prognostic model with C-index performance values (95% confidence interval) of 0.68 (0.66-0.69), 0.61 (0.59-0.63), and 0.83 (0.82-0.84) using FUSCC (PMID 30853353), METABRIC (PMID 22522925), and TCGA (PMID 23000897) test sets. The most heavily weighted features in this model were tumor stage and multiple immune signatures including an IgG signature, and this model had higher C-index values than a model trained using only tumor stage.
Conclusions: This study provides a comprehensive and integrated characterization of the DNA- and RNA-based landscape of a large stage II-III TNBC patient data set. Through the development of a multi-omic elastic net model of TNBC survival, we show that we may improve the prognostic accuracy for overall survival beyond stage alone by incorporating machine learning selected molecular features. Furthermore, the model’s ability to identify good overall survival outcome patients when given neoadjuvant chemotherapy illustrates its potential utility for informing treatment escalation/de-escalation decisions, which could be clinically valuable if further validated.

LB1-01 - immediate breast surgery versus deferral of surgery in women aged 70+ years with operable breast cancer: patient-level meta-analysis of the three randomised trials among 1,082 women

Robert Hills, CoRosie Bradley, Jeremy Braybrooke, Lucy Davies, David Dodwell, Gurdeep Mannu, Paul McGale, Mike Clarke, Hongchao Pan, Richard Berry, Richard Peto, Carolyn Taylor, Jonas Bergh, Sandra Swain, Stewart Anderson, Allan Hackshaw, Tom Bates, Eleftherios Mamounas, Giorgio Mustacchi, John Robertson, Richard Gray

Background: Endocrine therapy alone, with breast surgery offered only at local progression, is still sometimes considered for older women with operable early breast cancer, but the long-term risks of deferring surgery are uncertain. We evaluated long-term outcomes in the three unconfounded randomised trials that compared immediate breast surgery plus tamoxifen versus tamoxifen alone. None of these trials scheduled radiotherapy or chemotherapy.
Methods: Individual patient data meta-analyses compared effects on breast cancer

outcomes in 3 trials, initiated in the 1980s, among 1082 women (age ≥70, all to receive tamoxifen for at least 5 years) comparing immediate surgery versus surgery only in the event of local progression. Primary outcomes were time to locoregional failure, to distant recurrence, and to breast cancer mortality. Locoregional failure was defined as any locoregional recurrence after surgery or, if no immediate surgery, ≥25% increase in tumour diameter. Age-adjusted intent-to-treat log-rank analyses, stratified by nodal status, were used to estimate first-event-rate ratios (RRs).
Results: Median age at randomisation was 76 (IQR 73-80) years, and 63% (666/1082) had clinically estimated tumour diameter >20 mm. Mean follow-up while still alive was 7.3 woman-years. Of 518 women allocated immediate surgery, 45.7% had mastectomy, 47.3% had breast-conserving surgery, and 7.0% had neither. Locoregional failure was greatly reduced by allocation to immediate surgery (RR=0.24, 95% CI 0.19-0.30, p<0.00001). This extreme RR was little affected by age, disease stage, or time period. Although the proportional reduction in the annual rate of locoregional failure was similar during years 0-1, 2-4 and 5-9, the absolute reduction in locoregional failure was mainly before year 5 (Kaplan-Meier 5-year risks 12.1% vs 45.8%). On average over the whole follow-up period the rates of distant recurrence (RR=0.72, 0.57-0.90, p=0.003), breast cancer mortality (RR=0.68, 0.54-0.86, p=0.002), and all-cause mortality (RR=0.83, 0.72-0.97, p=0.016) were also reduced, but these benefits emerged only after years 0-1. The distant recurrence rate ratio was 0.97 (0.67-1.42) during years 0-1 after randomisation, 0.73 (0.49-1.07) during years 2-4 and 0.52 (0.36-0.76) after year 5 (trend: p=0.012).
Conclusion: In early breast cancer, immediate breast surgery greatly reduces locoregional progression rates during the first 5 years and approximately halves the annual rates of distant recurrence and of breast cancer death after the first 5 years, despite having had little clinically apparent effect on distant recurrence rates during the first few years. These findings could indirectly inform the planning and interpretation of trials of less extreme de-escalation of surgery or radiotherapy.

LB1-02: MARGOT/TBCRC052: A randomized phase II trial comparing neoadjuvant paclitaxel/margetuximab/pertuzumab (TMP) vs paclitaxel/trastuzumab/pertuzumab (THP) in patients (pts) with stage II-III HER2+ breast cancer

Adrienne Waks, Hillary Heiling, Paula Pohlmann, Mothaffar Rimawi, Natalie Sinclair, Rachel L. Yung, Jesus Anampa, Claudine Isaacs, Thomas O'Connor, Nadine Tung, Adam Brufsky, Lisa Carey, Rita Nanda, Nancy U. Lin, Antonio Wolff, Clare Strickland, Michelle DeMeo, Ashley Root, Tasnim Rahman, Abigail Recko, Molly DiLullo, Ashka Patel, Esther R. Ogayo, Philip Poorvu, Antonio Giordano, Erica Mayer, Tari King, Eric P. Winer, Elizabeth Mittendorf, Nabihah Tayob, Sara M. Tolaney, Ian E. Krop

Background: Margetuximab combined with chemotherapy modestly improves outcomes compared to trastuzumab plus chemotherapy in pts with heavily pre-treated HER2+ metastatic breast cancer. The efficacy of margetuximab for pts with newly diagnosed HER2+

early breast cancer (EBC) is unknown.
Methods: Eligible pts had previously untreated stage II-III HER2+ EBC, any hormone receptor (HR) status, and CD16A genotype FF or FV by central testing. Pts were randomized 2:1 to neoadjuvant TMP or THP for 4 cycles (weekly T x12; q3wk MP or HP x4). ER status and baseline clinical stage were stratification factors. The primary endpoint was pathologic complete response (pCR; ypT0/isN0). With 171 pts randomized, there was 80% power to detect improvement in pCR rate from 45% with THP to 65% with TMP with one-sided alpha 0.05. pCR rates were compared between arms using Fisher's exact tests. Additional endpoints included pCR rate according to CD16A genotype (FF vs FV), safety and tolerability of neoadjuvant TMP and THP, and event-free survival (EFS).
Results: 174 pts were randomized from 10/2020-5/2024, and 171 pts started tx on trial: 117 TMP and 54 THP. One pt was found to be ineligible and excluded from efficacy analyses. Pts were 100% female, with median age 53 yrs (range 30-79 yrs); 77% White, 10% Black, and 4% Asian; 13% were Hispanic. 65% of pts had HR-positive tumors, 87% had cT1-T2 tumor size, and 35% were clinically node-positive. On the TMP vs THP arms, 86% vs 89% of pts received 12 doses of neoadjuvant taxane, 97% vs 96% of pts received 4 doses of neoadjuvant M vs H, and 95% vs 94% of pts received 4 doses of neoadjuvant P. pCR rate was 56% vs 46% in the TMP vs THP arms, respectively (difference 10%, 95% CI [-8%, 27%]; p=0.25). Additional residual cancer burden (RCB) scores for TMP vs THP, respectively, were 7% vs 13% (RCB I), 25% vs 28% (RCB 2), and 2% vs 2% (RCB 3). 9% vs 11% of pts (TMP vs THP) received additional neoadjuvant tx due to incomplete clinical response to TMP or THP, and were considered non-pCR at surgery. Two vs 0 pts (TMP vs THP) did not undergo surgery on trial (one due to death that was unrelated to study therapy; one due to withdrawal of consent prior to surgery). Among HR+ pts (n=111), pCR rate was 48% overall (54% TMP vs 35% THP); among HR- pts (n=59), pCR rate was 63% overall (60% TMP vs 71% THP). Among HER2 IHC 3+ pts (n=130), pCR rate was 62% overall (66% TMP vs 55% THP); among HER2 IHC <3+ pts (n=40), pCR rate was 23% (27% TMP vs 10% THP). Pts with >1 grade 2+ treatment-emergent adverse event (TEAE) during neoadjuvant tx were similar by arm: 82% TMP vs 78% THP; those with >1 grade 3+ TEAE were also similar: 27% TMP vs 30% THP. The most common grade 2+ TEAEs were infusion-related reaction (27% TMP [4% grade 3-4] vs 15% THP [2% grade 3-4]), diarrhea (24% TMP [5% grade 3-4] vs 26% THP [6% grade 3-4]), alopecia (20% vs 4%), and hypertension (10% vs 24%). The only grade 2+ TEAEs that were more common in the TMP arm by >10% were infusion-related reaction and alopecia. There was one grade 5 AE (death unrelated to study tx) on the TMP arm. pCR rate according to CD16A genotype (FF vs FV) will be reported; all pts continue to be followed for EFS.
Conclusions: There was no statistically significant improvement in pCR rate with neoadjuvant TMP vs THP for pts with HER2+ EBC and CD16A FF/ FV genotype. Safety and tolerability were similar between the two regimens, aside from increased rates of infusion-related reactions and alopecia in the margetuximab arm (scalp-cooling use was not recorded). Given numerical improvement in pCR rate, comparative analysis of immune activation biomarkers between the two tx arms will be performed. EFS data remain immature; pCR rates by CD16A genotype will be presented.

LB1-03: Primary results of the randomised Phase III trial comparing first-line ET plus palbociclib vs standard mono-chemotherapy in women with high risk HER2-/HR+ metastatic breast cancer and indication for chemotherapy - PADMA study

Sibylle Loibl, Marc Thill, Julia Rey, Beate Rautenberg, Vesna Bjelic-Radisic, Thomas Decker, Joachim Rom, Matthias Kögel, Kristina Lübbe, Axel Nacke, Nader Hirmas, Marianne Just, Volkmar Müller, Renu Buss-Steidle, Jürgen Terhaag, Christoph Mundhenke, Carsten Denkert, Johannes Holtschmidt[1], Marcus Schmidt

Background: Whether chemotherapy (CT) or an endocrine therapy (ET) in combination with a CDK4/6 inhibitor in HR+/HER2-metastatic breast cancer (mBC) is the preferred option is still a matter of debate. The PADMA (NCT03355157; GBG 93) prospective, randomized, open-label, multi-center, phase III trial is the first trial to compare a standard mono-CT followed by maintenance ET with a CDK4/6 inhibitor plus ET as first-line therapy in high -risk mBC patients (pts).
Study Design: Pts previously untreated for HR+/HER2- mBC with an indication for chemotherapy were randomized to receive either palbociclib 125mg on days 1-21 q28 in combination with ET (palb/ET) or to mono-CT of physician's choice (PC) with or without following maintenance ET. Stratification factors included endocrine resistance and presence of disease symptoms as defined by the investigator. Treatment was administered until disease progression, unacceptable toxicity, withdrawal of consent, or modification to the initial treatment plan. The primary endpoint (EP) is time to treatment-failure (TTF) defined as time from randomization to discontinuation of treatment due to disease progression, treatment toxicity, patient's preference, or death. Secondary EPs included progression free survival (PFS), time to first subsequent treatment (TFST), time to first subsequent chemotherapy, time to second subsequent treatment regimen, overall survival (OS), safety, compliance, and well-being and health care utilization by daily monitoring content with quality of life, degree of bother by side-effects, number and duration of phone calls, site visits.
Results:A total of 130 pts (66 palb/ET; 64 CT) were enrolled at 28 German sites between Apr 2018 and Dec 2023 of whom 120 started treatment and were included in this analysis. 12 (10%) of the pts were pre-/perimenopausal, 90 (75%) had metastases in two or more organ systems, 52 (43.3%) had symptomatic disease, 10 (8.3%) were endocrine resistant at enrolment. The median age was 62 (range 31-85) years. CT of PC was capecitabine 40 (69.0%), paclitaxel 17 (29.3%) and vinorelbine 1 (1.7%). Out of 58 pts receiving CT, 13 pts (22.4%) switched to maintenance ET.
After a median follow-up of 36.8 (15.0-47.7) months (mo) 45 pts (73.8%) in the palb/ET arm and 55 (93.2%) in the CT arm experienced a TTF event. The median TTF was significantly longer with palb/ET 17.2 (7.2, 25.9) mo vs 6.1 (4.3, 8.8) mo with CT (HR 0.46 [80% CI 0.35-0.60], log-rank p=0.0002) meeting its primary EP. The leading cause of treatment failure was progression (52.5% with palb/ET vs 76.3% with CT). Median PFS was significantly longer with palb/ET 18.7 (10.6, 29.1) mo and 7.8 (6.0, 10.0) mo with CT (HR

0.45 [95% CI 0.29-0.70], log-rank p=0.0002). Median TFST was significantly longer with palb/ET 19.9 (11.0, 30.5) vs. 8.0 (6.8, 13.1) mo (HR 0.52 [95% CI 0.34-0.80], log rank p=0.0028). Median OS was numerically prolonged with palb/ET 46.1 (27.2, n.a.) vs. 36.8 (25.2, n.a.) mo with CT (HR 0.81 [95% CI 0.46-1.43], log rank p=0.4630).
Hematologic toxicity was significantly higher in the palb/ET arm (any grade 96.8% vs 70.7%, p<0.001; high grade 56.5% vs 10.3%, p<0.001) with non-hematologic toxicity being comparable between the arms. Serious treatment related adverse events were generally low with 4 (6.5%) in the palb/ET and 6 (10.3%) in the CT arm. One death was treatment related (palb/ET arm).
Conclusion: The phase III PADMA trial in high-risk HR+/HER2- mBC shows statistically significant and clinically meaningful improved TTF and PFS with a trend for improved OS for palbociclib plus ET over mono-CT as first-line therapy. These results support existing international guidelines advocating the use of ET + CDK4/6 inhibitors as standard in 1line treatment of HR+/HER2- mBC.

LB1-04: Efficacy and safety of trastuzumab deruxtecan (T-DXd) vs physician's choice of chemotherapy (TPC) by pace of disease progression on prior endocrine-based therapy: additional analysis from DESTINY-Breast06

Aditya Bardia, Xichun Hu, Rebecca Dent, Kan Yonemori, Carlos H Barrios, Jean-Yves Pierga, Fabio Puglisi, Jean-Marc Ferrero, Kyung Hae Jung, Nusayba A Bagegni, Joëlle Collignon, Miguel Gil-Gil, Xiaoling Wu, Aleksandra Andrzejuk-Ćwik, Maria Schwaederle, Giuseppe Curigliano

Background: The Phase 3 randomized DESTINY-Breast06 study enrolled patients (pts) with hormone receptor–positive, human epidermal growth factor receptor 2 (HER2)–low (immunohistochemistry [IHC] 1+, IHC 2+ / in situ hybridization–negative) or HER2-ultralow (IHC 0 with membrane staining) metastatic breast cancer (mBC) who had progression of disease (PD) after ≥1 endocrine-based therapy and had not received chemotherapy (CT) for mBC. In the intent-to-treat population (ITT; HER2-low + HER2-ultralow), pts had a statistically significant and clinically meaningful improvement in progression-free survival (PFS) with T-DXd vs TPC (median, 13.2 vs 8.1 months [mo]; hazard ratio [HR] 0.63, P<0.0001). A PFS benefit was observed regardless of the number of lines of prior endocrine-based therapy for mBC. Additional analyses investigated the impact of response to prior endocrine-based therapy on outcomes.
Methods: Pts were assigned 1:1 to T-DXd 5.4 mg/kg given intravenously every 3 weeks or TPC (59.8% capecitabine; 24.4% nab-paclitaxel; 15.8% paclitaxel). Pts had ≥2 lines of prior endocrine-based therapy for mBC, or 1 line if PD occurred within 24 months of adjuvant endocrine therapy (ET) or within 6 mo of first-line (1L) ET + CDK4/6 inhibitor (CDK4/6i) for mBC (the latter considered rapid progression). Subgroups were time to progression (TTP) on 1L ET + CDK4/6i, and primary vs secondary endocrine resistance (per 5th ESO-ESMO ABC criteria). Outcomes included PFS, confirmed objective response rate (ORR), and

duration of response (DOR) by blinded independent central review in the ITT, and safety.
Results
Most pts in the ITT (89.3% of n=866) received at least 1 prior line of ET + CDK4/6i. The TTP analysis included pts with PD on 1L ET + CDK4/6i (65.8% of the ITT), comprising 124 pts with <6 mo, 112 with 6–12 mo, and 334 with >12 mo TTP. Pt numbers, demographics, and baseline clinical characteristics were balanced across subgroups. A total of 58.9% of pts (<6 mo; n=73), 23.2% (6–12 mo; n=26), and 7.2% (>12 mo; n=24) received T-DXd/TPC as a second-line treatment after 1 prior line of ET + CDK4/6i. PFS on study was longer with T-DXd vs TPC in the <6-mo subgroup (median, 14.0 vs 6.5 mo; HR 0.38 [95% confidence interval {CI} 0.25, 0.59]); data were consistent in the 6–12-mo (13.2 vs 6.9 mo; HR 0.69 [95% CI 0.43, 1.12]) and >12-mo subgroups (12.9 vs 8.2 mo; HR 0.67 [95% CI 0.51, 0.88]). ORR favored T-DXd vs TPC in pts with <6 mo TTP (67.7 vs 25.4%), similar to those with longer TTP (6–12 mo: 60.0 vs 28.8%; >12 mo: 59.5 vs 33.1%). Median DOR favored T-DXd vs TPC across all TTP subgroups (<6 mo: 11.1 vs 7.3 mo; 6–12 mo: 13.7 vs 11.5 mo; >12 mo: 15.7 vs 11.1 mo). Efficacy outcomes were consistent in pts with investigator-assessed primary and secondary endocrine resistance. The incidence of Grade ≥3 treatment-emergent adverse events in pts receiving T-DXd and TPC in TTP subgroups was consistent with the overall safety population: 55.4 vs 42.4% (<6 mo; n=124); 59.3 vs 40.8% (6–12 mo; n=108); and 45.8 vs 42.9% (>12 mo; n=329), respectively.
Conclusion
T-DXd demonstrated a clinically meaningful efficacy benefit vs TPC, with a >12 mo median PFS across 1L ET + CDK4/6i TTP subgroups, notably in pts with rapid (<6 mo) progression. The safety profile in subgroups was in line with the overall safety population. Results highlight the potential role of T-DXd as an early line treatment after ≥1 line of endocrine-based therapy for pts with hormone receptor–positive, HER2-low/-ultralow mBC.

Clinical trial identification: NCT04494425

LB1-06: Primary results of SOLTI VALENTINE: neoadjuvant randomized phase II trial of HER3-DXd alone or in combination with letrozole for high-risk hormone receptor positive (HR+)/HER2-negative (neg) early breast cancer (EBC)

Mafalda Oliveira, Tomás Pascual, Kepa Amillano Parraga, Javier Salvador Bofill, Santiago González-Santiago, Clara Martínz Vila, Josefina Cruz, Xavier González-Farré, Elena Galve, Pilar Sánchez Henarejos, Juan Miguel Cejalvo, Maria-Eva Pérez-Lopez, Montse Muñoz, Serafin Morales, Alba González-Haba, Maria Borrell Puy, Encarnación González, Juan A. Guerra, Sergio Hoyos, Antonia Perelló, Pablo Tolosa Ortega, Juan De la Haba, Yenlik Zheteyava, David W. Sternberg, Fumitaka Suto, Esther Pang, Dalila Sellami, Rodrigo Sánchez-Bayona, Guillermo Villacampa, Samyukta Chillara, Mariana Paes Dias, Juan M. Ferrero-Cafiero, Aleix Prat

Background: Despite the activity of both chemotherapy (CT) and endocrine treatment in high-risk HR+/HER2-neg EBC, the risk of recurrence persists over time, highlighting the need for additional strategies to improve outcome. HER3-DXd is a potential first-in-class HER3-directed antibody-drug conjugate with activity in multiple breast cancer subtypes. In SOLTI TOT-HER3, a single dose of HER3-DXd was associated with increased CelTIL and clinical response in patients (pts) with HR+/HER2-neg EBC (Oliveira et al, Ann Oncol 2023).
Methods: SOLTI VALENTINE (NCT05569811) is a parallel, randomized, non-comparative, open-label neoadjuvant study of HER3-DXd +/- LET or CT in pts with operable stage II-III high risk (Ki67 ≥ 20% and/or high genomic risk) HR+/HER2-neg EBC. Pts were randomized 2:2:1 to: (A) HER3-DXd 5.6 mg/kg every (Q) 21 days (D) for 6 cycles; (B) HER3-DXd plus QD LET (+/- LHRH agonist); (C) CT with 4 cycles of EC/AC (epirubicin 90 mg/m2 or doxorubicin 60 mg/m2 and cyclophosphamide 600 mg/m2 Q14 or 21 D) followed by weekly paclitaxel 80mg/m2 for 12 weeks. The primary endpoint was pathological complete response (pCR, ypT0/is ypN0) rate at surgery. Secondary endpoints included residual cancer burden (RCB), overall response rate (ORR), CelTIL score change, safety, invasive disease-free survival, and overall survival. Baseline, C2D1, and surgical tissue samples were collected for evaluation of response and translational endpoints. The sample size was not selected to formally compare treatment arms in terms of pCR rate, but to achieve a certain level of precision estimating pCR. Assuming a pCR of 20%, a total of 48 per arm would provide a precision estimation of +-11.3% using asymptotic two-sided 95%CI.
Results: From Nov-2022 to Sep-2023, 122 pts were randomized to HER3-DXd (n=50), HER3-DXd + LET (n=48) and CT (n=24). Median age was 51 (29 - 82), 99.2% were females, and 52.9% pre/perimenopausal. Most pts had T2 (54.1%), N1 (70.5%), Stage II (64.0%), G2 (69.0%) tumors; median Ki67 was 35.0% (18.0; 90.0). Proportion of pts with Stage III tumors was 36.0%, 39.5% and 29.2% in Arms A, B, and C, respectively. The pCR rate was 4.0% (95%CI 0.5-13.7) in Arm A, 2.1% (95%CI 0.1-11.1) in Arm B, and 4.2% (95%CI 0.1-21.1) in Arm C. The RCB0/1 rate was 18.4%, 12.5% and 30.4%, and ORR was 72.0%, 81.3%, and 70.8%, in Arms A, B, and C, respectively. A significant change in CelTIL score from baseline to C2D1 was observed in HER3-DXd arms, but not in Arm C: median increase in CelTIL of 8.2 ($p<0.0001$) in Arm A, 7.4 ($p=0.001$) in Arm Band 3.8 ($p=0.13$) in Arm C. CelTIL change at C2D1 associated with radiological response in Arm A ($p<0.0001$) and B ($p=0.002$), but not in Arm C ($p=0.30$). A decrease in Ki67, as well as a switch from PAM50 Risk of Recurrence (ROR)-high/medium to ROR- low score and from PAM50 Luminal B subtype to Luminal A/Normal-like subtypes were observed in all treatment arms at C2D1, and was further enhanced at surgery. Treatment-emergent adverse events (TEAEs) grade≥3 were less frequent in the HER3-DXd arms (18.0% and 16.7% in Arms A and B, respectively), compared to Arm C (54.2%). The most common related TEAEs reported in Arms A/B were nausea (56%/72.9%), alopecia (52%/68.8%), fatigue (50%/68.8%), and diarrhea (42%/54.2%).
Conclusions: In SOLTI VALENTINE, treatment with HER3-DXd, with or without LET, resulted in similar pCR rates to CT, while exhibiting a lower incidence of grade ≥3 TEAEs. CelTIL score at C2D1 correlated with response to HER3-DXd, but not to CT. The ongoing

translational analysis, as well as the survival outcomes of VALENTINE, will provide further insights into the activity of HER3-DXd in EBC and clarify its potential role as a treatment strategy for high-risk HR+/HER2-neg breast cancer.

LB1-07: Exploratory Biomarker Analysis of the Phase 3 KEYNOTE-522 Study of Neoadjuvant Pembrolizumab or Placebo Plus Chemotherapy Followed by Adjuvant Pembrolizumab or Placebo for Early-Stage TNBC

Joyce O'Shaughnessy, Javier Cortes, Rebecca Dent, Lajos Pusztai, Heather McArthur, Sherko Kümmel, Carsten Denkert, Yeon Hee Park, Rina Hui, Nadia Harbeck, Masato Takahashi, Michael Untch, Peter A. Fasching, Fatima Cardoso, Razvan Cristescu, Andrey Loboda, Petar Jelinic, Lingkang Huang, Kim Kraynyak, Wilbur Pan, Jaime Mejia, Peter Schmid

Background: In the phase 3 KEYNOTE-522 (NCT03036488) study, neoadjuvant pembrolizumab (pembro) + chemotherapy (chemo) with adjuvant pembro significantly improved pCR, event-free survival (EFS) and OS vs neoadjuvant placebo (pbo) + chemo with adjuvant pbo in patients (pts) with high-risk, early TNBC. The key objectives of this exploratory biomarker analysis were to evaluate the association of tumor mutational burden (TMB), T-cell–inflamed 18-gene expression profile (TcellinfGEP), and a set of non-TcellinfGEP consensus signatures with pCR and EFS.
Methods: Eligible pts had newly diagnosed, previously untreated, high-risk, early TNBC (T1c N1–2 or T2–4 N0–2) and evaluable pretreatment tumor samples. TMB was assessed by whole-exome sequencing (WES) and TcellinfGEP and non-TcellinfGEP consensus signatures by RNA sequencing (RNAseq). Analyses followed a pre-specified statistical analysis plan. Associations of TMB, TcellinfGEP, and non-TcellinfGEP consensus signatures (proliferation, stromal/EMT/TGFβ, RAS, angiogenesis, gMDSC, glycolysis, hypoxia, mMDSC, MYC and WNT) with pCR were evaluated respectively by logistic regression and area under the receiver operating characteristic curve analysis with 95% CIs. Associations of these biomarkers with EFS were evaluated by Cox proportional hazards regression. No multiplicity adjustment was applied for TMB or TcellinfGEP analyses; nominal P values <0.05 (1-sided for pembro + chemo; 2-sided for pbo + chemo) were deemed sufficient to support an association. Non-TcellinfGEP consensus signatures were tested at an alpha of 0.10 adjusted by the Hochberg step-up procedure. Associations of RNAseq-based molecular subtypes, BRCA (germline and tumor)/HRD status, HER2 gene expression/signature, and PTEN loss signature with pCR and EFS were secondary objectives. Data cutoff was March 23, 2021.
Results: Of 1172 randomized and treated pts (pembro + chemo, n = 783; pbo + chemo, n = 389), 946 pts had WES data (pembro + chemo, n = 641 [81.9%]; pbo + chemo, n = 305 [78.4%]) and 904 had RNAseq data (pembro + chemo, n = 618 [78.9%]; pbo + chemo, n = 286 [73.5%]). Baseline clinical characteristics in the WES and RNAseq evaluable populations were similar to the overall population. TcellinfGEP was positively associated with pCR and EFS in both the pembro + chemo and pbo + chemo arms (P≤0.001). TMB showed a clear association with pCR and EFS in the pembro + chemo arm (P≤0.001) but not

in the pbo + chemo arm (P=0.011 pCR; P=0.422 EFS). Subgroup analyses by pre-specified cut-offs for TcellinfGEP (1st tertile) and TMB (175 mut/exome) showed EFS curves were well separated and favored pembro + chemo over pbo + chemo regardless of subgroup. Among non-TcellinfGEP consensus signatures, proliferation and glycolysis were positively prognostic for pCR but not EFS in both treatment arms. Among secondary endpoints, positive associations for PTEN loss signature and BRCA/HRD status with pCR were seen in both treatment arms. HER2 gene expression was negatively correlated (−0.32) with TcellinfGEP. HER2 levels and molecular subtypes did not show associations with pCR and EFS in the pembro + chemo arm after TcellinfGEP adjustment. Pre-specified cut-off based subgroup analyses of secondary biomarkers confirmed consistent benefit of pembro + chemo over pbo + chemo.
Conclusions: This exploratory analysis of KEYNOTE-522 found that TcellinfGEP was prognostic for improved pCR and EFS with or without addition of pembro. TMB was associated with improved EFS only in the pembro + chemo arm. Pembro + chemo had an efficacy advantage vs chemo alone regardless of subgroups defined by TMB, TcellinfGEP and other biomarkers assessed. These findings may be relevant to design of future studies looking to improve on immunotherapy + chemo as the standard of care.

P1-01-01: Mainstream Cancer Genetics Testing in Primary Care at a Federally Qualified Health Center: Preliminary Findings from the TestMiGenes Study

Pamela Ganschow, Vivian Pan, Angelina Izguerra, , Genesis Rios , Neha Awati

Introduction: Mainstream genetic testing (MGT) has been proposed as an alternative model to scale access to cancer genetic services utilizing established care providers to provide point-of-care genetic testing at the time of risk identification. However, MGT has primarily been adopted in the oncology setting. Expanding MGT into the primary care (PC) setting leverages the trusted relationship of providers within the patient's medical home increasing the opportunity for primary prevention. In 2023, the University of Illinois Cancer Center partnered with the Mile Square Health Center, a system of federally qualified health centers, to initiate a quality improvement (QI) initiative promoting the prevention and early detection of cancer through universal hereditary cancer risk assessment (HCRA) across PC sites. Building off this QI initiative is the TestMiGenes study, which compares the effectiveness of a standard-of-care referral model enhanced with navigation support to a mainstream/point-of-care testing (MGT) model on the uptake of genetic testing among adults identified at risk for hereditary cancer syndromes in PC settings.
Methods: A digital HCRA tool, developed in English and Spanish at a 7th-grade reading level, was administered by navigators to patients aged 25 and older presenting for routine PC visits across multiple FQHC sites. The HCRA tool identified patients meeting National Comprehensive Cancer Network (NCCN) criteria for genetic testing eligibility based on reported personal and family history. Patients who met NCCN criteria for genetic testing (GT) on HCRA received either a referral to genetic counseling or were offered GT by their PC

provider (MGT). From January to December 2023, the referral model was implemented with 10 PC providers across 2 clinics. Eight PC providers from these 2 clinics transitioned to the MGT model from September 2023 to mid-May 2024. PC providers were trained to provide brief education and conduct shared decision-making around HCRA, placing GT orders, and GT result disclosure via multiple educational sessions with cancer genetic counselors and cancer risk specialists.
Results: Overall, 1555 patients received HCRA, and 300 were eligible for GT. The majority of screened patients were Black or Hispanic (84%), under the age of fifty (52%), and female (68%). Of those eligible for GT, 68 received cancer genetic services under the MGT model and 232 received services under the referral model. Uptake of genetic testing was significantly higher among patients cared for in the MGT model (35%, n=24) compared to the referral model (23%, n=53) ($p<0.05$). Time from identification of GT eligibility to completion of GT also differed significantly from 7 days in the MGT model to 93 days in the referral model ($p < 0.05$). Of note, only 40% (n=69) of those eligible for GT in the referral model completed a GC visit, pointing to additional barriers in the current standard of care process.
Conclusion: Preliminary data suggests that an MGT model is feasible in the PC setting and can potentially increase uptake and reduce wait time for GT. Notably, cancer genetic services are underutilized in both models likely due to multilevel barriers. Further research is needed to explore acceptability, sustainability, facilitators and barriers, and potential harms of both MGT and referral models in PC. The TestMiGenes study is currently conducting patient and provider interviews to explore stakeholder perceptions of GT in primary care.

P1-01-02: T cell mediated breast cancer protection following lactation and involution.

Balaji Virassamy, Franco Caramia, Peter Savas, Michael A Harris, Jia-Wern Pan, Jianan Wang, Roberto Salgado, Heather Thorne, Soo-Hwang Teo, Jane Visvader, Paul J Neeson, Phillip K Darcy, Laura K Mackay, Sherene Loi

Background:The mechanisms by which parity and breastfeeding can mediate protection against breast cancer (BC), particularly triple-negative breast cancer (TNBC), remain unclear. CD8+ T cells with a tissue-resident (TRM)-like phenotype have been shown to be present in primary TNBCs with high quantities of immune infiltrate and are associated with better clinical outcomes. We have previously shown TRM-like cells are also present in healthy, non-cancer-affected normal human breast tissue. We hypothesized that the inflammatory processes induced post pregnancy could result in increased CD8+ T cell quantity and this could facilitate protection against BC in the normal breast.

Methods:We compared immune cell quantities in healthy, cancer-unaffected normal breast tissue collected from parous versus nulliparous women using flow cytometry and from single cell RNA sequencing datasets. Using immunocompetent and deficient murine models,

we characterised mammary tissue infiltrating lymphocyte populations at early (Day 10) and late involution (Day 28) timepoints, without and with lactation respectively. We next correlated immune cell profiles and rate of tumor growth by implanting mammary tumours at the different stages of involution. We further evaluated the quantity of immune infiltration from a dataset of 736 women who had developed BC with parity and breastfeeding history.

Results:We observed significantly higher quantities of CD45+ immune cells and CD8+ TRM-like cells in the normal cancer unaffected breast tissue of parous women compared to nulliparous women using both flow cytometry (n=90) and single cell RNA sequencing datasets (n=263).

In murine models, significantly more CD8+ TRM-like cells accumulated in mammary tissue at the later D28 vs earlier D10 involution timepoint compared with virgin control mice. The increase in TRM-like cells in mammary tissue correlated with significantly decreased tumor growth compared to virgin controls, whereas the early involution timepoint had similar tumor growth rates to virgin mice. The tumors implanted at D28 compared with the D10 involution also had significantly higher intratumoral T cell content.

To specifically investigate if these tumor protective effects were mediated by T cells, we used RAG2-/-yc-/- immunodeficient mice inoculated with AT3-OVA tumors into the mammary gland at the early D10 and late D28 involution timepoints after injection of OT-I cells (transgenic CD8+ T cells that specifically recognise OVA antigen) prior to mating. We observed significantly reduced mammary tumor growth at the later D28 vs earlier D10 timepoint, corresponding to increased conversion of naive OT-I cells to a resident memory phenotype (CD69+CD103+).

We next examined a cohort of patients who were diagnosed with BC and their intratumoral immune content according to subtype and parity/breastfeeding history (n=736). Consistent with the murine data, we found significantly increased tumoral immune infiltration in parous women who had developed postpartum TNBC compared with nulliparous women.

Conclusions:Our data, from both human normal breast samples and murine models of parity, provide evidence that lactation and involution modulate local breast immunity that results in increased quantity of resident CD8+ T cells in cancer unaffected normal breast tissue. In mice, these cells could restrain mammary tumor outgrowth, suggesting a protective mechanism by which lactation and involution can attenuate long term risk of BC development. Parity was also associated with increased tumor immune infiltrate in women who developed early stage TNBC, which has important implications for prognosis.

P1-01-03: Enhancing Patient Care: A Digital Approach Improves Universal Breast Cancer Risk Stratification in Imaging Centers

Jenna Cooke, Meghan E. Burgess, Heather Fecteau

Background:Identifying individuals at increased cancer risk is crucial for prevention and early breast cancer diagnosis. Integrating a risk assessment tool into imaging centers supports proactive cancer management by combining risk evaluation with immediate diagnostic capabilities. We present over 6 years of data from 15 sites of Midstate Radiology Associates (MRA), where breast cancer risk stratification was implemented and transitioned from paper screening form to a universally accessible digital platform. Our findings demonstrate that a digital approach for breast cancer risk assessment in imaging centers significantly improves the identification of individuals at elevated risk.
Methods: We conducted a retrospective study across 15 MRA Imaging Centers from 2018 to June 2024. From 2018 to 2021, 13 MRA centers used paper family history forms to screen mammography patients for eligibility for hereditary cancer genetic testing, with Tyrer-Cuzick scores included for those genetically tested. From 2021 onward, patients at 12 MRA centers used the Ambry CARE Program® before appointments to assess lifetime breast cancer risk using the Tyrer-Cuzick (version 8.0) algorithm, determining eligibility for genetic testing based on National Comprehensive Cancer Network (NCCN®) for hereditary cancers (breast, ovarian, pancreatic, prostate), Lynch syndrome, and familial adenomatous polyposis (FAP). We compared outcomes between paper screening and the digital tool, including risk assessment completion, genetic testing criteria met, pursuit of germline testing, positive germline results, and Tyrer-Cuzick scores ≥20%.
Results: During the years paper screening forms were used, there were 168,323 mammogram appointments. Of those, 24.6% (41,424) met criteria for genetic testing based on paper documentation. Among the 12.4% (5,133) who opted for testing, 6% (332) had positive results and 22% (1,133) had a ≥20% lifetime breast cancer risk. Looking into the years a digital screening tool was utilized, 84,122 individuals were invited to complete an assessment, 75.8% (63,749) responded, with 98% (60,438) being females aged 18 or older. At the time of assessment, 26.3% (16,819) met the criteria for genetic testing, and 20.7% (3,489) of these opted for germline genetic testing. Additionally, 1431 individuals who did not meet criteria chose to undergo testing. Among the 4,920 completed genetic tests, 9.6% (470) had positive results, with 46.8% (220/470) influencing breast cancer risk management options. Furthermore, 10.6% (5,984/56,245) of those females without personal history of cancer assessed using the Tyrer-Cuzick algorithm were identified as having a ≥20% lifetime risk of breast cancer, warranting modified medical management.
ConclusionWe observed poor documentation during the period when paper screening forms were used, suggesting that universal breast risk screening was not offered to all patients. Outcomes indicate that the digital tool not only increased hereditary cancer genetic testing uptake but also expanded access to lifetime breast cancer risk assessment. This study underscores the benefits of universally implementing a digital risk stratification tool in imaging centers. The digital tool ensures efficient identification of patients eligible

for modified management of breast cancer and other hereditary syndromes, thereby enhancing prevention and early treatment.

P1-01-04: EPLIN and EPLIN responsive protein APOC3 in breast cancer

Cai Wang,Tracey A. Martin, Jimmy J. Zeng, Amber X. Li, Eleri Davies, Fiona Ruge, Wen G. Jiang

Introduction. EPLIN (Epithelial Protein Lost in Neoplasm, also known as LIMA1) is a cytoskeletal associated element and has been shown to act as a tumour suppressive molecule in breast cancer and a few other cancer types. Little is known about the regulatory and the responsive proteins for EPLIN. The present study has explored the potential EPLIN responsive proteins in cancer cells and the possible clinical connections in prognosis and treatment in breast cancer.
Methods. EPLIN knockdown cell models were created by using lentiviral shRNA for EPLIN. The responsive proteins including phospho-proteins following EPLIN knockdown were systemically evaluated by MS based bioinformatics analysis. Clinical cohorts and tissue microarrays were used to evaluate the potential EPLIN interactive candidates at gene transcript and protein levels, respectively. The prognostic connection and therapeutic values were also explored.
Results. Knockdown EPLIN resulted in active responses of a number of proteins, of which APOC3 (apolipoprotein C3) was amongst the top ones (both total level and phosphorylated proteins). In clinical cohort, APOC3 were found to be significantly correlated with EPLIN in breast tumour tissues (r=-0.218, p=0.042) but not in normal mammary tissues (p=0.555). APOC3 expression in breast tumour tissues was found to be higher in ER negative tumour (p=0.0058) and in PGR positive tumours (p=0.039), and also in those who died of breast cancer (p=0.016, versus those who remained disease free). The expression profile of the EPLIN related molecule identified patients with high survival risk in those who had PGR negative breast tumours (p=0.014, HR=1.374 (95%CI 1.007-1.875) and in triple negative breast tumours (TNBC) (p=0.045). Multivariate analysis revealed that the expression profile is an independent prognostic factor for PR negative patients (p=0.037) against other clinical factors. Finally, we explored the value of APOC3 and EPLIN in relation to patient's response to drug treatments in a public database. It was clear that high levels of APOC3 in breast cancers rendered the patients with a significant chance of developing resistance to chemotherapies (p=0.000024) and this connection is independent on status of ER, ERBB2 and the molecular subtypes. Intriguingly, APOC3 was found to be a good indicator for sensitivity to anti-Her2 treatment (AUC=0.79, p=0.00076).
Conclusion. The present study identifies a key EPLIN response protein, APOC3 which together with EPLIN forms an important prognostic factor for patients with breast cancer particularly in those with PR negative tumours. It also forms a theranostic indicator for patient's response to drug treatment.

P1-01-05: Conducting Ancillary Studies during an Active NCTN/NCORP Screening Trial – The TMIST (ECOG-ACRIN EA1151) Experience

Etta Pisano, Constantine Gatsonis, Mitchell Schnall, Melissa Troester, Elodia Cole , Jean Cormack, Jon Steingrimsson, Ilana Gareen, Martin Yaffe, Laura Collins, Amarinthia Curtis, Ruth Carlos, Kathy Miller, Christopher Comstock

Background:The primary aim of the Tomosynthesis Mammographic Imaging Screening Trial (TMIST) is to determine whether women randomly assigned to be screened through 3-5 rounds with tomosynthesis (TM) have fewer advanced cancers than the population screened with digital mammography (DM) over 3-8 years after entry. In addition, there are 15 secondary aims with data being collected in the areas of imaging assessment, medical physics, breast biology and pathology, long-term follow-up, and health care utilization. Women ages 45 to 74 are eligible to participate. The study will enroll 108,508 women. Participants may also volunteer to contribute blood and/or buccal smears to the TMIST biorepository. Approximately 70% of TMIST participants have agreed to do so. Because of the size of the TMIST study and vast amount of data to be collected, there is an opportunity for investigators to utilize TMIST data to support various research questions not covered in TMIST.

Methods:The TMIST study team developed a process where investigators who would like access to the TMIST data can submit a concept while the trial is ongoing for access to data in a protected manner. The process starts with the project investigator reaching out to the TMIST study chair. If the study chair, lead statistician, and ECOG-ACRIN (EA) co-Principal Investigator think the project has promise; a timeline for when the project could take place (either (1) during the TMIST clinical trial or (2) after the end of the trial and publication of the primary paper) is developed. The next steps involve reviews by the TMIST Data Safety and Monitoring Board and the EA Executive Review Committee. All ancillary projects proposed will require an external funding plan and budget before the project moves out of concept review inside of EA. Once the project concept clears all required EA approvals it then goes to the National Cancer Institute (NCI) Division of Cancer Prevention (DCP) for their approval. NCI Central Institutional Review Board (CIRB) approval is also required for the project to start while the trial is still active but is not sought until funding has been received.

Two projects have secured external funding, have completed the EA committees' review processes, and have received NCI approval. One is a case control study assessing short-term breast cancer risk through image-based analysis of screening mammograms (Project PI: Jon Steingrimsson, PhD, Brown University). The second is a case control study to assess the impact of breast compression pressure versus force in screening mammography on the likelihood of developing interval breast cancers (Project PIs: Etta Pisano, MD and Aili Maki, PhD, University of Toronto). Both projects involve analysis of images where software is being applied to TMIST images on computer systems controlled by EA IT personnel. Both projects are expected to be completed in the next year.

Two additional projects have been approved for grant submission through the process described above. The PreSCRiB study (PI: Elizabeth Burnside, MD MPH, U of Wisconsin) will

utilize Machine Learning applied to TMIST and All of Us data, including genetics, mammograms, social determinates of health and other data to develop individualized screening strategies for women. The second project (PI; Marc Ryser, PhD, Duke University) will utilize TMIST data to validate an algorithm the investigators have developed to assess overdiagnosis.
Another project that is in development and will likely be submitted for approval and funding in the next 6-9 months is a collaboration between TMIST and UK-based clinical trial PROSPECTS study teams to compare rates of all cancers and advanced cancers for annual, biennial, and 3-year screening, with analysis by age, race, ethnicity, breast density and other factors.
The ongoing TMIST study, as of June 24, 2024, has enrolled 101,394 women. Total enrollment is expected by late 2024 or early 2025. Follow-up on enrolled participants is expected to end in early 2028.

P1-01-06: Whole-genome landscapes of 1,364 breast cancers with clinical outcomes

Ryul Kim,JongHan Yu, Joonoh Lim, Brian Baek-Lok Oh, Seok Jin Nam, Seok Won Kim, Jeong Eon Lee, Byung Joo Chae, Ji-Yeon Kim, Ga Eun Park, Bong Joo Kang, Pil Sun Baek, Soo Yeon Bae, Chang Ik Yoon, Young Joo Lee, Dooreh Kim, Kabsoo Shin, Ji Eun Lee, Jun Kang, Ahwon Lee, Erin Connolly-Strong, Sangmoon Lee, Bo Rahm Lee, Yuna Lee, Ki Jong Yi, Young Oh Kwon, In Hwan Chun, Junggil Park, Jihye Kim, Chahyun Choi, Jong Yeon Shin, Hyunjung Lee, Minji Kim, Hansol Park, Ilecheon Jeong, Boram Yi, Won-Chul Lee, Jeong Seok Lee, Woo Chan Park, Sung Hun Kim, Yoon-La Choi, Jeongmin Lee, Young Seok Ju, Yeon Hee Park

Recent advancements in genomic technologies have become critical tools for deciphering the genetic complexities of cancer tissues, enabling precision medicine strategies aimed at improving patient clinical outcomes. Here we performed a comprehensive analysis of clinically annotated whole genome and whole transcriptome sequences from 1,364 breast cancer cases. Our investigation provides the most detailed genomic landscapes of breast cancer to date, which allowed us to comprehensively correlate genomic changes with clinical characteristics. Our findings include, but not limited to, (1) whole-genome-based homologous recombination deficiency profiles effectively predict responses to adjuvant chemotherapy and first-line CDK4/6 inhibitor treatment, (2) focal ERBB2 amplifications, often arising via extrachromosomal DNA mechanisms, are strongly associated with a positive response to neoadjuvant chemotherapy. Additionally, our study identified (3) recurrent copy number amplifications linked to patient survival, and (4) whole-genome-based intratumoral heterogeneity profiles that can predict patient survival as well as response to anti-HER2 therapies. Our work underscores the power of highly annotated whole-genome and transcriptome sequencing of a population-scale cancer cohorts for uncovering clinically relevant genomic mutations and novel molecular targets, thereby advancing precision oncology strategies for breast cancer.

P1-01-07: Radiogenomics during neoadjuvant therapy with aromatase inhibitors: integrating dynamic magnetic resonance data and molecular biology

Stephanie Lee, Andliena Tahiri, Kjell-Inge Gjesdal, Torben Lüders, Laurens Reitsma, Marianne Lyngra, Alvaro Köhn-Luque, Vessela Kristensen, Jürgen Geisler, Jonn Terje Geitung

Background: Neoadjuvant treatment of locally advanced breast cancer (LABC) is now well-established and considerable progress has been made concerning drug development for subgroups of patients. However, reliable predictive markers are still lacking for many patients. Thus, radiological measures like repeated MRI of the breast and axilla, after 3 and 6 months of therapy, are used to follow the patients during neoadjuvant therapy to confirm successful downstaging. Although not established in clinical routine, dynamic MRI contains quantitative information that can provide valuable insight into the tumour microenvironment and, when combined with clinical and molecular data, has the potential to enhance the prediction of tumor responses. Here, we analyze split-dynamic MRI data in relation to clinicopathological and molecular data to further identify disease heterogeneity that can be used to improve prognostic accuracy and inform treatment decisions in breast cancer patients.
Methods: This study reports results from eligible patients with ER pos., HER2 neg. LABC that were enrolled in the NEOLETEXE-trial (1). Clinicopathological, molecular, and advanced MRI data were acquired from this trial, collected before, during, and after neoadjuvant endocrine therapy (NET) with aromatase inhibitors given in sequence. MR images were generated using a split-dynamic technique that simultaneously acquires high spatial resolution and high temporal resolution images, providing information on tissue permeability and vascularity. The images underwent post-processing on the nordicICE software where parametric values were extracted based on whole-tumour volumes of interest. These parametric values were analysed in correlation with clinico-pathological data and with molecular findings from bulk RNA-seq and single cell data from a subset of the same patients.
Results: From the kinetic MRI data, the volume transfer constant (Ktrans), a parameter reflecting capillary permeability, was significantly reduced after NET ($p = 0.005$). Bulk RNA-seq data was analysed for gene expression, pathway involvement, and cell type abundance before, during, and after treatment. Gene expression analysis revealed significant dysregulation of genes related to cell proliferation and cell cycle regulation following treatment. Biological pathway analysis revealed significant down-regulation of hemostatic activity and upregulation of cell cycle and interleukin signaling following treatment. Cell type analysis revealed a higher abundance of CD4+ T-cells and T-helper cells following treatment. These results will be further correlated with single cell data as well as measures of treatment response and clinical outcome.
Conclusions: Our findings suggest that the addition of MRI data to clinicopathological and molecular data enhances the characterization of tumor responses during NET for locally

advanced breast cancer.

1. The NEOLETEXE trial: a neoadjuvant cross-over study exploring the lack of cross resistance between aromatase inhibitors. Bahrami N. et al., Future Oncoloy 15 (32), 3675-3682, 2019.

P1-01-08: Chemoprevention Uptake Before and After the Release of Evidence-Based Guidelines for Low-Dose Tamoxifen Among Patients with Atypical Hyperplasia, Lobular or Ductal Carcinoma In Situ

Katherine Crew,Margaret H. Kyle, Katherine D. Crew

Background: Patients with a history of atypical hyperplasia (AH), lobular or ductal carcinoma in situ (LCIS/DCIS) are at elevated risk of developing invasive breast cancer, yet chemoprevention uptake with selective estrogen receptor modulators (SERM) or aromatase inhibitors (AI) in this population remains low. Efficacy of low-dose tamoxifen, for 3 years at 5 mg/day rather than 5 years at 20 mg/day, was established in 2019, which led to evidence-based guidelines from the American Society of Clinical Oncology (ASCO) and the National Comprehensive Cancer Network (NCCN). We aimed to assess changes in chemoprevention uptake before and after availability of low-dose tamoxifen and identify sociodemographic and clinical factors associated with uptake during this period.

Methods: Women diagnosed with AH, LCIS, or DCIS from 2016-2019 and 2020-2023 at Columbia University Irving Medical Center in New York, NY were identified using electronic health records (EHR). Patients under age 35 years, with concurrent or prior invasive breast cancer, with a history of bilateral mastectomy, and patients with estrogen receptor and progesterone receptor-negative DCIS were excluded from the analysis. The primary outcome, SERM or AI use, was dichotomized (yes/no ever used), as was use of low-dose tamoxifen. Descriptive statistics were generated and differences in clinical and sociodemographic variables by diagnosis date (2016-2019 vs. 2020-2023) and by chemoprevention use (yes/no) were assessed using chi-squared and two-sample t-tests. Logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (CI) for variables associated with any chemoprevention and low-dose tamoxifen uptake. Multivariable models were adjusted a priori for breast histology, age at diagnosis of high-risk breast lesion, and race/ethnicity, with significant covariates ($p<0.05$) in univariate analysis also included.

Results: Among 2258 evaluable women, mean age was 57.94 (SD 11.88), including 36% with AH, 15% with LCIS, and 48% with DCIS, with 37% ever chemoprevention use. Comparing pre/post low-dose tamoxifen periods (2016-2019 vs. 2020-2023), uptake of chemoprevention (33.99% vs 39.31%, $p=0.009$) and low-dose tamoxifen (3.27% vs 8.57%, $p<0.001$) significantly increased. During this period, low-dose tamoxifen use significantly increased for all of the following subgroups: age <50 vs. ≥50, White vs. non-White, AH/LCIS vs. DCIS. Among 834 women who initiated chemoprevention during this timeframe, 140 (17%) took low-dose tamoxifen. In multivariable analysis, women diagnosed with high-risk breast lesions in 2020-2023 compared to 2016-2019 were more likely to take low-dose

tamoxifen (OR=2.72, 95% CI=1.75-4.22). Younger women (<50 vs. ≥50) and women with less advanced breast histology (AH/LCIS vs. DCIS) were more likely to start low-dose tamoxifen (OR=3.14, 95% CI=2.07-4.74 and OR=2.97, 95% CI=2.00-4.40, respectively). Discussion/Conclusion: Since low-dose tamoxifen was introduced in 2019 as a breast cancer chemoprevention option for women with AH, LCIS, or DCIS, we observed a significant increase in low-dose tamoxifen use and chemoprevention uptake overall. Among women who initiated chemoprevention, low-dose tamoxifen use was higher among younger women and those with less advanced breast lesions. Low-dose options of proven chemopreventive agents for shorter duration may increase acceptance of risk-reducing medications for breast cancer prevention.

P1-01-09: Clinicopathological features, treatment patterns and outcomes of germline BRCA mutation (gBRCAm)-associated breast cancer compared with sporadic tumors in young women: a matched analysis.

Stefania Morganti, Se E. Kim, Qingchun Jin, Gregory Kirkner, Craig Snow, Yue Zheng, Kate E. Dibble, Tal Sella, Kathryn J. Ruddy, Shoshana Rosenberg, Laura C. Collins, Jeffrey Peppercorn, Lidia Schapira, Virginia F. Borges, Steven E. Come, Ellen Warner, Brittany L. Bychkovsky, Philip D. Poorvu, Nancy U. Lin, Matteo Lambertini, Sara M. Tolaney, Judy E. Garber, Nabihah Tayob, Ann H. Partridge, Filipa Lynce

Background: Up to 10% of early breast cancer (BC) occur in gBRCAm carriers. Patients with gBRCAm-associated BC are often reported to have similar survival as non-gBRCAm carriers, but data with modern treatment regimens are limited (Copson et al., Lancet Oncology 2018). We previously observed a slightly better outcome for gBRCAm-associated triple-negative breast cancer (TNBC) compared with matched sporadic TNBC in a real-world cohort of women of all ages (Morganti, ESMO 2023). With a similar approach, we compared clinicopathological features, treatment patterns and outcomes between gBRCAm carriers and matched non-carriers in a separate cohort of women age ≤40 at diagnosis.
Methods: Patients were identified from the Young Women's Breast Cancer Study (YWS), a multisite prospective cohort of 1302 women diagnosed with stage 0–IV breast cancer at age ≤40 years, enrolled from 2006 to 2016. Patients with stage I-III, HER2-negative BC with known gBRCA status were included. Clinical and germline genetic data were collected from patient surveys and medical records. gBRCAm cases were matched 1:2 with non-gBRCAm controls by age group in decades (20-30, 31-40 years old), stage, hormone receptor status and year of diagnosis. Clinicopathologic features and treatments were compared between gBRCAm carriers and non-gBRCAm controls using Fisher's exact test for categorical variables and Wilcoxon rank sum test for continuous variables. Survival outcomes were compared between the gBRCAm carrier vs. controls utilizing Cox proportional hazards model and associated Wald test for the p-value.
Results: We identified 113 gBRCAm (74 BRCA1, 39 BRCA2) carriers and 226 matched non-gBRCAm controls from the 802 patients with HER2-, stage I-III BC enrolled in the YWS. Median age was 36 years (yrs) in carriers and controls. Most patients had stage II (46.3%)

BC, 31% had stage I and 22.7% had stage III. Approximately half of patients had TNBC (51.3%), and half had hormone receptor-positive (HR+; 48.7%) BC. Only 6% of patients underwent genetic testing before BC diagnosis (14.8% of gBRCAm carriers and 1.7% of non-carriers; p<0.001).
Compared with sporadic tumors, gBRCAm-associated BC had higher tumor grade (p=0.014) and higher recurrence score by genomic testing if HR+ (median 31 vs 19, p<0.001). A similar proportion of gBRCAm carriers and non-carriers received chemotherapy (91.2% vs 86.7%, p=0.29), including anthracyclines (94.2% vs 90.8%, p=0.38) and platinum-based regimens (10.7% vs 9.7%, p=0.84). Endocrine therapy for HR+ tumors was less often administered to gBRCAm carriers than controls (80.9% vs 93.3%, p=0.041).
At a median follow up of 11.1 years (IQR 9.9-13.6), invasive disease-free survival (iDFS) did not differ between gBRCAm carriers and controls after adjusting for age, grade, and chemotherapy administration (hazard ratio [HR] 0.80, 95% CI 0.50-1.29; p=0.36), similarly for HR+ BC (HR 0.85, 95% CI 0.41-1.75; p=0.66) and TNBC (HR 0.82, 95% CI 0.44-1.53; p=0.53). A numerical trend towards lower risk of recurrence was observed for gBRCAm carriers compared to controls (5-yr iDFS 82.4% vs 78.0%). Similarly, recurrence-free survival (RFS) did not differ between carriers and controls (HR 0.71, 95% CI 0.44-1.17; p=0.18) but with a trend favoring gBRCAm over controls (5-yr RFS 84.4% vs 79.0% in the overall population; 90% vs 82% for HR+ BC; 79.3% vs 76.1% for TNBC). Overall survival was similar between carriers and controls (HR 0.71, 95% CI 0.40-1.26; p=0.24; 5-yr OS 88.1% vs 87.0%). Outcomes did not differ when comparing separately gBRCA1m carriers and gBRCA2m carriers with their controls.
Conclusions
In this multicenter cohort of young patients with BC, gBRCAm-associated BC had higher-risk pathologic features compared with matched non-gBRCAm BC. Rate of chemotherapy administration was similar between carriers and controls. After adjusting for chemotherapy treatment and clinicopathologic variables, outcomes did not differ in gBRCAm carriers vs controls.

P1-01-10: Comparison of different gene expression tests in breast cancer: poor correlation of Prosigna, EndoPredict and MammaPrint

Brigitte Schober, Andreas Bösl, MSc, Dr. Sylvia Blassnig, Dr. Barbara Aberer, Dr. Margit Sandholzer, Prof. Dr. Felix Offner

Background: The accurate estimation of the risk of disease recurrence in patients with early-stage estrogen receptor positive, human epidermal growth factor receptor 2 (HER2) negative breast cancer is of paramount importance in order to identify those patients in whom adjuvant chemotherapy can be avoided. In clinical practice, the implementation of this approach is becoming increasingly dependent on the results of gene expression assays. This present study aimed to assess the concordance between the 50-gene (PAM50) signature Prosigna®, the 70-gene MammaPrint® (MP) as well as the 12-gene assay EndoPredict® (EP).

Material and MethodsRepresentative tissue of 48 primary tumours was analysed by MP and EP during routine diagnostic procedures between 2008 and 2015. Corresponding formalin-fixed, paraffin-embedded tissue was thereafter analysed by the PAM50. The risk categories of the three tests were compared.
Furthermore, a decision impact analysis was conducted with the objective of a more accurate categorization of the outcomes obtained from Prosigna® in comparison to those yielded from MP and EP.
Results: 82% (39/48) of the samples showed valid results by all three tests, of which only 42% (20/48) of the cases had an identical risk classification and 40% (19/48) of the cases displayed a discrepancy between the results. 9 cases (18%) had missing data for at least one assay.
The correlation between the three tests in terms of risk classification is weak.
Comparing Prosigna® with the EPclin score shows an overall correlation of 24 cases (6 low risk, 18 high risk) with 57% concordance and a discrepancy of 10% (4/42). 14 cases (33%) were considered intermediate risk by Prosigna® with 5 (12%) low risk and 9 (21%) high risk classifications by EP.
56% (22 cases) show a correlation between MP and Prosigna® (6 low risk, 16 high risk) with a discrepancy of 11% (4 cases). An intermediate result was obtained for 33% (13 cases) of which 5 (13%) were considered low risk and 8 (21%) were considered high risk by MammaPrint.
The original therapeutic recommendation was based on the MP and would have been altered in 21% (10/48) of the patients following Prosigna® test results. Included in this group are the 14 cases classified as intermediate risk, where 5 cases (10 %) would have been treated differently than the original treatment plan. Consequently, no discernible trend was evident in this cohort, if the intermediate risk assessment results in either over- or undertreatment of the tumor.
Of the discrepant and intermediate cases, 4 have developed metastases and 1 has experienced a recurrence. 3 of the respective tumors were classified as intermediate by Prosigna®. 2 of 3 cases classified as intermediate were subsequently high risk by both MammaPrint and EndoPredict, while 1 was high risk in MP and low risk in EP. 1 tumor was classified high risk by Prosigna® and EP, but low risk by MP.
ConclusionThe results of the three tests indicated disparate recommendations for treatment in 10% of the patients. Moreover, all three tests provide distinct supplementary data regarding tumor subtype and risk of recurrence. Consequently, those tests cannot be employed interchangeably. The results emphasize the pressing necessity for further comparative analysis of multi-genomic tests to prevent misclassification of risk class and disease recurrence risk in breast cancer patients.

P1-01-11: Use of a Digital Navigator to Deliver Patient-Centered Genetic Services in Mammography

Tara Schmidlen, Emilie Simmons, Vivian Pan, Neha Awati, Lara Balay, Iris Fietko, Angelina Izguera, Genesis Rios, Moran Snir, Pamela Ganschow

The National Accreditation Program for Breast Centers (NAPBC) 2024 Standards require implementation of a protocol to identify and manage patients at increased risk for breast cancer due to personal risk factors or family history. In response, the University of Illinois Health partnered with Nest Genomics to implement a comprehensive digital platform to streamline and scale genetic services. The Nest Digital Patient Navigator for Hereditary Cancer Risk Assessment (HCRA) was introduced into a routine mammography setting in November 2023. To date, 4153 patients underwent HCRA with 17% meeting genetic testing (GT) criteria. Successful patient identification led to a new challenge: bottlenecks in access to genetic counseling (GC). To streamline care and empower patients to select their preferred follow-up approach, post-assessment digital navigation was implemented in January 2024 and offered to GT eligible patients.

Patients receiving screening mammograms completed HCRA in the waiting room prior to imaging. Patients who met GT criteria were asked via digital navigator to choose their preferred follow-up mechanism: digital pre-test education, virtual group GC, one-on-one GC, or not interested. The digital pre-test education module was developed by genetic counselors at Nest and UIC and utilized a teach-back approach to ensure understanding of the benefits and limitations of GT, possible GT results, how results impact care, and GT logistics. A GC reviewed completed HCRAs and follow-up preferences. Patients consenting to GT after digital pretest education received a phone call and MyChart message to confirm consent and inform them the test was ordered and a saliva kit shipped. For patients requesting GC services, appointments will be scheduled. GT eligible patients not engaging with the digital navigator received standard referral and GC scheduling.

In a pilot phase from January to early May 2024, 96 patients eligible for GT were sent a link to the digital navigator via text or email to capture GT follow-up preference. Only one third of those invited (n=31, 32%) engaged and only 38 (14%) selected a follow-up preference. To increase engagement, beginning mid-May, the workflow was updated such that patients meeting GT criteria select a follow-up preference immediately after completing the HCRA and only those selecting digital pretest education are sent a link via text or email. Additionally, a Spanish version of the HCRA was added at this time. These changes increased the percent of patients who selected a follow-up preference from 14% to 74%.

In total, from January through June 2024, 156 patients selected a follow-up preference via digital navigator, with most (n=98, 63%) opting for digital pre-test education, 4 selecting group GC, and 54 selecting one-on-one GC. Of the 73 completing digital pre-test education, 31 consented to GT, 7 were not interested in GT, and 19 were unsure about GT. Of the 31 who consented, 26 had a test order placed, 2 had prior GT, 2 had GT in progress, and 1 declined GT after GC outreach. Of the 4 patients requesting group GC, 1 completed and had GT ordered, 1 missed and has not rescheduled, and 2 are scheduled. Of the 54 patients requesting one-on-one GC, none have been scheduled yet due to an administrative backlog.

Pairing post-assessment digital navigation with HCRA allows patients to access education and GT based on individual preferences. Most patients completing digital HCRA and meeting GT criteria opted for digital pre-test education over one-on-one or group GC, allowing them to have a test ordered sooner. This digital solution has the potential to reduce bottlenecks and prioritizes limited GC availability for those who prefer one-on-one

or group counseling. Further work to optimize reminders to boost engagement with the digital navigator and to improve return of sample kits to the laboratory is underway.

P1-01-12: Impact of Preoperative BRCA Testing and National Health Insurance Coverage on Surgical and Risk-reducing Decision-making in Japanese BRCA-mutated Breast Cancer Patients

Kumiko Kida, Junko Takei, Misato Suzuki, Megumi Okawa, Risa Kasahara, Asaka Wada, Yuka Kajiura, Fumi Akitani, Kyoko Shiota, Michiko Yamanaka, Atsushi Yoshida

Introduction: BRCA1 or 2 (BRCA) germline mutations cause increased risks of breast and ovarian cancers. Therefore, preoperative BRCA testing could influence surgical strategies and preventive interventions for breast cancer patients with BRCA mutations. In Japan, BRCA genetic testing and risk-reducing surgeries became eligible for national health insurance coverage in 2020, previously conducted as costly private healthcare. When Japanese national insurance coverage is approved, patients' out-of-pocket expenses are reduced to 30% or less. This study aimed to investigate the impact of preoperative BRCA genetic testing and national health insurance coverage on surgical decision-making and risk-reducing surgeries among Japanese populations.
Methods:Japanese women with BRCA germline pathogenic mutations and early breast cancer who underwent definitive surgery from 2004 to 2024 were retrospectively identified from institutional databases at St. Luke's International Hospital in Tokyo, Japan. Factors including clinicopathologic information and surgical decisions were analyzed. We assessed whether undergoing BRCA testing before or after breast cancer surgery influenced the choice of surgical procedures and risk-reducing surgeries. Additionally, we examined whether approval for national health insurance coverage affected these decisions. The chi-square test was used for statistical comparisons.
Results: A total of 273 breast cancer patients with germline BRCA mutations were identified (BRCA1: 120, BRCA2: 153). Among them, 167 patients (61.2%) underwent BRCA testing prior to breast cancer surgery. Surgical treatments included breast-conserving surgery (BCS) for 78 patients (28.6%) and mastectomy for 195 patients (71.4%). Among the 167 patients who learned of their BRCA mutation before breast cancer surgery, while BCS was feasible for 113 patients based on preoperative imaging, 24 patients (21.2%) chose BCS, and 89 patients (78.8%) opted for mastectomy due to their mutation results. The breast-conserving rate was 14.4% for patients with preoperative BRCA testing compared to 50.9% for those tested after surgery ($p<0.0001$).
Risk-reducing mastectomy (RRM) was performed in 115 patients (52.0%, excluding cases with bilateral breast cancers). Among patients with preoperative testing, 94 (63.1%) underwent RRM, including 83 (55.7%) who had RRM simultaneously with breast cancer surgery. Risk-reducing salpingo-oophorectomy (RRSO) was performed in 98 patients (61.3%, excluding cases with previous non-preventive oophorectomy), including 67 (41.9%) who had RRSO simultaneously with breast cancer surgery. Patients who learned of their BRCA mutation after breast cancer surgery were subsequently less likely to undergo

risk-reducing surgeries compared to those with preoperative testing: 29.2% underwent RRM and 50.5% underwent RRSO (p=0.0001 and 0.097, respectively).
Before national health insurance approval, 46.6% underwent preoperative BRCA testing, 28.0% underwent RRM, and 17.5% underwent RRSO simultaneously with breast cancer surgery. After approval, these rates increased to 86.9% for preoperative BRCA testing, 51.7% for RRM, and 43.0% for RRSO (p<0.0001, 0.0004, and <0.0001, respectively, compared between before and after approval).
Conclusions: Most Japanese patients who learned of their BRCA mutation before their breast cancer surgery opted for mastectomy instead of BCS due to their mutation status. Preoperative BRCA testing and national health insurance coverage significantly increased the likelihood of undergoing risk-reducing surgeries. These findings emphasize the key role of preoperative BRCA testing and national health insurance coverage in informing surgical decisions and enhancing preventive care.

P1-01-14: Risk-reducing medications and primary breast cancer prevention: a network meta-analysis of randomized controlled trials.

Ghazaleh Pourali, Minglu Liu, Supriya Sthapit, Angela Hardi, Chongliang Luo, Adetunji T. Toriola

Background: Risk-reducing medications can substantially reduce the risk of breast cancer and represent a viable approach to reducing the rising breast cancer incidence. However, only a very limited number of medications, selective estrogen receptor modulators (SERMs), and aromatase inhibitors (AIs) are currently approved for breast cancer chemoprevention since these approvals are mainly based on findings from randomized controlled trials (RCTs), which are challenging to perform in the prevention setting; hence, very few studies exist for other medications. Our goal in this network meta-analysis (NMA) is to pool together estimates from various RCTs and identify medications that are associated with a reduction in breast cancer risk and can be used in primary breast cancer prevention.
Methods: We performed a comprehensive literature search using Embase.com, Ovid-Medline All, Scopus, and the Cochrane Library to identify RCTs on breast cancer prevention and various risk-reducing medications. The search, completed on November 16, 2023, identified 13,642 citations. Three researchers extracted the data and assessed the quality of the studies. After removing duplicates in Endnote, we screened 8,692 citations and included 43 studies that met our criteria. The inclusion criteria included RCTs on women without a history of invasive breast cancer, focusing on pharmacological interventions. We excluded lifestyle interventions, unspecified multivitamins, and herbal drugs without active ingredient specification. The primary outcome was the incidence of overall breast cancer. In the NMA for overall breast cancer, 35 studies evaluating 13 medications were included, as these were compared to other medications more than once. These medications included tamoxifen, raloxifene, third-generation SERMs (arzoxifene, bazedoxifene, lasofoxifene), AIs (anastrozole, exemestane), statins (pravastatin, simvastatin, lovastatin), thiazolidinediones (rosiglitazone, pioglitazone), sulfonylurea, metformin, metformin plus sulfonylurea,

fenretinide, tamoxifen plus fenretinide, calcium, and calcium plus vitamin D. For the secondary analysis, 16 studies evaluating AIs, tamoxifen, and raloxifene were included for invasive breast cancer. Efficacy was measured using risk ratios (RRs) with confidence intervals (CIs), and the number needed to treat (NNT) was calculated.
Results: Six medications were associated with reduced breast cancer risk compared to placebo: sulfonylurea (RR=0.18, 95%CI=0.03-0.90), thiazolidinediones (RR=0.26, 95%CI=0.08-0.79), third-generation SERMs (RR=0.46, 95%CI=0.33-0.66), AIs (RR=0.50, 95%CI=0.39-0.66), raloxifene (RR=0.63, 95%CI=0.47-0.84), and tamoxifen (RR=0.76, 95%CI=0.65-0.88). The NMA showed no significant inconsistency (Q=5.09, d.f.=7, p=0.65), indicating agreement between direct and indirect comparisons of medications, and between-study heterogeneity was low ($\tau 2$=0.0067, I2 = 9%). Notably, third-generation SERMs (RR=0.61, 95% CI=0.42-0.89) and AIs (RR=0.67, 95% CI=0.49-0.90) showed greater efficacy than tamoxifen. The NNTs were 43.9, 48.6, 67.3, 73.0, 96.9, and 149.7 for sulfonylurea, thiazolidinediones, third-generation SERMs, AIs, raloxifene, and tamoxifen, respectively. For invasive breast cancer prevention, AIs (RR=0.48, 95% CI=0.33-0.71), raloxifene (RR=0.63, 95% CI=0.47-0.86), and tamoxifen (RR=0.63, 95% CI=0.51-0.78) were effective compared to placebo. NMA inconsistency was significant (Q=7.48, d.f.=1, p=0.01), with moderate between-study heterogeneity ($\tau 2$=0.0323, I2 = 58.8%).
Conclusions
These results offer a comprehensive comparative analysis of risk-reducing medications in relation to breast cancer. Findings can guide future research in breast cancer prevention as well as clinical considerations and guidelines on breast cancer chemoprevention.

P1-01-15: Assessing BRCA1/2 Testing in Breast Cancer Patients: A Retrospective Analysis of Real-World Data From the IntegraConnect PrecisionQ De-Identified Database

Fred Kudrik, Rushir Choski, Vikram Gorantla, Debra Patt, Mike Gart, Anupama Vasudevan, Prateesh Varughese, Brandon Wang, Simon Blanc

Background: Additional clinical guidelines have been put forth by the American Society of Clinical Oncology and Society of Surgical Oncology for BRCA 1/2 testing in patients with breast cancer.1 We sought to understand from a de-identified real-world data set of patients the current rates of BRCA1/2 testing among all breast patients who were newly diagnosed or diagnosed with metastatic disease from 2021 to 2023.
Methods: We used the Integra Connect PrecisionQ real-world de-identified database of over 3 million cancer pts across 500 sites of care. From this database, we identified breast cancer patients who had undergone manual chart curation whereby BRCA testing was evaluated. Patients included in the assessment who were metastatic required a metastatic date between 1/1/2021 and 12/31/2023 and patients who were not metastatic required a diagnosis date between 1/1/2021 and 12/31/2023. Patients were stratified by age, race, hormone receptor and HER2 expression status. Testing rates were also evaluated by year. Descriptive analyses were performed and proportions were compared using a chi-squared

test.
Results: There were 2,638 metastatic patients (mets pts) and 1,754 patients without metastasis (non-mets pts). The median age of the mets pts at metastasis was 66 [IQR 55; 75] and the median age of the non-mets pts at diagnosis was 49 [IQR 52; 71]. The percentage of metastatic patients who were HER2- was 83%, HER2+ was 15% and unknown was 2%. The percentage of non-mets pts who were HER2- was 89%, HER2+ was 10%, and unknown was 1%. The percentage of mets-pts who identified as White was 72%, Black/African American was 15 % and Other was 14%. The percentage of non-mets pts who identified as White was 76%, Black/African American was 11% and Other was 12%. Among the mets pts BRCA testing was 71%. The rate of BRCA testing was 72% in 2021, 71% in 2022, and 72% in 2023 by year of patient metastasis. The rate of BRCA testing among HR+/HER2- pts was 67%, HR-/HER2- pts was 87%, and HER2+ pts was 59% (P <0.01). The rate of BRCA testing among patients age <65 was 81% and age >=65 was 63%. (P <0.01). The rate of BRCA testing among patients who identified as White was 70% and among those who identified as Black/African American was 73% (P >0.05). Among the non-mets pts BRCA testing was 52%. The rate of BRCA testing was 53% in 2021, 50% in 2022, and 52% in 2023 by year of patient diagnosis. The rate of BRCA testing among HR+/HER2- pts was 48%, HR-/HER2- pts was 65%, and HER2+ pts was 47% (P <0.01). The rate of BRCA testing among patients age <65 was 63% and age >=65 was 39%. (P <0.01). The rate of BRCA testing among patients who identified as White was 52% and among those who identified as Black/African American was 52% (P >0.05).
Conclusions: Based on our findings using real-world data for BRCA testing and in light of the current guidelines there will need to be considerable increases in BRCA testing among patients diagnosed with breast cancer regardless of stage who are less than age <65 as only 63% of non-metastatic patients are receiving BRCA testing and 81% of metastatic patients are receiving BRCA testing.

P1-01-16: Molecular landscape of HR+/HER2- male breast cancer (MaBC) compared with female breast cancer (FeBC)

Dario Trapani, Sachin Kumar Deshmukh, Sharon Wu, Joanne Xiu, Pooja Advani, Daniel L. Abravanel, Nancy U. Lin, Giuseppe Curigliano, William Flood, Stephanie L. Graff, Maryam Lustberg, Philip Spanheimer, George W. Sledge Jr, Sara M. Tolaney, Jose P. Leone

Background: Hormone receptor–positive/human epidermal growth factor receptor 2–negative (HR+/HER2−) breast cancer (BC) is more prevalent in male patients compared to female counterparts. Gender associated differences along with molecular differences, immune system, and other factors might play a crucial role in disease management. Here, we characterized molecular and immune differences between HR+/HER2- MaBC and FeBC.
Methods: 8156 female (HR+/HER2-, n = 5232) and 121 male (HR+/HER2-, n = 97) BC

samples were analysed by next-generation sequencing (NextSeq; WES, NovaSeq) and Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) (high ≥10 mt/MB) was calculated. Microsatellite-instability (MSI) was tested by IHC and NGS. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$).
Results: The proportion of HR+/HER2- subtype was significantly higher in MaBC (80.17% vs 64.14%, $p<0.05$) compared with FeBC. HR+/HER2- MaBC had higher frequency of BRCA2 (10.64% vs 4.38%, $p<0.05$), GATA3 (22.68% vs 14.11%, $p<0.05$), but lower frequency of TP53 (3.45% vs 30.76%, $q<0.05$), ESR1 (4.12% vs 13.62%, $p<0.05$) and CDH1 (1.06% vs 17.43%, $q<0.05$) compared to HR+/HER2- FeBC. Compared to HR+/HER2- FeBC, MaBC had lower frequency of TMB-high (2.2% vs 9.08%, $p<0.05$), but there was no difference in dMMR/MSI-high (0% vs 0.61%, $p=1$) or PD-L1 (IHC, 22C3) positivity (21.21% vs 19.47%, $p=0.72$). HR+/HER2- MaBC had lower expression of AR-RNA (fold change (FC): 1.4, $q<0.05$), higher AR-protein (IHC) positivity (97.94% vs 84.03%, $q<0.05$), but no difference was noted in the frequency of fusion variant-AR (1.04% vs 3.19%, $p=0.37$) compared to FeBC.
HR+/HER2- MaBC had increased expression of MHC class I gene HLA-B (FC: 1.2, $p<0.05$), MHC class II gene HLA-DQB2 (FC: 1.6, $q<0.05$), but decreased expression of drug efflux gene ABCC2 (FC: 1.4, $q<0.05$), and stem cell-related genes (KLF4, SOX2, POU5F1, PROM1, ALDH1A1, FC: 1.3-1.9, $q<0.05$) compared to HR+/HER2- FeBC.
Conclusions: These data indicate that HR+/HER2- MaBC has a differential mutational spectrum and TMB-high frequency, MHC Class I and MHC class II, drug efflux and stem cell-related gene expression compared to their HR+/HER2- FeBC counterparts. These suggest important differences in tumor biology between men and women with HR+/HER2- breast cancer. A better understanding of these differences with additional research may help in design future clinical trials and treatments for men with HR+/HER2- BC.

P1-01-17: PD-L1 Upregulation in Circulating Tumor Associated Cells Predicts for clinical outcomes in a phase I/II clinical trial using SV-BR-1-GM vaccine with the check point inhibitor retifanlimab in Metastatic Breast Cancer Patients, an Interim Analysis

Daniel Adams, Blaise Bayer, Cha-Mei Tang, Miguel Lopez-Lago, Giuseppe Del Priore, William V. Williams

Background: Circulating Tumor Cells (CTCs) are clinical indicators of poorer clinical outcomes in metastatic Breast Cancer (mBC) and may be monitored post therapy induction to identify patients not responding to treatment. However, CTCs are rare in mBC (i.e. <20% of patients), and many patients without CTCs also often progress. Recently an inflammatory pro-tumorigenic PD-L1 expressing macrophage (Cancer associated macrophage-like cell [CAML]) was identified in the blood along with CTCs which are common in mBC (i.e. >90% of patients) and also indicate tumor response to new therapies. SV-BR-1-GM, which is a mBC cell line derived vaccine with antigen presenting characteristics, developed for treatment of mBC as a monotherapy, or in combination with checkpoint inhibitors. Here we

report the results of CTC & CAML changes and their PD-L1 expression profiles monitored from the peripheral blood, pre and post inoculation with SV-BR-1-GM. We present Progression Free Survival (PFS) and Overall Survival (OS) at 24 months as part of the exploratory portion of the single arm open label roll over phase 1/2 trial (NCT03328026).
Methods: SV-BR-1-GM treatment includes low pre-dose cyclophosphamide, intradermal inoculation of ~20 million irradiated SV-BR-1-GM cells, post-dose local interferon-α with cycles and an anti-PD-1 inhibitor (retifanlimib), with cycles every 3 weeks. Blinded anonymized blood samples were taken at baseline (BL), prior to starting SV-BR-1-GM therapy (n=44), a 2nd sample (T1) taken after therapy initiation (~23 days) and if possible, a third sample (T2) taken at the standard tumor assessment (~75 days). To evaluate the predictive value of CTCs/CAMLs and their PD-L1 expressions, cells were isolated and quantified using the LifeTracDx liquid biopsy test. The quantities of CTCs & CAMLs and their respective PD-L1 were analyzed based on PFS using RECIST v1.1 and OS hazard ratios (HRs) by censored univariate analysis at 24 months.
Results: Peripheral blood was available from n=41 of 44 mBC pts at BL, prior to therapy induction. CTCs were found in 42% (n=17/41) of patients and CAMLs were found in 90% (n=37/41) at BL. Presence of CTCs at BL significantly correlated with worse PFS (HR=2.3, (CI95% 1.1-4.8, p=0.0351) and OS (HR=3.6, (CI95% 1.5-8.7, p=0.0091). T1 samples were available from 83% (n=34/41) of patients, with presence of CTCs at T1 not significantly correlating with worse PFS (HR=2.5, (CI95% 1.0-5.9, p=0.0743) nor OS (HR=1.6, (CI95% 0.6-4.5, p=0.5565). However, a drop in CAMLs or CTCs after treatment at T1 was observed in 38% of patients, correlating with a significantly improved PFS HR=2.5, (CI95% 1.2-2.5, p=0.0299), but not significantly improved OS HR=2.8, (CI95% 1.0-7.7, p=0.0883). Expression of PDL1 on CAML/CTC at BL was not correlated with improved PFS (HR=0.6, (CI95% 0.3-1.2, p=0.2355) nor OS (HR=0.8, (CI95% 0.4-1.9, p=0.7847), though an increase in PD-L1 was observed in CAMLs/CTCs at the T1 (n=7) and the T2 (n=8) time points. Further, patients with high PDL1 on CTC/CAML PDL1 at the T1 or T2 were not correlated with significantly improved PFS HR=1.9, (CI95% 0.9-3.9, p=0.1259), but were correlated with significantly improved OS HR=3.9, (CI95% 1.4-10.8, p=0.0164).
Conclusions: In an interim analysis of heavily treated mBC patient population, we observed that treatment with the SV-BR-1-GM regimen was associated with decreases in the presence of CTCs and CAMLs in 38% of patients, which significantly correlated with better PFS and trended for better OS within 2 years. Further, SV-BR-1-GM therapy appeared to upregulate PD-L1 in n=13 patients which appeared to have better responses to combination treatment with the anti-PD-1 check point inhibitor retifanlimab.

P1-01-18: Prevalence of functional HRD by the RAD51 assay: a pooled analysis with 367 patients from BRCA-associated tumor types

Guillermo Villacampa, Heura Domenech, Cristina Viaplana, Alba Llop-Guevara, Sara Simonetti, Carmen Garcia Duran, Joanna Domènech, Sara Arce, Sara Gutierrez-Enriquez, Rodrigo Dienstmann, Paolo Nuciforo, Mafalda Oliveira, Cristina Saura, Ana Oaknin, Judith Balmaña, Joaquin Mateo, Violeta Serra

Background: The functional biomarker RAD51 identifies patients with homologous recombination deficiency (HRD) tumors. Furthermore, RAD51 has been validated in different clinical trials in breast cancer (GeparSixto [NCT01426880] and GeparOla [NCT02789332]), showing both prognostic and predictive value. Here, we present a pooled analysis of RAD51 results to evaluate the prevalence of HRD status in BRCA-associated tumor types.
Methods: We conducted a pooled analysis of all patients evaluated with the RAD51 test between February 2021 and June 2024 at the Vall d'Hebron Institute of Oncology. RAD51, BRCA1 and yH2AX were quantified using an immunofluorescence assay. RAD51 was evaluated both as a continuous score (ranging from 0 to 100) and as grouped categories (low vs. high, with a pre-defined cut-off of 10%). The primary objective of this study was to evaluate the percentage of functional HRD by RAD51 (RAD51 low) across BRCA-associated tumor types and stages of the disease. Fisher's exact test was used to statistically quantify the differences between percentages.
Results: A total of 574 tumor samples were evaluated; 367 (63.4%) were successfully scored by RAD51 and included in the pooled analysis. The median age at time of the biomarker assessment was 60 years. Most patients were diagnosed with breast cancer (49.0%), followed by ovarian cancer (25.9%), prostate cancer (18.6%), and other tumor types (6.5%). Samples were collected from primary tumors (46.5%), metastases (43.4%), and local recurrences (10.0%). Overall, the prevalence of low RAD51 tumors was 25.1% (92/367) and the prevalence of BRCA1 nuclear foci low was 11.1% (41/367). The highest percentage of low RAD51 tumors was found in ovarian tumors (44.2%), while the percentages in breast and prostate tumors were 12.2% and 22.1%, respectively ($p<0.001$). The percentage of BRCA1 low was 32.1% ovarian, 5.1% in breast and 1.6% in prostate ($p<0.001$). Among patients with BRCA1 low (n=41), 75.6% of them had concomitant low RAD51 values. In the subset of ovarian tumors (n=95), a numerically larger percentage of low RAD51 tumors was found in metastatic samples compared with primary tumors (53.3% vs. 44.8%). In breast cancer (n=180), low RAD51 samples were more frequently found in primary tumors than in metastatic tumors (18.2% vs. 6.2%, $p<0.001$). No association was found between RAD51 and yH2AX values (Pearson´s correlation= 0.02).
Conclusions: Functional HRD prevalence varies by tumor type and stage. RAD51 identifies patients beyond BRCA status who could benefit from PARPi therapies. Results on the association between RAD51 and clinical outcomes will be presented at the conference.

P1-01-19: Predicting response to capivasertib in AKT1 mutant advanced breast cancer

Sarah Mearns, Alex Pearson, Ros Cutts, Heena Shah, Li-Xuan Sim, Belinda Kingston, Kathryn Dunne, Marta Lubowiecki, Andriani Hadjiconstanti, Hannah Johnson, Lucy Kilburn, Laura Moretti, Andrew M. Wardley, Iain R. Macpherson, Richard D. Baird, Rebecca Roylance, Angela Casbard, Margherita Carucci, Sacha J Howell, Robert H Jones, Judith Bliss, Alistair Ring, Alistair Ring

Introduction: Activation of the PI3K-AKT and mTOR pathways is a major feature of the biology of breast cancer (BC), with these pathways altered or dysregulated in most BC. Oncogenic mutations in AKT1, most frequently E17K, are found in ~5% of advanced BC and are targetable by the approved AKT inhibitor capivasertib. We conducted genomic and transcriptomic analysis of a cohort of AKT1 mutant metastatic BCs with the aim to identify determinants of response to capivasertib.

Methods: We identified 39 AKT1 mutant BC from the plasmaMATCH clinical trial (18/39; NCT03182634), the FAKTION clinical trial (7/39 NCT01992952), and the ABC-BIO tissue collection study (14/39; CCR3991). FFPE extracted DNA was subject to whole exome sequencing (WES), and RNA to Truseq RNA sequencing. Clonal dominance was assessed in circulating tumour DNA (ctDNA) using Guardant360. Allelic imbalance at the AKT1 locus and clonal dominance of the AKT1 mutation were associated with progression free survival (PFS) in plasmaMATCH Cohorts C (capivasertib plus fulvestrant) and D (capivasertib alone) combined.

Results:WES at median coverage 93x (range 55-169x) reconfirmed AKT1 mutations in 33/39 (85%) samples: 25/33 (76%) E17K; 3/33 (12%) L52R; 1/33 (3%) E49K; 1/33 (3%) L52R+C77F; 1/33 (3%) L52R+E375K; 1/33 (3%) S129L; 1/33 (3%) Q79K. 6/39 discordant samples principally reflected AKT1 mutations identified in ctDNA analysis which were not present in the single site tissue biopsy. Most common pathogenic alterations found in the AKT1 mutated cohort were TP53 9/33 (27%), CDH1 5/33 (15%), GATA3 3/33 (9%) and MAP3K1 2/33 (6%). Rates of mutations in PIK3CA (2/33; 6%) and ESR1 (2/33; 6%) were reduced compared to those expected in ER+HER- metastatic BC sets.

Analysis of the AKT1 locus revealed amplification of AKT1 gene in 14/33 (42%) and loss of heterozygosity (LOH) of the wild type allele in 10/33 (30%). Overall LOH and/or amplification (allelic imbalance) was observed in 18/33 (55%) of AKT1 mutant tumours. 15/33 (46%) of the patients with confirmed AKT1 mutations had received treatment with capivasertib in PlasmaMATCH. Median PFS in patients was 13.08 months (10/15 patients) with allelic imbalance and 3.19 months without allelic imbalance (5/15 patients; HR 8.798, 95% CI1.58-49.00, P=0.004, log rank test).

RNA sequencing data was obtained for 36/39 samples with median 13M reads (range 11-49M) including 31/33 of the confirmed mutant samples in WES. PAM50 subtypes for the cohort were LumA (12/31), LumB (7/31), HER2Enriched (7/31), Basal (1/31) and normal-like (2/31). RNAseq showed increased (0.87 log fold change, P=0.035) expression of AKT1 in tumours with allelic imbalance compared to those without, and high expression levels of mutant transcript.

Finally, in plasmaMATCH, clonality of the AKT1 mutation was assessed in ctDNA, with 16/24 (67%) patients having clonally dominant AKT1 mutations. Median PFS in patients with clonally dominant mutations was 10.2 months and subclonal mutations 3.2 months (HR 3.1, 95% CI0.9-10.5, P=0.014, log rank test).

Conclusions: Breast cancers with mutations in AKT1 frequently have allelic imbalance favouring the mutation, resulting in increased expression of mutant transcript. Allelic imbalance of AKT1, and/or clonally dominant AKT1 mutations, were prognostic for significantly greater PFS of patients treated with capivasertib.

P1-01-20: Spliceosome Mutations (Smut) in Metastatic Breast Cancer (MBC): An Analysis of a De-centralized Clinical Trial and Large Clinical-Genomic Dataset

David Choi, Hector Ibanez, Christine Hodgdon, Justin Kemp, Jessica Tao, Valsamo Anagnostou, Jeffery Reynolds, Jennifer Lehman, Rita Denbow, Faith Too, Gretchen Hubbard, Lishann Ingram, Harris Krause, Michael Demeure, Sourat Darabi, Leslie Cope, Elizabeth Jaffee, Natasha Hunter, Ben Park, Cesar A. Santa-Maria

Introduction: Smut's result in aberrant mRNA transcripts increasing neoantigen diversity. The Patient Response to Immunotherapy using Spliceosome Mutational Markers (PRISMM) trial is a prospective remote-supported decentralized clinical trial designed to assess responses to immunotherapy. We also evaluated Smut in MBC using a large clinical-genomic database.

Methods: PRISMM recruited patients (pts) online and directed them to a landing website to complete a form. Eligibility was defined as pts with metastatic solid tumors harboring an SF3B1, U2A1, or SRSF2 mutation. After confirming eligibility, pts were remotely consented and underwent review by the Johns Hopkins Molecular Tumor Board (MTB). If clinically appropriate, MTB recommended PD1/PDL1 inhibitor in a report provided to the patient and treating oncologist. Research blood was collected at local laboratories. Pts were followed with serial questionnaires. Feasibility was defined as enrolling 60 pts, conducting MTB reviews within 4 weeks of consent in at least 80% of pts, and achieving 80% patient response on at least 1 follow-up questionnaire.

The CARIS real-world (RW) dataset was utilized for Smut analysis in solid tumors focusing on SRSF2, SF3B1 U2AF1, and ZRSR2. Frequency distribution across cancer types and breast cancer subtypes was assessed. In pts with MBC, correlations were made with molecular aberrations, immunohistochemical biomarkers, and immune cell populations (RNA-seq). Real-world overall survival (rwOS: from time of biopsy to last contact) was assessed by Kaplan Meier. Statistical significance was determined using Mann-Whitney U and chi-square tests and adjusted for multiple comparisons ($p<0.05$).

Results: From the PRISMM study, a total of 18 subjects completed online recruitment forms. Tumor types included breast (n=10), pancreatic (3), salivary gland (1), prostate (1), and astrocytoma (1). 6 were from the South, 5 the Northeast, 4 the West, and 1 the Midwest. 2 subjects were rural, and 16 were from urban communities. 6 participants were eligible and were consented/enrolled; 4 (67%) underwent MTB review within one month of informed consent. All pts completed at least one follow up questionnaire. 3 (50%) pts were initiated on immunotherapy. Median duration of treatment was 3 months (1-4 months) and median OS after start of immunotherapy was 4 months (1-32 months). Research blood was collected for 4 pts (67%). There was concordance of Smut between ctDNA and tissue NGS in 3 pts (75%).

In the CARIS dataset of 49,150 samples were identified with Smut; bladder (7%), lung (4%), and breast (3%) cancer had the highest prevalence of Smut. Breast cancer subtype frequency distribution of Smut was as follows: HR+/HER2- (2.3%), HR-any/HER2+ (1.5%), HR-/HER2- (0.2%). In Smut MBC, genes most frequently mutated were GATA3, ESR1, and

MAP3K1 ($p < 0.05$); amplified were FGFR1 and FLT4 ($p < 0.05$). We observed expression of PDL-1 and HER2 was lower, and AR/ER/PR was higher ($p < 0.05$) in Smut MBC vs non-mutated. Smut MBC had higher B-cells and M2 macrophages, and lower CD8+ T-cell signatures ($p < 0.05$). Improved rwOS was observed in the spliceosome non-mutated vs mutated (HR=1.251, 95% CI: 1.0-1.565, $p <0.05$).
Conclusion: While the PRISMM trial did not meet its feasibility endpoint, it does demonstrate pt engagement and feasibility of remote-laboratory collections. We did not observe significant responses to immunotherapy in pts with Smut. The existence of a large clinical-genomic database allowed us to further examine Smut. Across breast cancer subtypes, HR+/HER2-had the highest frequency of Smut. Smut's were associated with genomic aberrations of endocrine resistance (ESR1, MAP3K1, FGFR1), an immune-cold phenotype (higher M2 macrophages, lower PDL-1 expression and CD8+ T-cell infiltration), and worse OS.

P1-01-23: Oncotype DX Breast Recurrence Score® distribution and prognostic value according to prior pregnancy status in young women with breast cancer

Guilherme Nader-Marta,Yue Zheng, Kate E. Dibble, Shoshana M. Rosenberg, Erica L. Mayer, Philip D. Poorvu, Kathryn J. Ruddy, Laura C. Collins, Jeffrey Peppercorn, Lidia Schapira, Virginia F. Borges, Christy A. Russell, Steven E. Come, Ellen Warner, Kornelia Polyak, Eric P. Winer, Ann H. Partridge

Background: Breast cancer (BC) diagnosed in the postpartum period has been associated with a worse prognosis compared to nulligravid patients (pts), possibly due to differences in carcinogenesis associated with prior pregnancies. Persistent changes in gene expression, structural composition, immune microenvironment, and epigenetic modifications within the mammary gland have been observed following pregnancy. Oncotype DX Breast Recurrence Score® test is a gene expression profile that has been incorporated into the management of early-stage, estrogen receptor-positive (ER+), HER2-negative (HER2-) BC as a prognostic and predictive biomarker of chemotherapy effect. However, there are limited data on the impact of previous pregnancies on the expression of the 21 genes analyzed in the Oncotype DX® test and on the prognostic accuracy of this assay. The aim of this study is to evaluate the influence of pregnancy status on the distribution of Recurrence Score® (RS) results and long-term outcomes of young pts with early-stage, ER+, HER2- BC.
Methods: Pts with stage I-III, ER+, HER2- BC were classified as "nulligravid" or "postpartum" based on the absence or presence of pregnancy history prior to BC diagnosis from the Young Women's Breast Cancer Study, a prospective cohort that enrolled women with BC diagnosed at age ≤ 40 years between 2006 and 2016. Pts whose BC was diagnosed during pregnancy were excluded. RS was obtained from banked samples when not clinically performed. RS was categorized as low (< 11), intermediate (11-25), or high (> 25). Multivariable Cox hazards models were used to assess factors associated with distant recurrence-free interval (DRFI).

Results: Among 387 included pts, 117 (30.2%) were nulligravid and 270 (69.8%) postpartum. Median time from last pregnancy was 4.72 years (range 0.96 – 21.84) for the postpartum group. Median age at diagnosis was 34 and 37 years, N+ rate was 28 (24.0%) and 118 (43.7%), and chemotherapy was administered to 74 (63.3%) and 202 (74.8%) of nulligravid and postpartum pts, respectively. The median RS was 17 (range: 3-66) for nulligravid pts and 21 (4 – 77) for postpartum pts (p=0.004). The proportion of pts with low, intermediate and high RS was 16 (13.68%), 76 (64.96%) and 25 (21.37%) in nulligravid pts; and 28 (10.37%), 157 (58.15%) and 85 (31.48%) in postpartum (p=0.11). Among pts with N0 BC, 11-year DRFI rates were 91.7 (95% CI: 53.9 - 98.8), 90.7 (79.1 - 96.0), and 83.0 (55.9 - 94.2) for pts with RS < 11, RS 11-25, and RS > 25 for nulligravid women, and 83.3 (48.2 - 95.6), 92.0 (82.8 - 96.4), and 77.6 (61.3 - 87.7) for postpartum, respectively. Among pts with N+ BC, 11-year DRFI rates were 100.0, 76.2 (48.1 - 90.4), and 57.1 (17.2 - 83.7) for pts with RS < 11, RS 11-25, and RS > 25 for nulligravid women, and 79.4 (48.8 - 92.9), 71.1 (57.6 - 80.9), and 75.6 (59.1 - 86.2) for postpartum pts, respectively. In multivariable model of pts with N0 or N1-3 nodes, adjusting for RS, T-stage, N-stage, pregnancy status, and chemotherapy use, only RS (HR 1.02 per 1 point increase, 95%CI 1.002-1.039), T-stage (HR 2.01, 95%CI 1.11-3.65), and N-stage (HR 1.83, 95%CI 1.01-3.31) were independently associated with DRFI.
Conclusion: Pts diagnosed with BC in the postpartum period had higher RS results compared to nulligravid women. After adjusting for stage and RS, previous pregnancy status was not associated with worse long-term outcomes in young women with node negative or 1-3 node positive ER+ breast cancer. While further analyses incorporating time since last pregnancy will be conducted, these data suggest inferior outcomes observed in these patients may be in part related to higher genomic risk tumors.

P1-01-24: Genomic comparison of rapid vs. typical progressors on CDK4/6 inhibitor treatment in advanced breast cancer

Katherine Clifton, Aaron Hardin, Nicole Zhang, Andrew Davis, Emily Podany, Cynthia Ma, Leslie Bucheit

Background: While response to CDK4/6 inhibitors (CDK4/6i) is often 24 months in clinical trials, a subset of patients with HR+/HER2- metastatic breast cancer (mBC) will experience rapid progression on CDK4/6 inhibitors (CDK4/6i). Determinants of rapid vs. typical responders (RP, TP) are lacking. Identifying factors that contribute to rapid progression on CDK4/6i may enable refined clinical management and decision-making. Here we describe genomic profiles of patients with rapid vs. typical progression on CDK4/6i from a real-world clinical-genomic database to inform clinical decision-making. Methods: GuardantINFORM, a clinical-genomic database with de-identified genomic results and aggregated claims was queried from 2014 through March 2024 to identify patients with mBC who had ctDNA testing completed (as part of routine clinical care) prior to CDK4/6i initiation. RPs were defined as patients who had real-world time to next treatment (rwTTNT) within 4 months of starting CDK4/6i whereas TPs had 12+

months rwTTNT. While up to 83 genes are reported clinically, 500 genes were analyzed to assess genomic and/or pathway differences between RP/TP. Progression was defined as having documentation of a new therapy, with the following therapies excluded: switch to another CDK4/6i, switch of endocrine backbone, switch to endocrine-only therapy, immunotherapy, and any anti-HER2 therapy. Between RP and TP cohorts, non-synonymous genomic variants were analyzed to assess differences using Fisher's exact test (significance: $p<0.05$) and pathways analyzed via the Reactome pathway database, which counts each mutated gene per patient at a cohort-level (genes listed). "Enriched" pathways were defined as significant presence of a pathway ($p<0.05$) for one cohort, yet not significant ($p>0.05$) for the comparative cohort. Results: 138 patients were included as RP and 165 as TP; most were treated with palbociclib (RP: 72%; TP 55%). There were no significant differences in age, co-morbidity index or smoking status between cohorts. When assessing variant frequency between RP and TP, TP53 mutations were the only genomic variant enriched in RP compared to TP ($p<0.05$). Upon pathway analysis, there were multiple enriched pathways (n=56) in the RP cohort compared to TP, of which MAPK/MAP2K or NOTCH-related genes were altered at high rates (MAPK: 64%, 36/56; NOTCH: 20%, 11/56). Fewer pathways were enriched in the TP cohort compared to the RP cohort (n=12), with VHL, CCNE1/CCND1 and/or RB1 genes altered frequently (VHL: 63%, 7/11; CCNE1/CCND1: 36%, 4/11; RB1: 27%, 3/11). There were no enriched pathway differences observed in ESR1-mediated or extra-nuclear estrogen signaling pathways between cohorts. Conclusions: This study highlights that the classification of rapid vs. typical progressors in response to CDK4/6i is likely complex genomically. While TP53 alterations are significantly more common in RP, this finding may not be unique to breast cancer or CDK4/6i exposure as TP53 can be a poor prognostic factor across many solid tumors. Additional exploration into pathways involving MAPK and NOTCH-related genes may enable future studies to better identify rapid progressors to CDK4/6i to inform treatment planning.

P1-01-25: Elacestrant vs SOC in ER+, HER2- advanced or metastatic breast cancer (mBC) with ESR1-mutated tumors: ESR1 allelic frequencies and clinical activity from the phase 3 EMERALD trial

Aditya Bardia, Javier Cortés, Francois Clement-Bidard, Guillermo Streich, José García-Sáenz, Janice Lu, Giulia Tonini, Simona Scartoni, Alessandro Paoli, Alessio Fiascarelli, Alessandro Bressan, Monica Binaschi, Tomer Wasserman, Virginia Kaklamani

Background: The EMERALD trial (NCT03778931) reported significantly prolonged progression-free survival (PFS) and a manageable safety profile with single-agent elacestrant vs standard of care (SOC) endocrine therapy (ET) in patients with ER+/HER2− mBC and tumors harboring ESR1 mutation following progression on prior ET+CDK4/6i; mPFS 3.8 months with elacestrant vs 1.9 months with SOC (HR=0.55; 95% CI, 0.39-0.77; P = 0.0005) (Bidard 2022). In those patients with prior ET + CDK4/6i ≥12 months and ESR1-mutated tumors, median PFS with elacestrant was 8.6 vs 1.9 months with SOC ET (HR =

0.41; 95% CI, 0.26-0.63) (Bardia 2022). The PFS benefit associated with elacestrant was maintained across ESR1 mutation variants D538G, Y537S, and Y537N, which represent nearly 90% of ESR1-mutated tumors. Variant allele frequency in circulating tumor DNA correlates with tumor disease burden and predicts outcomes in patients with advanced breast cancer. This new analysis evaluates the clinical benefit of single-agent elacestrant in patients with high vs low ESR1 variant allele frequency (VAF).
Methods: Patients with ER+/HER2- advanced or mBC who previously had 1-2 lines of ET, mandatory CDK4/6i, and ≤1 chemotherapy were randomized 1:1 to receive oral elacestrant or SOC (investigator's choice of AI or fulvestrant). A post-hoc subgroup analysis was performed in patients with ESR1-mutated endocrine-sensitive tumors (prior exposure to ET+CDK4/6i ≥12 months) detected in plasma ctDNA using Guardant Health360 gene panel to evaluate the benefit of elacestrant vs SOC by ESR1 VAF. Median VAF was 1.2% (95% CI 0.04-56.1). High and low VAF were defined as ≥1.2% and <1.2%, respectively.
Results: In patients with low ESR1 VAF (n=79) who received prior ET+CDK4/6i ≥12 months, a clinically meaningful improvement in mPFS favoring elacestrant compared with SOC was observed, 8.6 with elacestrant vs 1.9 with SOC (HR = 0.51, 95% CI 0.26-0.99, P = 0.049). In patients with high ESR1 VAF (n=79), mPFS with elacestrant was 9.1 vs 1.9 for SOC (HR=0.36, 95% CI 0.19-0.69, P = 0.001). Baseline characteristics and additional data will be presented at the meeting.
Conclusions: Elacestrant demonstrated a significant improvement in mPFS vs SOC in patients with both high and low ESR1 VAF. The clinical benefit and activity of elacestrant vs SOC was maintained regardless of type of ESR1 mutation variant and the abundance/quantity of ESR1 mutations in patients with ER+/HER2- mBC. In all patients with ER+/HER2, ESR1-mut mBC, elacestrant may replace fulvestrant-based combinations, and delay chemotherapy or ADC-based regimens.

P1-01-26: Genomic profiling of ctDNA & assoc. w/ efficacy in patients from the postMONARCH trial of abemaciclib + fulvestrant vs placebo + fulvestrant for HR+, HER2-, advanced breast cancer following progression on a prior CDK4/6i plus endocrine therapy

Seth A. Wander, Kevin Kalinsky, Rinath Jeselsohn, Giampaolo Bianchini, Erika Hamilton, Miguel Martin, Sara Hurvitz, Sarah Sammons, Peter A. Kaufman, Umut Demirci, Rachel M. Layman, Holly Knoderer, Helen Won, Yanhong Zhou, Elizabeth Ravenberg, Cynthia Sandoval, Bastien Nguyen, Lacey M. Litchfield, Stephanie L. Graff

Background: postMONARCH (NCT05169567) was a randomized, placebo-controlled, Phase 3 trial that demonstrated the benefit of continued CDK4/6 inhibition with abemaciclib after progression on prior CDK4/6 inhibitor (CDK4/6i) + endocrine therapy (ET) (progression-free survival [PFS] HR 0.73; 95% CI, 0.57–0.95) in patients with HR+, HER2- advanced breast cancer (ABC). Here, we report exploratory biomarker analyses from postMONARCH, describing the frequency and outcome associations of baseline circulating tumor DNA (ctDNA) alterations in treated patients.

Methods: postMONARCH randomized 368 patients 1:1 to receive abemaciclib + fulvestrant or placebo + fulvestrant (Kalinsky et al., ASCO 2024). ctDNA from baseline plasma samples was analyzed using the Guardant Infinity assay. Associations between investigator-assessed PFS and recurrent oncogenic alterations (as defined by OncoKB) were assessed using a Cox proportional hazard model using genomic subgroups (detected vs not detected) as interaction terms.

Results: Plasma samples for ctDNA testing were available for 87% of patients (161 abemaciclib; 159 placebo); 3 did not have detectable ctDNA at baseline (1 abemaciclib; 2 placebo). The ctDNA-evaluable subgroup (n=320) was largely representative of the intention-to-treat population in baseline clinical characteristics and benefit achieved from the addition of abemaciclib to fulvestrant (HR 0.77; 95% CI, 0.59–1.00).
The most frequently altered genes in the abemaciclib + fulvestrant arm compared to placebo + fulvestrant were ESR1 (40% vs 51%), TP53 (35% vs 43%), PIK3CA (36% vs 42%), RB1 (10% vs 14%), PTEN (11% vs 10%), CDH1 (12% vs 11%) and GATA3 (11% vs 11%). The most common ESR1 hotspot mutations in the abemaciclib + fulvestrant and placebo + fulvestrant arms were D538G (25% vs 36%), Y537S (18% vs 16%) and Y537N (13% vs 15%). Rarer baseline alterations were also identified in genes implicated in CDK4/6i resistance.
The abemaciclib treatment effect was generally consistent across genomic subgroups (detected vs not detected), including ESR1 (HR 0.79 [0.54-1.15] vs HR 0.78 [0.54-1.12]), TP53 (HR 0.88 [0.59-1.32] vs HR 0.73 [0.52-1.02]), PIK3CA (HR 0.76 [0.50-1.14] vs HR 0.80 [0.57-1.12]), CDH1 (HR 0.86 [0.42-1.74] vs HR 0.75 [0.57-1.00]) and GATA3 (HR 0.58 [0.28-1.20] vs HR 0.79 [0.60-1.04]). Patients with alterations (detected vs not detected) in RB1 and PTEN had diminished abemaciclib treatment effect (RB1 HR 1.19 [0.58-2.43] vs HR 0.76 [0.57-1.00] and PTEN HR 1.55 [0.74-3.23] vs HR 0.71 [0.54-0.94]). Differences were also observed across ESR1 variants (D538G HR 0.74 [0.45-1.21]; Y537S HR 0.49 [0.27-0.88]; Y537N HR 1.38 [0.73-2.61]). Efficacy by oncogenic pathways will be further presented to evaluate biological mechanisms associated with these alterations.

Conclusions: Analysis from this prospective Phase 3 study provided insight into the baseline genomic landscape following disease progression on a CDK4/6i + ET. Abemaciclib benefit after prior CDK4/6i progression was apparent regardless of common actionable alterations in ESR1 or PIK3CA. RB1 and PTEN alterations were infrequent and associated with diminished abemaciclib treatment effect, though sample size was limited. In summary, abemaciclib + fulvestrant offers a targeted therapy option for HR+, HER2- ABC after disease progression on a CDK4/6i, including for patients with actionable genomic alterations.

P1-01-27: HER2 Loss Following Treatment with Trastuzumab Deruxtecan in Patients with Metastatic Breast Cancer

Mohamed Gouda, Amrit Gonugunta, Ecaterina Dumbrava, Timothy A Yap, Jordi Rodon, Sarina A Piha-Paul, Paula R. Pohlmann, Senthil Damodaran, Rashmi Murthy, Vicente Valero, Jason Mouabbi, Debasish Tripathy, Aysegul Sahin, Hui Chen, Funda Meric-Bernstam

Background: Trastuzumab deruxtecan (T-DXd) is currently approved for treatment of patients with metastatic HER2-positive (immunohistochemistry (IHC) 3+ or ISH positive) or HER2 low (IHC 1+ or IHC 2+/ISH negative) breast cancer in addition to other disease-specific and tissue-agnostic indications. Because of potential clinical implications to treatment selection after exposure to T-DXd, we aimed to evaluate the changes in HER2 status, specifically loss or decrease in HER2 expression, following treatment with T-DXd in patients with metastatic breast cancer. Methods: We retrospectively reviewed patients with metastatic breast cancer who received treatment with T-DXd at The University of Texas MD Anderson Cancer Center (MDACC). We included patients who had post-treatment biopsy (or on-treatment biopsy within the 30 days prior to treatment discontinuation) with IHC re-evaluation of HER2 status at MDACC. We excluded patients who were taken off treatment for toxicity or death after the first cycle of treatment, patients who received T-DXd in addition to another agent concomitantly, and patients who received T-DXd at multiple times interspersed through their medical history. We reviewed pre-treatment HER2 IHC status in the most recent biopsy prior to T-DXd initiation and the biopsy with the highest score of HER2 across patients' medical history. For patients with multiple testing, the biopsy closest to treatment start- and end date was used to assess the change in HER2 expression status. Treatment dates were extracted from patients' medical charts and duration on therapy was calculated as the time between cycle 1 day 1 and end of treatment. A decrease in IHC score was defined as any change in IHC score from 3+ to 2+, 1+, or 0; from 2+ amplified to 2+ non-amplified, 1+, or 0; from 2+ non-amplified to 1+ or 0; or from 1+ to 0. HER2 loss was defined as an IHC score of 0 after treatment with any degree of positivity noted in the most recent sample before treatment initiation (1+, 2+, or 3+).Results: We included 45 patients with metastatic breast cancer who started treatment with T-DXd at MDACC between June 2017 and February 2024 and had come off therapy by the time of analysis. The highest HER2 score was 3+ in 14 patients (31%), 2+ in 20 patients (44%; 12 FISH negative, 5 FISH positive, and 3 FISH undetermined), and 1+ in 11 patients (24%). The median duration between pre-treatment biopsy and treatment start date was 355 days (range, 1 to 2663) and the median duration between treatment discontinuation date and post-treatment biopsy was 25 days (range, -14 to 1159). Five patients had HER2 score of 0 in the most recent biopsy before therapy and were excluded from further analysis. In those patients, treatment decision was based on another prior biopsy showing HER2-low or HER2-positive disease and the median time on treatment was 71 days. Out of 40 patients with baseline HER2 expression (1+, 2+, or 3+), almost one third (n=12; 30%) had HER2 loss following treatment with T-DXd. In addition to those 12 patients with HER2 loss, another 11 patients (28%) had a decrease in HER2 score after treatment with T-DXd. Conclusions: HER2 loss and decrease in HER2 expression are common in patients with metastatic breast cancer

receiving treatment with T-DXd. Re-evaluation of HER2 status post-therapy should be considered prior to considering alternative HER2 targeted therapy.

P1-01-28: Molecular Residual Disease Precedes Radiographic Confirmation of Recurrence in Patients with Stage III Inflammatory Breast Cancer

Jennifer Chen, Salyna Meas, Roland L. Bassett, Vanessa N. Sarli, Joshua Upshaw, Huong T. Le-Petross, Vicente Valero, Bora Lim, Wendy A. Woodward, Anthony Lucci

Background: Early detection of molecular residual disease (MRD) correlates with disease recurrence and survival outcomes in patients with inflammatory breast cancer (IBC). We sought to determine the lead time of circulating tumor cell (CTC) and circulating tumor DNA (ctDNA) detection prior to radiographic confirmation of disease relapse in stage III IBC.
Methods: Patients were enrolled in a prospective registry from 2015-2022 and underwent serial blood draws at baseline, throughout neoadjuvant treatment, and 6- and 12-months post-surgery. CTCs were enumerated using CellSearchTM and ctDNA quantification was performed using Oncomine Pan-Cancer Cell-Free Assay. MRD was defined as ≥ 1 CTC or ctDNA variant detected at any post-operative timepoint. Among patients with recurrence, lead time was calculated from date of first positive CTC and/or ctDNA variant after surgery to date of first imaging confirmation of disease relapse. Per standard of care guidelines, surveillance imaging was obtained based on patient symptoms and physical exam findings. For patients with recurrence but no detectable MRD, date of first negative CTC and/or ctDNA variant after surgery was used. Mann-Whitney U and Fisher's exact tests were used to compare differences between groups. Kaplan-Meier method was used to estimate time to recurrence (TTR) and Cox regression analysis was performed to assess the association with variables of interest.
Results: In total, 92 patients with stage III IBC were included. The median age was 51 years (IQR 17.8) and BMI was 28.9 (IQR 11.5). The study cohort consisted of 72.9% (70) White, 16.3% (15) Hispanic, and 6.5% (6) Black patients. Patients had predominantly node-positive (87, 94.6%), high-grade (64, 66.7%), ductal (83, 86.5%) disease. Almost all patients received trimodality therapy – neoadjuvant systemic therapy (100%), modified radical mastectomy (100%), and adjuvant radiotherapy (88, 95.7%). Baseline CTC and ctDNA detection rates were 60.7% (37/61) and 65.6% (21/32), respectively. MRD detection rate ranged from 34.5-39.4% at 6- and 12-months post-surgery. There were 6 patients who recurred who had persistently negative MRD assessments (range: 1-2 post-operative assessments). At a median follow up of 7.1 years (95% CI 4.7-9.4), overall survival was 71.7% and recurrence rate was 37.0%. Patients with negative CTC and ctDNA had significantly longer time to recurrence compared to those with a positive CTC and/or ctDNA assessment at any post-operative timepoint (estimated 6-year TTR: 93.3% vs. 58.3%, $p = 0.027$). CTC positivity was significantly associated with TTR (HR 3.8, 95% CI: 1.8-7.9, $p < 0.001$) in multivariable Cox regression analysis with time to CTC positivity as a time-varying covariate. There were no differences in age, race/ethnicity, nodal status, histology, receptor

subtype, grade, LVI, and pCR by recurrence status. However, patients with recurrence had more positive lymph nodes at resection (median 5 vs. 0, $p < 0.001$) and were more likely to have positive CTCs after surgery (71.4% vs. 43.9%, $p = 0.01$), compared to those who were relapse-free. Of the 35 patients who recurred, 80% had detectable MRD after surgery. Among these, 71.4% had MRD at a median time of 5.8 months (IQR 14.7) prior to radiographic detection of disease relapse, compared to a median recurrence time of 12.5 months (IQR 14.7) for patients with no MRD detected prior to positive imaging.
Conclusion: Among stage III IBC patients with relapse, MRD was detected with a median lead time of approximately 6 months prior to radiographic confirmation of disease recurrence. Incorporation of serial assessments of MRD may offer the opportunity for early systemic treatment intervention in IBC patients with high risk of relapse.

P1-01-29: Metabolomic signatures of fruit and vegetable consumption in relation to breast cancer

Emily Riseberg, Fenglei Wang, Oana A. Zeleznik, Megu Y. Baden, Clary B. Clish, Liming Liang, Julian Avila Pacheco, You Wu, Molin Wang, Walter C. Willett, Stephanie A. Smith-Warner, A. Heather Eliassen

Background. Fruit and vegetable intakes have been associated with a lower risk of breast cancer. However, few studies have explored metabolites, especially unknown peaks detected in the metabolomics platforms, related to fruit and vegetable consumption. No studies have assessed the relationship between a metabolomic signature for fruits and vegetables and breast cancer risk.
Objective. We developed metabolomic signatures that reflect usual consumption of fruits and vegetables in the Nurses' Health Study (NHS) and NHSII and investigated the relationships between these signatures and breast cancer incidence.
Methods. We used data from prior nested case-control studies in the NHS and NHSII (N=10,289) with metabolomic data. Plasma metabolomic profiling, including mainly lipids and amino acids, was conducted by liquid chromatography-tandem mass spectrometry; 206 named metabolites and 1591 unknown peaks were included. Fruit and vegetable consumption was estimated from food frequency questionnaires collected near blood draw. We identified metabolomic signatures using adjusted elastic net regression. The models were trained in all case-control studies except those for breast cancer (N=6388) and tested in the breast cancer studies (N=1948 cases; 1953 controls). We assessed associations of metabolites and the metabolomic signature with breast cancer risk overall and by estrogen receptor (ER) and menopausal status using conditional logistic regression, calculating odds ratios (ORs) and 95% confidence intervals per standard deviation (SD).
Results. At blood collection, participants were on average 55 years old and consumed 1.6 servings of fruit and 3.3 servings of vegetables per day. Metabolomic signatures of named metabolites were correlated with total fruit (N=21 metabolites; r=0.45 in the training set; r=0.42 in the testing set) and vegetable (N=26 metabolites; r=0.49 in the training set; r=0.51 in the testing set) intakes. Adding in unknown peaks did not substantially increase these

correlations. Ten metabolites were significantly associated with breast cancer risk, with inverse associations observed for eight metabolites. Two of these metabolites were included in the signatures: C20:5 cholesteryl ester (OR per 1 SD=0.93; 95%CI=0.87, 1.00) was included in the vegetable signature (β=0.003), and piperine (OR per 1 SD=0.91; 95%CI=0.85, 0.98) was included in the fruit signature (β=-0.01) and the vegetable signature (β=0.07). The signatures of named metabolites for fruit and vegetable intake were associated with lower risk of breast cancer overall (OR per 1 SD of the fruit signature=0.73; 95%CI=0.56; 0.95; OR for the vegetable signature=0.67; 95%CI=0.56; 0.82). Both signatures were associated with lower risk of postmenopausal tumors, and the signature for vegetable intake was also associated with lower risk of ER+ and premenopausal tumors.
Conclusions. Using a plasma metabolomics platform including named metabolites and unknown peaks, we identified metabolomic signatures that could help reflect fruit and vegetable consumption and the underlying biological processes that may link dietary intake with breast cancer risk.

P1-01-30: Generation and validation of primary breast cancer epigenetic classifiers of pathologic nodal stage in a multi-center breast cancer cohort

Miquel Ensenyat-Mendez, Sandra Iñiguez-Muñoz, Julie Le, Sookyung Ahn, Isabel Eng, Peggy Sullivan, Pere Llinas-Arias, Jennifer L. Baker, Diego M. Marzese, Maggie L. DiNome

Introduction: With increasingly effective systemic therapies and expanding indications for radiation, the role of axillary lymph node dissection (ALND) in the management of patients with node-positive breast cancer (BC) continues to evolve. However, while clinical trials have progressively demonstrated that ALND offers little to no added protection from local recurrence or death in various clinical scenarios, ALND remains the only method to fully stage the axilla and differentiate pN1 vs >pN1 disease. However, certain decisions for adjuvant therapies, such as CDK4/6 inhibitor therapy in patients with estrogen receptor (ER) positive BC, still rely on the nodal stage. In this study, we used machine learning algorithms to create epigenetic classifiers predictive of nodal stage (pN1 vs >pN1) based on DNA methylation profiling of primary BC tumors in two independent cohorts of patients (UCLA and Duke) with ER-positive, HER2-negative BC.
Methodology: Eligibility criteria included women aged 18-80 years with ER+, HER2-negative BC, clinically node-positive, who underwent ALND without NAC. Tumoral tissue was microdissected from 8 µm Formalin-Fixed Paraffin-Embedded (FFPE) slides, previously annotated by a trained pathologist, and DNA was extracted using the Quick-DNA FFPE Miniprep kit (Zymo Research). DNAm profiling was performed using the Illumina Infinium Methylation EPIC BeadChip v1. DNAm data was processed using the R/ChAMP package (v.2.34.0), and the batch effect was corrected using the “champ.runCombat” function. The cohort was split into a training cohort (60%, n = 53) and a validation cohort (40%, n = 34). R/VarSelRF (v.0.7-8) was used to identify the combination of probes with the fewest sites and the highest potential to predict the pathological nodal stage. The best-performing classifiers were tested in the validation cohort.

Results: DNAm profiling was performed on 91 primary BC samples, with four samples removed due to low data quality. The UCLA and Duke cohorts presented a significant batch effect, which was successfully corrected to avoid potential bias. We identified 1,653 differentially methylated sites between pN1 and >pN1 tumors in the training cohort, successfully stratifying both subgroups of patients. These sites were used to generate a Random Forest-based classifier with the minimum number of probes. We selected the three combinations of probes with the highest Area Under the Curve (AUC) and the fewest CpG sites. We identified three classifiers, comprising 8 to 12 genomic regions, with an AUC between 0.99 and 1 in the training cohort and between 0.81 and 0.82 in the validation cohort.
Discussion: As randomized trial data support the omission of ALND in select clinical scenarios in patients with node-positive BC, clinicians will lose the pathologic nodal data that is provided by surgical dissection that guides adjuvant therapy decision-making. This study generated three classifiers that successfully identified patients with higher nodal stage (>pN1). These classifiers use a small number of genomic regions (8 to 12) and can be optimized for low-throughput techniques such as pyrosequencing or quantitative Methylation-Specific PCR, increasing the availability of this diagnostic tool in the clinical setting.

P1-02-01: Body weight modification during adjuvant ovarian suppression for premenopausal women with luminal breast cancer.

Izabela Porto Ferreira, Giulia Zanetta, Hendrio Santiago, Deborah Catalah, Luciana Leite, Vladmir Lima, Solange Sanches, Monique Tavares, Felicia Cavalher, Marcelle Goldner

Introduction: Obesity is one of the major health problems in the world, directly affecting the quality of life and self-esteem of the population. While various factors contribute to its development, research indicates that ovarian hormone loss increases the likelihood of weight gain in women. Body fat mass tends to increase with ovarian function suppression (OFS) in premenopausal women, and endocrine therapy (ET) has been shown to mitigate weight gain in postmenopausal women. Methods: Retrospective analysis of all consecutive premenopausal patients diagnosed with early luminal breast cancer (eBC) and treated with adjuvant OFS + aromatase inhibitors (AI) between January 2017 and July 2024 in a single Brazilian institution (A. C. Camargo Cancer Center). The primary objective was to describe the body weight changes over the years of hormonal blockade use (baseline, six months [m], 12m, 36m, and 60m). The body mass index (BMI) variation (over-weighted: BMI ≥ 25Kg/m2; obesity: BMI ≥ 30Kg/m2) and the variations >1Kg from the baseline were considered for the analysis. Results: 318 premenopausal patients were recruited, with a median follow-up of 59 months. The median age was 40 years; the majority were white (56%) and had no comorbidities (72.3%). 23.3% had luminal HER2-positive eBC, and 93.1% underwent chemotherapy (chemo: 44.3% neoadjuvant and 48.8% adjuvant). 21.4% started ET with tamoxifen before switching to OFS + IA. Monthly OFS was the starting choice for 71.7% of patients, and 65.9% changed to an every-3-month posology during the

following years of therapy. 61.8% had a BMI >25Kg/m2 and 24.5% were obese at baseline. There was a notable trend of weight gain in this cohort. The rates of overweight in patients with available data increased to 63%, 63.3%, 65.2%, and 67.3% in 6, 12, 36, and 60 months, respectively. The obesity rates decreased in 6m to 23.4% but increased in the next years: 26%, 25.9%, and 25.9% in 12, 36, and 60m, respectively. In the first 6m of OFS + IA, most patients (41.1%) maintained weight (33.4% gained > 1 kg and 25.4% lost > 1 kg). However, in the subsequent months, weight increase prevailed: 38.9%, 45.2%, and 46.2% in 12, 36, and 60m. The percentage of patients with weight loss remained relatively stable over time. An average increase of 6kg was observed for this cohort. Among patients receiving chemo, weight gain >1 kg tended to occur later than for patients without chemo. The weight increase occurred regardless of the AI (anastrozole, letrozole, and exemestane) used. The study was not powered to evaluate associations between weight gain/BMI and oncological outcomes due to the low rates of recurrence and death events in the present cohort (5-year disease-free and overall survivals of 95.5% and 97.5%, respectively). Conclusion: These findings underscore the complex interplay between hormonal treatments and weight changes in premenopausal women with early breast cancer. Effective management strategies are essential to mitigate the risk of weight gain and its implications for patient outcomes. There were few recurrences, with a disease-free survival of 95.9% at five years. Future research should focus on optimizing treatment protocols to minimize adverse effects while maximizing therapeutic benefits in this population.

P1-02-02: Indirect comparison of sacituzumab govitecan (SG) and datopotamab deruxtecan (Dato-DXd) in advanced breast cancer (aBC): safety and efficacy analysis.

Neha Pathak, Sudhir Kumar, Yael Berner-Wygoda, Abhenil Mittal, Diego Malon, Massimo Di Iorio, Jacqueline Savill, Consolacion Molto Valiente, Meredith Li, Michelle Nadler, Eitan Amir

Background: SG and Dato-DXd are antibody drug conjugates (ADCs) used in aBC. Both target humanized anti-trophoblast cell-surface antigen 2 (TROP2) and both have a similar (irinotecan-based) payload. There are few comparative data on these drugs.
Methods: We searched MEDLINE, as well as proceedings from ASCO, ESMO and SABCS. Eligible studies were trials (dose expansion phase 1, phase 2 or 3) that evaluated Dato-DXd or SG in aBC patients. Safety (adverse effects [AE]) data were pooled as the mean, weighted by individual study sample size and indirect comparisons were performed using the test of two proportions (z score). For randomized trials of ADCs compared to chemotherapy, we performed a network metanalysis (using WINBUGS within Microsoft Excel) and report the hazard ratio (HR) for efficacy (overall survival [OS], progression free survival [PFS]) and odds ratio (OR) for AEs comparing Dato-DXd to SG. Statistical significance was defined as $p<0.05$.
Results: Nine studies were included in the analysis, 3 for Dato-DXd and 6 for SG. A total of 450 patients were treated with Dato-DXd and 831 with SG. Median prior lines of treatment were 1 (range 1-6) for Dato-DXd and 4 (range 0-7) for SG. There were no significant

differences in discontinuation due to toxicity (OR 0.97; 95% confidence interval [CI] 0.38-2.48)) or in toxic deaths (OR 1.11; 95% CI 0.15-8.34). Similarly, there were no significant differences in PFS (HR 0.95; 95% CI 0.71-1.28) or in OS (HR 1.06; 95% CI 0.74-1.53). Comparison of individual AEs between Dato-DXd and SG demonstrated the following: all grade AE (94.8% vs 100%, p < 0.01), grade≥ 3 AE (20.7% vs 75%, p< 0.01) and dose reduction (19.5% vs 26%, p=0.01). Ocular AE(all grade, 25.2%; grade ≥3, 1%), infusion reaction (all grade, 11.8%) and interstitial lung disease (ILD, all grade, 2.6%; grade ≥3 1%) were reported only with Dato-DXd, whereas febrile neutropenia (5.6%) and neuropathy (all grade, 11.8%; grade ≥3, 0.7%) were reported only with SG. SG showed more frequent hematological toxicities: anemia (grade ≥3, 1.7% vs 19%, p<0.01), neutropenia (grade ≥3, 1% vs 49%, p<0.01) and thrombocytopenia (grade ≥3, 0% vs 1.6%). SG was associated with more diarrhea (16.5% vs 58%, p<0.01, grade ≥3[SG only], 9.2%) while stomatitis was seen more with Dato-DXd (60.1% vs 11.9%, p<0.01; grade ≥3, 6.9% vs 1.4%, p<0.01). Alopecia (36% vs 45.6%, p<0.01) and fatigue (27% vs 46.7%, p<0.01; grade ≥3, 2.5% vs 5%, p=0.03) were more common with SG. Risk of grade 3 nausea and vomiting, as well as skin related AEs and dyspnea were similar.
Conclusions: Both Dato-DXd and SG have similar risk of discontinuation without progression and toxic death. The side effect profile of SG is driven by hematological toxicities. AEs such as ILD, ocular and infusion reactions appear unique to Dato-DXd. Febrile neutropenia, neuropathy and fatigue were observed predominantly with SG. Among GI AEs, stomatitis is prominent for Dato-DXd and diarrhea with SG. There does not appear to be any meaningful difference in efficacy. These results may inform choice of therapy in clinical practice.

P1-02-03: Major adverse cardiovascular events in postmenopausal women vs pre-menopausal women with hormone receptor-positive breast cancer treated with endocrine therapy

Savannah Roy, Adam Warren, Elizabeth Molina Kuna, Cathy J. Bradley, Virginia F. Borges, M, Lavanya Kondapalli, Jennifer R. Diamond

Background: In the Suppression of Ovarian Function (SOFT) and Tamoxifen Exemestane Trial (TEXT), breast cancer recurrence rates were significantly lower among premenopausal women treated with the aromatase inhibitor (AI) exemestane plus ovarian suppression to those treated with the selective estrogen receptor modulator (SERM) tamoxifen alone. The association between AIs and cardiovascular outcomes in women with breast cancer is controversial, with studies often focusing on postmenopausal women. The purpose of this study was to evaluate major adverse cardiovascular events (MACE) in women undergoing hormonal therapy for hormone receptor positive (HR+) breast cancer, specifically comparing postmenopausal women to those experiencing premature menopause or ovarian function suppression with GnRH agonists, oophorectomy, and/or ovarian irradiation.
Methods: Using the SEER-Medicare database, we identified 26, 505 women with HR+ breast

cancer diagnosed at age > 65 between 2007-2019. Using the University of Colorado Health Data Compass database, we identified 790 patients with HR + breast cancer experiencing premature menopause or undergoing OFS, diagnosed < 45 between 2005- 2022. HER2 patients were excluded due to the cardiotoxicity of HER2-targeted agents. We compared patient and clinical characteristics according to hormonal treatment regimen (AI versus SERM). Logistic regression was performed to estimate the odds ratio (OR) and 95% confidence intervals (CIs), MACE was defined as acute myocardial infarction, heart failure, potentially fatal arrhythmias, or cerebral vascular accident. Cardiac death was excluded from the analysis due to its rarity.
Results: In the SEER database cohort of postmenopausal women, AI treatment was not associated with higher odds of any MACE (OR 1.05, 95% CI [0.97, 1.13], p= 0.92), acute myocardial infarction (OR 1.02, 95% CI [0.90, 1.15], p=0.45), heart failure (OR 1.01, 95% CI [0.91, 1.13), p=0.44), potentially fatal arrhythmia (OR 1.13, 95% CI [0.91, 1.40], p=0.39), or cerebral vascular accident (OR 1.12, 95% CI [0.96, 1.27], p=0.49) compared to tamoxifen when controlling for traditional cardiac risk factors. Data from the Compass database for the premature menopausal and OFS group shows a lower proportion of MACE (3.54%, N= 28) compared to the SEER cohort (28.22%, N= 7479) when controlling for traditional risk factors, with this difference being statistically significant (p< 0.0001, Fisher's exact test).
Conclusion: Among postmenopausal women with HR+ breast cancer, AI treatment was not associated with increased risk of cardiac outcomes compared to tamoxifen. There was a lower proportion of cardiac events in young women with premature menopausal or those undergoing OFS compared to postmenopausal women. More work is needed to study the effects of premature menopause and to develop cardioprotective strategies.

P1-02-04: Impact of abemaciclib dose escalation on compliance and safety in hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) breast cancer

Heather Moore, Emma Erner, Susan Dent, Kelly Westbrook, Lexie Zidanyue Yang, Yaoyao Li, Rani Bansal

Background: Abemaciclib, a cyclin dependent kinase 4/6 inhibitor (CDK4/6i), is approved for the treatment of hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) early stage (EBC) and advanced breast cancer (ABC) patients (pts) in combination with endocrine therapy (ET). Abemaciclib (150 mg twice daily), when used in combination with ET, leads to high rates of adverse events (AEs) such as diarrhea which affects over 80% of pts resulting in dose omissions, dose reductions, and discontinuation (DC). While there is data to support dose reduction in the early and advanced setting without negatively impacting efficacy, there is limited data on the impact of a dose escalation strategy on AE profile and compliance. This retrospective study aims to determine an optimal dosing strategy of abemaciclib for early and advanced HR+, HER2- BC and to assess discontinuation rate (DCR) and AE rates.
Methods: This retrospective, single-center, cohort study included pts 18 years of age and

older with HR+, HER2- breast cancer who were treated with abemaciclib in combination with ET at the Duke Cancer Institute (DCI) from October 1, 2015 to September 22, 2023. EBC and ABC pts were divided into three cohorts based on dosing strategy at initiation: Cohort A (n=36), dose escalation (50 mg), Cohort B (n=12), non-traditional (100 mg), and Cohort C (n=80), standard (150 mg). In cohorts A and B, pts were dose escalated at varying intervals dependent on pt tolerance. The primary outcome was DCR within 90 days due to AEs. Secondary outcomes included DCR due to all causes within 90 days, reason for DC, grade of AE experienced, percentage of pts on the standard regimen (cohort C) requiring a dose reduction, highest dose maintained in the dose escalation group (cohort A), and time to progression for ABC pts. Logistic regression was used for the primary outcome to examine the association between DCR and dosing strategy, and descriptive statistics were used for the remaining outcomes.
Results: A total of 128 pts were included, 43 (34%) with EBC and 85 (66%) with ABC. All pts were female and the majority were postmenopausal (80.5%). DCR at 90 days due to AEs was 5.6% in cohort A, 8.3% in cohort B, and 11.3% in cohort C (p = 0.801). Pts in cohort A had 81% lower odds of abemaciclib DC within 90 days compared to cohort C (OR: 0.19, 95% CI 0.02 to 1.04, P = 0.07). For every 5-year increase in age, there was a 67% increase in the odds of DC due to AEs (OR: 1.67; 95% CI: 1.2 to 2.49, p = 0.004). 90.6% of pts reported AEs, with diarrhea and fatigue being the most frequently reported across all cohorts. 54.5% of pts with EBC and 50.7% of patients with ABC in cohort C required a dose reduction, with 43.9% of pts reducing to 50 mg. 37.9% and 14.3% in cohort A with EBC and ABC, respectively, achieved a dose of 150 mg. In the ABC group time to progression (TTP) of 278 days (Q1, Q3 146.5, 356) in cohort A and 287 days (Q1, Q3 149, 461) in cohort C.
Conclusion: An abemaciclib dose escalation strategy may be considered in an effort to reduce the rate of AEs experienced in women with HR+, HER2- EBC and ABC prescribed abemacicib. The DCR of abemaciclib due to AEs within 90 days was lower with a dose escalation strategy demonstrating reduced rates of diarrhea, although this was not statistically significant. Many EBC pts were able to successfully escalate to full dose abemaciclib, while half of pts who started at standard dose required a dose reduction. Additionally, TTP was similar in ABC patients regardless of dosing strategy. This study was limited by small sample size and uneven distribution between study groups. Additional prospective data is needed to further assess dose escalation strategies with abemaciclib.

P1-02-05: The association between statin use and risk of cardiovascular events among breast cancer patients receiving pembrolizumab

Xiaocao “Haze” Xu, Cho-Han Chiang, Kuan-Yu Chi, Yu-Cheng Chang, Yu Chang, Cho-Hung Chiang, Shuwen Lin

Background: The use of immune checkpoint inhibitors (ICIs), such as pembrolizumab, has been linked to serious immune-related cardiovascular events, including myocardial infarction, heart failure, and myocarditis. There is limited data on the prevention of these

immune-related cardiovascular events. Statins, a class of HMG-CoA reductase inhibitors, have long been used to prevent and reduce the risk of atherosclerotic disease. This study aimed to investigate if the use of statins might decrease cardiovascular adverse events associated with pembrolizumab in patients with breast cancer.
Methods: We conducted a retrospective, propensity score-matched cohort study using the TriNetX Analytics Network database, which includes de-identified electronic health records from over 70 healthcare organizations and 101 million individuals. We included adult female breast cancer patients treated with pembrolizumab and chemotherapy from November 2020 to June 2023. The inclusion criteria specified patients with hypertension, diabetes mellitus, or hyperlipidemia, as these comorbidities increase the risk of atherosclerotic disease and may indicate the use of a statin. We excluded patients who received endocrine or HER2-targeted therapies. The index date was the start of ICI therapy. We compared patients who received statins to those who had not received statins within one year prior to the index date. The primary outcome was major adverse cardiovascular events (MACE), including myocardial infarction, heart failure, and cardiac arrest. Secondary outcomes included individual MACE components, myocarditis, and pericarditis. All outcomes were captured within one year following the start of ICI therapy.
Results: We identified 747 eligible patients who received pembrolizumab and chemotherapy, of which 229 received a statin and 518 did not receive a statin within one year of starting pembrolizumab. After propensity score matching, 161 patients in each cohort were well-balanced for demographics, breast cancer-directed therapy, underlying comorbidities, and cardiovascular medication use. Over a one-year follow-up period, the incidence of MACE was lower in the statin cohort compared to the non-statin cohort (3.1 vs. 8.7 events per 100 patient-years). In a Cox proportional hazard analysis, statin use was associated with an approximately 65% lower risk of MACE (Hazard ratio (HR), 0.35 [95% CI: 0.12-0.96]; log-rank p = 0.033). Patients on statins had a lower incidence of heart failure (1.2 vs. 5.6 events per 100 patient-years) than those not on statins. Statin use was associated with a lower risk of heart failure (HR, 0.21 [95% CI: 0.05-0.99]; log-rank p = 0.030). There were no statistically significant differences in the rates of myocardial infarction (HR, 0.66 [95% CI: 0.19-2.35]; log-rank p = 0.521), myocarditis (no cases for statin vs. 1 case for non-statin), and pericarditis (HR, 0.97 [95% CI: 0.20-4.82]; log-rank p = 0.974) between the statin and non-statin cohorts.
Conclusion: The use of statins is associated with a lower risk of MACE, principally heart failure, among breast cancer patients receiving pembrolizumab.

P1-02-06: Efficacy analysis & updated safety from the phase 2 PRIMED study of prophylactic granulocyte-colony stimulating factor (G-CSF) & loperamide for patients (pts) with HER2-negative advanced breast cancer (ABC) treated w/ sacituzumab govitecan (SG)

María Gion, Manuel Ruiz-Borrego, Isabel Blancas, Elena López-Miranda, Salvador Blanch, Sabela Recalde, Lourdes Calvo, Xavier González, Nerea Ancizar, Serafin Morales, Patricia

Cortez, Zuzanna Piwowarska, Eileen Shimizu, José Antonio Guerrero, Miguel Sampayo-Cordero, Alejandro Martínez-Bueno, Javier Cortés, Antonio Llombart-Cussac

Background SG is a Trop-2 directed antibody drug conjugate that has shown a statistically significant and clinically meaningful overall survival benefit for pts with HER2- ABC in two phase III trials. The most common SG-related adverse events (AEs) were neutropenia and diarrhea, which frequently led to treatment modifications. The PRIMED trial previously demonstrated that primary prophylactic administration of G-CSF and loperamide resulted in a clinically meaningful reduction of neutropenia and diarrhea during the first two treatment cycles. Herein we report the extended safety follow-up and secondary efficacy endpoints.

Methods PRIMED (NCT05520723) is an open-label, single-arm, phase II trial. Pts with HER2- ABC previously treated with 1-2 lines of chemotherapy in the advanced setting were eligible. Pts with hormone receptor-positive (HR+) tumors had to be refractory to at least one prior endocrine therapy-based regimen and have received a CDK4/6 inhibitor for ABC. SG (10 mg/kg intravenously, days 1 and 8, every 21 days) was administered until disease progression or unacceptable toxicity. G-CSF (0.5 MU/kg/day subcutaneously, days 3, 4, 10, and 11) and loperamide (2 mg orally, twice a day or 4 mg daily, days 2, 3, 4, 9, 10, and 11) were given during the first two cycles and could continue based on physician's discretion. Secondary efficacy endpoints included progression-free survival (PFS), objective response rate (ORR), clinical benefit rate (CBR), and overall survival (OS).

Results Between February 2023 and September 2023, 50 pts were enrolled (triple-negative breast cancer [TNBC], n=32; HR+/HER2-, n=18). At data cut-off (May 5, 2024), with a median follow-up of 9.0 months (range; 0.2-13.5), 9 pts remained on SG treatment. The median PFS for TNBC pts was 6.4 months (95%CI; 6.1-10.3) and for pts with HR+/HER2- tumors, it was 5.8 months (95%CI; 2.2-NA). The ORR and CBR were 34.4% and 71.9% for TNBC, and 16.7% and 44.4% for HR+/HER2- pts, respectively. OS data was immature at the time of analysis. During the first two cycles, the incidence of any grade (G) neutropenia and diarrhea were 28.0% and 34.0%, respectively. A total of 8 pts (16.0%) had ≥ G 3 neutropenia (12.0% G3; 4.0% G4) and 8 pts (16.0%) had ≥ G 2 diarrhea (4.0% G3, with no G4). With the extended follow up, the incidence of any G neutropenia and diarrhea were 42.0% and 44.0%, respectively. A total of 12 pts (24.0%) had ≥ G 3 neutropenia (18.0% G3; 6.0% G4; with no febrile neutropenia) and 9 pts (18.0%) had ≥ G 2 diarrhea (4.0% G3, with no G4). The overall rate of all AEs associated with dose reductions and treatment interruptions was 22.0% and 50.0%, respectively. Four pts discontinued due to AEs, two of which were SG-related (G2 enteritis and G3 diarrhea). Conclusions The efficacy results of SG in the PRIMED study are consistent with previously reported data, with lower rates of all grade and ≥ G 3 neutropenia and diarrhea. G-CSF and loperamide should be considered as prophylactic treatment for pts receiving SG.

P1-02-07: Topical modulation of nociceptor epidermal terminals delays and ameliorates CIPN improving the quality of life of breast cancer patients

Sonia Servitja, Maria Castro-Henriques, Iñaki Álvarez-Busto, Carlota Díez-Franco, Alba Medina-Castillo, Maria Asunción Algarra-García, Elena López-Miranda, Margaret Lario-Martínez, Maria Isabel Luengo-Alcázar, Miguel Borregón, Ana Davó, Anna Gassull-Delgado, Sara Roque-García, Ana Gonzaga-López, Jesus Manuel Poveda-Ferriols, Severine Pascal, Clotilde Ferrándiz-Huertas, Ana María Mitroi-Marinescu, Marta García-Escolano, Asia Fernández-Carvajal, Antonio Ferrer Montiel

Background & Aims:There is strong evidence that >50% of patients undergoing chemotherapy are affected by peripheral polyneuropathy referred to as CIPN. Notably, up to 40% of these patients may develop a chronic neuropathy. A recent meta-analysis revealed that CIPN-associated neuropathic symptoms may persist in >80% of early breast cancer patients for 1-3 years after treatment. Considering the high survival prognosis of these patients, it appears essential to develop strategies that attenuate CIPN to increase their quality of life (QoL). Chemotherapeutic drugs such as paclitaxel and oxaliplatin produce neuropathic symptoms during or immediately after treatment. These drugs have been shown to potentiate thermosensitive receptors, sensitizing epidermal nociceptive terminals. Topical control of this sensitization may improve the sensory symptoms of CIPN and increase patients' quality of life. A previous pilot study in a cohort of 27 patients with CIPN grades I/II showed that topical application of a formulation containing a thermosensitive receptor modulator (Oncapsisens®) relieved sensory symptoms and increased patients' dermatological QoL. Therefore, preventive modulation of nociceptive epidermal endings with Oncapsisens® may help delay the onset of CINP and decrease the intensity of sensitive symptoms.
Methods: A randomized, double-blind study (hydrating cream (A) and nociceptive formulation Oncapsisens® (B) was approved by the Ethics Committees of participating hospitals. A cohort of 121 patients diagnosed with stage I-III breast cancer were included. Participants started a daily application of the assigned cream in hands. Upon appearance of sensory symptoms in hands or/and feet, participants applied the cream twice daily in hands and feet. Follow up of CIPN grade and adverse effects was conducted by oncologists, and quality of life questionnaires by sponsor. Differences between groups of qualitative variables were analyzed with the Fisher or Chi-square tests, and of quantitative variables with the non-parametric Wilcoxon signed-rank or Mann-Whitney rank tests.
Results: 60% of participants with a variety of chemotherapeutic treatments containing taxanes and/or platins developed distal CIPN. Withdrawals were similar in both groups. Application of cream B significantly delayed the appearance of sensory neuropathic symptoms (66.7% cream B vs. 49% cream A), attenuated the incidence of CIPN in hands, and improve sensory symptoms according to the Leonard scale. We also observed a lower incidence trend of CIPN in patients using cream B. Both creams were satisfying to patients. Only 2 patients in both groups complained of pruritus and were withdrawn from the study.

Conclusions: These findings suggest that topical modulation with a cream of nociceptor thermosensory sensitization delays the onset and improves CIPN symptoms.

P1-02-08: Incidence of cardiotoxicity in patients with breast cancer receiving human epidermal growth factor 2 (HER2) targeted monoclonal antibodies and antibody-drug conjugates: A Systematic review and meta-analysis.

Ilana Schlam, Maria Clara Saad, Judy Rabinowitz, Alex Julian, Jake Schwartz, Vasil Mico, Sara H. Hurvitz, Edith A. Perez, Jenica Upshaw, Natalia Kunst, Sara M. Tolaney, Stefania Papatheodorou

Background: Trastuzumab and other HER2-directed agents have changed the natural history of HER2-positive breast cancer; these agents have also been associated with cardiac dysfunction. Current guidelines recommend monitoring left ventricular ejection fraction (LVEF) every 3 months while patients are receiving selected HER2-directed agents. However, the incidence of symptomatic or clinically significant cardiotoxicity appears to be low, especially with ADCs, and the high frequency of cardiac monitoring may not be cost-effective. This study aimed to define the incidence of clinically relevant cardiotoxicity in patients receiving trastuzumab, trastuzumab emtansine (T-DM1), or trastuzumab deruxtecan (T-DXd).
Methods: A literature search of the Ovid Medline, Elsevier Embase, and Ovid Cochrane databases was conducted. The results were then uploaded to Covidence online software for the formal review by two independent reviewers. Statistical analysis was carried out using R software. This was a single-arm cumulative incidence meta-analysis investigating the cardiac safety of HER2-directed agents. A random-effects model was used for analysis, assuming the data come from varied populations with different distributions. The results were presented as pooled analysis in forest plots. We used the Cochrane Q chi-square test and I2 statistic to examine heterogeneity across studies; P values <0.10 and I2>50% were considered significant for heterogeneity. PROSPERO database ID: CRD42024513386.
Results: A total of 55 publications (n=39,335) were included: 37 for trastuzumab (n=28,808), 6 for T-DXd (n=2,331), 13 for T-DM1 (n=8,196), one used T-DM1 and T-DXd. We included one phase 1, two phase 1/2, 22 phase 2, and 30 phase 3 studies. A total of 25 studies included patients with early breast cancer and 30 with metastatic disease. A random-effects single-arm meta-analysis was completed to determine the incidence of cardiotoxicity associated with these drugs; the overall incidence of cardiotoxicity was 8% (95% CI 6; 10.4) with trastuzumab, 1.4% (95% CI 0.8; 2.6) with TDM-1, and 2% (95% CI 1.4; 2.9) with T-DXd. The incidence of symptomatic cardiotoxicity was 1.6% with trastuzumab, 0.4% with T-DM1 and 0.3% with T-DXd. There was a numerically higher incidence of decreased LVEF in those with metastatic disease relative to those with early breast cancer (trastuzumab: 9.8% vs. 7% and T-DM1: 1.7% vs. 0.9%, respectively). Patients treated with concurrent pertuzumab had a numerically slightly lower risk of decreased LVEF (trastuzumab 6.2 vs. 9% and T-DM1 1.3% vs. 2.5%).

Conclusions: In this meta-analysis, we concluded that the incidence of cardiotoxicity was higher with trastuzumab when compared to T-DM1 and T-DXd. Moreover, the risk of symptomatic cardiotoxicity is low across all these agents, ranging from 0.3-1.6%. The incidence of cardiotoxicity was lower with ADCs than with trastuzumab. Our findings suggest that the incidence of clinically relevant cardiotoxicity is low and low and therefore, monitoring LVEF every 3 months may not be necessary. Less frequent monitoring could decrease the number of visits for patients as well as financial toxicity. Future steps include developing a cost-effectiveness analysis to determine if cardiac monitoring every 3 months is the most appropriate for patients at standard cardiovascular risk.

P1-02-09: Evolution of Breast Cancer Management after Hodgkin Lymphoma: Towards a breast- Conserving Approach

Jihane Bouziane, Pierre Loap, Kim Cao, Lea Pauly, Alain Fourquet, Youlia Kirova

Background:The treatment of Hodgkin lymphoma (HL) has significantly evolved over the past few decades, combining less toxic chemotherapy and radiotherapy approaches. These advancements have improved relapse-free survival, particularly in the early stages of the disease. However, improved survival has led to an increase in secondary cancers, with breast cancer being the most frequent. Furthermore, despite transitioning to less extensive radiotherapy regimens like involved-node (INRT) and involved-site (ISRT) radiation, the risk of developing secondary breast cancer persists.
Purpose: The aim of this study was to analyze the clinical and histological characteristics of breast cancers occurring after Hodgkin lymphoma, as well as their outcome. Particular attention was given to the effectiveness and safety of breast-conservative surgery in this population.
Materials and Methods: We conducted a retrospective study on the records of 218 patients who developed stage 0 to III breast cancer (in situ or invasive) after treatment for HL at the Institut Curie between 1951 and 2022. Comprehensive demographic, clinical, and therapeutic data were collected, including treatment modalities for HL and breast cancer, as well as survival and locoregional control outcomes. Statistical analyses were performed using R software version 4.1.1.
Results: The median age at HL diagnosis was 24 years [7-79 years]. The median radiotherapy dose received by the mediastinum was 40 Gy, mainly using the mantle technique (79.8%). Breast cancer appeared at a median age of 47 years [22-86 years], with a median interval of 21 years [5-51 years] after Hodgkin lymphoma. A total of 12 patients (5.5%) were diagnosed with synchronous bilateral breast cancer. Locoregional treatment included mastectomy in 117 patients (56.0%) and lumpectomy in 92 patients (44.0%), with adjuvant radiotherapy in 99 patients (47.6%). Isocentric lateral decubitus irradiation (ILD) was performed for 48 patients treated by tumorectomy (63.2%).
With a median follow-up of 29.7 years after HL and 7.7 years after breast cancer, the 5-year overall survival and locoregional control rates were 89.2% and 86.4% for invasive cancers, and 100% for in situ cancers. There was no significant difference in terms of 5-year local

control between patients who underwent lumpectomy and those who underwent mastectomy: 95.1% and 88.1%, respectively (p=0.36). The 5-year survival rate without controlateral cancer was 93.8% [95% CI: 90.3–97.5%]. The 5-year metastasis-free survival rate was 87.4% [95% CI: 82.7–92.4%], with no difference observed between patients treated conservatively compared to those treated with mastectomy (96.5% versus 80.7%, p = 0.19). Long-term effects and aesthetic outcomes were evaluated in all patients, respectively. No late sequelae were reported, only slight decreases in glandular volume were observed.
Conclusion: Breast-conserving surgery, combined with appropriate radiotherapy, can be considered in the treatment of breast cancers after HL despite prior thoracic irradiation. This approach provides comparable outcomes in terms of local control and survival while reducing the risk of long-term complications associated with mastectomy. Incorporating techniques such as the lateral decubitus isocentric radiotherapy approach further enhances the efficacy and safety of breast-conserving therapy in this patient population.

P1-02-10: Real-world analysis of interstitial lung disease in patients with HER2-positive unresectable or recurrent breast cancer treated with trastuzumab deruxtecan: all-patient post-marketing surveillance study in Japan

Junji Tsurutani, Kengo Noguchi, Ayumi Tanabe

Background: Trastuzumab deruxtecan (T-DXd) has been initially approved for the treatment of HER2-positive unresectable or recurrent breast cancer after prior chemotherapy in Japan. While there is accumulating evidence demonstrating the efficacy of T-DXd in various types of cancers, interstitial lung disease and pneumonitis (ILD/p) are recognized as important identified risks associated with the use of T-DXd. Understanding the risk of ILD/p is crucial for optimizing ILD risk management and promoting the safe use of T-DXd. We conducted an all-patient post-marketing surveillance (PMS) study in patients with HER2-positive unresectable or recurrent breast cancer in Japan to investigate the incidence of ILD/p and factors associated with its development.
Methods: This study was conducted as an observational, multicenter, PMS (jRCT1080225197) with an observation period of 18-months that enrolled all patients treated with T-DXd for breast cancer in Japan. Patients who initiated T-DXd treatment between May 2020 and November 2021 were enrolled. Physician-assessed ILD/p events were retrospectively reviewed by an independent adjudication committee; events adjudicated as drug-related ILD/p were summarized. The factors associated with the development of adjudicated drug-related ILD/p were investigated using a Cox proportional hazards model.
Results: A total of 1731 patients (99.5% females) with a median age of 60 years (range: 27-87) were included in the safety analysis set. The majority of patients (92.1%) had an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 1 or less. The

median duration of T-DXd treatment was 9.4 months (range: 0.7-17.9), and the discontinuation rate during the 18-month observation period was 74.9% with the most common reason for discontinuation being progression of primary disease (46.0%). The incidence of any grade, grade ≥3, and grade 5 adjudicated drug-related ILD/p were 16.1%, 3.0%, and 1.0%, respectively. More than 80% of adjudicated drug-related ILD/p had resolved, were resolving, or resolved with sequelae within 24 weeks from onset. A multivariate analysis indicated that medical history and/or comorbidity of ILD/p [hazard ratio (HR) = 2.237, 95% confidence interval (95% CI): 1.210, 4.134], baseline renal impairment [mild impairment (creatinine clearance, 60≤ to <90 mL/min; HR = 1.719, 95% CI: 1.272, 2.322), moderate impairment to end stage (creatinine clearance, <60 mL/min; HR = 1.850, 95% CI: 1.240, 2.761)], higher body mass index (BMI ≥21.3 kg/m2 [median], HR = 1.649, 95% CI: 1.275, 2.133), and male gender (HR = 3.634, 95% CI: 1.299, 10.163) were associated with the development of ILD/p.
Conclusions: This study provides the first real-world experience with T-DXd, including over 1700 patients with breast cancer in Japan. The findings indicate that the risk of ILD/p in the real-world setting does not differ from that observed in clinical trials, suggesting that no new safety concerns were identified by this PMS. Medical history and/or comorbidity of ILD/p, baseline renal impairment, higher BMI, and male gender were identified as factors of interest associated with the development of ILD/p in patients with breast cancer. Further investigation into the identified factors of interest may offer insights into the development of ILD/p among T-DXd treated breast cancer patients in Japan.

P1-02-12: Prospective phase II study on the efficacy and safety of hetrombopag for the treatment of cancer therapy-induced thrombocytopenia in patients with breast cancer

Hanfang Jiang, Anjie Zhu, Huiping Li, Yaxin Liu, Ran Ran, Guohong Song, Bin Shao, Jiayang Zhang, Nan Wang

Background: Cancer therapy-induced thrombocytopenia (CTIT) is a common hematologic toxicity for patients with breast cancer (BC) causing anti-cancer therapy delays, dose reductions, and discontinuation. As a novel oral thrombopoietin-receptor agonist (TPO-RA), hetrombopag might raise platelets in patients with CTIT. We carried out a prospective, single-arm trial to assess the efficacy and safety of hetrombopag monotherapy in CTIT among patients with BC (ChiCTR2200062811). Methods: Thrombocytopenic patients with BC (Age ≥18 years, platelet counts<75×109/L) caused by anti-tumor treatments were eligible. The enrolled patients received hetrombopag monotherapy (5.0mg, qd) until reaching a recovery in PLT ≥ 80×10 9 /L or an increase of ≥50×109/L compared to the baseline. The treatment would stop when patients accepted 14 consecutive days of treatment or reached the discontinuation criteria. Platelet examination was taken every 3 days during the study period. The daily blood test was required if the baseline platelet counts <50×109 /L. The primary endpoint was platelet response within 14 days, denoted by a recovery in PLT ≥75×109/L compared to the baseline. The secondary endpoints included

the proportion of patients with platelets recovered to ≥ 100×10 9 /L, the proportion of patients with platelet transfusion, the incidence of dose reduction, delay, or discontinuation of consecutive cancer therapy cycles, and the safety. Results： From January 1, 2024, to June 30, 2024, 19 patients were screened for eligibility. The baseline characteristics were as follows: The median age was 51, with the majority (89.5%,17/19) at clinical stage IV. All patients with BC were treated with different anti-tumor regimens (31.6% (6/19) with chemotherapy therapy only, 21.1% (4/19) with antibody-drug conjugate (ADC) therapy, 15.8% (3/19) with chemotherapy plus targeted therapy, 15.8% (3/19) with endocrine therapy plus targeted therapy, 5.3% (1/19) with chemotherapy plus PD-1 inhibitors, 5.3% (1/19) with chemotherapy plus PD-1 inhibitor and antiangiogenic agent, 5.3% (1/19) with ADC plus antiangiogenic agent). Among them, 42.1% (8/19) of patients have received ≥3 lines of therapy. The median time from the last anti-tumor treatment to meet the inclusion requirement was 7 days (range, 1-22 days). The median value of baseline platelet counts was 65×10 9 /L (range, 28-74×10 9 /L). All patients experiencing ≥ grade 2 thrombocytopenia (PLT<75×10 9/L) after anti-tumor received hetrombopag monotherapy 5.0mg/day. Among them, 10.5% (2/19) experienced grade 3 thrombocytopenia. Treatment response was 89.5% (17/19), with a median time of 3 days (range, 3-9 days) to respond. The proportion of patients with platelets recovered to ≥100×109/L was 68.4% (13/19), with a median time of 6 days (range, 3-6 days) to respond. The incidence of dose reduction and delay of consecutive planned chemotherapy cycles were 18.8% (3/16, 3 patients had changed treatments due to disease progression or turning into maintenance therapy) and 42.1% (8/19), respectively. Especially, the platelet counts of 2 patients with severe thrombocytopenia (PLTs were 28×109/L and 39×109/L at baseline, respectively) increased to ≥100 × 109/L in 6 days after hetrombopag treatment. For safety, during the treatment of herombopag, there were 15.8% (3/19), 10.5% (2/19), and 5.3% (1/19) experienced grade 3-4 white blood cell count decreasing, neutrophil count decreasing, and anemia, respectively. No thrombosis was observed. There were no ≥ grade 3 increased AST and/or ALT. Conclusion: In this study, hetrombopag monotherapy is efficacious and well tolerated, substantiating its potential role as a novel treatment strategy for CTIT patients with breast cancer.

P1-02-13: Longitudinal analysis of cancer-related cognitive impairment in patients with luminal-like breast cancer undergoing chemotherapy and/or endocrine therapy - the Champalimaud-Helsinki study

Berta Sousa, Paula Poikonen-Saksela, Isabel Manica, Milla Vestvik, Silvia Almeida, Diana Frasquilho, Haridimos Kondylakis, Helena Gouveia, Leonor Matos, Joana Ribeiro, Arlindo Ferreira, Pedro, David Pinto, Maria João Cardoso, Johanna Mattson, Jan-Henry Stenberg, Marcelo Mendonça, Raquel Lemos, Fátima Cardoso,, Albino J. Oliveira-Maia

Background: Cancer-related cognitive impairment (CRCI) negatively impacts the quality of life (QoL) of patients with breast cancer (BC) and their ability to return to work. CRCI is a complex and multifactorial condition, with consensus that longitudinal studies are

necessary to study this phenomenon. This study aimed to investigate differences in the trajectory of cognitive function in patients with BC following exposure to chemotherapy (CT) or endocrine therapy (ET).
Patients and Methods: The Champalimaud-Helsinki study is a prospective cohort study developed as part of the BOUNCE project (H2020 Grant Agreement 777167), to assess cognition in patients with BC undergoing systemic treatment. Women aged 18-70 years, with Stage I-III Luminal-like BC treated with curative intent, and with no neurological or major psychiatric diseases, were eligible. All patients received local treatment with surgery and some with radiation therapy, according to standard practice. Two longitudinal cohorts were defined: 1) High-risk disease, where patients received neo (adjuvant) CT with taxanes with or without anthracyclines, and sequential ET; 2) Low risk disease, where patients received ET only. Cognitive complaints (Cognitive Function domain of the EORTC QLQ-C30 questionnaire), and battery of objective neuropsychological tests covering the domains of memory, attention, and executive function were assessed before starting systemic treatment, and at 6 months and 1 year after the baseline assessment Baseline comparisons were made between the CT and ET groups. Longitudinal analysis was conducted using a Linear Mixed-Effects Models.
Results: A total of 207 patients were recruited between February 2020 and October 2021, 102 in the CT group and 105 in the ET group, and 19.5% and 18.1% attrition rates, respectively. Women in the CT group were younger [mean age 51.4 years (SD 9.1) vs 55.7, (SD 8.8)], were more frequently in pre- or perimenopausal status (51% vs 31.4%), and had a more advanced disease (stage II/III: 76.4% 20.1%). There were no differences in education or other relevant sociodemographics known to affect cognition. At baseline, the CT group had higher rates of clinically significant anxiety (24.7% vs. 4.1%) and depression (3.7% vs. 0%; $p<.001$), but no differences were observed regarding cognitive complaints or neuropsychological test performance. In the first 6 months, both groups reported a decline in self-reported cognitive function, indicating more cognitive complaints ($p<0.001$), with partial recovery at 1 year. A time-group effect was not found ($p=0.40$). No decline or time-group effect was seen in objectively assessed memory, attention, or executive function.
Conclusions: Six months after initiating systemic treatment, patients with luminal-like BC experienced increased cognitive complaints, regardless of whether they received chemotherapy or endocrine therapy only, with no decline observed in objective neuropsychological performance. This underscores the impact of endocrine therapy on self-reported cognitive function. A better understading of CRCI is essential for developing interventions in the early-phase of BC systemic treatments, aiming to lessen CRCI severity and duration and improve QoL.

P1-02-14: Rate of Fracture After Discontinuation of Bone Modifying Agents in Patients with Early-Stage Breast or Prostate Cancer on Hormonal Therapy

Mara Hofherr, Alisar Aljundi

Background: Breast cancer patients on adjuvant aromatase inhibitor (AI) therapy or ovarian failure secondary to treatment are at high risk of decreased bone mineral density (BMD). NCCN[VP1] (National Comprehensive Cancer Network) currently recommends non-hormonal agents to prevent the loss of BMD, i.e. bisphosphonates and denosumab. The duration of denosumab treatment can vary, however will typically be discontinued after AI treatment is stopped. When discontinued, the decreased osteoclast activity can increase significantly, causing a rebound effect. It is becoming common practice to administer a dose of zoledronic acid, which does not carry the rebound effect, after discontinuing denosumab. There is minimal evidence that this practice is clinically necessary in the oncology population.
Methods: In this retrospective, single center study we examined patients with early-stage breast cancer who received and discontinued denosumab or zoledronic acid. IRB approval was obtained. Number and length of treatments, fractures of any kind, and delay in BMA were collected from the electronic medical record using diagnosis codes.
Results: Of the 587 patients with cancer treated from July 1, 2018 – July 1, 2023 who received hormonal therapy (AI) and received more than one dose of zoledronic acid or denosumab, 258 did not have bone metastases, alternative indication for bone modifying agents, or other primary cancers. Baseline characteristics were well balanced. 185 patients received zoledronic acid. 11 patients (5.9%) had a fracture after stopping zoledronic acid, with an average of 240 days after treatment. 73 patients received denosumab. 32 patients (44%) had a dose of zoledronic acid after denosumab, 41 patients (56%) did not receive zoledronic acid. After stopping denosumab and receiving a dose of zoledronic acid, 4 (13%) patients had a fracture an average 656 days after the last dose. Patients who [VP2] did not receive a dose of zoledronic acid after stopping denosumab, 3 patients (7%) had a fracture at an average of 627 days. 5 patients had a significant delay in treatment (gap of ≥1 month or greater) with either denosumab or zoledronic acid and no patients had a fracture during or after treatment.
Conclusions: The authors saw similar rates of fracture after discontinuing zoledronic acid or denosumab. If patients had discontinued denosumab, there were similar rates of fracture whether they received a dose of zoledronic acid to prevent the rebound effect or not. Further research needs to be completed to continue to investigate if the rebound effect of denosumab is clinically relevant in early-stage breast cancer patients for risk of fracture.

P1-02-15: Natural history including the incidence, severity and management of diarrhea in patients with breast cancer receiving abemaciclib and pertuzumab-based therapies with or without standard chemotherapy: Data from placebo arm of the OnTarget study

Pablo C. Okhuysen, Eric Roeland, Lee Schwartzberg, Hope Rugo, Stacy Tinianov, Kelly Shanahan, Enoch Bortey, Jim Bolognese, Pravin Chaturvedi

Background: Cancer therapy-related diarrhea (CTD) is a common adverse effect of targeted therapies (e.g., TKIs, CDK4/6 inhibitors), resulting in treatment modifications and poor

clinical outcomes. Yet, longitudinal patterns of CTD's impacts on cancer therapy (e.g., dose reductions, delays, and/or discontinuation) remains poorly characterized. Here we present patient reported outcomes (PRO) data on the incidence and severity of diarrhea in adult patients with breast cancer receiving abemaciclib and pertuzumab-based therapies in the placebo arm of the OnTarget study (NCT04538625).

Methods: OnTarget was a randomized, multicenter, double-blind, placebo-controlled prophylactic trial evaluating crofelemer versus placebo in adults with solid tumors receiving targeted therapies with or without standard chemotherapy. Patients were randomized to crofelemer or placebo given orally twice daily for 12 weeks. PRO-based diarrhea events were captured real-time using a mobile device. Key exclusions included immunotherapy, neratinib, irinotecan, colitis/ostomy/abdominal surgery ≤3 months, and antidiarrheal or antibiotic use ≤7 days. PRO grading used The National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) Version 5.0 for the number of loose/watery stools (LWS)/day using the Briston Stool Form Scale (6 or 7) for grades 1-4 of diarrhea. The incidence of diarrhea was evaluated as the proportion of days with LWS for each 21-day period of the 84-day treatment period. The proportion of patients requiring targeted therapy or chemotherapy dose modifications, including reductions, interruptions or discontinuations, were evaluated over each 21-day period. The proportion of patients using antimotility drugs as rescue medications for each cycle were also evaluated.

Results: The OnTarget study enrolled 287 adults with 10 solid tumor types and 24 unique targeted therapies. Patients were randomized 1:1 to placebo (n=142) or crofelemer (n=145) to prevent diarrhea. The safety population of patients with solid tumors randomized to the placebo arm was 135. The median age was 59 yrs [IQR: 51-57 yrs], 18.5% non-White). PRO data on diarrhea were available for 126 patients with different solid tumors over the 12-week period. Specifically, 81 (57%) were patients with breast, 18 (12.7%) lung, 14 (9.9%) renal, 9 (6.3%) liver, and 4 (2.8%) gastrointestinal cancers in the placebo group. Kinase inhibitors were administered to 49 (38.9%) patients with lung, renal, liver, breast and gastrointestinal cancers; two cohorts of patients with breast cancer received abemaciclib [n=44; 34.9%] and pertuzumab-based therapies with chemotherapy [n=29; 23%]. Abemaciclib patients experienced their maximum grade diarrhea during days 22-42 of their treatment, with a median of 7.1 LWS/week (IQR: 3.1-10.4). Over the 12-week, abemaciclib treatment period, a total of 18 (43.9%) patients with breast cancer required a dose modification due to diarrhea, and 24 (58.5%) reported rescue loperamide use. In contrast, those receiving pertuzumab/trastuzumab/docetaxel and carboplatin [n=17] had maximum median grade diarrhea during cycle 1 with 7.1 LWS/week (IQR: 4.6-12.3), and 75% of these patients reported rescue loperamide use. For the 4-cycle period for this pertuzumab cohort, the median LWS/week was 6.19 (IQR: 3.3-8.4), with all patients requiring a dose modification and 88.2% reporting rescue loperamide use.

Conclusion: This PRO-based prophylactic study on the incidence of diarrhea in patients with breast cancer receiving abemaciclib or pertuzumab-based therapies with standard chemotherapy over a 12-week period showed that most patients with breast cancer required dose modifications due to diarrhea and/or used rescue medications to remain on

their cancer therapy. The use of real-time PRO data on CTD in adult patients with breast cancer shows that diarrhea remains a neglected and under-reported comorbidity of cancer treatment.

P1-02-16: Matched pair single-cell RNA-sequencing highlights the impact of abemaciclib and endocrine therapy on different myeloid cell populations in advanced ER+/HER2- breast cancer

Sarah Sammons, Corinne Strawser, Binita Chakraborty, Daniel Michaud, Susan Dent, Jaycee Cushman, Vaibhav Jain, Sara Tolaney, Kent Weinhold, Sandra McAllister, Katherine Miller, Katelyn Steadman, Stephanie Arvai, Emily Hocke, Charles Perou, Shom Goel, Donald McDonnell, Jennifer Guerriero, Sarah Sammons

Background: The integration of cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors with endocrine therapy (ET) has revolutionized the management of estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) breast cancer. The ability of CDK4/6 inhibitors to induce cell cycle arrest is well documented, however, their potential to modulate the tumor immune microenvironment (TIME) has recently been appreciated. Pre-clinical studies suggest that CDK4/6 inhibitors elicit an anti-tumoral immune response through increased antigen presentation, activation of T- cells, and suppression of T regulatory cells. However, these data lack the granularity to characterize the impact of CDK4/6 inhibitors on the diverse immune cell populations including the myeloid compartment within the TIME. Here, we use single-cell RNA-sequencing (scRNA-seq) of isolated CD45+ cells to characterize the baseline immune landscape and the immunomodulatory effects of abemaciclib and ET in matched advanced ER+/HER2- breast tumor biopsies.
Methods: Sixteen patients with ER+/HER2- advanced breast cancer with lesions amenable to biopsy and beginning 1st-line abemaciclib and ET were enrolled (NCT04352777) and underwent a biopsy at baseline and 4 weeks post-treatment. Biopsies were immediately dissociated into single-cell suspensions and viably cryopreserved. Prior to scRNA-seq, cryopreserved single-cell suspensions were thawed and CD45+ cells were isolated. scRNA-seq libraries were prepared using 10X Genomics 3' Gene Expression kit and raw data were processed using Cell Ranger (10X Genomics). Data integration, clustering, and differential expression analysis were performed using Seurat. Clusters were annotated using canonical cell type markers. Responders were defined as patients on treatment for greater than 6 months without progression as assessed by RECIST 1.1. Changes in relative cell type proportion were assessed per patient, timepoint and lineage (myeloid or lymphoid). Survival analyses were performed with gene expression data from the METABRIC cohort.
Results: In total, 13 matched pairs were evaluable with an average patient age 60.8 years. Of these patients, 8 were classified as responders, 3 as non-responders, and 2 were not evaluable. From the 170,798 cells analyzed, we identified T-cells, NK cells, B-cells, plasmablasts, myeloid cells, and a cluster of proliferating immune cells. Responders had an expansion of activated, GZMA+/IFNG+ CD8+ T-cells and NK cells ($p < 0.05$) and a

concordant decrease in exhausted TIGIT+/PD-1+ T-cells. Additionally, our data reveal a complex and functionally heterogeneous myeloid subpopulation. We identified 14 diverse myeloid populations. Within the myeloid compartment, we identify a population of TREM2+ lipid-associated macrophages (LAMs), associated with a highly suppressive phenotype in multiple solid tumor types including breast, that decrease in relative proportion following treatment with abemaciclib and ET in treatment-responsive patients. Differential expression analysis was used to generate a gene signature defining this population. Lower expression of our TREM2+ LAM signature is significantly associated with improved overall survival in ER+/HER2- breast cancer patients from the METABRIC cohort.
Conclusions: Using scRNA-seq analysis, we show that response to abemaciclib and ET is associated with an increase in cytotoxic lymphoid populations and a decrease in exhausted T-cells. For the first time, we show an immunosuppressive population of TREM2+ LAMs decreases following treatment with abemaciclib and ET in responsive patients. In a separate dataset, lower expression of a TREM2+ LAMs gene signature is associated with improved overall survival. Further translational work is ongoing to assess the promise of targeting TREM2+ LAMS in ER+/HER2- MBC.

P1-02-17: Rediscovering Denosumab: Immunomodulation of the Tumor Microenvironment in Early-Stage Breast Cancer through RANK Pathway Inhibition

Andrea Vethencourt, Eva M. Trinidad, Eduard Dorca, Teresa Soler-Monsó, Anna Petit, Alexandra Barranco, Gema Pérez-Chacon, Marina Ciscar, Gonzalo Gomez, Gonzalo Soria Alcaide, Elena Piñeiro, María Jimenez, Elvira Purqueras, Silvia Vazquez, Agostina Stradella, Bartomeu Fullana, Adela Fernández, Rafael Villanueva, Veronica Obadia, Sabela Recalde, Miguel Gil-Gil, Sonia Pernas, Catalina Falo, Eva Gonzalez-Suarez

Background: The RANK signaling pathway has emerged as a potential therapeutic target in breast cancer (BC). Preclinical and clinical data support that RANK inhibitors enhance the anti-tumor immune response. Recently, we have presented the primary outcomes of our window-of-opportunity clinical trial D-BIOMARK (NCT03691311), although denosumab did not reduce tumor cell proliferation (Ki67) or survival (Cleaved Caspase 3), an increase in stromal tumor-infiltrating lymphocytes (TILs) was observed. The present report focuses on the immunomodulatory effects (IME) of denosumab in the tumor microenvironment (TME).

Methods: A total of 58 evaluable patients were randomized 2:1 to receive two doses of 120 mg of denosumab before surgery or no treatment. Paired biopsies at surgery and baseline from each patient were compared using paired sample t-tests. The expression of RANK and RANKL was analyzed by immunohistochemistry (IHC). Serial tissue sections were stained for CD3, CD4, CD8, CD20, CD68, MUM1, CD4/FoxP3, PD1, and PDL1 by IHC. Quantification was performed using QuPath software, with some parameters confirmed by manual quantification. RNA sequencing was performed in 47 of the 58 included cases (31 in the experimental group and 16 in the control group). Differentially expressed genes (DEGs) and

gene set enrichment analysis (GSEA) were performed, and finally CIBERSORT analysis was used to infer immune cell content from gene expression data.

Results: An increase in CD8+ cytotoxic T lymphocytes was observed in patients treated with denosumab by QuPath analysis (paired t-test 0.002 in the experimental group vs. 0.052 in the control group). Manual quantification showed a significant increase in CD3+, CD8+ and CD68+ macrophages in both groups, but only the control group showed an increase in immunosuppressive regulatory T cells (Treg). Transcriptomic analysis revealed that the increase in DEGs between diagnostic and surgical specimens was higher in the experimental group (adjusted p-value <0.05). GSEA confirmed that denosumab regulates immune activation, metabolism and oxidative phosphorylation pathways. CIBERSORT analysis showed an increase in global TILs in the experimental (p=0.01) and control (p=0.04) arms, consistent with manual TILs quantification. Importantly, changes exclusive to the experimental group included a significant decrease in immunosuppressive cells: M2 macrophages (experimental p=0.008; control p=0.230) and regulatory T cells (experimental p=0.016; control p=0.314), with a similar trend for neutrophils (experimental p=0.065; control p=0.372) and conversely an increase in monocytes (experimental p=0.014; control p=0.436). Tumor and stromal RANK basal expression were associated with highly proliferative tumors, as indicated by Pearson correlation with Ki67 (tumor RANK: 0.290, p=0.032; stromal RANK: 0.418, p=0.001). Basal expression of RANK or RANKL in both tumor and stroma did not function as a response biomarker for the increase in TILs, and potential biomarkers are still under investigation.

Conclusion: Denosumab exhibited IME effects in early BC particularly a reduction of M2 macrophages and immunosuppressive cells. These results highlight the importance of the RANK pathway in modulating the TME and encourage further investigation into the potential targeting of the RANK pathway as an IME treatment in breast cancer.

P1-02-18: Cancer-Associated Fibroblast-Mediated Suppression of T Cell Activity as a mechanism of Resistance to Immunoradiotherapy in Breast Cancer

Rongrong Wu, Yoshiya Horimoto, Masanori Oshi, Takashi Ishikawa, Kazuaki Takabe

BACKGROUND: Neoadjuvant pembrolizumab (Pembro) is now a standard of care for triple negative breast cancer (TNBC), but not all patients respond and that is also the case even when radiation (RT) is added. To this end, elucidation of the mechanisms of treatment resistance is in urgent need. Cancer-associated fibroblasts (CAFs), consist of inflammatory CAFs (iCAFs, which secrete cytokines and suppress immune cells) and myofibroblastic CAFs (myCAFs, which remodel the extracellular matrix), have been shown in in Vitro system that they promote tumor growth and metastasis while suppressing immune reactions by interacting with the other cells. This study aims to elucidate the mechanisms how CAFs play a role in resistance to Pembro or Pembro with RT in breast cancer patients using single-cell

analyses in NCT03366844 clinical trial.
METHODS: Phase Ib/II trial, Breast Cancer Study of Preoperative Pembrolizumab + Radiation (NCT03366844) collected biopsy samples longitudinally from the primary TNBC tumor in 34 patients; at baseline prior to any intervention, after a single dose of Pembro, and after RT while on Pembro. 23 patients achieved pathologic complete response (R) and 11 did not (NR) when treated with chemotherapy after biopsies prior to surgery. Among R group, R1 was the patients who continued to have strong immune cell infiltrates from baseline, and R2 was the patients that immune cell infiltration gradually increased while on treatments. In total of over 510,000 cells were collected and analyzed using Single-cell RNA sequencing,
RESULTS: The proportion of CAFs to all cells was higher in the NR group (18.6%) compared to the R group (7.3%). However, the proportions of iCAFs and myCAFs within CAFs were constantly similar at any point during the treatments in both R and NR groups (iCAFs: 60-70%, myCAFs: 30-40%). The proportion of CAFs to total stromal cells was about 80% at baseline, but it decreased by treatments, with an increase in the endothelial cell fraction (0-25%) regardless of R or NR. In R1, the myCAF fraction increased while the iCAF fraction decreased by treatments. In R2, the myCAF fraction was initially high but decreased, with the iCAF fraction increasing, reversing their ratios by the end of Pembro and RT. Additionally, almost no stromal cells other than CAFs were detected in R1, whereas endothelial cells increased from 38% to 65% in R2 after a single dose of Pembro. We next analyzed which cell express what as a ligand to which target cell in cell-cell communication. In the R group, T cells expressed TGF-beta1 and Interferon-Gamma, and B cells expressed IL-1beta as ligands to CAFs. Meanwhile, in the NR group, T cells expressed TGF-beta1, while B cells expressed IL-1alpha and IL-1beta when compared after first Pembro treatment to baseline. However, the ligand response from immune cells disappeared after the first Pembro treatment. CAFs expressed CXCL12 as ligands to T cells after RT+Pembro treatment in the NR group. The ligand response from CAFs to cancer cells was smaller in the R group. In contrast, CAFs expressed CXCL12 and Insulin like growth factor 1(IGF1) as ligands to cancer cells in the NR group.
CONCLUSION: Cell-cell interaction analysis using clinical specimens suggests that CAFs suppress T cell immune activity, contributing to immunoradiotherapy resistance in breast cancer.

P1-02-19: Spatially defining T-cell clonal evolution in post-neoadjuvant breast cancer and association with molecular residual disease.

Julia Ransohoff, Mia A. Carleton, Sofia Miron Barroso, Gregory Bean, Alisha Maltos, James Ford, George Duran, Michael Khodadoust, Melinda L. Telli, Ash A. Alizadeh, David M. Kurtz

Background: Tumor-infiltrating lymphocyte (TIL) enrichment in primary breast cancers is predictive of treatment response, and specific CD4 and CD8 subsets are associated with neoadjuvant chemotherapy (NAC) and immunotherapy response. Spatially defined T-cell receptor (TCR) evolution patterns in resection tissues associated with NAC response and

survival have not been described.
Methods: To define such patterns, we applied high-throughput TCR profiling to pre- and post-NAC tissues and associated immune dynamics with tumor evolution and clinical outcomes. We generated TCR repertoires of 29 primary breast cancers and 768 spatially catalogued, post-NAC specimens from matched cases (median 24 post-treatment samples/case) using Sequence Affinity capture & analysis By Enumeration of cell-free Receptors (SABER) applied to tissue-based Cancer Personalized Profiling by Deep Sequencing (t-CAPP-Seq). To profile each primary tumor's genomic and immunologic response to NAC, we designed personalized oligonucleotide panels using pretreatment whole exome sequencing and a fixed panel of recurrently mutated genes to capture emergent alterations, as well as a comprehensive panel of TCR-β regions. Leveraging information from fragmented TCRs in FFPE tissues, we spatially enumerated TCR clonotype count and composition in each post-NAC sample and compared the relative abundance of clones shared with each pretreatment tumor. For a subset of cases, we enumerated TILs and tumor cellularity in post-NAC samples (N = 119). To interrogate clonotype composition, we computed Jaccard similarity indices between each pre- and post-NAC sample pair. We associated post-NAC clonal abundance and clonotype composition with tMRD burden and genomic composition. Finally, we associated TCR repertoire dynamics with quantitative tMRD assessment and survival.
Results: TIL density was strongly correlated with the presence of post-NAC residual disease ($R=0.94$, $p<0.001$ for histologic invasive carcinoma cellularity; $R=0.6$, $p<0.001$ for mean tMRD allele frequency (AF)). Because TILs are defined in the presence of histologic residual disease, we defined tMRD-TILs by TCRs sequenced in tMRD positive tissues, which demonstrated greater repertoire diversity than non-tMRD TCRs (greater ShannonE and inverse Simpson diversity indices, $p=.007$ and $p=1.3e-5$, respectively), suggesting a spatially defined tumor neoantigen response. Within cases with low tMRD burden (mean AF ≤3%), which experienced longer progression-free survival than those with high tMRD burden ($p=0.034$), we observed greater TCR clone count in the post-NAC tissue ($p=.012$), greater shared clone count with the pretreatment tumor ($p=5.7e-8$), and greater similarity of the post-NAC clonotypes to the pretreatment tumor ($p=5.1e-6$, Wilcoxon test of Jaccard indices). Presence of a pretreatment CSPP1 lesion was associated with decreased TCR repertoire diversity in chemotherapy-treated resection tissues (ShannonE index, $p=0.00056$), and CSPP1-mutated tMRD was associated with inferior PFS (HR 23.45, $p=.0007$)
Conclusions: By spatially defining changes in the genomic and immunologic microenvironment following NAC, we found superior molecular response is correlated with preservation of the clonal relationship between tMRD-TILs and the primary tumor with simultaneous generation of a rich TCR repertoire. Ongoing investigations involve computationally predicting neoantigen targets of clonally dominant tMRD-TILs through NAC for in vivo validation, representing an avenue for refining selection of molecularly targeted adjuvant therapies.

P1-02-20: Visceral adiposity is associated with survival and distinct gene expression patterns in HER2-enriched subtype tumors

Elizabeth Cespedes Feliciano, Anlan Cao, Sophia Fuller, Jorge Gómez Tejeda Zañudo, Patrick Kurnia, Bette Caan, Elizabeth A. Mittendorf, Rinath Jeselsohn, Rodrigo Fonesca Abreu, Tabata Alves Domingos, Wendy Chen

Background: Greater patient adiposity is thought to promote tumor progression and increase mortality after a breast cancer diagnosis, but data are lacking in less common subtypes such as HER2-enriched. Most prior studies relied on body mass index and associations have been inconsistent. Here we directly measured visceral adiposity on clinically acquired images and examined differences in cancer-specific survival and the breast tumor microenvironment (TME) within and across a diversity of molecular intrinsic subtypes of breast cancer.
Methods: We included women with a primary, stage 2 or 3 invasive breast cancer diagnosed and treated in the community setting at Kaiser Permanente Northern California between 2005 and 2015. Using computed tomography scans collected as part of routine clinical care, we measured visceral adipose tissue (VAT) areas in cm2 at the third lumbar vertebra. We isolated RNA from n=1378 breast tumors collected at biopsy or excision; these cases were a random sample within each immunohistochemical subtype group. We verified RNA quality prior to performing NanoString BC 360™ assays to calculate the PAM50 molecular intrinsic subtype and measured the expression levels of genes associated with the TME. Using Cox proportional hazards models, we examined the associations of VAT scaled to height (m2) with cancer-specific survival within PAM50 subtype adjusting for age, stage at diagnosis and race/ethnicity. We additionally examined the mean change in gene expression associated with high vs. low VAT (>=42.5 cm2/m2).
Results: Mean (SD) age at diagnosis was 56 (13) years; a majority of women were either overweight (BMI 25-<30-kg/m2: 30%) or obese (BMI>30-kg/m2: 38%), and most were diagnosed with stage 2 (58%) vs. stage 3 (42%) breast cancer with representation from each PAM50 subtype: n (%) HER2-enriched 342 (25%), Basal-like 423 (31%), Luminal B, 312 (22%) and Luminal A 301 (22%). Overall, higher VAT (present in 533 [39%] of patients) was not associated with cancer-specific mortality (Hazard Ratio [HR]; 95% Confidence Interval [CI]: 0.98; 0.78, 1.24). By contrast, in the HER2-enriched subtype, patients with higher VAT had twice the risk of cancer-specific mortality (HR= 2.00; 1.19, 3.34), which was not observed for other tumor types (Basal-like HR=0.82; 0.57, 1.20, Luminal B HR=1.01; 0.63, 1.62; and Luminal A HR=0.68; 0.37, 1.23). Within patients with HER2-enriched breast cancer, we found genes associated with stroma (FAP, COL6A3, ADAM12) and mammary stemness (VIM, DDR2, HEG1, FHL1) were differentially expressed and enriched in tumors with high VAT (FDR<0.1).
Conclusion: Excess visceral adiposity was associated with shorter survival and increased expression of stroma and mammary stemness genes in tumors of patients with HER2-enriched breast cancer, suggesting adiposity's contribution to breast cancer progression differs by molecular intrinsic subtype. This translational study provides additional evidence

for the importance of excess adiposity as is a major modifiable risk factor for patient survival.

P1-02-21: Dissecting the tumor immune microenvironment by single cell transcriptomics and immune repertoire analysis in breast tumors treated with the aromatase inhibitor letrozole and the CDK4/6 inhibitor ribociclib.

Xavier Tekpli, Villads Winton, Marie Fongaard, Pål Marius Bjørnstad, Tatjana Bosnjak-Olsen, Knut Selsås, Stephanie Beate Geisler, Kamilla Fjermeros, Manouchehr Seyedzadeh, Unn-Cathrin Buvarp, Nam Thi Nguyen, Torben Lüders, Diether Lambrechts, Marianne Lyngra, Arnoldo Frigessi, Victor Greiff, Vessela Kristensen, Jürgen Geisler, Xavier Tekpli

Background: Combining aromatase inhibitors with CDK4/6 inhibitors is regarded as a significant advancement in the treatment of estrogen receptor (ER) positive breast cancers. Increasing evidence suggests an immunomodulatory role for CDK4/6 inhibitors in cancer. The impact of CDK4/6 inhibitors on the breast cancer immune microenvironment is still incompletely understood.

Clinical trial: The NEOLETRIB-study is a multicenter, single-arm, open-label phase II clinical trial. Patients with locally advanced, ER positive, human epidermal growth factor receptor 2 (HER2) negative breast cancer, characterized by cT3-cT4 tumors and/or cN2-3 lymph node involvement, receive six cycles of ribociclib (600 mg daily, 21 days on and 7 days off) in combination with letrozole (2.5 mg daily) as neoadjuvant therapy. Patients with large T2 cancers could also be enrolled.

Aim of the study: We aim at studying the immune microenvironment as well as the T and B cells repertoires of 30 breast cancer patients along the course of the neoadjuvant therapy by analyzing longitudinal single-cell data from the NEOLETRIB-trial.

Methods: Single-cell RNA (scRNA), T cell receptor (scTCR), and B cell receptor (scBCR) sequencing were performed on the tumor biopsies collected (i) before treatment, (ii) at day 21, the end of the first ribociclib cycle, and (iii) day 21 of the 6th ribociclib cycle. The transcriptomic data was analyzed using cellRanger and the Seurat package. Analysis of scTCR and scBCR data was conducted with MiXCR and scRepertoire packages.

Results: Through unsupervised clustering of scRNA-seq data, we were able to identify the major cell types present in breast tumors, including T/NK cells, B cells, myeloid cells, epithelial cells, endothelial cells, and cancer-associated fibroblasts. Additionally, single cell TCR and BCR sequencing allowed us to determine the pairing of α/β chains and heavy/light chains on individual immune cells, and to identify T and B cell clones.
By analyzing the expansion and contraction of these clones during therapy, we were able to further characterize the states of T and B cells involved in expansion, as well as understand the dynamics of the tumor environment associated with T and B cell activation.

Furthermore, through network analysis, we investigated the connectivity of the immune repertoire in the tumors.

Conclusions: Our use of single cell transcriptomics and immune repertoire analyses provided a comprehensive characterization of the tumor microenvironment in breast cancer before and during neoadjuvant endocrine therapy. Our longitudinal analysis of biopsies from the NEOLETRIB trial also allowed us to identify clonal evolution and the adaptive immune response during therapy.

P1-02-22: The role of tumor-infiltrating lymphocytes (TILs) in the progression of human high-grade ductal carcinoma in situ (DCIS) to invasive breast carcinoma (IBC)

Hossein Schandiz, Lorant Farkas, Daehoon Park, Elin Edda Seland Agustsdottir, Berit Gravdehaug, Yan Liu, Torill Sauer, Jürgen Geisler

Background: We investigated the distribution of tumor-infiltrating lymphocytes (TILs) in the extracellular matrix (ECM) of high-grade breast ductal carcinoma in situ (DCIS) among various subtypes.
Methods: This study included formalin-fixed, paraffin-embedded specimens from 494 female patients diagnosed with DCIS between 1996 and 2018. Due to reservations received from 10 patients, we excluded these cases from further analysis. Using the Van Nuys classification system, experienced breast pathologists actively graded histopathological specimens. The extent of DCIS was recorded when this information was available. Routine diagnostic immunohistochemical (IHC) staining was performed. ER and PR IHC positivity was defined as > 1% positive tumor cells, in accordance with the updated guidelines of the American Society of Clinical Oncology (ASCO) and the College of American Pathologists (CAP). HER2 IHC was scored based on the ASCO and CAP guidelines, as in the routine diagnostic procedures for invasive breast carcinoma (IBC). HER2 silver in situ hybridization was performed when the IHC score was 2+. We calculated the Ki67 ratio by counting 200 intraductal epithelial cells in two separate hotspot foci. DCIS cases were classified as Luminal A (LumA), LumB $HER2^-$, LumB HER2+, HER2-enriched, or triple-negative subtypes according to the 2013 St. Gallen guidelines, which is used for molecular subtyping of IBC. Each subtype was divided into three categories: "Pure", which indicates no invasive component, "W/invasive", which indicates an invasive component, and "All", which represents the entire group of the given subtype.
Results: Of the 484 DCIS cases, 422 were identified as high-grade, of which 60 (14%) presented with invasive lesions. A significant number (31 out of 60; 52%) of the “W/invasive” cases contained TILs, compared to those classified as “Pure” (118 out of 362; 32%), ($p < 0.0055$, Fisher’s exact test). We found a significant portion of TILs in the ECM in 149 of 484 (31 %) cases. All these cases (100%) were classified as high-grade DCIS. We were able to subtype 140 out of 149 of these cases. We found that 66% (n = 92) of high-grade DCIS cases with TILs showed strong membrane positive HER2 overexpression (IHC

score 3+). Of these, 27% (n = 37) were LumB HER2+, and 39% (n = 55) were HER2-enriched subtypes ($p < 0.0001$, Fisher's exact test). The proportions of LumA was 12% (n = 17), LumB $HER2^-$ was 13% (n = 18), and finally TPN was 9% (n = 13), respectively. DCIS extent differed significantly between "Pure" cases and "W/invasive" cases with a median of 20 mm and 30 mm, respectively, ($p = 0.0197$, Mann-Whitney test) and between those with TILs and those without TILs, with a median of 28 mm and 20 mm, respectively ($p = 0.0040$, Mann-Whitney test). Differences in age between patients with TILs and those without TILs were not significant, with median ages of 55 and 57 years, respectively ($p = 0.2534$, Mann-Whitney test).
Conclusion: We found that high-grade DCIS cases with an invasive component exclusively showed the presence of TILs in the ECM, highlighting their potential as a tumor progression marker. Notably, a substantial proportion of high-grade DCIS simultaneously exhibited TILs in the ECM and strong HER2 overexpression (IHC score 3+). We found this association to be particularly pronounced in the HER2-enriched subtype ($p = 0.0035$, Fisher's exact test).

P1-02-23: Deciphering VISTA immunoreceptor mechanisms to target VISTA+ triple-negative breast cancers

Joshua Gruber, Yan Zhao, Tina Andoh, Fatima Charles, Ishrat Durdana, Priyanka Reddy, Kristina Paul, Harsh Goar, Caiden Golder, Marisa Juntilla, Yan Peng, James Ford, Allison Kurian, Melinda Telli, Song Zhang, Robert West, Andrew Lipchik, Michael Snyder

Introduction: Current FDA-approved immunotherapeutics for triple-negative breast cancer (TNBC) are only available for a subset of patients, highlighting the need to develop improved immune-targeting strategies. VISTA (V-domain Ig suppressor of T cell activation) is a single-pass transmembrane immune checkpoint receptor that is an emerging clinical target for cancer immunotherapy. It is expressed widely on lymphoid and myeloid cells in healthy individuals, is commonly expressed on cells of the tumor microenvironment and can be abnormally upregulated on tumor cells in a wide variety of tumors. Although VISTA confers quiescence to naïve T cells, molecular mechanisms responsible for this effect remain unclear. Also, the effects of VISTA expression on tumor cells remains poorly defined.
Results: Through cell line multi-omics profiling and histologic examination of 250 human TNBC clinical specimens we identify a subtype of TNBC with extremely high VISTA expression (~10% of all primary tumors). These tumors had undetectable PDL1 expression, very low infiltrating tumor lymphocytes and diminished proliferative rates (Ki67 ~50%, compared to >75% for VISTA-low tumors). We characterized VISTA-high tumor biology by expressing VISTA in TNBC cell lines and monitoring tumor growth in vivo after mammary fat pad injections. In all tested cell lines (HCC1806, MDA-MB-231, 4T1, EO771) enforced expression of VISTA significantly diminished tumor growth, which was evident in both immunocompetent and immunosuppressed hosts. Molecular investigations revealed that VISTA could decrease tumor growth through its intracellular domain, which repressed EGFR trafficking and decreased EGF-dependent cell growth. We purified proteins bound to the VISTA intracellular domain, which identified PTB-domain-containing proteins and

Rab11 effector proteins as functional VISTA interactors responsible for suppressing EGFR activity. These effects were mapped to a four amino acid (NPGF) motif in the VISTA intracellular domain, which could directly bind and recruit NUMB, a PTB-domain containing protein. Mutation of the VISTA NPGF motif completely reverted binding to NUMB, repression of EGFR activity and the slow tumor growth phenotype of VISTA+ tumors in vivo. To further demonstrate the functional significance of the VISTA NPGF motif we generated mice with VISTA NPGF mutations (homozygous NP□AA) and studied their T cells, which naturally express high VISTA levels. T cells from NP□AA mutant mice evinced increased proliferation in response to T cell receptor stimulation compared to control, demonstrating that the NPGF motif is a bona fide repressor of cell division in both tumors and T cells. Mice bearing VISTA NP□AA mutations in their immune system also had diminished tumor growth compared to WT mice when injected with TNBC cell lines.
Conclusions: We report a distinct subtype of TNBC characterized by high VISTA expression, low PDL1 expression and decreased proliferative index. This work identifies mechanisms by which VISTA can diminish cell division of tumors or T cells through recruitment of effector proteins to an NPGF motif in its intracellular domain. Clinical trials of VISTA-blocking monoclonal antibodies are ongoing and may have relevance for VISTA+ TNBCs that are unlikely to respond to PD1-targeted agents. In addition, therapeutic strategies to target the VISTA intracellular domain in T cells are predicted to improve immunotherapy responses and could be considered for VISTA-negative TNBCs.

P1-02-24: Leveraging bulk and single-cell RNA sequencing to identify features predicting response and survival to abemaciclib in six mouse models of breast cancer.

Yash Agrawal, Kevin Mott, Tulay Yilmaz-Swenson, Charles M. Perou

Introduction: Combining CDK4/6 inhibitors (CDK4/6i) with endocrine therapy (ET) is a standard-of-care treatment modality for hormone receptor-positive/HER2-negative breast cancer in the metastatic and adjuvant settings. Identifying biomarkers of response to CDK4/6i in breast cancer to improve their application is a subject of great clinical interest. We present a therapeutic and transcriptomic analysis of six Genetically Engineered Mouse Models (GEMMs) of breast cancer treated with abemaciclib to shed further light on tumor cell and microenvironment features correlating with response that may mirror similar patterns in human breast cancer.
Methods: Mice from six GEMMs –TP53null-2153 (luminal), TP53null-2208L (luminal), MMTV-PyMT (luminal), MMTV-Neu (luminal), C3-Tag (basal), and RBnull/TP53null-626 (claudin-low) - were used to evaluate tumor response to abemaciclib vs. no treatment (control). Acute changes in tumor volume with treatment were measured, and survival monitored. Tumor specimens from each GEMM were obtained before treatment and at day 7, whereupon they were evaluated with bulk mRNA-sequencing (mRNAseq) using 873 published gene expression signatures, and with single-cell RNASeq (scRNAseq).
Results: Tumors from 3 GEMMs demonstrated statistically significantly less growth in

tumor volume ($p<0.01$) on abemaciclib vs. control – 2153 ($p<0.0001$), MMTV-PyMT ($p=0.003$), and MMTV-Neu ($p=0.001$). Only these same 3 models also demonstrated significantly improved survival with abemaciclib vs. control as assessed by the log-rank test ($p <0.0001$, $p=0.009$, and $p<0.0001$, respectively). Notably, two non-responder GEMMs (C3-Tag and 626) are known RB1-deficient models.
Differential expression analysis of gene expression signatures using supervised learning (FDR 0%) and hierarchical clustering revealed that for the 3 responder GEMMs, abemaciclib-treated tumors had lower expression of proliferation signatures and higher expression of innate immunity-related signatures at day 7 compared to untreated tumors. The 3 non-responder GEMMs showed no significantly differentially expressed signatures between treated and untreated tumors at day 7. We next compared the pretreatment tumor profiles of the responder vs. non-responder GEMMs and identified higher expression of multiple luminal-related signatures and lower expression of innate and adaptive immunity-related signatures in responder GEMMs. All six models were also assayed using scRNAseq, which is currently being analyzed and will be presented.
Conclusions: Tumors from GEMMs with known RB1 loss were insensitive to abemaciclib, and tumors from responder GEMMs had greater luminal gene expression features, despite being ER-negative. Responder GEMMs had lower tumor immune-related gene expression than those that did not respond, and adaptive immunity-related signatures did not change significantly with abemaciclib vs. control in responders, whereas innate immunity-related signatures showed increased expression with treatment. These findings add to a growing body of evidence, including correlative analyses from human clinical trials, which support RB1 loss as a biomarker of resistance and luminal intrinsic subtype and low tumor immune features as biomarkers of response to CDK4/6i in breast cancer.

P1-02-25: New Murine Mammary Tumor Cell Lines for Syngeneic Studies Including Immunotherapy

Thomas Kalantzakos, Anusha Soni, Cameron Durfee, Chris Mullally, Benjamin Troness, Reuben S. Harris, Harshita B. Gupta

Breast cancer (BC) is the most common cancer diagnosis in women globally, accounting for more than 1 in 10 new cancer diagnoses. While BC has historically been a poor candidate for immune checkpoint blockade (ICB), recent studies in triple-negative BC (TNBC) have demonstrated anti-PD-1 treatment efficacy when employed in conjunction with chemotherapy1. APOBEC3 (A3) enzymes, such as A3A and A3B, catalyze cytosine-to-uracil deamination in single-stranded DNA, leading to signature single base substitution mutations (SBS2 and SBS13). A3 expression and mutagenesis have been associated with poor clinical outcomes, including drug resistance2,3. Murine models for studying ICB and mutagenesis by human A3A and A3B are underdeveloped. Here, we address this gap by generating two independent mammary tumor cell lines and studying responsiveness to ICB. Two novel mammary cancer cell lines, MM001 and MM008, were isolated from

spontaneously arising tumors in C57BL/6 MMTV-Cre+;p53fl/+ mice. Each tumor line was passaged serially in the mammary fat pads of C57BL/6 (WT) mice to obtain conditioned cell lines MM001i and MM008i, which formed consistent and reproducible tumors. Tumor immune infiltrates were investigated by immunohistochemistry for CD45 (pan-immune marker), CD3 (pan-T cell), CD8 (cytotoxic T cells), B220 (B cells), Mac-1 or CD11b (macrophages), and PD-L1. Cells were also assessed via flow cytometry for surface expression and interferon inducibility of immune markers PD-L1, MHC-I component H2-Kb, and CD155.
Reproducibly growing tumors for each of MM001i and MM008i were achieved, with 50% of the tumors reaching the endpoint of 1000 mm3 around day 18 and day 21, respectively. Interestingly, despite a shared ancestral genetic background, ICB treatment of WT mice injected with MM001i and MM008i revealed differential responses. MM001i was poorly responsive, whereas MM008i showed complete tumor regression following treatment with anti-PD-1. In contrast, both MM001i and MM008i responded rapidly to anti-CTLA-4. These differential responses were not explained by surface expression of PD-L1 and MHC-1 component H2-Kb, which appeared to be basally and inducibly (IFN-β or IFN-γ) expressed at similar levels. Experiments are ongoing to deduce the underlying molecular mechanism, test additional ICB therapies, and study the impact of A3 mutagenesis.
Thus, two novel murine mammary breast cancer cell lines have been established to evaluate immunotherapies in fully immune-competent C57BL/6 mice.

P1-02-26: Biomarkers in metastatic breast cancer with brain metastases – a subanalysis of matched tumor samples of the BMBC registry

Elena Laackmann, Kerstin Riecke, Sivaramakrishna Rachakonda, Volkmar Müller, Isabell Witzel, Marcus Schmidt, Klaus Junker, Peter A. Fasching, Mustafa Aydogdu, Leticia Oliveira-Ferrer, Paul Jank, Kristina Lübbe, Maria M. Karsten, Thomas Karn, Patricia von Kroge, Julia Teply-Szymanski, Thomas Decker, Martin Peters, Akira Hattesohl, Marion van Mackelenbergh, Marc Thill, Uta Ringsdorf, Anika Pehl, Christoph Mundhenke, Tanja Fehm, Julia Rey, Bärbel Felder, Sibylle Loibl, Carsten Denkert*, Elena Laakmann*, *authors contributed equally to this work.

Background: The incidence of brain metastases (BM) from primary breast cancer (BC) increased over the past decades. Despite the increasing incidence of BM in BC, the biology and development of BM are still poorly understood. Therefore, it is crucial to understand the pathogenesis of BM development in order to find prophylactic and therapeutic

approaches. The Brain Metastases in Breast Cancer Registry (BMBC) has collected clinical data of more than 4000 BC pts. with BM and tumor tissue samples (n= 400).

Methods: For this study, gene expression data (HTG EdgeSeq Oncology Biomarker Panel) was generated from BM and the corresponding primary BC tissue samples (n= 76), followed by differential gene expression analysis. Molecular subtypes were classified according to classical IHC (ultralow, 0, 1+, 2+, 3+) based on HER2 protein overexpression and additionally Absolute Intrinsic Molecular Subtyping (AIMS) was assessed using HTG data.

Results: In total 76 corresponding BM and primary BC tissue samples were included in this analysis. Median age at BM diagnosis was 55 years. 50% of the patients had singular BM, 27.6% 2-3 BM and 22.4% >=4 BM. 46.7% were HER2-pos., 17.3% triple-negative and 36.0% ER-positive. Subtypes according to AIMS in BC were 35.5% HER2-pos., 27.6% lum. A, 17.1% lum. B, 14.5% basal-like and 5.3% normal-like. Distribution of AIMS subtypes in the corresponding BM were 43.4% HER2-pos., 11.8% lum. A, 22.4% lum. B, 21.1% basal-like and 1.3% normal-like. Following AIMS switches could be identified from BC to BM: Lum. A BC switches to lum. B and HER2-pos. BM; primary normal-like BC switch to lum. A, HER2-pos. and basal-like BM; primary lum. B BC switch to HER2-pos., normal-like, lum. A BM; primary HER2-pos. BC switch to lum. B and basal-like BM. There were no AIMS switches detected in basal-like BC to BM. AIMS subtypes in BC and BM were not statistically associated with overall survival in patients with metastatic BC and BM (primary BC p= 0.13; BM p= 0.19). HER2 IHC in primary BC were: 7.1% ultralow, 44.6% IHC 0, 16.1% 1+, 32.1% 3+. HER2-IHC in BM were: 12.5% ultralow, 37.5%, IHC 0, 14.3% 1+, 5.4% 2+ and 30.4 % 3+. HER2 switches from primary BC to BM were detected as following: ultralow to IHC 1+, 0, ultralow; IHC 0 to ultralow, 1+ and 0; IHC 1+ to ultralow, 0, 1+, 2+ and 3+; IHC 3+ to 1+, 2+ and 3+. HER2 status was not statistically associated with OS in BC and BM (Primary BC p= 0.42 and BM p= 0.46).
Among the significantly upregulated genes (logFC > 0.58) in BMs in comparison to primary tumors heat shock proteins (HSPA1B), mitochondria-related genes (COX5 and MRPL13) as well as cell cycle-related factors (CDC20, CCNF and PTTG1) were detected.

Conclusions:Our analysis identified AIMS subtype and HER2 IHC classification switches from primary BC to BM in matched pairs that could be relevant for prognosis and treatment decisions. In addition, our preliminary differential gene expression analyses showed clear differences in various cellular processes between BC and BM tissues. Whether these differences reflect a selection process or rather an adaptation mechanism to a new environment remains to be investigated.

P1-02-27: A novel 1st-in-class RAS/β-catenin inhibitor concurrently targets cancer cells and MDSC to reverse the immunosuppressive tumor microenvironment: antitumor activity in mouse models of breast and other cancers

Gary A. Piazza, Khalda Fadlalla, Adam B. Keeton, Yulia Y Maxuitenko, Xi Chen, Kristy L. Berry, Md Yeashin Gazi, Gang Zhou

While RAS mutations rarely occur in breast cancers, RAS signaling is well-known to be involved in breast cancer development resulting from constitutive activation of receptor tyrosine kinases. The Wnt/β-catenin pathway is also activated and associated with more aggressive forms of breast cancer. We found that the cyclic nucleotide degrading enzyme, phosphodiesterase 10A (PDE10), is overexpressed in breast cancer cell lines and tumors compared with normal human mammary epithelial cells (HMEC) or tissues, respectively. PDE10 selective inhibitors and gene silencing inhibited the growth of cancer cell lines expressing PDE10, while normal cells lacking PDE10 were relatively insensitive. We identified a novel PDE10 inhibitor, ADT-030, that potently and selectively inhibited breast cancer cell growth by synthesizing and screening a focused library of indenes, followed by chemical optimization for oral bioavailability and metabolic stability. ADT-030 binding to recombinant PDE10 was confirmed by enzymatic assays measuring cyclic nucleotide hydrolysis and in intact cells by cellular thermal stability assays. The growth inhibitory activity of ADT-030 was associated with cGMP/PKG activation, blockage of RAS-MAPK/AKT signaling, and suppression of Wnt/β-catenin transcriptional activity, all of which occurred within the same concentration range. ADT-030 strongly inhibited primary tumor growth, blocked lung metastasis, and increased survival in the orthotopic 4T1 mouse model of breast cancer. The antitumor activity was observed at dosages causing no discernable toxicity. ADT-030 also inhibited tumor growth in mouse lung, colon, and pancreatic cancer models. Notably, ADT-030 caused tumor regression in patient-derived xenograft mouse models of pancreatic cancer, increased survival in orthotopic mouse models of lung cancer with “cures,” and synergized with anti-PD1 in the CT26 mouse model of colon cancer to enhance survival. Other studies revealed a significant impact of ADT-030 on the tumor immune microenvironment by inducing apoptosis of myeloid-derived suppressor cells (MDSC), accompanied by increased tumor infiltration of effector CD8+ T cells. Furthermore, ADT-030 treatment of cancer cells led to immunogenic cell death and enhanced dendritic cell activation. These results support further development of ADT-030, a novel PDE10 inhibitor capable of suppressing oncogenic RAS and β-catenin signaling, as a monotherapy or combined with immunotherapy or standard-of-care drugs for treating breast or other cancers with activated RAS and β-catenin signaling.

P1-02-28: PDGFRa+/FAP- fibroblasts at multiplex in situ resolution are associated with resistance to HER2 blockade in neoadjuvant treated HER2+ breast cancer: results from the Swedish PREDIX HER2 trial

Georgios Manikis, Evangelos Tzoras, Nikos Tsiknakis, Alfonso Martin Bernabe, Yazing Zhu, Kang Wang, Ioannis Zerdes, Jonas Bergh, Thomas Hatschek, Arne Östman, Alexios Matikas, Theodoros Foukakis

Introduction: The predictive role of cancer associated fibroblasts (CAFs) to neoadjuvant therapy in breast cancer is still under investigation. The aim of this study was to identify predictive biomarkers of response to HER2 blockade at multiplex in situ level for HER2+ breast cancer.
Methods: The PREDIX HER2 (NCT02568839) is a randomized phase II trial that compared neoadjuvant docetaxel, trastuzumab, and pertuzumab (THP) with trastuzumab emtansine (T-DM1) for HER2-positive breast cancer. Pathologic complete response (pCR) rates did not differ between the THP (45.5%) and T-DM1 (43.9%) groups (Hatschek et al, JAMA Oncology 2021). A core biopsy was obtained at baseline, after two cycles of treatment and at surgery. By using FFPE biopsies from all timepoints we performed multiplex in situ fluorescent immunohistochemistry. Two panels, one immune (CD4, CD8, CD20, FOXP3, CD68, CD163, CK and DAPI) and one stromal (FAP, aSMA, PDGFRa, PDGFRb, vimentin, pSMAD2, ki67, CK and DAPI) were selected. Each biopsy was processed by the PhenoImager HT (Akoya Biosciences, Marlborough, Massachusetts, United States) and the inForm software (version 3.0) was trained for tissue and cell segmentation. The invasive cancer area was manually drawn in QuPath.
Results: Two sub cohorts of PREDIX HER2 consisting of 57 patients for the stromal (24 pCR cases) and 54 patients for the immune (19 pCR cases) panels were used. Cancer associated fibroblasts (CAFs) were isolated from the stromal compartment (tissue segmentation from InForm) of the invasive cancer area (defined in QuPath). The different combinations of the aSMA, PDGFRa, PDGFRb and vimentin identified 15 fibroblast subsets. Tumor infiltrating immune cells were identified at the epithelial and stromal compartments of the invasive cancer area. The total populations of CAFs and TILs were not associated with pCR at baseline (adjusted p=0.4). We then looked at the specific subpopulations. Higher densities of PDGFRa+/FAP- CAFs were associated with residual disease at baseline (adjusted p=0.011). The prognostic effect remained significant for T-DM1 treated (adjusted p<0.001) and ER- patients (adjusted p= 0.061), while it was lost for THP treated patients (adjusted p>0.9). From the immune panel, higher densities of CD20+ B-cells and CD4+/FoxP3+ Tregs were associated with pCR (adjusted p=0.012). The prognostic effect of B cells remained significant for T-DM1 arm (adjusted p=0.015). Bulk RNA-sequencing from 185 patients in PREDIX HER2 at baseline verified the correlation between higher PDGFRa gene expression and residual disease at baseline. (p<0.05) Similarly, digitally enumerated TILs and CAFs in H&E slides of 171 patients in the cohort didn't correlate with pCR at baseline (adjusted p=0.14 and 0.2 respectively), highlighting the importance of subpopulations.
Conclusion: Higher densities of PDGFRa+/FAP- CAFs and lower densities of B cells are associated with residual disease at baseline to HER2 blockade. Further validation studies,

longitudinal assessment of the densities' changes under pressure of treatment as well as analysis at a spatial level are ongoing.

P1-02-29: Targeting RANK pathway in combination with CDK4/6 inhibitors decreases the growth of palbociclib-resistant breast tumors via cancer cells and tumor microenvironment-mediated effects

Sandra Casimiro, Maria Martelo, Rúben Vilela, Inês Gomes, Luis Costa

The Receptor Activator of NFkB (RANK) signaling pathway has emerged as a relevant drug target in the context of breast cancer prevention and treatment, due to its role in progesterone-induced breast carcinogenesis and breast cancer progression. We have previously reported that, in Luminal breast cancer, a decreased proliferation rate and resistance to therapy accompany the RANK-induced stem cell-like and mesenchymal-like characteristics, suggesting that RANK-expressing cells may constitute a reservoir of slow-cycling therapy-tolerant cells. Recently, we have disclosed a link between RANK signaling and intrinsic or acquired resistance to CDK4/6 inhibitors (CDK4/6i) plus endocrine therapy in luminal breast cancer; and demonstrated that pharmacological inhibition of RANK pathway improves response to CDK4/6i-based therapy. Since it has been shown that loss of RANK signaling induces anti-tumoral immunomodulatory effects; and that CDK4/6i themselves can boost anti-tumor immune responses, we aimed to assess if therapy-induced immunomodulation improves the efficacy of co-targeting CDK4/6 and RANK ligand (RANKL) in breast cancer.
With this in mind, we conducted a drug-response in vivo assay, using two Rb-proficient/RANK-positive syngeneic models of breast cancer, TS/A-E1 (ER+HER2-) and 4T1 (ER-HER2-), which were characterized by having poor response to CDK4/6i in vitro (1μM Palbociclib: 41.8% and 8.2% decreased cell viability from control, respectively; 1μM Ribociclib: 13.2% and 3.4% decreased cell viability from control, respectively; assessed by clonogenic assay, mean of n=4 experiments). Cells were inoculated in the flank of 6 weeks-old Balb/C female mice (n=4, TS/AE-1; n=6-8, 4T1), and tumor-harboring mice were treated with 30mg/Kg/day p.o. Palbociclib, 10mg i.p. OPG-Fc (RANKL inhibitor) 3x/week or both. Tumor growth was monitored externally and experimental endpoint was set at Tvol ≥1000mm3 or bigger axis ≥1cm in any group. At sacrifice, tumor tissue was processed for RNAseq and immunohistochemistry (IHC) using standard methods.
Unlike monotherapy, the combination of OPG-Fc and Palbociclib was able to restrain tumor growth in both models ($p=0.0644$ and $p=0.0099$, TS/A-E1 and 4T1, respectively), and led to significantly decreased tumor volume, tumor weight and Ki67 proliferation index (assessed by IHC) at sacrifice ($p<0.05$). Accordingly, gene set enrichment analysis (GSEA-mh, FDR Q-value<0.05) has highlighted hallmarks associated with cell cycle, proliferation and senescence in Palbociclib and combination-treated tumors.
The immune cells' infiltrate was characterized using two complementary approaches. First, the mouse immune cell abundance was predicted from RNAseq data obtained from the 4T1 bulk tumors (n=3) using the ImmuCellAI-mouse software. The infiltration score was

significantly higher in the combination group ($p<0.05$), where M1 macrophages, cDC2 cells, eosinophils and basophils were the more abundant immune cells. OPG-Fc-treated tumors were characterized by increased cDC2 cells; a feature also observed in Palbociclib-treated tumors that also had decreased M2 macrophages and neutrophils. Next, the immune cells specifically infiltrating the non-necrotic tumor parenchyma were quantified by IHC in both models. Significant therapy-induced immune alterations included increased CD4+ and CD8+ T cells in all treated groups, and a decrease in tumor-associated macrophages (F4/80+, TAMs) in OPG-Fc and combination groups. M1 TAMs (iNOS+) were particularly increased in the combination group, whereas M2 TAMs (CD163+) were particularly decreased in these tumors.
Overall, our data supports that RANKLi can be an important add-on to CDK4/6i, in both luminal and TNBC, warranting future clinical studies. The benefit from this combination therapy spans from the direct anti-tumoral effect to the immunomodulatory roles of both drugs, towards an anti-tumoral microenvironment.

P1-02-30: A Stromal Proteomic Investigation of the RAHBT Cohort: Collagen Molecular Patterns Link to Recurrence in Ductal Carcinoma in Situ

Taylor S. Hulahan, Laura Spruill, Jeffrey R. Marks, Elizabeth N. Wallace, Siri H. Strand, Anand S. Mehta, Robert Michael Angelo, Graham Colditz, E. Shelley Hwang, Robert West, Richard R. Drake, Peggi M. Angel

Introduction: While ductal carcinoma in situ (DCIS) is a not lethal breast pathology, its progression to invasive breast cancer (IBC) significantly increases a patient's mortality risk. It remains currently unknown which DCIS patients will experience a later breast cancer event following their primary DCIS diagnosis. Genomic and clinicopathological features have been explored for their predictive value, but stromal protein regulation, particularly of collagens, has yet to be understood in DCIS progression to IBC. We recently reported that collagen stromal signatures differentiate DCIS pathologies and distinguish DCIS from IBC. Here, we hypothesize that specific stromal molecular signatures provide a means to predict DCIS progression to IBC.
Methods: Tissue microarrays of the clinically annotated Resource of Archival Human Breast Tissue (RAHBT) cohort from 232 DCIS patients (White women; n=176, Black women; n=55, Pacific Islander women; n=1) were used under Exemption 4 of the Medical University of South Carolina IRB. The median age of diagnosis was 53 years old with a 6-year median time to recurrence. Stroma-targeting mass spectrometry imaging was used to report collagen stromal molecular patterns linked to DCIS clinical outcomes. The spatial distribution of collagen peptides was further evaluated on 20 lumpectomies (White; n=10, Black; n=10) followed by proteomic sequencing to match to the mass spectrometry imaging data.
Results: We report that the stromal microenvironment is linked to recurrence outcomes and DCIS pathologies. From the RAHBT cohort, DCIS-annotated regions and their adjacent

microenvironments were linked to 479 stromal peptides by spatial mass spectrometry imaging studies. Comparing DCIS specimens (n=232) to normal breast controls (n=36), 265 peptides were found to have significantly different intensity patterns (two-sample t-test; $p<0.01$). A comparison of the primary DCIS event from non-progressors (n=151) and patients (n=40) with ipsilateral recurrence revealed 4 peptides with differential intensity patterns (two-sample t-test; $p<0.05$). In a subset of DCIS patients who experienced ipsilateral recurrence and with matched primary and recurrence specimens (n=17), a comparison of the primary DCIS event to the recurrence revealed 120 stromal peptides to have differential expression between the primary tumor and later breast event (two-tailed t-test; $p<0.05$). Interestingly, most peptides decreased in intensity in recurrence compared to the primary DCIS event. This trend of decreased intensities with recurrence was maintained in the comparison of the contralateral recurrence cases to the primary DCIS event (n=13). Notably, 41 stromal peptides were differentially expressed between non-progressors (n=151) and patients with contralateral recurrence (n=29; two-sample t-test; $p<0.025$). Two peptides were found to be differentially expressed between Black (n=55) and White (n=176) patients in the cohort (two-sample t-test; $p<0.05$). As comedo necrosis has been associated with increased recurrence risks, stromal molecular profiles were investigated per architectural pattern (solid; n=75, cribriform; n=65, papillary; n=6, comedo necrosis; n=47). Between comedo necrosis and cribriform patterns, 21 peptides were reported to be significantly increased in comedo necrosis (two-sample t-test; $p<0.025$). Between comedo necrosis and solid patterns, 32 peptides were reported to be significantly increased in comedo necrosis (two-sample t-test; $p<0.025$).
Conclusions: The collagen matrix appears to undergo distinct spatial alterations with recurrence as well as vary by architectural pattern and ancestry. These extracellular matrix differences could contribute to observed disparities in recurrence associated with these clinical features. Stromal collagen patterns linked to recurrence could lead to novel prognostic development in DCIS.

P1-03-01: Towards Universal Germline Screening for Breast Cancer, Planning for a Sustainable Future: A Single-Center Retrospective Analysis

Adela Rodriguez Hernandez Barbara Adamo, Fara Brasó-Maristany, Benedetta Conte, Olga Martínez-Sáez, Miriam Potrony, Lorena Moreno, Elia Grau, Esther Sanfeliu, Raquel Gómez, Isabel García, Beatrice Fatrini, Elia Segui, Maria Vidal, Montserrat Muñoz, Teresa Ramón y Cajal, Francesc Balaguer, Aleix Prat, Barbara Adamo

Background: The implementation of germline genetic testing is complex due to emerging therapeutic indications such as adjuvant Olaparib for BRCA-mutated breast cancer (BC). Understanding the clinical-pathological characteristics of individuals meeting testing criteria for genetic testing can provide insights into the factors associated with identifying pathogenic germline variants (PVs) and likely pathogenic germline variants (LPVs). This knowledge can enhance the precision of genetic counseling and testing strategies. In this study, we reviewed our single-center experience of testing selected patients meeting clinical

and pathological features, to develop a progressive and more sustainable model on the way towards universal germline screening.
Methods: We evaluated 1,060 consecutive individuals with a personal history of breast cancer (BC) who met regional criteria for germline testing at the Hospital Clinic of Barcelona between 2016 and 2022. We excluded individuals diagnosed before 2000 (n=70), those women with DCIS (n=60), and those with missing clinical information (n=18). Clinical-pathological and molecular characteristics between carriers of PV/LPV and non-carriers. Chi-square tests or Student's t-tests were used to compare the distribution of variables between two groups. Logistic regression analysis was then employed to evaluate the association of each variable with PV/LPV. The significance level for all statistical analyses was set at a two-sided alpha of 0.05.
Results: A total of 912 individuals were evaluated. Most cases were women (n=898, 98.5%) with a median age of 49 (range 24-88) and had a family history (n=706, 78.3%). The main reasons for testing were family aggregation (n=357, 39.1%), BC onset ≤40 yrs-old (n=199, 21.8%), and triple-negative breast cancer (TNBC) onset ≤60 yrs-old (n=162, 17.7%). The rate of PV/LPV was 14.9% (n=136), and 151 individuals (16.6%) had variants of unknown significance (VUS). Overall, 776 (85.1%) had no PV/LPV identified. A higher number of PV/LPVs were identified in the BRCA2 gene (n = 41, 30.1%), followed by BRCA1 (n=31, 22.8%), CHEK2 (n=17, 12.5%), ATM (n=15, 11.0%), PALB2 (n=13, 9.6%), BRIP1 (n=5, 3.7%), TP53 (n=5, 3.7%), BARD1 (n=2, 1.5%), MSH2 (n=2, 1.5%), PTEN (n=2, 1.5%), BAP1 (n=1, 0.7%), CDKN2A (n=1, 0.7%), and RAD51C (n=1, 0.7%). Notably, 2 individuals with a PV in BRCA2 had another PV (i.e., MSH6 and CDK2NA), and 2 individuals with a PV in PALB2 had another PV (i.e., both in CHEK2). Most VUS (n=151) were identified in ATM (n=38, 25.2%), BRCA2 (n=23, 15.2%), PALB2 (n=15, 9.9%), MSH6 (n=12, 7.9%), and BRCA1 (n=10, 6.6%). The BC subtype distribution was 62.4% (n=563) HR+/HER2-, 15.0% (n=141) HER2+, and 22.0% (n=198) TNBC. The clinical-pathological variables significantly associated in univariate analyses with the identification of PV/LPV were sex, age, personal history of other cancer types, advanced TNM stage, TNBC, and bilateral BC. In a multivariable analysis, all the previously mentioned variables remained significantly associated with the identification of PV/LPV. The highest odds ratios (OR) were found for the following 2-group variables: male (OR=4.8), stage IV versus stage I (OR=3.1), bilateral BC (OR=2.7), other personal histories of cancer (OR=2.2), and TNBC (OR=1.7). Age was considered a continuous variable, and for every 10-year increase, the odds of detecting a PV/LPV decreased by approximately 34%.
Conclusions: Based on established historical testing criteria, specific clinicopathological features were significantly and independently associated with the detection of clinically significant variants. As we move towards universal germline screening for breast cancer, well-established information continues to help prioritize individuals who will benefit most from early detection of breast cancer susceptibility.

P1-03-02: Unveiling Genetic Predispositions: Germline Genetic Testing in Arab Male Breast Cancer Patients

Tamer Al-Batsh, Faris Tamimi, Hira Bani Hani, Baha' Sharaf, Sarah Abdel-Razeq, Suhaib Khater, Ahmad Issa, Zaid Muhanna, Omar Almuhaisen, Anas Zayed, Hikmat Abdel-Razeq

Introduction: Breast cancer predominantly affects women, but it can also occur in men, accounting for less than 1% of all breast cancer cases. Male breast cancer presents unique challenges in diagnosis, treatment, and management due to limited awareness and research compared to female breast cancer. Understanding the differences in pathology, genetics, and treatment responses between male and female breast cancer is crucial for improving outcomes. This study aims to investigate the baseline characteristics, genetic predispositions, treatment approaches, and outcomes specific to male breast cancer patients.
Methods: This retrospective study analyzed data from male breast cancer patients diagnosed between 2003 and 2022 at the King Hussein Cancer Center (KHCC) in Jordan. The study included all male patients with a confirmed breast cancer diagnosis within this period. Data collected encompassed demographic and clinical characteristics, including age at diagnosis, family history, tumor stage and grade, receptor status, and treatment modalities (surgery, chemotherapy, radiotherapy, and hormonal therapy). Disease-Free Survival (DFS) and Overall Survival (OS) were estimated using the Kaplan-Meier method to evaluate patient outcomes.
Results: The cohort consisted of 102 male breast cancer patients, mean age at diagnosis 58.4 (range, 24- 90) years. Invasive ductal carcinoma (IDC) was the predominant histological type (n= 97, 95.1%) of cases. The tumors were primarily grade 2 (n= 58, 56.9%) or grade 3 (n=33, 32.4%). Hormone receptors were positive in 98 patients (96.1%), while 12 (11.8%) were HER2-positive, and notably, none of the patients had triple-negative disease. Eleven (10.8%) patients had de- novo metastatic disease. For early-stage breast cancer, 61 patients (59.8%) were clinically staged as T2, with positive axillary lymph nodes in 56 patients (54.9%). Pathologically, 43 patients (42.2%) were staged as T2, with 27 patients (26.5%) had N1 and 35 patients (34.3%) had N0 axillary lymph node involvement. A family history of cancer, mostly breast, was present in 58 patients (56.9%), and almost 50% in first-degree relative. Genetic testing was performed on 47 patients (46.1%) and 7 patients (14.9%) were tested positive for pathogenic/likely pathogenic variants; mostly in BRCA2 (n=6, 12.8%), while the other patient had CDH1. None of the patients had BRCA1 mutation. Additionally, one patient (2.1%) was a carrier for MUTYH and another patient had an APC increased risk allele mutation. Variants of uncertain significance (VUS) were seen in 20 patients (42.6%). At the time of analysis, 73 (71.6%) of the patients were alive with a median disease-free survival (DFS) of 106 months (95% CI, 76 - NA), and a median overall survival (OS) of 105 months (95% CI, 96.7 -NA).
Conclusion: This study highlights the unique characteristics and challenges associated with male breast cancer. The predominance of invasive ductal carcinoma, high hormone receptor positivity, and the significant presence of familial cancer history and genetic mutations, particularly in BRCA2, underscore the need for targeted awareness, early detection, and

personalized treatment strategies. Despite a relatively high survival rate, the data emphasizes the necessity for increased research and tailored therapeutic approaches to improve outcomes for male breast cancer patients.

P1-03-03: Impact of Mainstreaming Protocol in Clinical Practice of Breast Cancer Patients

João Araújo, Inês Soares de Pinho, Raquel Lopes Brás, Patrícia Miguel Semedo, Mariana Soeiro e Sá, Ana Berta Sousa, Pedro Filipe, Rita Teixeira de Sousa, Luís Costa

Background: The most commonly affected genes in hereditary breast and ovarian cancer are the breast cancer 1 (BRCA1) and breast cancer 2 (BRCA2) genes. For patients carrying BRCA pathogenic variants (PV), lifetime risk for ovarian, breast and prostate cancer is substantially higher. Therefore, identifying them is important to tailor treatment decisions, acknowledge a patient's risk for other cancers and identify healthy relatives with the variant. The traditional model of genetic counseling involves visiting twice a geneticist: once to assess risk and obtain informed consent for testing (pretest counseling) and a second time to present test results and discuss future implications considering risk management for the patient and relatives. This multivisit model often delays testing, increases waiting times, costs and cannot attend to the high volume of patients requiring it. To deal with shortfall of resources and increased demand for testing, “Mainstreaming Cancer Genetics” program was developed in the United Kingdom Royal Marsden Hospital in 2013 with very successful and cost-effective results. In this initiative, the oncologists are responsible and trained for counseling, obtaining informed consent and ordering genetic testing for selected cancer patients, bypassing the need for pre-test counseling by a geneticist. If the test is positive the patient is referred to Genetics. In our center the Mainstreaming protocol (MP) was implemented in September/2018 through collaboration between the Departments of Genetics and Medical Oncology testing a number of high-risk mutations including BRCA1/2. Aims and Methods: To ascertain patient comprehension about genetic testing aims and results obtained in the MP, often in busy first appointments. Retrospective and descriptive analysis was made of all patients with breast cancer diagnosis followed at the Department of Oncology of our center that have been submitted to MP (BRCA1/2 genetic testing) between January/2018 and December/2021. Telephone questionnaires (TQ) regarding perception of results of the genetic test (9 questions) were made up to June/2024. Results: Of 193 breast cancer patients referred to MP, 160 had a test result available and were considered for analysis. Criteria referrals were as follows: 75 (46,9%) had age 31 to 39; 20 (12,5%) had multiple breast tumors (bilateral/synchronous/metachronous before age 60); 50 (31,3%) were triple negative; 8 (5,0%) had male breast cancer; 21 (13,1%) were tested due to potential targeted therapy. A total of 13 (8,1%) had PV and 10 (6,3%) had a variant of uncertain significance (VUS). TQ were obtained from 108 (67,5%) patients of which 97 (89,8%) remembered taking the test. The latter only were considered for questioning as follows: 83 (85,6%) were given written information regarding the test; 93 (95,9%) understood why the test was asked; 88 (90,7%) had been informed by their

doctors about the test results; 84 (86,6%) understood the result of the genetic testing; 68 (70,1%) understood that result could impact their treatment and 89 (91,8%) that could impact their relatives; 85 (87,6%) of patients were satisfied for having done the test. Also, 18 (78,3%) of patients with reported variants (either pathogenic or VUS) mentioned having had a Genetics appointment following their result.
Conclusions: MP is a way of fast-tracking BRCA PV diagnosis in clinical setting with a vast number of geneticist appointments being obviated. In fact only the 22 (14,3%) patients with a found variant had the need for a formal Genetics appointment. This led to communication challenges as medical oncologists took charge of counseling regarding genetic testing. In fact, a relevant 10,2% of patients did not remember being tested, showing great need for improvement in objectives and risk communication.

Breast cancer related lymphedema rates following sentinel lymph node biopsy: how concerned should patients and clinicians be?

Lyndsey Kilgore, Tateum Mattingly, Sabrina Korentager, Shane R Stecklein, Kelsey E Larson, Christa R Balanoff, Elizabeth J Jeffers, Lynn Hinton, Jordan Baker, Jamie L Wagner

Background: Breast cancer-related lymphedema (BCRL) is a feared side effect following nodal surgery and breast cancer treatments. While long-term rates of BCRL after axillary lymph node dissection are known, little and highly variable historical data exists on rates following sentinel lymph node biopsy (SLNB). Since our institution has been prospectively utilizing bioimpedance spectroscopy (BIS) for screening and early-detection of lymphedema, we sought to examinate the incidence of BCRL following SLNB to help guide patient discussions regarding surgical risks, adjuvant treatment decisions, and the optimal method for long-term lymphedema surveillance.
Methods: A retrospective review of a prospectively maintained, single institution, breast cancer database was performed. All patients underwent SLNB between 11/2014-11/2017. BIS measurements were obtained on all patients preoperatively, postoperatively, and then every 3 months for 1 year, every 6 months for 1 year, then annually. BIS > 3 standard deviations above preoperative baseline was considered abnormal. Any abnormal reading was followed up with a repeat measurement one month later. Patients who received adjuvant radiotherapy and/or chemotherapy, and those who had a recent surgical procedure, were only diagnosed with BCRL if a repeat BIS four weeks later was still abnormal. Additionally, BCRL diagnosis resulted in clinical evaluation and initiation of self-directed home interventions with subsequent reassessment for resolution versus persistent BCRL (pBCRL). Groups were compared using t-tests or Wilcoxon rank sum tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. Analyses used R (version 4.2.1) and $p<0.05$ was statistically significant.
Results: A total of 324 patients underwent SLNB and had both pre-operative and post-operative BIS measurements. A single abnormal BIS occurred in 58 (18%) patients. Of these, 41 (71%) returned to baseline on BIS reassessment without intervention and were therefore not diagnosed with lymphedema. Of the 17 patients (5%) with confirmed BCRL,

15 (88%) had stage 0 lymphedema and only two had stage 1 lymphedema at diagnosis. After self-directed home interventions, only two patients had pBCRL for a pBCRL rate of 0.6% for all patients following SLNB. Development of pBCRL was not associated with age (p=0.39), BMI (p=1.00), receipt of radiotherapy (p=0.52), receipt of taxane chemotherapy (p=1.00), or the number of nodes examined (p=0.40). However, the average number of positive nodes was statistically significant for the development of pBCRL (p=0.01). Conclusions: The incidence of BCRL among patients undergoing SLNB is low. When identified early, at-home interventions can be employed and pBCRL is extremely uncommon. The only risk factor associated with the development of pBCRL following SLNB is the average number of positive nodes. We speculate that increasing nodal disease burden is associated with more frequent use of adjuvant nodal radiotherapy and systemic therapy, both of which are known to contribute to risk of BCRL. It is important to recognize that isolated abnormal BIS measurements are not uncommon, and that the majority of these instances reflect intermittent fluctuations in BIS that do not reflect BCRL. Repeat BIS should be performed before BCRL is diagnosed. Clinicians should be aware of the extremely low incidence of pBCRL when determining surveillance models and counseling patients on the risks and benefits of SLNB, especially because foregoing SLNB may impact adjuvant treatment recommendations.

P1-03-05: RNA-sequencing data in diverse women diagnosed with ductal carcinoma in situ

Emma Berdan, Thomas Walsh, Sarah A. Lyons Humble, Jen Tappenden, Katherine DeSchryver, Deborah Veis, Kiran Vij, Shannan Ho Sui, Graham A. Colditz, Aditi Hazra

Black women have a higher risk of subsequent breast cancer events (SBEs) but are underrepresented in ductal in situ carcinoma (DCIS) biomarker research compared to Non-Hispanic White women. We performed RNA sequencing using the Illumina NovaSeq 6000 technology on formalin-fixed paraffin embedded (FFPE) DCIS specimens. We integrated transcript data with clinical and social factors that drive SBEs in the Resource of Archival Breast Tissue population, including 35% Black women. Cases were diagnosed with DCIS from 1999-2019 with SBEs, including invasive breast cancer or ipsilateral or contralateral local DCIS. Controls matched 1:1 were diagnosed with DCIS from 1999-2019 without SBEs during similar follow-up times. The mean age at DCIS diagnosis was 56.3. The mean follow-up was 147.8 months. Principal Component Analyses (PCA) of 19,821 protein-coding genes were conducted on 141 DCIS samples, with >20 million total reads. PC1, representing 9.0% of the variation, was significantly correlated with race. PC3, representing 4.03% of the variance, correlated with follow-up time. We detected enrichment for interleukin and PD-1 pathways but no significant differentially expressed genes (DEGs) by case-control status. We identified significant DEGs with age, follow-up time, grade, race, and invasive SBEs. Generating high-quality RNA-seq data is feasible and elucidates novel insights on DEGs in diverse DCIS samples.

P1-03-06: Abrupt Involution Leads to Long-Term Mitochondrial Dysfunction and Metabolic Shift – Increasing Risk of Breast Cancer

Kate Ormiston, Neelam Shinde, Gautam Sarathy, Allen Zhang, Morgan Bauer, Rajni Kant Shukla, Sara Alsammerai, Annapurna Gupta, Djawed Bennouna, Xiaoli Zhang, Rachel Kopec, Eswar Shankar, Ramesh Ganju, Kristin I. Stanford, Sarmila Majumder, Bhuvaneswari Ramaswamy

Epidemiological data links higher parity and lack of breastfeeding with increased risk of breast cancer, specifically triple negative breast cancer (TNBC). TNBC is the aggressive hormone receptor and HER2 negative subtype associated with higher mortality rate1. Following pregnancy and lactation, breast remodels to near pre-pregnancy stage through apoptotic cell death and adipocyte repopulation process2. Long-term breastfeeding and gradual weaning of an infant leads to gradual involution (GI) of the breast, while lack of or abrupt discontinuation of breastfeeding after birth leads to abrupt involution (AI), when rapid and massive cell death takes place2. Our studies comparing GI vs. AI in a mouse model have shown several precancerous changes, such as increased collagen deposition, inflammation, and hyperplasia in the mammary gland of mice after AI2. While our preliminary data indicates metabolic shifts in the AI glands, the impact of AI on mammary gland metabolism and how this increases risk of breast cancer is yet to be elucidated.

Objectives: Determine the impact of AI on metabolic changes within the mammary gland and decipher the underlying mechanism that could link AI to increased breast cancer risk. Methods: Eight-week-old FVB/n mice were paired for breeding. At partum (day 0), dams were randomized to AI or GI cohort, standardized to 6 pups per dam and housed individually. AI mice had pups removed on day 7 postpartum (ppm) to mimic short-term breastfeeding. For GI mice 3 pups each were removed on day 28 and 31 ppm to mimic gradual weaning. Mammary glands were harvested on day 28, 56, and 120 ppm to assess short-term, intermediate, and long-term effects of AI vs. GI. Total mammary gland RNA was subjected to global gene expression analysis using Affymetrix and analyzed Ingenuity pathway analysis software. Differentially expressed genes were validated by qPCR and western blot. Oxidative stress was measured via MitoSox and H2CDFDA using Flow Cytometry. Whole mammary glands were subjected to untargeted metabolomics and lipidomics.

Results: On day 28 ppm, AI glands had marked upregulation of oxidative phosphorylation, ATP synthesis, and mitochondrial fatty acid b-oxidation compared to GI glands. AI glands had significantly higher levels of mitochondrial oxidative stress and enrichment of oxidized glycerophospholipids. On day 56 ppm, AI glands were metabolically comparable to GI glands. However, AI glands had an upregulation of genes related to fatty acid synthesis (PPARg, ACLY, Chrebp, GLUT4 and SLC25A1) and mitochondrial biogenesis (PGC1a). Interestingly, on day 120 ppm, AI glands showed significant downregulation of oxidative phosphorylation, ATP synthesis, glucose metabolism, and marked upregulation of mitochondria dysfunction. Amyloid precursor protein (APP) associated with mitochondria

dysfunction and downregulation of energy metabolism, was found to be elevated in AI vs. GI glands on day 120 ppm.

Conclusion: AI of the mammary gland leads to metabolic changes over time that disrupt mitochondrial function. Multiple studies have associated high levels of APP in human breast tumors and breast cancer cell lines with disruption of mitochondria function, enhanced cell proliferation, metastasis and invasion. Increased expression of APP in AI mammary glands suggests a key role of this protein in mitochondrial and metabolic dysfunction induced by AI. Further investigation is underway to decipher the role of APP in AI induced changes.
Significance: For the first time, this study demonstrates a metabolic shift in the mammary gland caused by AI. Targeting one or more key players in this metabolic deregulation could provide options for lowering breast cancer risk in women who are unable to breast feed.

*Funding NCI RO1 – CA237185 PI-Ramaswamy/Ganju

P1-03-07: Identifying risk factors for Benign Breast Disease in Donors to the Komen Tissue Bank

Rina Yadav, Vidya Patil, Jessica Moss, Aradhana Kaushal, Michele L. Cote

Background: An estimated 1.6 million breast biopsies are performed annually in the United States. Most of these tissue samples are noncancerous and classified as benign breast disease (BBD). Women diagnosed with BBD are 2 times more likely to be diagnosed with breast cancer (BC) than women without BBD. Studies have shown that the increased risk of BC remains elevated for at least 20 years after a BBD diagnosis. Currently, there is no standard surveillance algorithm or society-guided treatment guidelines for these patients. Furthermore, scant literature guides BBD etiology and strategies for risk-stratification for future BC development. Variables such as hormone use, physical activity, diet, breast density, and genetics are associated with BBD and risk calculators (Gail and Tyrer-Cuzick scores) use some of these variables to help predict a patient's risk of BC. However, neither of these models include smoking history in their assessment.
Evidence supports that smoking is associated or causal with a wide range of cancers, but there is inconsistent data to prove its connection to BBD and/or BC. To further understand smoking and its relation to BBD and/or BC, breast tissue repositories, such as the Komen Tissue Bank (KTB) (established in 2007 at the Indiana University and is the only resource of normal, healthy breast tissue that is representative of the US population) can be utilized to evaluate modifiable behaviors, such as smoking. The aim of our study was to evaluate demographic, personal health, and modifying behaviors in females diagnosed with BBD versus those who have never had the need for a clinically indicated biopsy.
Methods: Data from 5,118 individuals who donated to the KTB (2007–2023) were compiled into an analytic dataset. Men (n=37) and those with a baseline history of BC (n=206) were excluded. The final study population consisted of 4,875 women, those with a

self-reported history of BBD (n = 807) versus those without BBD (n = 4,061). Characteristics including demographics, personal health, reproductive histories, and modifiable behaviors, were analyzed and compared using chi-square tests, and p-values of <0.05 were considered to be statistically significantly different between the groups. The BC risk assessment scores (Tyrer-Cuzick and Gail Scores) were calculated for 3,447 participants (aged 35 to 85) between those with and without BBD, recognizing the women with BBD would likely be at higher risk.
Results: Donors with BBD had increased frequencies of family histories (FH) of BC, being menopausal/older age, having prior hormone (HRT) use, and having mammograms (MMG) performed ($p<0.0001$). Modifiable risk factors such as smoking were more common in individuals with BBD ($p<0.0001$). However, alcohol and body mass index (BMI) did not differ between groups. Tyrer-Cuzick Scores in BBD patients had a 10% higher frequency of being intermediate risk for BC compared to those without BBD. Gail Scores in BBD patients had a 50% higher frequency of being intermediate risk for BC ($p<0.0001$).
Conclusions: In the KTB donors, there is an increased frequency of smoking in patients with BBD. Smoking is not a variable used in standard breast cancer risk calculators and data are inconsistent regarding smoking and BC. However, smoking is known to decrease circulating estrogen and result in women becoming menopausal two years earlier than their non-smoking counterparts. Dysregulation of estrogen levels and menopausal status are two critical variables known to increase one's risk of BC. Clinicians should be aware of this potential risk factor and subsequently better educate patients who smoke about their increased risk of BBD and possible BC. Further research needs to be done to elucidate etiology, pathophysiology and management of BBD.

P1-03-08: Clinico-pathological Characteristics of Breast Invasive Lobular Carcinoma in non-CDH1 genetic predisposition. Experience from the Institut Curie.

Lounes Djerroudi, Rigleta Brahimaj, Chrystelle Colas, Victoire Montecalvo, Lisa Golmard, Claire Saule, Bruno Buecher, Hélène Delhomelle, Jessica Le Gall, Mathilde Warcoin, Mélanie Pagès, Nicolas Pouget, Fabien Reyal, Caroline Malhaire, Youlia Kirova, Dominique Stoppa-Lyonnet, Emmanuelle Mouret-Fourme, Anne Vincent-Salomon

Background: Invasive lobular carcinomas (ILC) represent 15% of breast cancers and are characterized by inactivation of E-cadherin (encoded by the CDH1 gene). Hereditary ILCs are rare and may be linked to germline mutations in CDH1, or to other genes (including BRCA2 and PALB2). The clinical and histopathological features of hereditary ILC unrelated to CDH1 mutation remain poorly described in the literature to date.
Materials and Methods: A retrospective series of ILC diagnosed in a context of constitutional genetic predisposition unrelated to CDH1 was retrospectively identified within Institut Curie's department of Genetics database. The selection criteria were patients with ILC and a pathogenic or likely pathogenic germline mutation in genes other than CDH1 over the period 2020 to 2023. The following data were collected from the electronic patient record:

mutated gene associated with hereditary breast cancer predisposition, patient age at ILC diagnosis, bilaterality, occurrence of other cancers, histological type, grade, hormone receptor (HR), and HER2 status.
Results: Seventeen patients with BRCA1 mutations, 80 with BRCA2 mutations and 12 with PALB2 mutations were identified. ILC was the first cancer diagnosed in almost all patients (13/14 [93%] for BRCA1, 55/59 [93.2%] for BRCA2 and 8/10 [80%] for PALB2). Patients were index cases in 75% (9/12) for BRCA1, 63.6% (35/55) for BRCA2 and 57.1% (4/7) for PALB2. The mean age at diagnosis was 42.1, 45.9 and 49.3 years, respectively for patients with BRCA1, BRCA2 and PALB2 mutation. The occurrence of bilateral disease at diagnosis was not common (0/9 [0%] for BRCA1, 6/57 [10.5%] for BRCA2, and 1/8 [12.5%] for PALB2). BRCA2- and PALB2-related cases exhibited mainly grade 1-2 (46/62 [74.1%] for BRCA2, and 8/10 [80%] for PALB2), and HR-positive ILCs (55/59 [93.2%] for BRCA2, and 8/8 [100%] for PALB2). In BRCA1-mutated patients, ILCs were enriched in grade 3 (5/13 [38.4%]) and HR-negative phenotype (4/12 [33.3%]). The prevalence of HER2-positive status was found to be slightly higher among patients with BRCA1 and PALB2 mutations (1/10 [10%] and 1/9 [11.1%], respectively) in comparison to those with a BRCA2 mutation (3/51 [5.8%]).
Conclusion: ILCs diagnosed in the context of a germline BRCA1, BRCA2 or PALB2 mutation occured at a younger age than sporadic ILCs. Hereditary BRCA2- and PALB2-related ILCs exhibit histo-phenotypical features comparable to sporadic tumors (predominantly grade 1-2, HR-negative, HER2-negative). Interestingly, ILCs associated with germline BRCA1 mutations appear to have a distinct phenotype in our series (enriched for grade 3 and HR-negative status), although this gene has not yet been identified as a predisposing factor for ILC.

P1-03-09: Predicted Probability of Germline Genetic Testing and Counseling of Breast Cancer Patients in Eastern North Carolina

Joshua Zweigle, Hui Bian, Srijan Valasapalli, Emily Wyatt, Ahmed Hebishy, Mahvish Muzaffar, The REDCap Consortium

Background: Germline genetic testing is recommended for all patients diagnosed with breast cancer under 65 years old and for other select patients. Referrals for these patients to undergo genetic testing are often placed but are not always finished for various reasons. Following the Covid-19 pandemic, the travel barrier was mitigated by offering genetic counseling online to patients. Information on who remained at risk was needed to determine the patients most likely to have incomplete genetic counseling.
Methods: Records of all the patients referred for a genetics consultation at the ECU Health Medical Center were tracked and recorded from 2020-2023. Information from these patients was identified and stored in a REDCap database. The information included demographic information provided in the patient's chart including their race, marital status, employment status, and religion. Visit information including the care at the time of genetics referral, and cancer that each of the patients or their family members had as well as

whether they proceeded with germline or somatic testing. Logistic regression was used to estimate the effects of race, type of insurance, employment, marital status, religion, and timing of genetics referral relative to cancer treatment on the probability of starting germline genetic testing and post-test counseling (PTC). Predictive probabilities were derived through logistical regression using SPSS software deriving odds ratios (OR) and 95% confidence intervals (CI) while controlling for the other measured variables.
Results: Out of the 618 patients referred for genetic counseling, 312 were referred for a personal or family history of breast cancer. Of these patients, 114 (36.5%) were white, 187 (59.9%) were black, 259 completed genetic counseling with testing, and 122 were positive for a germline variant with 23 (18.9%) being pathogenic. Of patients referred to genetic risk assessment for breast cancer, those referred for personal history before undergoing treatment were more likely to complete testing than those referred for family history (OR: 3.52; 95% CI 1.42-8.76). Among patients who underwent genetic testing, those with private insurance were more likely to test positive for a germline variant than those with Medicare (OR:2.85; 95% CI 1.39-5.85) or Medicaid (OR: 2.75; 95% CI 1.22-6.25). These patients who completed genetic testing and were referred for screening were also more likely to undergo PTC (OR: 2.05; 95% CI 1.01-4.17) than those referred before treatment. Additionally, those unemployed were more likely to have follow-up after the genetic testing than those with current employment (OR: 9.70; 95% CI 1.83-51.29). Of the patients who were positive for a variant, black patients were more likely to test positive for a variant of undetermined significance (VUS) than white patients (OR: 4.77; 95% CI 1.44-15.87). Those referred for family history were more likely than those referred after treatment to undergo post-test counseling (OR: 3.08; 95% CI 1.00-9.43).
Conclusion: Patients in Eastern North Carolina referred for genetic risk assessment for a personal or family history of breast cancer, were likely to start genetic testing if they were referred before treatment began. Of those who were positive for a variant, Black patients were more likely to test positive for a VUS. Of those who completed genetic testing, having private insurance increased their likelihood of testing positive for a variant. Patients who started genetic testing who were referred for screening were more likely to get post-test counseling than those referred before treatment and those who were not employed were more likely to get follow-up. Additionally, those referred for screening were more likely to get PTC than those referred after treatment.

P1-03-10: Prevalence of BRCA mutations in patients with HER2-negative breast cancer and high-grade serous ovary in the Dominican Republic.

Rosa Vassallo, Juana Espinal Irene Estévez, Katty López, Millyant Rojas, Yaresy Mendoza, Ivonne Pérez, Gilberto Fernández

Introduction: Breast cancer (BC) worldwide is the most common cancer in women; in the Dominican Republic, it is the second in frequency (3,244) and mortality (1,457) (1). Hereditary breast cancer is 5-10%, the BRCA mutation (mBRCA) is the most frequently identified (45-68%) (2). mBRCA is more frequent in African and Latino populations (3) (4),

and in the Dominican Republic, a multiracial country (5), they have not been studied. It is important to study them due to their prognostic and predictive value of innovative, effective and safe treatments; In healthy carriers, prevention would contribute to lower mortality.
Objective: Determine the prevalence of mBRCA in patients with (BC)-HER2 negative and high-grade serous ovarian cancer (OC) in the Dominican Republic, in the years 2020 - 2022 and mBRCA 1/2, in patients with BC- HER2 negative, in early and metastatic stage, and high-grade serous OC in first and second line (1L and 2L).
Method: It is a non-experimental, retrospective, cross-sectional, multicenter investigation in patients with BC- HER2 negative, high-grade serous OC, who underwent BRCA 1/2 testing, in 15 centers in the Dominican Republic, data obtained from the program "AstraZeneca BRCA 1/2 Testing", for the Dominican Republic.
The Medgenome laboratory received 881 tests, 82.5% with BC and 17.5% with OC, to determine sequence variants by NGS on the Illumina platform and analyze large deletions or duplications by MLPA, in the BRCA1/2 genes. The sample, composed of 856 valid tests to be processed, 25 invalid tests (2.9%) were excluded from the prevalence analysis. In the clinic, patients with negative BC-HER2 were stratified into two groups: hormone receptor positive BC (HR+) and triple negative breast cancer (TNBC), early stage or metastatic.
Inclusion criteria: TNBC IIA- IIIB; BCHR+ 1L neoadjuvant or adjuvant chemotherapy, under 45 years of age or family history of 1st or 2nd degree cancer; patients with advanced high-grade serous or endometroid OC, stage III or IV.
Results: 720 BC-HER2 negative tests were analyzed, 13.2% were mBRCA, 60% mBRCA1 and 40% mBRCA2. 52% were BCHR+, 11% mBRCA, 4% VUS and the rest non-pathogenic. 6% was mBRCA1 and 5% was mBRCA2. TNBC 48%, with 16% mBRCA, mBRCA1 was observed in 10% and 6% mBRCA2 and 0.3% mBRCA1/m BRCA2. VUS at 5%. In BCRH+ 52.5% were staged, 67.7% in early stage (EE) and 32.3% in metastatic (ME), PV 9% and 12% respectively. mBRCA1 5% in EE and 4% mBRCA2; in ME 6% mBRCA1/2; VUS in 3% EE and 4% ME. TNBC was staged in 47.5%, in EE 69.3% and ME 30.7%, VP mBRCA in 15% and 21% respectively. In EE 7% mBRCA1 and 8% mBRCA2; in ME 16% in BRCA1 and 5% mBRCA2. 5% VUS in EE and 3% in ME. 77% of BCRH+ were between 31 and 60 years old, with 102 patients (29%) predominating in the group between 41 and 50 years old. In TNBC aged 31 to 40 years the mBRCA1 VP was 25%.
136 OC tests were analyzed, 41.2% germline (G) and 58.8% somatic (S). VP 16.2%, VPG 18% and VPS 15%; mBRCA1 in 12.5% VPG and VPS; mBRCA2 5% in VPG and 2.5% VPS; VUSS 5% and VUSG 1.7%. In (1LG) 80% and 86% (1LS); in (2LG) 20% and 16% (2LS); 20% VP mBRCA in (1LG) and 14% (1LS). VP mBRCA in 9% in (2LG) there was no VP in (2LS). mBRCA was observed over 41 to 50 years of age, but 67% of patients were 51 to over 60 years of age.
Conclusion
The Prevalence in the Dominican Republic of BRCA mutations in patients with BC-HER2 negative is 13.2% and in OC is 16.2%. BRCA1 was the most frequent mutation, TNBC is the molecular subtype that most frequently presented the mutation; the BRCA mutation was observed more frequently in the metastatic stage. In OC, IPV was more frequent in (1L) and the most affected age group was 41 to 50 years, at a younger age for BC.

P1-03-11: Unique double BRCA2 mutations c.2254_2257del/c.5351dup in Patients with Breast Cancer from Jordan

Hira Bani Hani, Faris Tamimi, Baha' Sharaf, Yazan Talab, Suhaib Khater, Tamer Al-Batsh, Hanan Khalil, Mariam Al-Atrash, Hikmat Abdel-Razeq

Background: Given the increased co-occurrence of pathogenic and likely pathogenic variants (P/LP) in hereditary cancer syndromes as a result of multigene panel genetic testing, this study focuses on the prevalence and characteristics of double mutations in patients with breast cancer.
Methods: We reviewed all patients undergoing genetic testing for breast cancer from Jan 2016- Jun 2024. Data on patient demographics, cancer characteristics, and genetic testing results were compiled and analyzed. The statistical tests used were Linear Model ANOVA and Pearson's Chi-squared test. STATA software was used.
Results: A total of 5896 breast cancer patients underwent genetic testing. Among these, 36 (0.61%) patients had two different P/LP variants. Of these patients, 35 were female, with a median age at diagnosis of 40 years (range: 20-76 years). Four patients had two primary breast cancers, one had ovarian cancer, and one had sarcoma. At diagnosis, 10 patients had metastatic disease, three had triple-negative breast cancer, and histopathology revealed invasive ductal carcinoma in 33 patients.
Among these 36 patients, 23 had the unique double BRCA2 mutation c.2254_2257del/c.5351dup, identified exclusively in breast cancer patients from the Jordanian population. This mutation was previously reported by our institution as a potential founder mutation and has not been identified in other populations. Conducted at the King Hussein Cancer Center, the median age at diagnosis was 42.1 years (range: 20-76). Family history of cancer was positive in 95.7% of the cases. Notably, cascade testing was performed on 10 family members of the 23 patients with the double mutation, and all were found to have the same mutation, suggesting it is most likely a cis mutation, indicating that both mutations are on the same allele.
The other 13 patients had various combinations of P/LP: CHEK2 and PMS2; EPCAM and MSH2; BRIP1 and MUTYH; BRCA2 and CHEK2; BRCA2 and RAD51D; ATM and BRCA2; BRCA2 and PALB2; BRCA2 and PTCH1; ATM and BRCA2; BRCA1 and PTEN; ATM and RAD50; ATM and MUTYH. One patient had three P/LP variants: CHEK2, PALB2, and RAD51D.
No significant differences were found between the unique double BRCA2 mutation c.2254_2257del/c.5351dup group and the group of patients with various combinations of P/LP in terms of age at diagnosis (p=0.981), sex (p=0.446), TNBC status (p=0.174), presence of other cancers (p=0.689), histopathology (p=0.174), and family history of cancer (p=0.674).
Conclusion: The BRCA2 double mutation c.2254_2257del/c.5351dup was identified exclusively in the Jordanian population. Future research should focus on the implications of these mutations on treatment outcomes and long-term prognosis.

P1-03-12: Reprogramming SREBP1-dependent metabolism and inflammation in high-risk breast to prevent cancer: the example of licochalcone A

Atieh Hajirahimkhan, Elizabeth T Bartom, Carolina H Chung, Xingyu Guo, Kyli Berkley, Ruohui Chen, Wonhwa Cho, Sriram Chandrasekaran, Susan E Clare, Seema A Khan

Breast cancer (BC) risk reducing drugs have minimal impact on cancer incidence due to their adverse effects and low acceptance by risk-eligible women. Further, they are ineffective against hormone receptor negative (HR-) BC. Novel non-endocrine agents with reduced toxicity and efficacy not limited to HR+ BC are needed. Sterol regulatory element binding protein 1 (SREBP1) has been shown to have a key role in tumorigenesis in the breast through reprogramming immune and microenvironmental factors, epithelial to mesenchymal transition, cell cycle, and programmed cell death. It has a prognostic value in breast cancer patients and is an independent factor of 5-year overall and disease specific survival. Targeting this metabolic vulnerability presents opportunities to reverse tumorigenesis in several tissues such as breast and endometrium. We recently presented data which revealed that in the microstructures from the contralateral unaffected breast (CUB) of postmenopausal women with unilateral BC, LicA significantly upregulated antioxidant pathways and downregulated NF-kB dependent inflammatory pathways as well as SREBP1-dependent lipogenesis. We also showed that metabolic flux in the CUBs treated with LicA supports these effects. In addition, LicA exhibited suppression of proliferation in pre-malignant and malignant HR+ and HR- breast cell lines and in their xenografts in mice. Now we present confirmatory evidence that the mechanism through which LicA prevents HR+ and HR- BC is by reducing SREBP1-dependent metabolism and inflammation. We also show the promising PK profiles of novel oral formulations we have developed.
We performed NanoString metabolism panel analysis in MDA-MB-231 (HR-) and MCF-7 (HR+) breast cancer cells treated with LicA (5 μM) for 24 h. We also performed western blots to confirm the significantly modulated metabolic pathways. In addition, we evaluated spatiotemporal changes in the concentrations of cholesterol in the inner leaflet of plasma membrane of these cells. Four proprietary novel formulations of LicA were developed and administered orally to female BALB/c mice and Sprague-Dawley rats followed by LC-MS/MS analysis of the plasma and mammary tissue. Using SAAM II we modeled their pharmacokinetic (PK) profiles.
We observed significant (adj $P < 0.05$) upregulation of antioxidant (up to 9-fold), and downregulation (up to 6-fold) of NF-kB-dependent inflammatory pathways such as prostaglandin E2 synthesis. These results were consistent with our previous observations in animal models and in the high-risk women's CUBs. We also observed significant downregulation of SREBP1 dependent lipogenesis genes such as ACAT2, FASN, and SCD in these cells, which is in line with our data in the CUBs. Our western blot analysis showed a significant suppression of SREBP1 (4-fold) particularly in HR- cells, along with the reduced phosphorylation of PI3K (5-fold) and AKT (6-fold, on Ser 473). These results were confirmed by the depletion of cholesterol in the inner leaflet of plasma membrane in HR- (8-fold) and HR+ (4-fold) cells. Consistent with our data from the CUBs and in vivo models, we

observed 2- to 3-fold reduction in proliferative markers such as MKI67, BCL2, and RRM2 in HR+ and HR- cells after 24 h exposure to LicA. These results provided additional evidence that LicA exerts its antiproliferative effects by suppressing SREBP1-dependent lipogenesis and inflammation. Two of the novel LicA oral formulations showed promising PK, sufficient for efficacy with less frequent dosing which make them suitable for BC prevention.
Our data suggests that suppression of SREBP1 dependent metabolism and inflammation can prevent BC and presents evidence that LicA is an excellent candidate for HR+ and HR- BC prevention through this mechanism. We will test LicA's oral formulation in intraductal models of precancer lesions in immunocompetent animals to further establish its preventive efficacy.

P1-03-14: Lympho-Vascularized Breast-Skin Platform for Modeling Lymphovascular Space Invasion in Advanced Breast Cancer

Melika Mehrabi-Dehdezi, Wendy A. Woodward, Bisrat G. Debeb, Marissa N. Rylander

Inflammatory Breast Cancer (IBC) is an aggressive form of breast cancer, accounting for 10% of breast cancer deaths despite its relatively rare occurrence. A significant characteristic of IBC is the invasion of cancer cells into the lymphatic and blood vessels near the skin, leading to the formation of tumor emboli and lymphovascular space invasion (LVSI). Eventually, LVSI progresses into the overlying skin through the breast stroma and causes dermal lymphatic invasion (DLI). The mechanisms underlying LVSI and DLI remain poorly understood. Current experimental platforms, including 2D cell cultures, animal models, and more recent 3D in vitro models, have limitations in recapitulating the complexity of the tissue microenvironment, biomechanical cues, and cell behavior intrinsic to IBC. These limitations make it challenging to elucidate the mechanism of LVSI and develop effective therapeutics. While most 3D tumor models typically incorporate the blood vasculature, they often overlook the crucial role of the lymphatics, despite compelling evidence that for certain breast cancer subtypes, lymph vessels serve as the predominant pathways for tumor metastasis. Existing experimental systems also do not incorporate surrounding metastatic sites. Therefore, multi-tissue on-a-chip platforms (MTCP) that possess integrated blood and lymphatics would have tremendous value for elucidating cell migratory patterns and underlying mechanisms of the immune response and cancer metastasis. In this study, we created the first breast-skin platform with functional blood and lymphatic vessels that are connected between tissue layers of a breast tumor and skin. The platform's fabrication involved polymerizing type I collagen for the matrix around parallel 22-gauge needles (0.718mm). To mimic breast tumor tissue, 7 mg/mL collagen solution seeded with 1 million MDA-IBC3 cells/mL were injected into the platform and underwent polymerization. The skin platform was created using a layer of 4 mg/mL collagen solution seeded with 0.1 million cells/mL of primary normal human dermal fibroblasts (NHDFs) at the top of the breast tumor layer and then polymerized. Next, needles were extracted to create hollow vessels. Vessels were perfused with 1×107 cells/mL mKate-labeled tumor microvasculature endothelial (TIME) cells for blood vessels and 1×107 cells/mL RFP

Expressing Human Dermal Lymphatic Microvascular Endothelial Cells (HDLMVECs) for lymphatics. All Breast-Skin platforms were then placed in 6 well plates with 1.5-2 mL of complete endothelial cell media in each well surrounding the platform and put back on the rocker for 3 days to allow formation of a confluent vessel. Utilizing this platform, we have shown that MDA-IBC3 breast cancer cells invaded the skin through the stroma. We observed angiogenic sprouting occurs when TIME cells begin to bud from the peripheries of the endothelial vessel which advances towards MDA-IBC3 cells. Also, we have shown MDA-IBC3 emboli surrounded by these vessels, attempting to intravasate. The observation of vascular endothelium sprouting, and adjacent tumor emboli is solely facilitated by interactions between tumor and endothelial cells, representing the in vivo behavior of IBC. This novel platform allows for the high-throughput and controllable study of LVSI, DLI, and skin metastasis. It serves as a valuable tool for dissecting the metastatic process, generating functional cell selection and signaling targets for further research. Multiple functional endpoints, such as collagen alignment, immunofluorescent staining, live cell imaging, and cytokine quantification, can be assessed simultaneously. Our goal is to use the Breast-Skin platform to further our understanding of the mechanisms that drive skin metastasis in breast cancer and ultimately identify effective therapeutic targets.

P1-03-15: Characterization of metabolic and energetic risk factors and preventative breast surgical decisions in a cross-sectional survey cohort of hereditary cancer pathogenic variant carriers

Lauren Nye, Catie J. Knight, Jennifer R. Klemp, Lyndsey Kilgore

Background: About 10% of all breast cancers (BC) result from an inherited pathogenic variant (PV). Energetics and Lifestyle in Inherited Syndromes (ELLIES) Project is a survey-based study examining diet, exercise and metabolic risk factors in individuals with hereditary cancer pathogenic variants (HCPVs). This study describes metabolic risk factors and lifestyle habits among the first 750 participants in this cohort. We are interested in exploring how metabolic and energetic risk factors such as BMI, diet, and physical activity (PA) levels influence breast surgical decisions in both preventative and therapeutic settings.

Methods: The online self-administered survey, developed in REDCap, includes questions on demographics, personal health, cancer risk factors (menopausal status, reproductive history, hormone use, breast density, family history of cancer), and metabolic risk factors (weight, height, hypertension, diabetes, and hyperlipidemia). Physical activity (PA) levels were assessed using a modified International Physical Activity Questionnaire (IPAQ), and dietary intake was evaluated with the 14-item Mediterranean Diet Adherence Screener (MEDAS). Participants aged ≥18 years with a HCPV provided electronic consent and received a $10 e-gift card upon survey completion. The survey, disseminated through social media and the advocacy group Facing Our Risk of Cancer Empowered (FORCE), also includes a Spanish version. The survey remains open with the goal of reaching 1,000

responses. Descriptive statistics were used to analyze participant demographics, cancer risk factors, and metabolic risk factors.

Results: From August 2019 to December 2023, 750 participants completed the survey; mean age: 45.1 years (SD=12.6) and 96.1% were female. Self-reported race/ethnicity was 91.5% White, 3.9% Black/African American, 2.3% Asian, 2.8% Hispanic, 17.1% Ashkenazi Jewish, and 2.3% Other. Among female participants (n=721), 66.6% are previvors and 33% are survivors. In previvors, 47% have a BRCA1 or BRCA2 PV and 33.5% of previvors have had risk reducing mastectomy (RRM); mean age at RRM was 42 years (SD=11.0). Rates of RRM in previvors by PV were 42.7% BRCA1, 38.3% BRCA2, 38.9 PALB2, 28.6% ATM, 14.3% CHEK2. Family history of BC was higher in previvors with RRM (87%) compared to those without (80%). Mean BMI 26.7 (SD=6.6) for previvors with RRM and 27.3 (SD=6.7) for those without. Previvors without RRM reported moderate intensity PA (43.9%) compared to those with RRM (38.5%). Over half of previvors (62.3%) reported they were currently trying to lose weight; 183 (38%) reported ≥5 meaningful weight loss attempts in their lifetime. Perceptions of weight, diet, and PA as important cancer risk factors were similarly distributed among previvors with and without RRM. In survivors, 137 (57%) have a BRCA1 or BRCA2 PV and 91 (37.8%) of survivors have had RRM; mean age at cancer diagnosis was 43 years (SD=10.9); mean age at RRM was 45.8 years (SD=10.2). Family history of BC was reported in 64.8% of survivors with RRM compared to 61.7% without. Mean BMI was 26.4 for survivors with RRM (SD=6.0) and 25.6 (SD=5.4) for those without. Nearly half of survivors without RRM (49%) engaged in moderate intensity PA compared to survivors with RRM (38.5%). Of survivors, 55.6% reported trying to lose weight and 32% reported ≥5 meaningful weight loss attempts in their lifetime.

Conclusion: Individuals with a HCPV may elect to undergo bilateral mastectomy in the preventative setting or at the time of a BC diagnosis to decrease their risk of a future BC. A better understanding of how metabolic risk factors, diet and PA impacts BC risk in PV carriers is needed. Based on this initial descriptive analysis, examination with longitudinal follow up of the cohort will further explore how these metabolic and energetic factors impact breast surgical decisions.

P1-03-16: Multimodal analyses of clinical, radiology, pathology and genomic information for enhanced prediction of response to neoadjuvant therapy in breast cancer

Sarah Eskreis-Winkler, Francisco Sanchez Vega, Armaan Kohli, Enrico Moiso, Mirella Alto, Chris Fong, Doori Rose, Edaise M. Da Silva, Timothy Dalfonso, David Joon Ho, Anika Begum, Mehnaj Ahmed, Danny Martinez, Andrew Aukerman, Kevin Murphy, Julia An, Mathew Hanna, Jianjiong Gao, Yanis Tazi, Arfath Pasha, Katja Pinker-Domenig, Hong Zhang, Elizabeth Sutton, Sohrab Shah, Pedram Razavi

Background: Neoadjuvant chemotherapy (NACT) is the standard of care for early-stage breast cancer patients (pts) with high-risk clinical features and pathologic complete

response (pCR) is considered the best predictor of favorable long-term outcomes. We developed machine learning models to predict pCR from a series data modalities available at the time of diagnosis. We compared the predictive value of unimodal radiology, pathology, genomic, and clinical features, and their multimodal integration to improve pCR prediction.

Methods: We analyzed a multimodal cohort of 1,192 early-stage breast cancer pts treated with NACT at Memorial Sloan Kettering (MSK) between 2014 and 2021. Clinicopathologic features including hormone receptor subtype, demographic information (self-reported race, age at diagnosis), grade and stage were collected and curated for all pts, and combined to build a logistic regression prediction model. Digital pathology whole-slide images (WSIs) from pre-NACT tumor biopsies were collected for 1,101 patients. We used a pre-trained transformer model and attention-based multiple instance learning (MIL) to predict pCR from H&E WSIs. Pre-NACT magnetic resonance imaging (MRI) exams, which included T2-weighted images, T1-weighted precontrast images and T1-weighted post-contrast images, were collected for 838 pts, and were used to build a deep learning (DL) model to predict pCR. Tumor biopsies and matched blood specimens from 315 pts underwent targeted DNA sequencing using the MSK-IMPACT platform, which identified mutations, copy number changes, and structural rearrangements in a selected panel of up to 505 cancer genes. These genomic features were combined using an elastic net regularized logistic regression model for pCR prediction. Multimodal integration was performed using existing methods, and results were compared for early and late fusion strategies. Predictive performance was measured by computing the area under the receiver-operator curve (AUC) metric.

Results: Individual data modalities exhibited varying levels of predictive performance for different receptor subtypes. For example, clinical and pathology models performed better for HR+ subtypes, while the genomic prediction model outperformed the rest in the triple negative breast cancer (TNBC) set. Automated DL models using MRI inputs achieved moderate predictive performance on the HR+/HER2-, HR+/HER2+, and HR-/HER2+ subtypes. Subtype-specific models tended to outperform subtype-agnostic models trained in the larger, pan-subtype cohort. End-to-end DL pathology and radiology models that can be deployed and run automatically without human curation to predict pCR directly from images had comparable performance to clinical models using variables curated by expert pathologists and radiologists. Multimodal predictors combining the genomic data with the other three data modalities readily available at initial presentation exhibited the best overall predictive performance, but the gain in predictive performance was small and may not justify the increased requirements in terms of data acquisition and model complexity for certain receptor subtypes.

Conclusions: Multimodal data can be incorporated into machine learning models for improved prediction of pCR to NACT in breast cancer. Additional work is needed to validate the clinical utility of these types of multimodal approaches, as well as to determine the most informative data modalities for each hormone receptor subtype and the subset of patients that are most likely to benefit from the use of these models. Automated workflows using DL pre-trained models may provide valuable clinical decision support, guiding escalation and

de-escalation therapeutic and monitoring strategies to improve outcomes for pts with high-risk early breast cancer.

P1-03-17: Disseminated tumor cell (DTC) quantities are associated with Ki67 and pCR rate in breast cancer

Laura Weydandt, Ivonne Nel, Senol Dogan, Susanne Briest, Anne Kathrin Höhn, Bahriye Aktas

Background: The prognostic relevance of disseminated tumor cells (DTCs) in the bone marrow (BM) of patients with primary breast cancer was reported manifold and therapeutic strategies are still controversially discussed. Despite successful treatment of the primary tumor, recurrence occurs in about 30% of breast cancer patients. One reason might be hematogenous spread as an early event in the disease, when single tumor cells split of the primary tumor and migrate into the lymphatic and blood system or into the bone marrow, where they are believed to become dormant and hence persistent against chemo-therapy. Little is known concerning the association of DTC quantities and the clinic-pathological data, including Ki67proliferation index in primary tumors and affected lymph nodes, though.
Methods: Between January 2019 and December 2023, we collected 430 BM aspirates from the anterior iliac crest of patients with primary (n=399) and recurrent (n=32) breast cancer during oncologic surgery. Patients either had neoadjuvant chemotherapy (NACT, n=153), neoadjuvant endocrine (n=90) or no neoadjuvant treatment (n=184).
After density gradient centrifugation, cell suspensions were transferred onto glass slides and subjected to immunocytochemical staining against pan-cytokeratin. DTCs were visualized using alkaline phosphatase and short counterstaining with hematoxylin. DTCs were semi-automatically detected and enumerated using a microscope based scanning system with a rare events algorithm to identify DTC candidates according to color, shape, intensity and size. We correlated DTC quantities to clinico-pathological parameters using Pearson correlation and Chi-Square tests.
Results: Per patient about 4 million BM cells were analyzed. The DTC-positivity rate was 40%. Patients were divided into subgroups based on the immunohistochemically determined subtype of the tumor: of the patients with luminal A tumors (n=210) 39.5% were DTC positive (mean=11), with luminal B/HER2- tumors (n=31) 41% (DTC mean=14), of Luminal B/HER2+ (n=28) 53.5% (DTC mean=12), of TNBC (n=70) 41.4% (DTC mean=15.2), and of HER2-enriched (n=33) 24.2% (DTC mean= 15) were positive.
The DTC mean was elevated in clinical nodal positive patients (n=92; DTC mean: 15.6) compared to clinical nodal negative patients (n=326; DTC mean:11.7; p=0.122) except for cases with luminal B/HER2+ tumors.
We found a positive correlation between the DTC count and the proliferation index Ki67 of the core needle biopsy (CNB; p=0.008; r=0.279). Additionally, we separated the patients into different groups with Ki67 from 1-9%, 10-29% and >30% as determined in the CNB (DTC mean: 11 vs. 13.3 vs.14), the affected lymph nodes (LN; DTC mean: 12.6 vs. 13.1 vs.

17.1) and the resected tumor tissue (DTC mean: 11.5 vs.11.3 vs.17.6). Among DTC-positive patients, the mean DTC number was increased gradually with increasing Ki67 in all 3 specimens (CNB, LN and tumor tissue).
Comparing the different neoadjuvant strategies, we found an increased DTC mean in all molecular subtypes, except Luminal B/HER2+, when the patients did not receive NACT (n=184; DTC mean: 14.5) compared to patients undergoing NACT (n=153; DTC mean: 11.9; p=0.134). Ki67 index was elevated in the lymph node metastases compared to the tumor biopsy and the resected tissue: LN_Ki67>CNB_Ki67>tissue_Ki67 among all molecular subtypes in patients receiving NACT.
Looking at the pCR rate of DTC-positive patients (46%; 25 of 54), it was lower compared to DTC-negative patients (57%; 54 of 94) receiving NACT underlining the higher risk profile for DTC-positive patients.
Conclusion: Our data suggest that DTC quantities are equally high among the different intrinsic subtypes. DTC-positive patients are less likely to achieve a pCR. Additionally, we found a positive correlation between the DTC quantity and the proliferation index Ki67.

P1-03-18: Correlates of Breast Adipose Inflammation after Primary Breast Cancer Diagnosis in the Pathways Study

Lawrence Kushi, Lia L. D'Addario, Domenick J. Falcone, Dilip Giri, Thaer Khoury, Chi-Chen Hong, Heather Greenlee, Warren Davis, Rochelle Payne Ondracek, Janise M. Roh, Daniel F. Fernandez, Elizabeth M. Cespedes Feliciano, Bette J. Caan, Christine B. Ambrosone, Marilyn L. Kwan, Neil M. Iyengar

Background: Excess adiposity is associated with higher rates of breast cancer recurrence and increased mortality. Insights into the mechanisms by which adiposity influences these outcomes may lead to improved disease management. A histologic marker of white adipose inflammation, crown-like structures of the breast (CLS-B), is associated with excess adiposity, adipocyte hypertrophy, and increased in-breast aromatase levels. CLS-B are comprised of dead or dying adipocytes surrounded by macrophages, and may be measured in slides obtained from breast surgical specimens. We are conducting a prospective cohort study of these inflammation-related markers and breast cancer outcomes. We describe here select correlates of CLS-B and adipocyte diameter in 630 women diagnosed with breast cancer in the Pathways Study.
Methods: The Pathways Study is a prospective cohort study with 4,504 women who were diagnosed with invasive breast cancer from late 2005 through May 2013 in the Kaiser Permanente Northern California healthcare system. From women who underwent mastectomy, formalin-fixed paraffin-embedded tissue blocks from definitive surgery enriched in white adipose tissue were obtained, sectioned and stained by hematoxylin & eosin and CD68 immunohistochemistry. Slides were then examined for adipocyte diameter and CLS-B. Blood specimens collected around the time of enrollment into the cohort were also assayed for high-sensitivity C-reactive protein (hsCRP). Data related to cancer diagnosis, demographic characteristics, anthropometry, and other variables were obtained

from baseline in-person visits, surveys, and electronic health records.
Results: To date, 630 women have complete data on adipocyte diameter and presence of CLS-B. Most women were diagnosed with Stage I-III disease, 79% had estrogen-receptor positive-tumors, and 19% had HER2-positive tumors. Mean and median adipocyte diameters were 103.6 and 103.4 μ, respectively, with an inter-quartile range of 94.4 to 113.9 μ. CLS-B were observed in 267 (42.4%) of the 630 women, and among these women, median CLS-B density was 0.3 per cm2, with an interquartile range of 0.16 to 0.77 per cm2. In univariate associations, there was some suggestion that adipocyte diameter varies by self-reported race and ethnicity ($p=0.056$), with largest mean values for Blacks (n=50, adipocyte diameter 110.4 μ) and smaller for Whites, Asians, and Latinas (n=390 and 102.8 μ; n=97 and 103.8 μ; and n=76 and 103.7 μ, respectively). These differences aligned with differences in body mass index (BMI) by race and ethnicity, and were strongly associated with BMI ($p<0.0001$), with adipocyte diameter across increasing BMI categories (kg/m2) of 95.8 μ for $18.5 \leq BMI < 25$, 106.2 μ for $25 \leq BMI < 30$; 109.0 μ for $30 \leq BMI < 35$, and 111.7 μ for $35 \leq BMI$. Similar associations were observed for waist circumference and waist-to-hip ratio, as well as hsCRP (all $p<0.0001$). Presence of CLS-B differed somewhat across race and ethnicity ($p=0.097$), with 58.0% of Blacks, 39.2% of Whites, 49.5% of Asians, and 38.2% of Latinas having CLS-B present. Presence of CLS-B was also strongly associated with BMI, waist circumference, waist-to-hip ratio, and hsCRP. For example, across the increasing BMI categories above, the proportions of women with CLS-B were 27.2%, 44.8%, 51.3%, and 63.6%., and across increasing hsCRP quartiles were 22.5%, 34.5%, 53.6%, and 56.9%.
Summary: These observations indicate that breast adipose tissue inflammation and adipocyte size correlate with anthropometric measures of adiposity and systemic inflammation, and vary by race and ethnicity. As we continue to obtain measurements of these variables, we will determine how they relate to more precise body composition compartments and whether they are also associated with recurrence, mortality, and other outcomes after breast cancer.

P1-03-19: Comprehensive Analysis of ADC Target Expression in Invasive Lobular Carcinoma

Jason Mouabbi, Azadeh Nasrazadani, Senthil Damodaran, Vladimir Kushnarev, Daria Goncharova, Oleg Baranov, Kostantin Chernyshov, Sofia Kust, Nikita Kotlov, Patrick Clayton, Paula Pohlmann, Debu Tripathy, Funda Meric-Bernstam

Introduction: Antibody-drug conjugates (ADCs) targeting specific surface antigens have represented a notable advance in therapeutic efficacy in solid tumors. Herein, we analyzed RNA sequencing (RNA-seq) data from invasive lobular carcinoma (ILC) samples to identify novel cell surface protein candidates for designing new and highly specific ADCs, aiming to minimize side effects and improve patient outcomes.
Methods: RNA-seq data from the BostonGene internal breast cancer (BC) cohort (non-ILC n=518, ILC n=138), TCGA-BRCA (non-ILC n=815, ILC n=233) cohort, and normal tissue samples in the Adult GTEx dataset (n=7862) for 82 cell surface protein genes were assessed

together. BC samples were classified as histo-molecular ILC if they showed at least one of the following: ILC histology, CDH1 truncation, gene loss, Z-scores of < -1.5 for gene expression. Among the ILC samples, some were classified as classic (low-grade and Lum A or B; n=224) and non-classic ILC (high-grade, HER2-enriched, or Basal-like; n=28). We also classified all ILC samples as high- (HG-ILC, n=142) or low-grade (LG-ILC, n=229) based on molecular grading. Information on ADC targets and relevant clinical trials were extracted from ClinicalTrials.gov.
Results: Among the 82 cell surface protein genes assessed, 18 demonstrated high expression levels defined as ≥4 log2 transcripts per million (TPM) in at least one subtype and include LYPD3*, FOSL2, CD276*, CRIM1*, PRLR*, PVRL4*, TPBG*, VTCN1*, ERBB3**, ALCAM, CD46, ERBB2**, SLC39A6**, ST14*, CD74, TACSTD2*, GPNMB, and MUC1*. Genes marked with * showed low expression in normal tissues (<2 log2 TPM), while genes marked with ** showed low expression in normal tissue and are being investigated in ≥5 clinical trials.
Both non-ILC and ILC groups showed high expression of ERBB3**, ERBB2**, ALCAM, CD46, SLC39A6**, ST14*, CD74, TACSTD2*, GPNMB, and MUC1*.
Among the ILC samples, CRIM1*, PRLR*, and PVRL4* showed high expression in LG-ILC and classic ILC. LYPD3* was highly expressed only in non-classic ILC. FOSL2, CD276*, TPBG* and VTCN1* showed low expression in HG-ILC. However, TPBG* and VTCN1* were highly expression in LG-ILC and classical ILC.
Interestingly, the low expression of several targets in normal tissues (marked * and **) indicate their suitability as ADC targets for treating ILC while minimizing adverse effects.
Conclusion: We defined distinct ADC target expression landscapes in classic and non-classic ILC, further distinguished from non-ILC. While both classic and non-classic ILC show high expression of several ADC targets, they differed notably in TPBG, CRIM1, PRLR, and VTCN1 expression. The low expression of several analyzed genes in normal tissues revealed their potential as targets for highly specific ADCs with anticipated reduced adverse effects. Our findings underscore the need for clinical trial designs encompassing ADC target expression data across ILC subtypes to optimize efficacy and safety of ADC-based treatments, subsequently improving patient outcomes.

P1-03-20: Role of MCM2 and the licensing complex in predicting endocrine and CDK4/6 inhibitor resistance in ER+ breast cancer

Alekya Raghavan, Jonathan T. Lei, Carmine De Angelis, Sarmistha Nanda, Luca Malorni, Ilenia Migliaccio, Cristina Guarducci, Matteo Benelli, Meenakshi Anurag, Cynthia Ma, Carolina Gutierrez, C. Kent Osborne, Mothaffar F. Rimawi, Ahmed Elkhanany, Rachel Schiff

Background: Metastatic ER+/HER2- breast cancer (BC) is inevitably associated with resistance to endocrine therapy (ET) and CDK4/6 inhibitors (CDK4/6i). However, there remains a need for comprehensive understanding of resistance mechanisms and better predictive biomarkers for patient selection or new treatment strategies. We previously reported that in the NeoPalAna trial (NCT01723774), high expression of the origin licensing

complex (LC) was associated with resistance to CDK4/6i and a similar trend, though lessened, was observed for ET. The LC factors ORC1-6, CDC6, and CDT1 load the MCM complex (MCM2-7) onto the origin in G2/M, priming it for initiation of DNA replication in S phase. Within the LC, we identified MCM2 to be the gene most significantly associated with resistance. We hypothesize that high expression of MCM2/LC presents a new, highly effective predictor of resistance to ET and CDK4/6i in ER+ BC.
Methods: Publicly available primary (TCGA, PanCancer Atlas; METABRIC, Nature 2012 & Nat Commun 2016) and metastatic (The Metastatic Breast Cancer Project, Provisional 2021) BC datasets in cBioPortal were used to define copy number (CN) aberrations and their correlation to mRNA expression data for LC components. Clinical subtype for METABRIC regression analyses was refined using genomic data and the mRNA expression distribution of clinically defined ER, PR, and HER2 tumors (PMID 30867590, 34725325). K-means clustering was performed on MCM2-7 complex and entire LC gene sets for signal discovery. Number of k was determined using the elbow and silhouette analyses. Logrank p-values and hazard ratios were derived from Cox-proportional hazard models examining the association between mRNA expression by RSEM in METABRIC of LC components, individually or as gene sets, with breast cancer-specific survival (BCSS) or distant recurrence-free survival (DRFS) using R (v4.3.1) and calculated via log rank. Nominal p-values underwent Bonferroni correction as needed. For all analyses, datasets were filtered for clinical ER+/HER2- status.
Results: cBioPortal genomics revealed that MCM2 is amplified in 20% and <1% in metastatic versus primary BC and increases to 58% and 9-17%, respectively, when also considering CN gains. This trend was largely consistent for most other LC components as well. Higher MCM2 mRNA was associated with CN amplification and gains of the gene. Furthermore, high MCM2 transcript levels correlated with PR negativity (p=2.51e-05), Luminal B versus A status (p<2e-16) and high tumor grade (p<2e-14). MCM2 expression was also associated with worsened DRFS and BCSS, both in univariate (HR=1.51, p=7.23e-12; HR=1.49, p=2.17e-11) and multivariate regression analyses (HR=1.35, p=6.88e-05; HR=1.23, p=5.35e-03), after adjusting for PR, grade, age, and PAM50 intrinsic subtype. BCSS also decreased with high MCM2 mRNA regardless of type of endocrine therapy received (log rank p=2.32e-08). Low versus high MCM2-7 and LC clusters were associated with better DRFS (HR=0.52, p=7.89e-09; HR=0.56, p=3.63e-07) and BCSS (HR=0.57, p=1.14e-07; HR=0.57, p=3.91e-07). DRFS for MCM2-7 and LC clusters remained significant in same multivariate analysis (HR=0.68, p=4.13e-03; HR=0.74, p=2.89e-02).
Conclusions: Our analysis demonstrates that MCM2 and the LC gene set are independently poorly-prognostic for both DRFS and BCSS in a large, well-annotated BC dataset. This impact is significant and does not wane after multivariate analysis. Most LC components, including MCM2, are not routinely included in targeted next-generation sequencing panels, and their incorporation can help validate the predictive nature of these genes in real-world cohorts. Our results also provide a strong rationale for clinical development of a set of predictive biomarkers including these genes, particularly MCM2, in the setting of ER+/HER2- BC.

P1-03-21: Improving gene signatures for predicting the progression of ductal carcinoma in situ

Diego Marzese, Miquel Ensenyat-Méndez, Sandra Íñiguez-Muñoz, Andrés F. Bedoya-López, Siri Strand, Robert West, Maggie L DiNome, E Shelley Hwang, Diego M Marzese

Introduction: Ductal carcinoma in situ (DCIS) is a non-invasive form of breast cancer characterized by abnormal cells confined within the milk ducts. While DCIS is not life-threatening, its clinical significance lies in its potential to progress to invasive ductal carcinoma (IDC). This progression is driven by molecular imbalances from genetic and epigenetic alterations, including increased expression of matrix metalloproteinases (MMPs). Our recent study demonstrated that MMP1 expression modestly predicts DCIS progression to IDC, independent of tumor subtype (AUC = 0.76). In this study, we aimed to identify additional informative genes that could enhance the predictive potential of MMP1 based on molecular data from DCIS clinical studies.
Methods: We analyzed molecular and clinical data from 380 DCIS specimens across three cohorts: the Sweden Cancerome Analysis Network - Breast (SCAN-B, n = 85), the Translational Breast Cancer Research Consortium (TBCRC, n = 216), and the Resource of Archival Breast Tissue (RAHBT, n = 79). Potential gene candidates were identified in TBCRC and RAHBT cohorts. First, DESeq2 v 1.40.2 was employed to select differentially expressed genes between cases with ipsilateral breast events (n = 121, considering both DCIS and IDC) and without reported events (n = 95) within five years in the TBCRC study. Additionally, we considered the genes encoding the 37 proteins analyzed by ion beam imaging by time of flight (MIBI-TOF) technology in the RAHBT cohort. Multiple score values based on the percentile expression of selected genes were evaluated in the SCAN-B cohort (n = 85). AUCs were computed using pROC version 1.1.8.
Results: We identified 89 genes that improved the predictive power (AUC > 0.8) when combined with MMP1 on the TRCRC and RAHBT studies. These genes were combined into four-gene signatures using the formula: (MMP1+X)/(Y+Z), generating 92,070 unique combinations. 3,821 of these signatures improved the AUC of MMP1 alone. To avoid redundancy in the information, we restricted combinations to genes uncorrelated with MMP1 (28 dividend genes and 34 divisor genes) and tested the predictive performance in an independent cohort (SCAN-B). We identified that the ratio between the percentiles of (MMP1+MMP27)/(CD36+IGFBP6), showed a strong predictive performance in the SCAN-B cohort (AUC = 0.91). Other genes that enhanced the predictive signature included transcriptional regulators (SP1, SF3B4, and CTNNBIP), metabolic enzymes (GNMT, TKT, and PGD), and mitochondrial proteins (NDUFB7, MRPL9, and FH).
Conclusions: The identified four-gene ratio signature significantly enhanced the prediction of DCIS progression to IDC across different study cohorts. We have designed and are developing an assay based on immunohistochemistry (IHC) to assess these proteins in FFPE tissues, enabling retrospective exploration of DCIS cohorts. Our current studies are focused on validating this signature in larger independent cohorts and exploring its utility in prospective clinical settings. This approach has the potential to refine diagnostic algorithms for DCIS patients, ultimately improving clinical decision-making and patient outcomes.

P1-03-22: Comprehensive characterization of the androgen receptor in male breast cancer

Priya Jayachandran, Sachin Kumar Deshmukh, Sharon Wu, Jennifer R. Ribeiro, Irene Kang, Joanne Xiu, Francesca Battaglin, Darcy V. Spicer, Daphne B. Stewart, Shivani Soni, Wu Zhang, Janice Lu, Karam Ashouri, Joshua Millstein, William Flood, Jose P. Leone, Dario Trapani, Maryam Lustberg, Stephanie L. Graff, George W. Sledge Jr., Heinz-Josef Lenz, Evanthia T. Roussos Torres

Background: Male breast cancer (BC) accounts for less than 1% of new BC cases annually. Androgen receptor (AR), a member of steroid and nuclear receptor superfamily is emerging as an important factor in pathobiology of BC. While the estrogen receptor (ER) is well-studied in BC, the role of the AR is less understood, particularly in male patients. Here, we aimed to characterize the molecular and immunological features of AR gene expression in male BC.
Methods: 191 samples from male breast cancer patients were tested by NGS (592, NextSeq; WES, NovaSeq) and WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). MSI was tested by IHC and NGS. Tumor mutational burden (TMB) totaled somatic mutations per tumor (high>10 mt/MB). Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Tumors with AR-high(H) and AR-low(L) RNA expression were classified as above or below the 50th percentile, respectively. Real world overall survival (OS) and treatment-associated survival was obtained from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons (q<.05).
Results: AR-H male BC had lower frequency of TP53 mutations (20% AR-L vs 7% AR-H, p=0.02) compared to AR-L male BC tumors. AR-H had numerically higher frequency of PIK3CA (34.8% vs 27.2%) and CHEK2 (3.7% vs 1.1%), but lower frequency of BRCA2 (7.1% vs 13.6%) and PTEN (2.3% vs 6.9%) compared to AR-L, all p = 0.1-0.2. AR-H male BC had lower frequency of TMB-high (3.45% vs 12.22%) and PD-L1 positivity (5.08% vs 18.57%), all p<0.05. Analysis of inferred immune cells revealed that AR-H had higher infiltration of NK cells (3.58% vs 2.56%), dendritic cells (2.43% vs 1.98%), and B cells (5.93% vs 5.26%), all p<0.05. AR-H had higher T-cell inflamed score (19 vs -72) and MAPK activation score (-0.24 vs -1.6) but lower IFNg score (-0.38 vs -0.33), all p<0.05. AR-H had higher expression of immune checkpoint genes (CD274, FOXP3, HAVCR2, LAG3; FC: 1.3-1.5) and stem cell-related genes (CD34, CD44, POU5F1, KLF4, ALDH2; FC: 1.2-1.4) compared to AR-L male BC, all p<0.05. AR-H male BC had higher AR protein (IHC) expression (100% vs 86.8%, q<0.05) and numerically higher frequency of AR-fusion variant (3.2% vs 0%, p=0.08) compared to AR-L male BC. AR-H male BC had worse OS (mOS: 35.9 vs 92.4 month; HR 1.6, 95% CI 1.0-2.5, p = 0.043) compared to AR-L BC. When analyzed by TP53 mutation status, AR-H with TP53-wt had numerically better survival (mOS: 35.6 vs 25.7 months, HR 0.52, 95% CI 0.20-1.35, p=0.17) compared to TP53-mt. Similarly, AR-L with TP53-wt had numerically better survival (mOS: 48.3 vs 23.2 months, HR 0.58, 95% CI 0.22-1.33, p=0.18) compared to TP53-mt.
Conclusions: Our analysis suggests a strong association between AR expression and TP53

mutations, TMB-H, and PD-L1 positivity, immune cell infiltration, immune checkpoint and stem cell-related gene. Also, T cell inflamed and IFNy score were inversely related. Further exploration of specific alterations and immune-oncology markers associated with AR expression may help in clinical trial design for male patients with BC.

P1-03-23: Identification of Stage 1 Breast Cancer Biomarkers Using Extracellular Vesicle Proteomics and Machine Learning

Todd Hembrough, Zack Opheim, Poorva Mudgal, Cheryl Bandoski, Issa Issac, Valesca Anschau, Martin Mehnert, Alan Ezrin

Abstract: Breast cancer is one of the most common cancers among women worldwide, and early detection is critical for successful treatment and improved survival rates. However, early-stage breast cancer presents significant diagnostic challenges due to the small size of tumors and the limited presence of tumor-specific biomarkers in the bloodstream. Traditional diagnostic methods often struggle to detect these early signs, making it imperative to develop more sensitive and specific approaches.
Circulating extracellular vesicles (EVs) have emerged as a promising solution for early breast cancer detection. EVs are stable proteomic substrates that allow for the deep enrichment of biologically relevant and informative biomarkers from plasma. This enables comprehensive analysis of multiple tumor-associated and host response proteins. Cancer and tumor microenvironment cells produce approximately 20,000 EVs per day, providing a substantial pool of circulating biomarkers. EVs offer a means to detect and monitor small tumors through both direct detection of tumor-associated biomarkers and host response/tumor microenvironment biomarkers within the EV milieu.
Methods: To identify novel biomarkers, we performed proteomics analysis on EVs purified using size exclusion chromatography and a proprietary buffer system that enhances EV and corona protein recovery. TrueDiscoveryTM data-independent acquisition (DIA) mass spectrometry (MS) analysis was conducted on EVs from 30 Stage 1 Breast cancer patients and 75 normal patient plasma samples. This was followed by performing an in-house developed machine learning pipeline to identify candidate multiplexes with an Accuracy > 0.98.
Results: After quality control correction, an average of 2,562 proteins was identified per sample. Comparative analysis between Stage 1 Breast Cancer and Control cohorts using the in-house Machine Learning Pipeline identified 585 differentially expressed proteins (t test FDR corrected qvalue < 0.01, Logistic Regression cross validation AUC > 0.5, and absolute log2 fold change > 0.5). Of the 585 differentially expressed proteins, 71 have an AUC > 0.85. Support Vector Machine Learning revealed 43 significant 3-plexes with Accuracy > 0.98, consisting of 38 candidate proteins. Interestingly, 18 of the 38 candidate proteins appear in multiple 3-plexes. Finally, we performed ELISA assays of top candidate proteins showing differential expression between cancer EVs and normal patient EVs, indicating we can translate discovery proteomics to fast, easy, and scalable immunoassays.
Conclusions: Key biomarkers from breast cancer patient EVs indicate the potential to detect

and diagnose early-stage and low tumor burden cancers using our methods. Interestingly, no significant differences were noted when biomarkers were evaluated in pre-EV enriched patient plasma. This highlights the unique nature of the EV microenvironment and suggests that early detection of breast cancer may be effectively captured in the EV microenvironment of the patient. An unbiased approach was used for EV proteomics to examine all EVs in the patient. By taking this unbiased approach, we can expand our discovery of biomarkers that may be associated with the patient's response to disease presence.
These findings confirm that the EV microenvironment represents a distinctive oncological ecosystem with highly specific and sensitive disease biomarkers that do not appear dysregulated in whole plasma. Finally, the ability to translate discovery proteomics to ELISA based immune-assays for a clinical assay highlights the power of our approach and data. This novel approach to cancer proteomics holds great promise for the future of cancer diagnostics and monitoring, allowing for the identification of biomarkers indicative of early-stage breast cancer.

P1-03-24: Genomic and Clinicopathologic Profiling of Breast Invasive Lobular Carcinoma in Patients with Germline Predisposition

Christopher Schwartz, Jung Hun Oh, Satshil Rana, Matteo Repetto, Andrea Gazzo, Sherry Shen, Hong Zhang, Dara Ross, Britta Weigelt, Larry Norton, Hannah Y. Wen, Edi Brogi, Panieh Terraf, Fresia Pareja

Background: Invasive lobular carcinoma (ILC) is the second most common histologic subtype of breast cancer (BC), characterized by biallelic CDH1 inactivation. While germline pathogenic/likely pathogenic variants (P/LPVs) in certain cancer susceptibility genes (CSGs), such as CDH1, have been linked to ILC, the comprehensive germline landscape of P/LPVs in ILC remains to be unveiled. This study aims to elucidate the spectrum of germline P/LPVs affecting CSGs in ILCs, compared to non-lobular BCs, and to characterize clinicopathologic features and the repertoire of somatic genetic alterations in this group.
MATERIALS AND METHODS
The sequencing data from 5,160 BC patients who underwent genetic testing and/or tumor sequencing with the FDA-cleared MSK-IMPACT assay was queried, including 586 patients with ILC and 4,574 patients with non-lobular BCs. Variant pathogenicity was reviewed according to ACMG criteria. Loss of heterozygosity (LOH) was determined using FACETS. The frequency of germline P/LPVs was compared between ILCs and non-lobular BCs. ILCs were subclassified following the WHO criteria. The clinicopathologic features and repertoire of somatic alterations of ILC with germline P/LPVs (gILC) were compared to those of consecutive sporadic ILCs (sILCs) at a 3:1 ratio.
Results: We identified 80 P/LPVs affecting CSGs in 77 (13%) ILC patients. CHEK2 (16%), MUTYH (10%), BRCA2 (9%), and ATM (6%) were the most frequently altered CSGs, followed by CDH1, BRCA1, BRIP1, LZTR1 and PMS2 (5%, each). Compared to patients with non-lobular BCs who underwent genetic testing, patients with ILCs more frequently had

germline P/LPVs in CDH1 (0.68% vs 0%; OR=Inf; P<0.001) and PMS2 (0.68% vs 0.15%; OR=4.5; P=0.03) and fewer P/LPVs in BRCA1 (0.7% vs 2.4%; OR=0.28; P=0.006) and APC (0% vs 0.8%; OR=0; P=0.02). Median age at diagnosis in gILC patients was 54 (30-84) years. 23% (18/77) had a first degree relative with BC. gILCs were mostly classic ILCs (55%), followed by ILC variants, including pleomorphic/pleomorphic features (35%), solid/alveolar (4%), and mixed ductal-lobular BCs (6%). Most gILCs (87%) were ER+/HER2- and 10% were HER2+. Most patients with gILCs (67%) were node-positive on excision. Compared to sILCs, gILCs were enriched for HER2+ disease (10% vs 3%: P=0.017). No differences in other clinicopathologic features were observed. Tumor-specific bi-allelic inactivation of the CSGs affected by P/LPVs, by LOH (n=29) or somatic inactivating mutation (n=1), was seen in 42% of gILCs. Analysis of somatic genetic alterations revealed CDH1 (75% and 84%), PIK3CA (31% and 43%) and TP53 (22% and 29%) as the most frequently altered cancer genes in primary and metastatic gILCs. Compared to primary sILCs, genetic alterations in various chromatin remodelers, such as KMT2C (17% vs. 5%; P=0.01), ARID1A (17% vs 4%, P=0.001) and KMT2D (11% vs. 3%; P=0.03), were enriched in primary gILCs. In the metastatic setting, gILCs showed enrichment in genetic alterations in ERBB2 (29% vs 14%; P=0.03), MYC (12% vs 4%; P=0.04) and the chromatin remodelers KMT2B (13% vs 2%; P=0.01) and KDM6A (6% vs 0; P=0.01), compared to sILCs.
Conclusions: The spectrum of CSGs affected by germline P/LPVs in ILC is heterogenous and encompasses genes playing key roles in genomic instability. Despite the similarities between ILCs arising in the germline and sporadic settings, significant differences in their clinicopathologic and genomic features were identified, such as a higher rate of HER2-positivity and an enrichment in somatic genetic alterations in ERBB2 and in chromatin remodeling genes. These findings highlight opportunities for treatment personalization in patients with ILC who have germline predisposition.

P1-03-25: Characterization of the tumor immune microenvironment (TIME) and somatic landscape of metaplastic breast cancer (MpBC)

Shaveta Vinayak, Lynn Symonds, Eric Konnick, Natasha Hunter, William Gwin, Denise Shieh, Matina Fragkogianni, Michelle Harris, Jacob Mercer, Hannah Linden, Jennifer Specht

Background: MpBC is a rare, aggressive subtype with a dismal prognosis. Standard of care treatments are limited and novel therapies are needed. Recent clinical studies have demonstrated a response to immune checkpoint inhibitors. However, characterization of the immune and genomic environments in MpBC is paramount to inform new biomarker-selected strategies. Here, we investigated the TIME and somatic landscape of MpBC.
Methods - We retrospectively analyzed de-identified next-generation sequencing data from unique patients with a breast cancer diagnosis (n=13,512) in the Tempus database. We selected patients with MpBC (n=171, 1.3%) and non-MpBC (n=13,341,98.7%) histologies based on clinical documentation reported within 180 days of sample collection. For patients with multiple samples sequenced, the sample closest to the date of reported diagnosis was utilized. Tumors were sequenced with the Tempus xT DNA (648-gene panel) and/or xR

RNA assays. Somatic alterations, immune cell infiltration predicted from gene expression patterns, PD-L1 from IHC, TMB (tumor mutational burden), and MSI (microsatellite instability) were evaluated. Wilcoxon rank-sum and Pearson's Chi-squared/Fisher's exact tests assessed statistical significance ($p<0.05$, $q<0.05$ for false discovery rate correction for multiple testing).
Results: The MpBC and non-MpBC cohorts comprised a diverse population (White, 72% vs 73%, Black/African American, 12% vs 15%, Asian, 7.9% vs 4.4%, Other, 7.9% vs 7.7%) ($p=0.5$). The median age at diagnosis in the MpBC and non-MpBC cohorts were 61 and 57 years, respectively ($p<0.001$). Breast cancer receptor subtype distribution for MpBC vs non-MpBC was HR+/HER2- (20% vs 58%), TNBC (72% vs 24%), and HER2+ (1.9% vs 9.2%) ($p<0.001$). PD-L1 expression (CPS ≥ 10) was higher in the MpBC (35%) vs non-MbBC group (14%) ($p<0.001$). In MpBC, the proportion of M1 macrophages and neutrophils was higher vs non-MpBC ($p<0.001$ for both), and the proportion of B and NK cells was lower ($p<0.001$ for both). There was no clinically significant difference in the percentage of patients with TMB-H or MSI-H status ($p>0.05$ for both). The top five somatic alterations that were more frequent ($q<0.001$) in MpBC vs non-MpBC were: TERT (23% vs 1.3%), CDKN2A (23% vs 5.1%), CDKN2B (21% vs 5.1%), MTAP (16% vs 3.3%), and PIK3R1 (13% vs 3%). Additional potentially therapeutic-relevant alterations associated with PI3k pathway were prevalent in the MpBC and non-MpBC groups: PTEN (25% vs 10%, $q<0.001$), PIK3CA (26% vs 32%, $q=0.2$) and AKT1 (1.8% vs 3.7%, $q=0.3$). Within the MpBC group, there was a similar incidence of PD-L1 expression (CPS ≥ 10) in both TNBC (38%) and HR+/HER2- subtypes (33%). No significant difference was observed between the immune cell subsets within MpBC subtypes ($p>0.05$). Somatic alterations between TNBC and HR+/HER2- subtypes in the MpBC group were analyzed and there was a trend towards differences in PIK3CA (23% vs 39%) and PTEN (22% vs 33%) ($q=0.6$ for both).
Conclusion: In this large, real-world analysis, patients with MpBC displayed a distinct molecular phenotype compared to non-MpBC patients. In patients with MpBC, TNBC was more common, whereas the HER2+ subtype was rare. Patients with MpBC had higher PD-L1 expression and therapeutically relevant alterations, including those within the PI3k pathway, were frequently encountered in MpBC. Although limited by sample size, this is one of the first studies to compare the molecular phenotypes between subtypes within MpBC. These findings are hypothesis-generating and provide further rationale for developing novel combinatorial therapeutic clinical trial strategies for MpBC.

P1-03-26: Genomic Landscape of prImary vs seconDary Endocrine Resistance in HR+/HER2- advanced breast cancer: the GLIDER study

Grazia Castellano, Luca Boscolo Bielo, Chrysanthi Koukouzeli, Gilda Gaudio, Enzo Martino, Matteo Cavallone, Edoardo Crimini, Riccardo Adorisio, Alberto Ranghiero, Konstantinos Venetis, Monica Milano, Paola Zagami, Beatrice Taurelli Salimbeni, Antonio Marra, Carmen Belli, Zhan Yinxiu, Nicola Fusco, Carmen Criscitiello, Elena Guerini Rocco, Elisabetta Munzone, Dario Trapani, Giuseppe Curigliano

Background: Resistance to endocrine therapy (ET) in HR+/HER2- advanced breast cancer (BC) can be classified as primary (PETR) or secondary (SETR). It is unclear if the two clinical patterns are characterized by distinct molecular mechanisms. In the GLIDER study, we analyzed the genomic landscape of PETR and SETR BCs to identify the possible drivers of the different resistance patterns.
Methods: PETR and SETR were defined as per ABC 6-7 consensus definitions (PETR: relapse while on the first 24 months of adjuvant ET or progressive disease within the first 6 months of 1st line ET for advanced BC; SETR: PETR criteria not met). Clinical-genomic data were retrieved from a cohort of HR+/HER2- metastatic BC that received any lines of ET (single agent or combination) and that were subjected to Next Generation Sequencing (NGS) using tumor-only panels between March 2016 and July 2024 at the European Institute of Oncology. Genomic data were compared between BCs showing PETR vs SETR. Signaling pathways were identified as previously described in The Cancer Genome Atlas. The occurrence of oncogenic/likely oncogenic genomic alterations (OncoKB) was described in PETR and SETR BCs, and compared with Fisher's exact test and logistic regression. Progression-free survival (PFS) under ET was estimated with Kaplan-Meier and compared with Cox regression. Median follow-up (FUP) was calculated using the Reverse-Kaplan Meier method. No family wise correction was applied for multiple hypothesis testing.
Results: A total of 122 patients were included, of whom 17.21% (n=21) with de novo metastatic BC: 59.32% (n=45) patients received aromatase inhibitor and 38.14% (n=45) fulvestrant, as monotherapy (22.13%, n=27) or combined with CDK4/6 inhibitors (CDK4/6i) (72,95%, n=89). ET was received mostly in 1st line (94.17%, n=113). With a median FUP of 49.0 months (IQR 25.4-81.9) and 105 (88.98%) PFS events, median PFS was 20.7 months (95%CI 17.8 to 25.1) to the first-ET received in the metastatic setting. 17.21% (n=21) patients displayed PETR and 82.79% (n=101) SETR. NGS was performed on tissue (23%, n=28) and liquid biopsy (77%, n=94). A total of 437 genetic alterations were identified, with PIK3CA (50%, n=61) and ESR1 (46%, n=56) being the most commonly altered genes. Tumors showcasing PETR exhibited more PTEN deletions/indels (14.3% vs. 1.9%, Odd-ratio [OR] 16.0, P=0.03), MDM2 amplifications (9.5% vs. 0.0%, P=0.02), IGF1R amplifications (9.5% vs. 0.0%, P=0.02), MUTYH alterations (9.5% vs. 1%, OR 10.2, P=0.08) and MYC amplifications (14.3% vs. 2.9%, OR 5.3, P=0.06), while showing lower occurrence of ESR1 alterations (14.3% vs. 31.7%, P=0.18). At the pathway level PETR exhibited a higher prevalence of alterations involving the MYC-pathway (14.3% vs. 2.9%, OR 5.3, P=0.06) and tyrosine kinase receptors (TRK) (23.8% vs. 9.9%, OR 3.2, P=0.13), while presenting less cell-cycle alterations (4.8% vs. 11.9%, OR 0.4, P=0.4). In the multivariable model accounting for altered signaling pathways, MYC (OR 12.1, P=0.02) and TRK (OR 4.2, P=0.052) status appeared to predict PETR. BCs harboring altered TRK (18.9%, n=23) (mPFS 8.1 vs. 18.5 months, hazard ratio [HR] 1.29, P=0.3) and MYC (6.6%, n=8) (mPFS 11.5 vs. 18.0 months, HR 2.2, P=0.06) displayed inferior PFS with ET. Neither the type of endocrine agent nor progesterone receptor status at immunohistochemistry appeared to induce specific pathway alterations; tumors exposed to CDK4/6i exhibited less cell-cycle (OR 0.26, P=0.02) and ESR1 alterations (OR 0.41, P=0.04). Further subgroup analyses and PFS adjustments will be provided in the full poster.

Conclusion: In GLIDER study, we provide evidence that distinct molecular mechanisms may connote primary (MYC and TRK alterations) vs secondary (ESR1 mutations) endocrine resistance, warranting ad hoc therapeutic approaches.

P1-03-27: Circulating tumor DNA (ctDNA) dynamics as a predictor of treatment response: a review of Liquid Biopsy-RECIST (LB-RECIST) criteria in Metastatic Breast Cancer (MBC)

Lorenzo Foffano, Andrew A. Davis, Carolina Reduzzi, Emily Podany, Arielle J. Medford, Marko Velimirovic, Katherine Clifton, Annika Putur, Laura Munoz-Arcos, Letizia Pontolillo, Rachel O Abelman, Caterina Gianni, Shaili Tapiavala, Elisabetta Molteni, Marla D Lipsyc-Sharf, Eleonora Nicolò, Eleni Andreopoulou, Fabio Puglisi, William J Gradishar, Cynthia X. Ma, Aditya Bardia, Lorenzo Gerratana, Massimo Cristofanilli

Background: Radiological imaging currently represents the cornerstone for monitoring disease response in patients with MBC. However,issues exist with imaging assessments despite standardized response criteria such as RECIST and iRECIST. Recently, dynamics of ctDNA emerged as an alternative to evaluate molecular treatment response through the introduction of LB-RECIST criteria, with a proposed cut-off of 10% in the Variant Allele Frequency (VAF) variation to define patients with radiographic progression. However, specific assessment in setting of MBC is lacking.
Methods: This study retrospectively analyzed 107 patients (pts) with MBC enrolled in a prospective, longitudinal study, NU16B06 trial at Northwestern University (2016-2021), who were longitudinally characterized for ctDNA at baseline (BL), first radiological evaluation (EV1), and progression (PD). For validation, a cohort of 104 pts with MBC enrolled within a multicenter academic consortium, was analyzed. ctDNA characterization was performed through the Guardant360 NGS panel in both cohorts. VAF variation (VAFv) was defined as the percentage change in VAF between the analyzed timepoints. Differences in VAFv across subgroups were assessed using the Mann-Whitney test, and a receiver operating characteristic (ROC) curve was applied to determine the optimal cut-off for distinguishing progressors from non-progressors.
Results: In the clinical study, hormone receptor positive (HR-positive) MBC was the most represented subtype (56 patients, 52%), followed by triple-negative (28 patients, 26%) and HER2-positive (23 patients, 22%). The most common metastatic site was bone (49 patients, 45%), followed by lymph nodes (43 patients, 40%) and liver (26 patients, 24%). Considering BL and EV1 timepoints, with a median interval of 4.4 months, a significant difference in VAFv ($P<0.001$) emerged between progressors (30 pts, 28.3%) and non-progressors (76 pts, 71.7%) at first radiologic evaluation (VAFv = +48%, Inter Quartile Range - IQR 0% to 230% and VAFv = -72%, IQR -99% to -29%, respectively). The best cutoff to define PD was evaluated through a ROC curve as -1.32% (sensitivity 86.7%, specificity 80.3%); however, a cut-off of 0% showed the same predictive capability and was therefore considered optimal. Among the 61 patients with PD samples and a previous sample within 6 months, the median VAFv was 188% (IQR 0% to 1585%). A VAFv ≥ 10% was observed in

42 pts (68%), while utilizing the ≥0% cut-off 50 pts (82%) were included.
In the validation cohort of 104 pts with BL and PD samples, the median VAFv between baseline and progression was 27% (IQR -40% to +440%), with a median interval of 3.1 months. A VAFv ≥ 10% was observed in 53 pts (51.0%), while 74 pts (71.2%) were correctly categorized considering the cut-off of VAFv ≥ 0%.
Conclusions: This analysis confirms the potential of utilizing ctDNA dynamics as a surrogate biomarker for radiographic treatment response. While a 0% cut-off appears to better capture progression compared to a 10% cut-off in both the initial and validation cohorts, prospectives studies are ongoing to standardize and validate LB-RECIST and determine whether optimal VAF cutoffs may be assay and disease context dependent.

P1-03-28: Agreement between the DESTINY-Breast04/06 VENTANA 4B5 HER2 IHC clinical trial assay and other comparator assays for HER2-low breast cancer: Overall results of a large-scale, multicenter global ring study

Sunil Badve, Corrado D'Arrigo, Gelareh Farshid, Annette Lebeau, Vicente Peg, Fréderique Penault-Llorca, Josef Rueschoff, Wentao Yang, Neil Atkey, Jessica Baumann, Anika Altenfeld, Elisabeth Beyerlein, Amy Hanlon Newell, Alexander Penner, Akira Moh, Giuseppe Viale

Background: Treatment with trastuzumab deruxtecan improved outcomes compared with standard of care for human epidermal growth factor receptor 2 (HER2)-low (immunohistochemistry [IHC] 1+ or IHC 2+ with in situ hybridization negative) metastatic breast cancer (BC) in DESTINY-Breast04 and DESTINY-Breast06. The VENTANA Pathway 4B5 IHC assay, approved in the US as a companion diagnostic, was used in both trials. This global ring study assessed concordance between VENTANA Pathway 4B5 and comparator assays (CAs) in identifying HER2-low BC, with the first phase of the study including laboratories in the US, Canada, and Europe. Concordance in the first phase varied, with positive percent agreement (PPA) tending to be high, especially with 4B5 laboratory-developed tests (LDT). Here, we report the overall results combining the first and second phases of the ring study.
Methods: 50 clinical BC samples were chosen from a cohort of 300 by a steering committee of expert pathologists. Samples were stained using VENTANA Pathway 4B5 and scored as HER2 IHC 0, 1+, 2+, and 3+ by a central laboratory and a panel of experts before being sent to laboratories for HER2 IHC testing per American Society of Clinical Oncology-College of American Pathologists (ASCO-CAP) 2018 guidelines. Laboratories were actively scoring HER2 IHC for BC in a clinical setting, had two independent pathologists, and did not routinely use VENTANA Pathway 4B5. The second phase analyzed data from laboratories in Australia, New Zealand, Brazil, Chile, China, Hong Kong, Taiwan, Malaysia, and the Philippines. Pathologists first scored samples with their routine protocols and assays (HercepTest [Omnis or Link48], Leica Oracle, non-4B5 LDT, or 4B5 LDT); then, following virtual alignment on interpretation of HER2 IHC scoring guidelines, they rescored the samples 2 weeks later. Postalignment scores were compared with the reference VENTANA

Pathway 4B5 scores. The primary endpoint was PPA and negative percent agreement (NPA) for HER2-low versus HER2 IHC 0 (includes both ≤10% faint, incomplete membrane staining and no membrane staining) based on postalignment scoring.
Results: A combined 6580 scores from 135 pathologists at 70 laboratories were recorded before virtual alignment. Of these, 129 pathologists from 68 laboratories received alignment guidance, and 6270 postalignment scores were available for analysis. Following alignment, PPA (agreement in identifying HER2-low), NPA (agreement in identifying HER2 IHC 0), and overall agreement were 84.8% (95% CI, 83.6-86.0), 69.2% (95% CI, 67.0-71.2), and 79.4% (95% CI, 78.3-80.5), respectively, with Cohen's κ of 0.54 (corresponding to moderate agreement). Virtual alignment did not substantially affect PPA, NPA, or overall agreement (prealignment scores were 85.1%, 69.5%, and 79.7%, respectively). Postalignment, PPA by assay type ranged from 61.6% (Leica Oracle, N = 196) to 95.5% (HercepTest Omnis, N = 467) and NPA ranged from 36.9% (HercepTest Omnis) to 81.7% (Leica Oracle). PPA by regional subgroup ranged from 62.0% (Latin America, N = 335) to 95.6% (France, N = 391), while NPA ranged from 52.8% (Europe [Other], N = 776) to 89.0% (Australia/New Zealand, N = 395).
Conclusions: Interassay and interlaboratory variability was observed in concordance between VENTANA Pathway 4B5 and CAs in identifying HER2 low versus HER2 IHC 0. PPA tended to be higher than NPA, suggesting more consistent detection of HER2-low compared to HER2 IHC 0. Awareness of available novel treatment options, deliberate pathologist training, and optimization of analytical assay methods and their choice are indicated for accurate identification of patients with clinically actionable HER2 expression levels.=

P1-03-29: Targeted Human Plasma Metabolomics for Lobular Breast Cancer Biomarker Discovery

Jean-Francois Haince, Maria L. Vaida, W. Rand Ford, Rashid Ahmed Bux, Paramjit S. Tappia, Bram Ramjiawan, Andrew Maksymiuk

Background: Women with lobular breast cancer (LBC) face several unique challenges compared to those with invasive ductal carcinoma (IDC). LBC often presents with several histological and clinical features, such as a diffuse growth pattern and exhibit poorer long-term outcome and a unique pattern of metastasis. Overall, LBC presents diagnostic and therapeutic challenges due to its unique growth pattern. Despite these unique features, the exact metabolic pathways involved in LBC development remains unclear. Metabolomic profiling of plasma from women with LBCmay help to identify new biomarkers to understand the molecular pathways involved in the clinical characteristics of LBC. The purpose of this study is to identify a panel of metabolomic biomarkers that would improve clinical assessment of LBC using plasma samples, and to understand the intersection between LBC and IDC.
Methods: Our study included a total of 185 plasma samples from women with biopsy-confirmed BC and 56 samples of healthy controls. All biospecimens were obtained from the Cooperative Human Tissue Network (CHTN) biobank. A targeted, quantitative mass

spectrometry (MS)-based metabolomics approach was used to analyze 138 metabolites in plasma samples using a combination of direct injection (DI) MS and reverse-phase high performance liquid chromatography (HPLC) tandem mass spectrometry (MS/MS). A large-scale stochastic approach was implemented, generating 500,000 logistic regression models with balanced class weights. Each model utilized a randomly selected subset of features. The variables from all high-performing models as measured by subtype-specific performance thresholds (>98% accuracy for lobular carcinoma vs. healthy controls, >95% accuracy for ductal carcinoma vs. healthy controls, and >95% AUC for ductal vs. lobular carcinoma) were aggregated to create a comprehensive set of potentially significant features.
Results: Our multi-stage feature selection approach yielded distinct sets of discriminative features for each comparison, demonstrating high accuracy in differentiating between breast cancer subtypes and healthy controls. For the lobular carcinoma vs. healthy controls comparison, our stochastic modeling process identified 231 feature subsets with an accuracy exceeding 98%. Subsequent frequency-based feature selection resulted in a parsimonious set of four features (three metabolites and age). This refined feature set achieved accuracy and AUC values of 100%. In the ductal carcinoma vs. healthy controls comparison, we retained 33 models with accuracies above 95%. The frequency-based feature selection identified a set of five discriminative features containing four metabolites and age. This feature panel yielded an accuracy of 95% and a bootstrapped AUC of 97%.
Conclusions: This study presents a multi-stage approach for identifying discriminative biomarkers in breast cancer subtypes. Our methodology, which integrates stochastic modeling, ensemble techniques, and iterative feature selection, has demonstrated high efficacy in distinguishing metabolic profiling differences between ductal carcinoma, lobular carcinoma, and healthy controls. The identified panels offer promising avenues for non-invasive differentiation between ductal and lobular carcinomas. This may represent a step towards therapy improvement for target therapy in lobular breast cancer. Future research should focus on external validation of these findings and exploration of the biological significance of the identified metabolites using larger cohorts.

P1-03-30: Genomic risk score distribution and outcomes of patients with early-stage breast cancer diagnosed during pregnancy

Guilherme Nader-Marta, Yue Zheng, Kate E. Dibble, Shoshana M. Rosenberg, Erica L. Mayer, Philip D. Poorvu, Kathryn J. Ruddy, Laura C. Collins, Jeffrey Peppercorn, Lidia Schapira, Virginia F. Borges, Christy A. Russell, Steven E. Come, Ellen Warner, Kornelia Polyak, Eric P. Winer, Ann H. Partridge

Background: Breast cancer (BC) diagnosed during pregnancy has been associated with worse prognosis, potentially due to pregnancy-associated changes in the local and systemic hormonal and immune environments, and cytokine profiles. Oncotype DX Breast Recurrence Score® test is a prognostic biomarker, predictive of chemotherapy benefit in patients (pts) with early-stage, estrogen receptor-positive (ER+), HER2-negative (HER2-)

BC, though there are limited data regarding its use in pregnant women. The aim of this study was to evaluate the distribution of Recurrence Score® (RS) results and the long-term outcomes of pts with ER+, HER2- BC diagnosed during pregnancy.
Methods: Women with stage I-III, ER+, HER2- BC diagnosed during pregnancy were identified from a prospective cohort study of pts newly diagnosed with BC at age ≤40 years, enrolled from 2006 to 2016. Pts were classified as pregnant or not pregnant at the time of BC diagnosis. The non-pregnant group was subdivided into nulligravid or in the postpartum period. RS were obtained from banked samples when not clinically performed. RS results were classified as low (<11), intermediate (11-25) or high (> 25) and were correlated with clinicopathological characteristics and outcomes. Descriptive analyses were summarized for pts characteristics. RS results were compared by Wilcoxon Rank Sum test. Distant recurrence-free interval (DRFI) was estimated with Kaplan-Meier methods.
Results: From 403 pts with stage I-III, ER+, HER2- BC, with clinical or research-obtained RS results and available gravidity history, 16 (4.0%) were pregnant and 387 (96.0%) were not pregnant at BC diagnosis (117 [29.0%] nulligravid and 270 [67.0%] postpartum). Median follow-up was 11.1 years. Median age at diagnosis was 36 and 37 years, node positivity (N+) rate was 8 (50.0%) and 146 (37.7%), and chemotherapy was administered to 15 (93.8%) and 276 (71.3%) pregnant and non-pregnant women, respectively. Among pts diagnosed during pregnancy, 15 (93.8%) had had prior pregnancies and 5 (31.3%) were diagnosed with stage I, 7 (43.7%) with stage II, and 4 (25%) stage III BC. From those with N+ BC, 6 pts (37.5%) had N1, and 2 pts (12.5%) had N2 disease. Within the pregnant group, median RS was 30.5 (range 21-68), with 6 (37.5%) pts having an intermediate RS and 10 (62.5%) a high RS. This contrasts with non-pregnant patients whose median RS was 20 (3-77, P=0.0002). The 11-year DRFI rates for pregnant pts with node-negative BC were 100% for RS 11-25 and 75% for RS > 25; while for N+ BC, 11-year DRFI was 100% for RS 11-25 and 50% for RS > 25.
Conclusion: Pts with early-stage, ER+ BC diagnosed during pregnancy had genomically intermediate- or high-risk tumors. RS results were higher among pregnant pts compared to non-pregnant women. Most pregnant pts had prior pregnancies, which may have influenced the biological characteristics of the BC diagnosed during a subsequent pregnancy. Although most pregnant patients received chemotherapy, distant relapse rates were elevated among pts with high RS.

P1-04-01: Impact of Obesity, Skeletal Muscle Index, and Comorbidities on Chemotherapy-Related Outcomes in Early Breast Cancer: A Retrospective Subanalysis

Jasmin Hundal, Gabriel F. P. Aleixo,, Stephanie A. Valente, Chen, Po-Hao Wei, Halle C. F. Moore

Introduction: Women with early breast cancer (EBC) generally have a very good prognosis, with 5-year survival rates approaching 90%. Chemotherapy can cause significant side effects that decrease quality of life. Many patients with EBC also have comorbidities, but it is

unclear which of these is more strongly associated with chemotherapy intolerance. In our previous retrospective study, we found correlation between sarcopenia detected by bioelectrical impedance spectrometry and worse chemotherapy tolerance; in addition, older age and the presence of multiple comorbidities were also associated with greater chemotherapy toxicity in unadjusted analyses. Here we seek to better understand the relationship between specific comorbid conditions and chemotherapy tolerance.
Methods: This retrospective sub-analysis included 323 patients who received chemotherapy for EBC Patient characteristics, treatment details, and toxicity-related outcomes were obtained. Multivariate logistic regression models were used to associate sarcopenia status with toxicity endpoints, adjusting for other patient characteristics. Age (<65 years old), obesity (BMI>30), and sarcopenia (low SMI <6.75 kg/m2) were forced into the final model. Analysis included 16 comorbidities: hypertension (HTN) , diabetes mellitus (DM), congestive heart failure, cirrhosis, renal disease, chronic obstructive pulmonary disease, tobacco use, hypothyroidism, previous breast cancer, previous cancer, osteoarthritis (OA), rheumatic arthritis, coronary artery disease, peripheral vascular disease, osteoporosis/osteopenia, and stroke. Significant comorbidities were identified through a backward elimination procedure.
Results: Obesity was significantly associated with higher chemotherapy toxicity (OR = 3.58, 95% CI: 1.39-9.24, p=0.02). Patients with sarcopenia also had a notably increased risk of chemotherapy toxicity (OR = 6.94, 95% CI: 3.07-15.62, p<0.0001), as did those with HTN (OR = 1.98, 95% CI: 1.01-3.87, p=0.048).
Regarding chemotherapy dose delay or reduction, patients with an SMI below 6.75 kg/m^2 were more likely to experience dose delays (OR = 2.48, 95% CI: 1.10-5.56, p=0.03). Patients with renal disease had an elevated risk of dose delays as well (OR = 4.41, 95% CI: 1.17-16.66, p=0.03). Early termination of chemotherapy was more common in obese patients compared to those of normal weight (OR = 4.67, 95% CI: 1.36-16.07, p=0.006), and in patients with osteoporosis (OR = 3.46, 95% CI: 1.24-9.58, p=0.02).
Hospitalization rates were significantly higher among obese patients (OR = 8.00, 95% CI: 1.75-36.64, p=0.003), those with SMI below 6.75 kg/m^2 (OR = 8.70, 95% CI: 2.53-30.30, p=0.0006), patients with DM (OR = 3.22, 95% CI: 1.07-9.67, p=0.04), renal disease (OR = 7.09, 95% CI: 1.56-32.171, p=0.01), and those with OA (OR = 4.34, 95% CI: 1.35-13.98, p=0.01).
For neuropathy, likelihood was higher in obese patients (OR = 3.62, 95% CI: 1.20-10.87, p=0.006) and in those with an SMI below 6.75 kg/m^2 (OR = 5.92, 95% CI: 2.27-25.38, p=0.0003). No other comorbidity was significantly associated with neuropathy status.
Conclusion: Obesity and low SMI significantly increase the risk of adverse chemotherapy outcomes in EBC patients. Notably, specific comorbidities such as HTN, kidney disease, DM, and OA play a crucial role in predicting chemotherapy-related toxicity and complications. Our subanalysis provides a more detailed examination of how individual comorbidities uniquely contribute to chemotherapy tolerance. This underscores the importance of a comprehensive, personalized approach in managing EBC patients, considering not only body composition but also the presence of specific comorbidities. Tailoring interventions to address these factors could improve treatment outcomes and quality of life. Future research

should aim to develop and validate personalized interventions in clinical settings to manage these risks better.

P1-04-02: Longitudinal multi-omics study reveals potential targets against chemotherapy induced peripheral neuropathy during taxane treatment

Anukriti Sharma, Ken B. Johnson, Alper Sen, Bihua Bie, Emily E. Rhoades, Courtney Hershberger, Mei Wei, N. Lynn Henry, Carla Bou Dargham, G. Thomas Budd, Joseph Foss, Daniel M. Rotroff

Background: Taxanes are effective but pose a significant clinical challenge due to the risk of chemotherapy-induced peripheral neuropathy (CIPN) that can result in treatment discontinuation or dose reduction. In a multi-omic, longitudinal study, patients with early-stage breast cancer undergoing taxane therapy as part of their (neo)adjuvant treatment regimen were evaluated over 12 months. Using selected panels of mRNAs, miRNAs, cytokines, and metabolites obtained from blood, we examined changes in molecular markers over time to elucidate biological pathways involved in CIPN and identify potential targets for therapeutic intervention. We hypothesized that a biomarker profile could be identified to track CIPN predisposition and its progression over time.

Methods: 400 breast cancer patients were evaluated at 7 time points—pre (visit 1), during (visits 2-4), and after taxane chemotherapy (visits 5-7). CIPN was measured using the Chemotherapy-induced Peripheral Neuropathy 20-item (CIPN20) questionnaire. Patients with linearized CIPN20 scores (range 0-100) of 8 points above baseline at a time point were classified as having neuropathy. Panels of 194 mRNAs, 798 miRNAs, 13 cytokines, and 85 metabolites were assessed at each of the 7 time points. Changes in molecular markers from pre-treatment baseline through treatment and post-treatment phases were analyzed using a semi-parametric approach, the OmicsLonDA package. Changes in mRNA expression over time were used to examine the activation (Z score > 0) and inhibition (Z score < 0) of selected molecular pathways associated with CIPN, mapped using Ingenuity Pathway Analyses (IPA).

Results: 99 mRNAs, 55 miRNAs, and 10 metabolites showed significant differences between patients with and without CIPN over six time intervals; no significant differences were found for the cytokine panel (P>.05). For example, among the mRNAs, expression of OPRM1 was significantly higher in the CIPN negative group from visit 3 to 7 (int3-7), while expression of CAMK1D mRNA was significantly higher in the CIPN positive group for int2-6 (FDR P<.05). Among the miRNA candidates, miR.31.5p.0 was significantly higher in the CIPN negative group for int3-6, whereas miR.184.0 was significantly higher in the CIPN positive group for int6-7 (FDR P<.05). Among the 10 statistically significant metabolites, tyrosine was significantly higher in the CIPN positive group compared to the CIPN negative group for int2-7 (FDR P<.05).

Total 99 significant mRNA candidates were identified in 120 pathways over time, including 18 genes in cAMP-response element binding protein (CREB) signaling, 14 in opioid signaling, 6 in neuropathic pain signaling, and 10 in endocannabinoid neuronal synapse pathways. Additionally, interval-specific (i.e. between visits) comparative analyses of these pathways longitudinally revealed general predicted activation (Z-score > 0) of CREB signaling in int1-2, inhibition (Z-score < 0) from int2-3 to int5-6, and further activation at int6-7 in the CIPN negative group. A similar activation-inhibition pattern was also observed for the opioid signaling pathway.

Conclusions: Using our multi-omic approach, we observed that CIPN is associated with changes in CREB signaling and opioid signaling pathways, which may provide novel opportunities for therapeutic intervention and biomarker development.

P1-04-03: Model-predicted Neurokinin-1 (NK1) Receptor Occupancy of Netupitant versus Aprepitant Over an Extended Time Period: Implications for Controlling Nausea and Vomiting Associated with Antibody-Drug Conjugates (ADCs)

Matti Aapro, Hirotoshi Iihara, Silvia Olivari Tilola, Alberto Bernareggi

Background: Nausea and vomiting (NV) are expected side effects of anticancer treatment and have traditionally been assessed up to 120 h (5 days) post-treatment. However, following a recent systematic review by Chow et al. (Supp Care Cancer 2023) which assessed the prevalence of “long-delayed” NV (beyond 120 h), attention has begun shift to this unmet need, particularly as data emerges with novel targeted therapies such as ADCs. Evolving data with ADCs in breast cancer indicates NV are not only among the most frequent treatment-related side effects but can occur for a longer time, potentially resulting in detrimental effects on quality of life and on maintaining dose-intensity. Using guideline-recommended antiemetic prophylaxis [i.e., an NK1 receptor antagonist (RA)-containing regimen] when initiating ADCs is critical to optimize patient outcomes. Netupitant (NETU), a highly selective NK1 RA used in combination with palonosetron, has shown favorable comparative efficacy to an aprepitant (APR) regimen up to 168 h, likely due in part to its longer half-life. As receptor occupancy (RO) is assumed to serve as proxy for clinical efficacy, we conducted an analysis aimed at evaluating the RO in the brain striatum with netupitant versus aprepitant for an extended time interval.
Methods: Mean plasma concentration-time curves of NETU and APR from previous pharmacokinetic (PK) studies in the Caucasian population were analyzed by compartmental PK modelling upon single administration of the therapeutic doses of 300 mg and 125 mg po, respectively. Emax pharmacodynamic (PD) models were fitted to the % NK1 RO data in the striatum region after NETU and APR administrations as a function of PK model predicted plasma concentrations. The % NK1 RO in the striatum region up to 480 h for 300 mg NETU

on day 1 versus 3-day APR (125 mg day 1 and 80 mg days 2-3) were then assessed by PK/PD model predictions.
Results: The RO patterns for NETU and APR were quite distinct. The NK1 RO reached 90% by 3 h for both agents. RO remained high up to 120 h (day 5) for both NETU (76%) and APR (81%) but then dropped substantially for APR and gradually declined for NETU. At 168 h (day 7), the RO was 70% for NETU and 39% for APR. The RO for NETU and APR, respectively, at 192 h (day 8), 240 h (day 10), and 480 h (day 20) was 67% vs 19%, 60% vs 3%, and 22% vs 0%.
Conclusions: There was a persistent and gradual decline of % NK1 RO over a period of 20 days following a single dose of NETU compared with a rapid decline in RO for APR after 6 days. These findings suggest that NETU has the potential to prevent NV over a prolonged duration, making it a promising antiemetic for prevention of NV with new anticancer targeted therapy like some ADCs. Preserving patients' quality of life and ensuring uninterrupted treatment is vital to optimizing outcomes and maximizing treatment effectiveness.

P1-04-04: evelopment and validation of a nomogram for axillary lymph node metastasis risk in breast cancer

Xiaoyun Mao, Shijing Wang

Purpose: Preoperative assessment of axillary lymph node (ALN) status is essential for breast cancer treatment planning. To prospectively analyze risk factors for ALN metastasis in breast cancer patients, comparing high-resolution computed tomography (HRCT) imaging with pathology, and to develop and validate a nomogram predicting the status of each node.
Methods: From April 2023 to May 2024, patients with pathologically proven breast cancer were enrolled in the study. All patients underwent a chest HRCT examination within one week prior to surgery. ALN specimens were subjected to pathological examination and anatomically matched to HRCT imaging. The least absolute shrinkage and selection operator (LASSO) regression was employed to refine the features for the metastasis lymph node (MLN). Subsequently, the final selected features were determined through multivariate logistic regression analysis and utilized to construct a nomogram. The discrimination, calibration, and clinical utility of the predicting model were evaluated using the concordance index (C-index), area under the curve (AUC), receiver operating characteristic (ROC) curve, calibration plot, and decision curve analysis. Internal validation was conducted through bootstrapping validation.
Results: A total of 302 ALN from 98 patients were included in this study. The patients were divided into two groups based on pathology: a MLN group (71 nodes) and a non-metastasis lymph node (NMLN) group (231 nodes). The predictors included in the prediction nomogram encompassed the mean CT value, short diameter, border, and shape of ALN, as well as the Ki-67 status and histological grade of the primary tumor. The model exhibited satisfactory discrimination, with a C-index of 0.869 [95% confidence interval (CI): 0.826-

0.912] and an AUC of 0.862 (95% CI, 0.815-0.909). Moreover, in the interval validation, the model demonstrated its high performance, achieving a C-index of 0.845 and an AUC of 0.857. The calibration curve demonstrated a high degree of concordance between the predicted and actual probabilities. The decision curve analysis demonstrated that the prediction nomogram was clinically useful when the threshold for intervention was set at the metastasis possibility range of 1% to 86%.
Conclusion: The prediction nomogram combined with preoperative pathology and HRCT imaging have the potential to improve the evaluation of ALN status. This integrated approach can serve as a valuable reference for the management of breast cancer patients.

P1-04-05: Stroke-Related Mortality Trends Among Breast Cancer Patients in the United States from 1999 to 2020: A Retrospective Analysis

Moazzam Shahzad, Zain Ali Nadeem, Eeman Ahmad, Umar Akram, Eeshal Fatima, Bilal Sardar, Muhammad Kashif Amin, Aimen Nadeem

Background: Breast cancer is the second most common cancer worldwide, and the most diagnosed cancer in women. It is associated with an increased risk of stroke, which may prove fatal. However, contemporary data regarding stroke-related mortality in breast cancer patients in the United States (US) is limited. We aim to assess the temporal trends in stroke-related deaths in women with breast cancer in the US from 1999 to 2020, stratified by race/ethnicity, age groups, census regions, and urbanization.
Methods: We used the Centers for Disease Control and Prevention's Wide-ranging Online Data for Epidemiologic Research database for death certificate data of all decedents with stroke as the underlying cause of death and breast cancer as a contributing cause of death. Crude mortality rates (CMRs) and age-adjusted mortality rates (AAMRs) with 95% confidence intervals (CIs) were calculated per 100,000 people, and the temporal trends were analyzed by determining the annual percentage change (APC) and the average APC (AAPC) using Joinpoint regression.
Results: From 1999 to 2020, a total of 12,767 stroke-related deaths in patients with breast cancer were recorded in the US. We observed a declining trend in AAMRs from 1999 to 2014 (APC -5.68, 95% CI -6.70 to -4.97), which stabilized thereafter till 2020 (APC 2.46, 95% CI -0.64 to 11.17). The highest AAMR was exhibited by Non-Hispanic (NH) Blacks or African Americans (0.202) and the lowest by NH Asian or Pacific Islander (0.083). AAMRs declined till 2013 for NH Blacks or African Americans and till 2014 for NH Whites, stabilizing afterward. Older individuals showed much higher CMRs, with about five-fold greater rates in the 85+ years age group (5.291) than in the 75 to 84 years age group (1.325). While the CMRs initially declined for all age groups, they stabilized for the 55 to 64 years group after 2016 and the 65 to 74 years group after 2013, and increased for the 75 to 84 years group after 2018 and the 85+ years group after 2016. Regional variation was evident, with higher AAMRs in the Midwest (0.197) and the West (0.181) compared to the South (0.157) and the Northeast (0.154). Initially, declining AAMRs were observed in all regions, with stable trends in the Northeast after 2018, the Midwest after 2012, and the

South after 2014. However, rising AAMRs were observed in the West from 2014 to 2020. Greater AAMRs were exhibited by rural areas (0.19) than urban areas (0.166), with rural areas showing a decline in AAMR throughout the period but urban areas showing an initial decline till 2012 and stable AAMRs thereafter till 2020.
Conclusion: While stroke-related deaths in breast cancer patients initially declined in the US, the mortality rates have stabilized in recent years. The highest burden of deaths was observed in NH Blacks or African Americans, older individuals, residents of the Midwest, and those living in rural areas. Focused efforts are needed to reduce the disparities and effectively mitigate stroke-related deaths in breast cancer patients.

P1-04-06: Reasons for Cannabis Use and Perceptions in Breast Cancer Patients Compared to Other Cancer Patients

Cristina Truica

Background: Cannabis use has increased significantly in the US with 38 states having passed laws allowing access to cannabis (C) and among cancer patients and survivors the estimated prevalence rates range from 8% to 40%. While the evidence supporting the efficacy of medical C for cancer symptoms is generally limited, some studies suggest benefits in managing pain, sleep disturbances, anxiety, nausea and vomiting, which are common symptoms in breast cancer (BC) patients. This study explores C use and attitudes/perceptions among cancer patients in general and BC patients specifically, and how BC patients may differ. Previous reports relied exclusively on online questionnaires, potentially excluding disadvantaged patients. We used an in-person survey to broaden our reach given our predominately rural catchment area. Methods: Between June 2023-June 2024, we conducted in-person surveys using anonymous paper questionnaires of adult (≥18y) cancer patients diagnosed within the previous year who visited the Penn State Cancer Institute. Responses from BC patients were compared to patients with other cancer types using Fisher's exact test. Results: Out of 186 surveyed patients, 50 (26.9%) reported having BC, with other common sites being lung (14.5%), melanoma/skin cancer (11.8%), non-Hodgkin Lymphoma (9.7%) and leukemia (9.1%). Of the full sample, 51.4% lived in rural areas and 14.7% were economically disadvantaged, reporting finding it difficult or very difficult to get by on present income. BC patients were significantly younger (mean = 58.9 years) and more likely to be employed and have early-stage cancer. The C use rate in our general sample (26.1%) was lower than in other studies done in predominantly urban centers. Compared to other cancers, BC patients had higher rates of C use since diagnosis (36.0% vs. 23.4%), C use during cancer treatment (30.6% vs. 22.2%) and current use (26.0% vs. 18.6%), although these differences were not statistically significant. BC patients were more likely than other patients to have used C instead of opioids to manage pain (47.6% vs. 23.1% of C users, p = .05) and were less likely than other patients to be concerned about C interacting with other medicines (3.1% vs 18.4%, p = .04). The most common reason for C use in our sample was to help with sleep and BC patients were more likely to have used C to improve sleep than others (88.2% vs. 54.8%, p = .03). The most

common reason for not using C in our full sample (52.2%) and in BC patients (40.6%) was that their health care providers had not suggested or recommended it. Most BC patients (60.0%) thought that C is safe for cancer patients to use and a large majority (92.0%) thought there are benefits related to C use, citing pain management most often (93.5%). However, most BC patients (69.4%) also thought there are risks related to C use, with an inability to drive (50.0%) cited most, while 32.7% thought that C is addictive. 52.0% of BC patients reported being mostly open or very open to C use and 49.0% reported being at least moderately confident about their C knowledge, with 46.0% wanting their provider to talk to them about C use. Importantly, most BC patients (55.1%) reported being likely or very likely to consider participating in research studies involving C, with the preparation most likely to interest them being in food such as brownies (69.6%) followed by oral intake (60.9%) or topically (60.9%). Conclusions: The prevalence of C use among the BC patients in our sample was higher than in other cancer types. BC patients were more inclined to use C instead of opioids for pain management and to utilize C to improve sleep. The BC patients perceived C as safe and potentially beneficial, expressing interest in research with C all the while acknowledging associated risks.

P1-04-07: Incidence and Risk Factors of Immune-Related Adverse Events in Metastatic Breast Cancer Patients: Findings from a Multi-Institutional Study

Nikita Baclig, Andrew Soliman, Saya Jacob, Alexis LeVee, Samantha Fisch, Carolyn Face, Madhuri Chengappa, Saliha Chaudhry, Dame Idossa, Laura Huppert, Laura Quintal, Michelle Melisko, Melanie Majure, Jo Chien, Joanne Mortimer, Anne Blaes, Hope S. Rugo, Melissa Lechner, Kelly E. McCann

Background: For patients (pts) living with metastatic breast cancer (mBC), treatment with immune checkpoint inhibitors (ICI) offers the promise of improved outcomes. However, immune-related adverse events (irAE) are a potentially irreversible, dose-limiting toxicity of treatment and can significantly impact quality of life. There is a lack of real-world data on incidence of and risk factors for irAE among patients with mBC.
Methods: This multi-institutional, retrospective study identified pts with mBC treated with ICI between 2014-2024. Pts on ICI therapy at time of study were excluded. Demographic, clinical, treatment, and irAE data were collected. Events were considered irAE if the treating team indicated toxicity was related to or likely related to ICI. Descriptive statistics were used to describe incidence of irAE. Pearson's chi-squared, two-sample T tests, simple and multivariable logistic regression models were used to evaluate risk factors for irAE including demographics, body mass index (BMI), comorbidities, breast cancer subtype, menopausal status, Programmed Death-Ligand 1 (PD-L1) expression, baseline lab values, ICI type, number of ICI cycles, combination vs. monotherapy, and clinical trial participation.
Results: 277 mBC pts were included. Mean age at start of ICI was 54 (SD 13.7, range 23-89). The study population was racially diverse (63.8% White, 8.7% Black, 12% Asian, 2.5% Latino), mostly pre-menopausal (52.3%), and more likely to have triple negative breast

cancer (62.8%) than hormone receptor positive (31.0%) or human epidermal growth factor receptor 2 (HER2) positive (6.1%) disease. 18.1% had documented PD-L1 positivity. 15.9% had a history of autoimmune disease at time of ICI initiation. 128 (46.2%) experienced a total of 173 irAEs, most commonly thyroiditis (20.8%), rash (20.2%), and colitis (19.1%). 24.0% of irAEs were grade 3-4 at onset. IrAEs per patient ranged from 0-4; pts who experienced irAE had 1.35 (SD 0.63) on average. Pts were on ICI for an average of 138.4 (range 0-1380) days before their first irAE. Compared to those without irAE, mBC pts with irAE were more frequently post-menopausal (54.3% vs. 42.0%, p=0.04), more likely to have hyperlipidemia (HLD; 33.9% vs. 22.0%, p=0.03), had more comorbidities (1.0 vs. 0.7, p=0.01), and had higher baseline hemoglobin (Hb; 12.4 vs. 11.5, p<0.01). In unadjusted logistic models, being post-menopausal (OR 1.30, p=0.03) and having HLD (OR 1.78, p=0.03) were associated with greater likelihood of irAE. Similarly, for each additional baseline comorbidity (among type II diabetes, hypertension, lung disease, HLD, chronic kidney disease, and coronary artery disease) and for each increased point of baseline Hb, the odds of irAE increased by 30% (OR 1.30, p=0.02) and 40% (OR 1.40, p<0.01), respectively. Increasing cycles of ICI had a modest but statistically significant increased association with irAE (OR 1.04, p<0.01). Adjusted for demographics, clinical factors, comorbidities, baseline labs and treatment characteristics, higher baseline Hb (OR 1.30, p=0.02) and increasing number of ICI cycles (OR 1.03, p=0.03) were associated with increased likelihood of irAE.
Conclusions: For a diverse population of women with mBC treated with ICI, real-world data demonstrates that irAEs are more common than previously reported in trials, with 46.2% of pts affected. The most common irAE, thyroiditis, often leads to irreversible physical effects. Pts that developed irAE were more frequently post-menopausal and had a greater number of baseline comorbidities. Adjusting for covariates, higher baseline Hb levels and increasing number of ICI cycles were associated with increased risk of developing irAE. This study identifies the frequency of and risk factors for irAEs among mBC pts, for whom balancing quality of life with prolonged courses of ICI therapy is paramount. This study may help mBC patients and their providers make informed decisions about ICI treatment.

P1-04-08: Feasibility Evaluation and Implementation of a Digital Health Intervention (DHI) Mobile Health (mHealth) Electronic Patient-Reported Outcome Measure (ePROM) Based Platform for Telemonitoring Patients with Breast Cancer Undergoing Chemotherapy

Alessandra Menezes Morelle, Daniela Donadon de Oliveira Rodrigues, Bianca Sakamoto Ribeiro Paiva, Domicio Carvalho Lacerda, Sérgio Vicente Serrano, Carlos Barrios, Matheus Soares Rocha, Carlos Eduardo Paiva

Background: Breast cancer (BC) is the most prevalent cancer globally and a leading cause of morbidity and mortality among women. Symptoms and treatment-related side effects often go undetected during routine follow-ups. Digital Health Interventions (DHIs) offer promising tools for real-time monitoring and personalized care, potentially improving

clinical outcomes through enhanced symptom detection and informed decision-making. We aimed to implement and evaluate the feasibility of a DHI mobile health (mHealth) electronic Patient-Reported Outcome Measure (ePROM) based platform (ThummiOnco) for telemonitoring patients with BC undergoing neoadjuvant or adjuvant chemotherapy.
Methods: A prospective observational study was conducted at the Women's Outpatient Clinic of Barretos Cancer Hospital in Brazil. The study enrolled patients with localized breast cancer (TNM stages I-III) who were initiating adjuvant or neoadjuvant chemotherapy with any therapeutic regimen. Participants were monitored using the ThummiOnco platform for 4 to 6 months, following a standardized protocol. The feasibility of ThummiOnco telemonitoring was assessed through platform usage, resolution of patient-reported symptoms, and healthcare outcomes. Platform usage was defined as the median number of platform accesses per patient and the frequency of daily symptom reports. The resolution of patient-reported symptoms was determined by symptoms reported by patients that were resolved (i.e., no further complaints regarding the reported symptom) according to the healthcare team within 48 to 72 hours. Healthcare outcomes were measured in terms of number of complementary consultations, dose reductions, treatment interruptions or discontinuations, hospitalizations, and treatment-related mortality. Statistical analysis was performed using descriptive statistics.
Results: Between October 11, 2022, and June 21, 2023, 67 patients (median age 51) were enrolled. The majority (52%) had stage III disease, and 62% received neoadjuvant chemotherapy. The median number of app accesses per patient was 38, with an average of 6.65 symptom reports daily. In total, 919 patient-reported symptoms were recorded. Of these symptoms, 67.7% (n=622) were fully resolved within 48 hours, 26.5% (n=243) were partially resolved, and 6% (n=54) remained unresolved and under monitoring. Among the partially resolved or unresolved symptoms at 48 hours (32.3%, n=297), 23.9% (n=71) were fully resolved and 62% (n=184) partially resolved within 72 hours. The overall resolution rates at 72 hours were 75.4% (n=693) for full resolution and 20.0% (n=184) for partial resolution. Regarding symptom resolution by grade, 83% of grade I, 69.5% of grade II, and 54.8% of grade III symptoms were fully resolved, exclusively with the use of the ThummiOnco platform. Complementary consultations were required for 34 patients, with 30 conducted in person and 4 via teleconsultation. Dose reductions occurred in 10 patients (14.9%), treatment interruptions or discontinuations in 35 patients (52.2%), and hospitalizations in 7 patients (10.4%). One patient died due to progressive disease.
Conclusions: ThummiOnco telemonitoring facilitated early symptom identification and management, reducing the need for in-person consultations. Most reports were fully resolved using the ThummiOnco platform, with minimal additional demands on the medical team. Continuous monitoring of patient symptoms through e-PROM-based platforms is helpful in the management of patients with cancer under active chemotherapy for early BC.

P1-04-09: Evaluating the Necessity and Impact of Cardiac Imaging on Breast Cancer Care in Northwestern Ontario

Hannah Shortreed, Rabail Siddiqui, Olexiy Aseyev

Background: Over 25,000 women are annually diagnosed with breast cancer in Canada. Their survival rates have improved significantly due to advances in screening and treatment. However, many treatments are cardiotoxic, and cardiovascular disease is currently the leading competing cause of death in older breast cancer survivors. Baseline left ventricular ejection fraction (LVEF) is a reliable predictor of heart failure (HF) in patients receiving anthracyclines (AC) and/or trastuzumab. Identification of reduced LVEF can promote interventions to prevent HF and improve patient outcomes. Accordingly, pre-treatment cardiac imaging is supported by the National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines.

Research Question:Despite the perceived necessity of cardiac imaging before and during breast cancer treatment, the recommendations underlying its use is mostly based on expert opinion rather than specific data. This research aims to analyze local data to determine the impact of cardiac imaging on treatment outcomes for breast cancer patients receiving AC and/or trastuzumab and offer evidence-based guidance for ordering physicians at the Thunder Bay Regional Health Sciences Centre (TBRHSC).

Methods: This is a retrospective cohort study including all female patients seen at the TBRHSC who were treated with AC and/or trastuzumab for newly diagnosed breast cancer between January 1, 2012, and December 31, 2017. Data, including baseline characteristics, treatment regimen, imaging tests ordered from diagnosis until one-year post-treatment, and clinical outcomes were collected from the patient's medical records and recorded in a secure REDCap database. Patients were grouped into three cohorts based on treatment regimen: trastuzumab only (A), AC only (B), and both trastuzumab and AC (C). Initially, 125 patients were identified, but those who did not receive either treatment or had no imaging tests recorded were excluded from this study.

Results: A total of 93 patients met the exclusion criteria for this analysis, with an average age at diagnosis of 59.5 years (SD = 10.4). Invasive ductal carcinoma was the most common cancer (97.8%, n=91). Most cancers were diagnosed at stage 2 (51.6%, n=48), followed by stage 1 (24.7%, n=23), and stage 3 (14.0%, n=13); 9.7% (n=9) had unknown stages. Regarding receptor status, 69.9% (n=65) were ER-positive, 62.4% (n=58) were PR-positive, and 34.4% (n=32) were HER2-positive. BRCA1/2 status was unknown for 79.6% (n=74) of the patients included in this study.
In cohort A (n=3), 14 scans (4.67 per patient) led to 1 change in care (7.1%). Cohort B (n=60) had 75 scans (1.25 per patient) resulting in 10 changes in care (13.3%), including changes in chemotherapy (4.0%, n=3), care provider (5.3%, n=4), and medication (4.0%, n=3). Cohort C (n=30) had 144 scans (4.80 per patient) leading to 6 changes in care (4.2%).

Conclusion: This study found that the most significant changes in patient care based on cardiac imaging occurred in patients receiving only AC treatment, with changes happening in 13.3% of cases and each patient receiving an average of 1.25 scans. However, patients receiving only trastuzumab or a combination of trastuzumab and AC had fewer changes in

care (7.1% and 4.2%, respectively) despite having more scans per patient (4.67 and 4.80, respectively). This indicates that more frequent scans do not always lead to more useful information. The study highlights the importance of focusing cardiac imaging on those most likely to benefit, especially in areas with limited resources like Northwestern Ontario. Future research will aim to identify predictive factors for the optimal use of cardiac imaging to enhance resource allocation and patient outcomes.

P1-04-10: Peripheral blood cells as predictors of immune-related toxicity in early triple negative breast cancer (eTNBC)

Benedetta Conte, Beatrice Ruffilli, Ida Taglialatela, Veronica Martini, Simone Gobbato, Valentina Rossi, Francesca D'Avanzo, Francesca Vezzoli, Giorgia Ferrari, Carmen Branni, Jacopo Gennari, Alessandra Gennari

Background: Immune Checkpoint Inhibitors (ICI) acquired an impactful role in high risk early triple negative breast cancer (eTNBC). In particular, KEYNOTE-522 study has demonstrated that the addition of pembrolizumab to neoadjuvant chemotherapy (NACT) improves pCR rate and survival outcomes. Therefore, this novel regimen is characterized by an enhanced and potentially irreversible toxicity profile. The identification of biomarkers able to predict immune-related adverse events (irAEs) is ongoing in different neoplasms. Recent evidence showed a potential emerging role of blood cell counts and ratios, such as lymphocytes and monocytes.
With these premises, the aim of our study is to explore if peripheral blood biomarkers should predict irAEs in eTNBC patients candidate to receiving immunotherapy in peri-operative setting.
Methods: The study enrolled 20 eTNBC patients undergoing NACT containing pembrolizumab. Patients were divided into two subgroups based on the development of irAEs; patients who experienced toxicity were selected depending on the immunotherapy's discontinuation. Patients performed blood samples at baseline before starting treatment and Flow Cytometry analysis was used to characterized monocytes, circulating T cells (CD3, CD4 and CD8) and Myeloid Derived Suppressor Cells (MDSCs).
The statistical analysis was performed using Mann Whitney U Kruskal-Wallis ($p<0.05$) for estimating the frequency of monocytes, and T cells and MDSCs subtypes according to toxicity development.
These analyses were performed with R packages v. 4.3.1.
Results: Overall, 20 patients with eTNBC undergoing NACT were enrolled from July 2022 to February 2024. 12 patients developed irAEs (60%); severe adverse events (grade 3 or higher) were observed in four patients (20%). Particularly, 7 patients experienced hypotiroidism (35%), 3 patients developed a cardiac event (15%), 1 patient had adrenal insufficiency (5%), 2 patients developed acute kidney injury (10%). irAEs led to discontinuation of pembrolizumab in 10 patients (50%).
Considering the various types of peripheral white blood cells, patients with irAE had significantly higher level of monocytes compared to other ones ($p = 0.004$). Although, the

analysis suggested a statistical trend in an augmented expression of non-classical monocytes (CD14-, CD16+), the small sample size precluded statistical significance (p = 0.08). Patients experiencing irAEs showed also an increased expression of T-senescent lymphocytes (p= 0.08). Then, considering patients with irAEs who required treatment discontinuation we observed higher levels of monocytes (p=0.03), especially for the non-classical type (p=0.02).
Conclusion: the addition of immunotherapy to NACT is known to significantly increase the pCR rate and improve the survival outcomes. Despite that, the KEYNOTE-522 regimen is marked by a high rate of adverse events and predictive biomarkers useful to their identification are needed. Our study suggest that peripheral white blood count can be an accessible and easy way to early detect patients with higher risk to develop irAEs, but further studies with larger samples are needed to confirm our findings.

P1-04-11: Examining the risk factors for trastuzumab related cardiotoxicity in a predominantly Hispanic South Texas population: a descriptive study

Zuha Alam, Aditi Sharma, Maria E. Fierro, Samuel Governor, Aishwarya Kothare, Stella Pak, Karen Liu, Prince Otchere

Background: Trastuzumab, a monoclonal antibody targeting human epidermal growth factor receptor 2 (HER2), stands as first line treatment for HER2 positive breast cancer. Despite its efficacy, trastuzumab's association with cardiotoxicity requires monitoring via serial transthoracic echocardiograms (TTEs). We aimed to evaluate the risk factors for trastuzumab related cardiotoxicity in a South Texas population that is uniquely a majority-minority Hispanic population.

Methods: A retrospective chart review study was conducted of all female patients with HER2-positive breast cancer who received trastuzumab treatment from 2015-2021. A total of 180 patients were identified. Patients without baseline TTE or a baseline left ventricle ejection fraction (LVEF) less than 53% were excluded. The final sample size included 132 patients. Cardiotoxicity was defined as a decrease in LVEF of more than 10% during the 1-year study period.

Results: The mean age at the time of diagnosis in the study population was 54.2 years. The average BMI of the study participants was 30.89. The incidence of cardiotoxicity in this study population was 6%. Among those who developed cardiotoxicity, 50% had hypertension, 25% had hyperlipidemia, 12.5% had type 2 diabetes mellitus, and 12.5% had previous coronary artery bypass surgery (CABG). In terms of cancer treatment, 12.5% of patients had a history of radiation, 25% had a history of anthracycline therapy, and 12.5% had their trastuzumab treatment ended prematurely. Of the cardiotoxicity population, 37.5% of patients were former smokers and 25% were former alcohol users. Hispanic/Latino patients composed 58% of the study population and represented 50% of patients who experienced cardiotoxicity. Conclusions: The incidence of trastuzumab-

related cardiotoxicity in this Hispanic/Latino majority-minority population was 6%, lower than the 9% observed in a predominantly white population in our previous study. However, further studies are needed to determine the factors contributing to this reduced cardiotoxicity rate in this population.

P1-04-12: Optimizing Tolerability of Pyrotinib in HER2-Positive Early-Stage High-Risk Breast Cancer: A Multicenter, Randomized, Three-Cohort Study

Qiao Cheng, Hongyuan Li, Xiaowei Qi, Zhen Zhang, Fuyun Tong, Maoshan Chen, Hai Lei, Lei Xing, Xiang Zhang, Mengyuan Wang, Chao Zhang, Chunyan Li, Qian Wang, Yuxian Wei, Fan Li, Jinxiang Tan, Xuedong Yin, Yixiao Feng, Xiaoyi Wang, Man Huang

Background: HER2-positive breast cancer patients with a high risk of recurrence are recommended extended treatment involving sequential therapy with anti-HER2 monoclonal antibody followed by maintenance therapy with HER2-targeted tyrosine kinase inhibitor (TKI). Pyrotinib, an oral irreversible pan-HER TKI, commonly induces diarrhea. This study aims to develop strategies to reduce the incidence and severity of diarrhea and evaluate the efficacy and safety of pyrotinib as an extended adjuvant treatment for early-stage HER2-positive breast cancer.
Methods: In this multicenter, prospective, randomized cohort study (ChiCTR2200060339), stage II-III HER2-positive high-risk breast cancer patients who had completed adjuvant treatment post-surgery, stratified by disease stage (II vs. III) and hormone receptor (HR) status (positive vs. negative), were randomized 1:1:1 into three cohorts to receive extended adjuvant therapy with 12 months of pyrotinib. Cohort 1 received pyrotinib 240 mg daily from D1-14, 320 mg from D15-28, and 400 mg from D29-364. Cohort 2 received pyrotinib 320 mg daily from D1-28 and 400 mg from D29-364. Cohort 3 received pyrotinib 400 mg daily from D1-364, combined with loperamide 4 mg thrice daily from D1-7 and twice daily from D8-28. The primary endpoint was the incidence of grade ≥3 diarrhea. Secondary endpoints included serious adverse events (AEs), other AEs, incidence of diarrhea, invasive disease-free survival, and overall survival.
Results: Between June 2022 and May 2024, 102 patients were enrolled, with 34 patients in each cohort. Twelve patients (35.3%) in Cohort 1, 13 (38.2%) in Cohort 2, and 13 (38.2%) in Cohort 3 had ≥4 lymph nodes involved post-surgery. Additionally, 19 patients (55.9%) in Cohort 1, 21 (61.8%) in Cohort 2, and 19 (55.9%) in Cohort 3 were HR positive. Grade ≥3 diarrhea was reported in 9 (26.5%) patients in Cohort 1, 9 (26.5%) in Cohort 2, and 5 (14.7%) in Cohort 3. The median time to the first occurrence of grade ≥3 diarrhea was 15 days (range: 8-296) in Cohort 1, 4 days (range: 1-43) in Cohort 2, and 3 days (range: 1-14) in Cohort 3. The median number of grade ≥3 diarrhea episodes was 1 (range: 1-3) in Cohort 1, 3 (range: 1-4) in Cohort 2, and 1 (range: 1-2) in Cohort 3. The median duration of each grade ≥3 diarrhea episode was 1 day (range: 1-2) in Cohort 1, 1 day (range: 1-4) in Cohort 2, and 1 day (range: 1-3) in Cohort 3. Dose reduction due to diarrhea occurred in 2 (5.9%) patients in Cohort 1, 7 (20.6%) in Cohort 2, and 10 (29.4%) in Cohort 3. Dose interruption for diarrhea was observed in 14 (41.2%) patients in Cohort 1, 15 (44.1%) in Cohort 2, and

16 (47.1%) in Cohort 3. Discontinuation of pyrotinib due to diarrhea was reported in 2 (5.9%) patients in Cohort 1, 4 (11.8%) in Cohort 2, and 2 (5.9%) in Cohort 3. The most common AEs were diarrhea (79.4% vs. 91.2% vs. 88.2%), nausea (17.6% vs. 20.6% vs. 44.1%), vomiting (11.8% vs. 8.8% vs. 35.3%), fatigue (14.7% vs. 17.6% vs. 26.5%), abdominal pain (8.8% vs. 11.8% vs. 20.6%), and abdominal distension (5.9% vs. 5.9% vs. 17.6%). Grade 1 constipation was observed in 1 patient (2.9%) in Cohort 1, 1 patient (2.9%) in Cohort 2, and 3 patients (8.8%) in Cohort 3.
Conclusions: Loperamide prophylaxis showed a numerically lower incidence of grade ≥3 diarrhea. Diarrhea is a predictable and manageable side effect of pyrotinib treatment, occurring early after initiation and rarely in the later treatment course. It is advisable to combine loperamide with pyrotinib to reduce grade ≥3 pyrotinib-induced diarrhea. Additionally, timely adjustment of loperamide dose is necessary to prevent other gastrointestinal AEs, such as nausea and abdominal distension.

P1-04-13: Comparison of Time-to-Pregnancy in Young Breast Cancer Survivors versus the general population: a Prospective Case-Control Study (FEERIC) from a collaborative research network

Anne-Sophie Hamy, Agathe Chabassier, Clara Sebbag, Clémentine Garin, Christine Rousset-Jablonski, Isabelle Ray Coquard, Laura Sablone, Lauren Darrigues, Elise Dumas, Angélique Bobrie, William Jacquot, Marc Espié, Sylvie Giacchetti, Floriane Jochum, Aullène Toussaint, Geneviève Plu-Bureau, Lorraine Maitrot-Mantelet, Anne Gompel, Paul Gougis, Raphaëlle Bas, Christine Decanter, Bernard Asselain, Lili Sohn, Guillemette Jacob, Florence Coussy, Fabien Reyal

Introduction: Breast cancer (BC) is the most prevalent cancer among women, and increasing attention is being paid to the side effects of treatments, including the potential impact on fertility. Concerns about pregnancy-induced recurrence have existed for decades, but recent data suggest that pregnancy after BC is safe. Additionally, there is a growing interest in understanding the fertility potential and pregnancy outcomes in BC survivors. However, data on fertility rates post-BC compared to the general population remain sparse.

Objectives: The FEERIC study aims to compare the time-to-pregnancy between women with and without previous BC who initiate pregnancy attempts over a three-year follow-up period.

Materials and Methods: The FEERIC (FErtility, ContracEption After Breast Cancer) study is a prospective case-control study involving women aged 18-43 years, with localized, relapse-free BC, and completed treatment. Controls were women of the same age group without BC. Data were collected via online questionnaires over three years. Participants were recruited through Seintinelles, a French social network for cancer research. The primary endpoint was time-to-pregnancy, with secondary endpoints including factors associated with time-to-pregnancy, use of ART, and pregnancy outcomes. Statistical analysis involved Kaplan-

Meier survival analysis and multivariate Cox Proportional-Hazards models, adjusted for confounding factors using Inverse Probability of Treatment Weighting (IPTW).

Results: From December 2018 to June 2019, 4351 women were enrolled, and a total 642 women (76 cases, 566 controls) initiated pregnancy attempts and had follow-up data available. Median time-to-pregnancy was 5 months (IQR: 2.0-7.0) for cases and 3 months (IQR: 2.0-6.0) for controls, with no significant difference between the groups (p=0.34). Most women (61 cases (80.3%) and 541 controls (95.5%)) attempted to conceive through unprotected intercourses only. A total of 7 cases (9.2%) and 25 controls (4.5%) used ART methods. In cases, only 8 women (10.5%) reused cryopreserved materials during their attempts. Most pregnancies occurred spontaneously: among these 50 cases and 402 controls who achieved pregnancy, 42 cases (84.0%) and 382 controls (95.0%) conceived after unprotected intercourses only, while 8 cases (16.0%) and 20 controls (5.0%) conceived after ART methods.
After univariable and multivariable analyses, age at pregnancy attempt, previous children at study inclusion, menstrual cycle regularity, BMI, and ART use were independent predictors of time-to-pregnancy, while the case or control status was not.
Conclusions: The probability of pregnancy for women attempting conception post-BC treatment is comparable to that of the general population. Future research should explore long-term reproductive health and the psychosocial impacts of fertility post-BC treatment to guide supportive care practices.

P1-04-14: Vaginal oestradiol pessaries for the treatment of genitourinary symptoms in women with early breast cancer: a single arm phase 2 study (OVGUS)

Antonia Pearson, Haryana Dhillon, Jill Chen, Rachel Dear, Anuradh Vasista, Andrew Parsonson, Rachel Campbell, Martha Hickey, Tanya Hall, Janine Lombard, Nicole McCarthy, Belinda E Kiely

Introduction: Genitourinary syndrome of menopause is common in breast cancer survivors. Guidelines recommend first-line non-hormonal vaginal treatments, and if these fail, consideration of vaginal oestrogens. Yet, product labels warning against their use continues and fear of cancer recurrence (FCR) is a perceived barrier to use.

Purpose: We aimed to determine the feasibility of a 12-week course of vaginal oestrogen in women with early breast cancer (EBC) on aromatase inhibitors (AIs).

Methods: We conducted a single arm phase 2 feasibility study of oestradiol (10mcg Vagifem Low™) administered intravaginally daily for 2 weeks then twice weekly for 10 weeks. Primary endpoint was adherence to treatment for 12-weeks (>70% participants completing >80% of doses). Secondary endpoints, assessed baseline, 2, 12-weeks, were: improvement in individual vaginal symptoms (dryness, pain, itch, irritation, pain on penetration), most

bothersome symptom (MBS) (none=0, mild=1, moderate=2 or severe=3), and urinary symptoms (ICIQ FLUTS); improvement in sexual function and quality of life (DIVA, EORTC QLQ C30); fear of cancer recurrence (FCRI SF); patient acceptance & ease of use; adherence to endocrine therapy; changes to serum hormone levels (oestradiol, oestriol, FSH); safety.

Results: We recruited 64 participants across 5 sites from November 2020 to July 2024, 2 participants withdrew. Here we report data for the first 56 participants (6 remain on study), final results will be available October 2024. Participants' median age was 57, 70% (39/56) were currently sexually active, 52% (29/56) postmenopausal at EBC diagnosis, and 21% (12/56) were on AI+ovarian function suppression. The primary endpoint is likely to be met with an 88% (49/56) adherence rate to date. We saw significant moderate-to-large improvements in MBS (2 weeks mean Δ -1.37, p<.001, 12 weeks mean Δ -1.48, p<.001) and each individual symptom after 2 weeks (dryness mean Δ -1.38, p<.001; itch mean Δ -0.37, p=.001; pain mean Δ -0.46, p=.001; irritation mean Δ -0.65, p<.001; dyspareunia mean Δ -0.92, p<.001) and 12 weeks (dryness mean Δ -1.46, p<.001; itch mean Δ -0.39, p.001; pain mean Δ -0.45, p<.001; irritation mean Δ -0.68, p<.001; dyspareunia mean Δ -1.08, p<.001). Additionally, day-to-day impact of vaginal ageing (DIVA questionnaire) domains daily living (mean Δ -0.36, p=0.01); emotional well-being (mean Δ-0.85, p<.001); sexual functioning (mean Δ-1.27, p<.001); self-concept & body image (mean Δ-0.79, p<.001) improved after 12 weeks. FCRI-SF scores indicated moderate FCR levels at baseline (M=17) but improved at 12 weeks (mean Δ-1.4, p=0.01), suggesting no short-term increased FCR with use of vaginal oestrogens. Few adverse events reported were reported and all were grade 1 or 2.

Conclusion: Women adhered to vaginal oestrogens over 12 weeks in our study. Our results suggest a randomised controlled trial involving vaginal oestrogen administration would be feasible and acceptable to women with EBC.

P1-04-15: Real-World Analysis of Safety and Efficacy of Metastatic Breast Cancer Patients Receiving Capivasertib

Mara Hofherr, Katherine Clifton

Background: CAPItello-291 was a randomized, double-blind, placebo-controlled trial which resulted in the FDA approval of capivasertib, an AKT inhibitor. Improvement in progression free survival (PFS) was only seen in patients with PIK3CA/AKT1/PTEN-alterations. For patients with these alterations, capivasertib with fulvestrant is an option after progression from at least one endocrine based therapy. To date, real world outcome analyses are limited.
Methods: In this retrospective, single center study we examined patients with metastatic breast cancer who received at least one week of capivasertib and one dose of fulvestrant. IRB approval was obtained. Patient specific alterations, previous treatments, weeks on treatments, and adverse drug events (ADE) were collected from a central EMR.
Results: 29 patients with metastatic breast cancer treated from November 30, 2023 – July 1,

2024 who received capivasertib and fulvestrant were analyzed. Mean age was 63.9. All patients were female and had a PIK3CA/AKT1/PTEN-alteration. 12 patients had ECOG 0, 13 patients had ECOG 1, 4 patients had ECOG 2-3. Patient previously received an average of 3.6 lines of treatment (1 – 11). 19 patients continue on capivasertib with an average of 17 weeks. 9 patients stopped capivasertib due to progression or intolerance with an average of 5.8 weeks on treatment. 25 patients (86%) reported any ADE. 9 patients (36%) reported grade 3 or higher side effects. Expected side effects included diarrhea (50%), rash (24%), nausea (24%), hyperglycemia (24%). Unexpected side effects included AKI (6.8%), DRESS (3.4%), LFTs 5x ULN (6.8%), colitis (3.4%). Median onset of diarrhea was 9 days (1-45 days). Patients were prophylactically prescribed cetirizine to prevent rash. Two patients with severe rash did not receive prophylactic cetirizine.
Conclusions: The authors saw similar rates of ADE that were described in CAPItello-291 and continue to explore underreported ADE. All ADE seen in this trial were appropriately managed. Median event free survival and progression free survival was not reached as of this analysis. Capivasertib appears to be safe and effective in a real-world population.

P1-04-16: Racial Disparities in the Pro-Metastatic Tumor Microenvironment of Treatment-Naive Breast Cancer

Burcu Karadal-Ferrena, Andrew Miller, Suryansh Shukla, Priyanka Parmar, Cien Huang, Chenxin Zhang, Timothy D'Alfonso, Rachel Han, Esther Adler, Nurfiza Ladak, Paula S. Ginter, Xianjun Ye, Malka Felder, Mindy Ginsberg, Chedva Rosenbaum, Thomas E. Rohan, John S. Condeelis, Jesus D. Anampa, David Entenberg, Xiaonan Xue, Joseph A. Sparano, Maja H. Oktay

Background: Black women have higher rates of distant recurrence and poorer survival in estrogen receptor-positive (ER+) breast cancer compared to white women. Such disparity may be attributed to underlying biological differences related to the pro-metastatic tumor microenvironment (TME). Our group has recently shown that residual estrogen receptor-positive (ER+) breast cancer after neoadjuvant chemotherapy (NAC) exhibits a higher density of Tumor Microenvironment of Metastasis (TMEM) doorways in Black women compared to white women. TMEM doorways are portals for hematogenous dissemination of cancer cells to distant organs. However, the baseline levels of TMEM doorways in treatment-naïve breast cancer tissues across different racial backgrounds have not been previously investigated. We hypothesize that racial disparity in pro-metastatic markers is due to baseline biological differences in the treatment-naïve tumor microenvironment between racial backgrounds. To address this question, we conducted a multi-institutional study to evaluate TMEM doorway score, macrophage density, and microvascular density in treatment-naïve breast tissues from a large cohort of 330 patients (184 Black patients and 146 white patients).
Methods: We performed TMEM doorway triple immunohistochemistry which visualizes each of the three components of the doorway: macrophage (CD68), tumor cell (panMena), and endothelial cell (CD31). Following staining, digitally scanned slides were imported into

and analyzed using the Visiopharm image analysis software. Self-identified race was used per patients' medical records. Patient demographics were analyzed with Wilcoxon rank sum test (continuous variables), Chi-squared tests, and Fisher's exact tests (categorical variables). Distant recurrence-free survival was analyzed using log-rank test and multivariate Cox regression model.
Results: Black patients compared to white patients had higher TMEM doorway scores in the entire cohort ($p<0.001$). This disparity was evident in the ER+/HER2- breast cancer subtype ($n = 142$, $p = 0.015$) but not in the TN breast cancer ($n = 79$, $p = 0.86$). In addition to TMEM doorways, we evaluated the individual components of TMEM doorways: macrophage density and microvascular density. While macrophages followed a similar pattern as TMEM doorways, microvascular density did not show any racial disparity. In the entire cohort, Black patients had higher BMI compared to white patients (mean=24.3) ($p=<0.001$). Black and white patients did not differ with respect to age, tumor stage, tumor grade, or lymph node stage. In this cohort, white patients were more likely to develop distant recurrence compared to Black patients (56% vs. 41%, $p=0.007$). Unadjusted Kaplan-Meier curves showed that higher macrophage density was associated with better DRFS ($p=0.04$), while TMEM doorway score and microvascular density were not associated with DRFS in the entire cohort. A multivariable Cox model showed no association between TMEM doorway score and DRFS ($p=0.15$).
Conclusion: In summary, our study shows that pro-metastatic tumor microenvironment (higher TMEM doorway score and macrophage density in the TME) is more pronounced in treatment-naïve breast cancer from Black patients compared to white patients. In contrast to our previous study's finding of an association between higher TMEM doorway scores and poorer DRFS in patients who received NAC, TMEM doorways in treatment-naïve tissue was not associated with DRFS in this cohort. This difference could be explained by changes in TME that occur after NAC and needs further evaluation.

P1-04-17: Exosomes as drivers and biomarkers of TAM recruitment and immune evasion in inflammatory breast cancer

Serena Lucotti, Mara Serena Serafini, Amanda Kaylan Strickland, Maroua Manai, Elisabetta Molteni, Letizia Pontolillo, Eleonora Nicolo', Caterina Gianni, Nadia Bayou, Valerie Fraser, Carolina Reduzzi, Massimo Cristofanilli, David Lyden

Background. Inflammatory breast cancer (IBC) is a rare and aggressive type of BC with a very poor prognosis and that accounts for 10% of BC-related deaths. Diagnosis and treatment of IBC are particularly challenging, as its symptoms resemble mammary infection, and the tumor has already metastasized at the time of diagnosis. Compared to non-IBC (nIBC), IBC tumors are enriched in pro-tumorigenic, M2-polarized tumor-associated macrophages (TAM) with immunosuppressive functions. Despite growing body of work, the mechanisms controlling IBC development and immune landscape are largely unknown. In particular, we still do not understand (a) how tumor cells drive infiltration of TAMs in the tumor microenvironment; (b) whether IBC intra-tumor TAMs dampen T cell

responses as in other types of cancers, thus allowing tumor growth; (c) how to identify patients at high risk of developing IBC and, once diagnosed, the individuals at risk of disease progression. Exosomes are small circulating extracellular vesicles that mediate cell-to-cell communication that are released by cancer cells locally in the primary tumor and in the blood circulation, thus potentially serving as predictive biomarkers and therapeutic targets for the systemic effects of the disease. We have previously shown that exosomes are functional determinants of BC progression and prepare distant sites for metastatic seeding by establishing favorable pre-metastatic niches, but their role in IBC outcomes is not known.
Methods. We have analyzed the proteomic profile of exosomes from IBC (MDA-IBC3, SUM-149, SUM-190, KPL4, and FC-IBC-02) and nIBC cell lines (MCF-7 and MDA-MB-231) as well as plasma exosomes from IBC and nIBC patients and healthy controls by liquid chromatography mass spectrometry. The functional role of cell line- or patient-derived exosomes was tested via incubation with THP-1 cells.
Results. We have identified a signature of IBC-specific proteins that were enriched more than 2-fold in IBC cell exosomes compared to nIBC cell exosomes, regardless of estrogen receptor (ER) or human epidermal growth factor receptor 2 (HER2) status. Among them, polypeptide N-acetylgalactosaminyltransferase 7 (GALNT7) was found up-regulated 5-fold in IBC exosomes. GALNT7 is an O-glycosylating enzyme that is highly expressed in cancer cells of BC patient biopsies. O-glycosylation in TAMs is associated with polarization towards a pro-tumorigenic, M2-like phenotype and significantly increases tumor growth. Moreover, interaction of macrophages with membrane O-glycans expressed on GALNT7-expressing tumor cells or other macrophages receiving GALNT7-enriched exosomes triggers the expression of activation markers found in IBC-associated TAMs, including CD206, CD163, and PD-L1. We also detected a specific, TAM-related protein signature in exosomes from plasma of IBC patients compared to nIBC or healthy controls that may help with stratification and treatment of IBC patients.
Conclusions. Based on our preliminary data, we propose that IBC cell-derived exosomes promote reprogramming of TAMs to shape an immune-suppressive tumor microenvironment and support disease progression, and as such may serve as “liquid biopsy” biomarkers for IBC diagnosis and prognosis.

P1-04-18: Mediator Subunit 1 (MED1) and tumor-secreted small extracellular vesicles (sEV) in breast cancer immune evasion and progression

Mahendra Jadhao, Yongguang Yang, Gregory Bick, Xioating Zhang

Breast cancer is the most common malignancy in women and HER2+ breast cancer has one of the poorest prognosis. HER2-targeted therapies in combination with immune checkpoint inhibitors (ICI) have shown promising preliminary results; however, acquired HER2 resistance limited the efficacy of advanced therapeutics. MED1 is a transcription regulator co-amplified with HER2 and plays a critical role in the progression and metastasis of HER2+

breast cancer. We recently generated a MMTV-HER2/MED1 double overexpression mouse model and observed increased tumor burden, stemness, and metastasis. Single-cell sequencing revealed MMTV-HER2/MED1 tumors had lower tumor-infiltrating CD4 and CD8 T cells and increased accumulation M2 macrophage population; which was further confirmed by IHC analysis. We also found that MMTV-HER2/MED1 tumor cells secreted more and larger small extracellular vesicles (sEVs) than MMTV-HER2 tumor cells. Importantly, MMTV-HER2/MED1 but not MMTV-HER2 tumor cell-secreted sEVs promote M2 polarization of BMDMs while depletion of sEVs abolished that effect. Next, we performed sEV miRNA-seq and identified mmu-miR125b as a top upregulated miRNA involved in M2 macrophage polarization. We found that mmu-miR125b mimic treatment promotes M2 polarization of mice BMDMs in a dose-dependent manner but miR125b-depleted sEVs lose that capability. Moreover, we have carried out in vivo MED1 depletion using p-HER2apt-siMED1 RNA nanoparticles in MMTV-HER2/MED1 mice and found greatly reduced tumor burdens. Consistent with the above, IHC analysis revealed MED1 depletion reduced M2 macrophage (F4/80+ and CD206+) population with an increased accumulation of cytotoxic TIL (CD8α+ and CD4+) populations. Interestingly, we have also observed the downregulation of IRF1/PD-L1 signaling axis in MMTV-HER2/MED1 tumor tissues after the treatment. We further confirmed upregulation of IRF1/PD-L1 in MMTV-HER2/MED1 tumor cells compared to that of MMTV-HER2 tumor cells while MED1 knockdown inhibited IRF1/PD-L1 signaling axis in both MMTV-HER2/MED1 and human BT474 cells. ChIP-qPCR results further supported the direct recruitment of MED1 on IRF1 promotors to regulate PD-L1 expression. Finally, p-HER2apt-siMED1 RNA nanoparticles cotreated with anti-PD1 antibody significantly attenuated MMTV-HER2/MED1 tumor burden; highlighting potential adjuvant effect of p-HER2apt-siMED1 RNA nanoparticles. Collectively, our studies revealed the roles of MED1 in regulating breast cancer immune microenvironment and the potential use of MED1 targeted therapy alone or in combination with current regimens for better treatment of breast cancer

P1-04-19: Regulating Stress to Improve Antitumor Immunity in Breast Cancer Models.

Gilberto Gastelum Martinez, Marc E. Lippman, Barry Hudson, Philip Miller, Courtney Pine, Yalini Anbalagan

Chronic stress significantly impacts cancer progression by fostering an immunosuppressive microenvironment that promotes tumor growth and diminishes therapeutic efficacy. Dysregulated stress hormones, like norepinephrine, mediate β-adrenergic stimulation, orchestrating a cascade of immunomodulatory events within the tumor microenvironment (TME). In estrogen receptor-positive (ER+) breast cancer, immunosuppression presents a challenge due to resistance to immunotherapy driven by molecular characteristics dampening antitumor immune responses.
We explore the hypothesis that chronic stress, mediated by dysregulated stress hormones, drives immunosuppression in ER+ breast cancer, hindering treatment efficacy.

Manipulating thermal stress in the laboratory setting provides a unique approach to studying β-adrenergic stimulation in cancer, particularly its impact on the immune microenvironment. Standard housing conditions for mice result in an environment below their thermoneutral point, inducing increased β-adrenergic stimulation. Conversely, housing mice near their thermoneutral point maintains basal levels of β-adrenergic stimulation, which is associated with delayed tumor growth and improved antitumor phenotypes in different cancer models. Leveraging a syngeneic ER+ breast cancer model, we investigated housing mice at thermoneutral temperatures to mitigate stress-induced immunosuppression.
Tumor-bearing mice housed at thermoneutral temperatures exhibited decreased stress hormone levels compared to those housed at standard conditions, correlating with delayed tumor growth. Further analysis revealed notable shifts in immune cell composition within the TME. Mice subjected to thermal stress regulation displayed increased accumulation of CD8+ T cells, reduced PD1 expression on CD8+ T cells, and decreased accumulation of regulatory T cells (Tregs), indicating a shift towards a more immunostimulatory microenvironment.
In conclusion, disrupting stress-induced immunosuppression and promoting cytotoxic T cell activity holds profound clinical relevance for individuals with stress-mediated diseases, particularly cancer. By exploring how stress influences immune responses within tumors, our research aims to uncover underlying mechanisms driving tumor progression and immunosuppression in ER+ breast cancer. These insights could inform the development of targeted therapies aimed at modulating stress-related pathways or enhancing immune function to improve treatment outcomes in patients with ER+ breast cancer. Furthermore, understanding the intricate interplay between stress and the immune system may have broader implications for managing stress-related comorbidities in cancer patients, such as anxiety or depression, which can influence immunosuppression, impact treatment efficacy, and overall quality of life. Therefore, the knowledge gained from our study could provide valuable insights into the role of stress in cancer progression and guide the development of therapeutic strategies to mitigate its detrimental effects on the immune response and overall disease outcomes in ER+ breast cancer patients.

P1-04-20: Difference in transcriptional expression and immune infiltration analysis between recurrent and de novo stage IV HER2-negative breast cancer in the NEWBEAT trial; WJOG9917BTR.

Yukinori Ozaki, Shigehisa Kitano, Kazuma Kiyotani, Makiko Yamashita, Lifang Wang, Daiki Ikarashi, Junji Tsurutani, Tsutomu Iwasa, Masato Takahashi, Toru Mukohara, Norikazu Masuda, Manabu Futamura, Hironobu Minami, Koji Matsumoto, Yuko Tanabe, Hidetaka Kawabata, Kenichi Yoshimura, Toshimi Takano

Background: We have conducted a phase II trial (NEWBEAT) to evaluate the efficacy of triple therapy with nivolumab, paclitaxel, and bevacizumab in patients (pts) with HER2-negative metastatic breast cancer (MBC). Transcriptional expression is expected to differ

between recurrent and de novo stage IV breast cancer (BC); however, the data on this topic are limited. In an ancillary study (WJOG9917BTR), RNA sequence analyses were performed to elucidate this question.
Methods: The NEWBEAT study enrolled 57 pts and showed that the median progression-free survival (PFS) and overall survival (OS) were 14.0 months and 32.5 months, respectively, with a median follow-up of 29.5 months. In this biomarker study, transcriptional expression of tissue samples from surgical specimens or biopsies before treatment in pts treated with triple therapy was assessed by RNA sequencing. Immune infiltration analysis was performed using the CIBERSORT method.
Results: The biomarker study included 50 pts (36 with recurrent BC and 14 with de novo stage IV BC). Although the PFS and OS were not significantly different between recurrent and de novo stage IV pts (PFS: 14.3 and 18.8 months [p = 0.230], OS: 29.5 and 32.9 months [p = 0.1287], respectively), a significantly higher rate of responders (defined as PFS ≥1 year) was observed in de novo stage IV pts compared to recurrent pts (79% and 47%, respectively, p = 0.0393). Among 50 pts, 24 tumor samples were available for RNA sequence (RNA-seq) analysis, including 19 recurrent disease and 5 de novo stage IV. In recurrent disease, RNA-seq showed activation of the Wnt signaling pathway, the p53 pathway, and the endothelin signaling pathway, which are involved in angiogenesis and cell proliferation, compared to de novo stage IV. CIBERSORT analysis revealed a lower expression of plasma cells, gamma-delta T cells, and eosinophils in recurrent disease, indicating a lower immune infiltration status. Activation of these pathways may contribute to immune evasion and the formation of an immunosuppressive environment, suggesting that anti-angiogenic agents could potentially play an important role when combined with immune-checkpoint inhibitors in recurrent disease.
Conclusions: Our analysis showed a different immune status between recurrent and de novo stage IV BC. These data suggest that recurrent BC may require a different immunotherapeutic strategy compared to de novo stage IV BC. (UMIN000029590)

P1-04-21: Suppressing suppression: histone deacetylase inhibition primes the metastatic tumor microenvironment to respond to checkpoint inhibition by dynamic rewiring of cell interactions

Evanthia Roussos Torres, Edgar Gonzalez, Jesse Kreger, Yingtong Liu, Sarah M. Shin, Arianna Barbetta, Sarah-Elisa B. Bangerth, Julie Jang, Matthew Jacobo, Batul Al-Zubeidy, Aaron G. Baugh, Vered Stearns, Roisin M. Connolly, Won Ho, Juliet Emamaullee, Adam MacLean

Immune checkpoint inhibition (ICI) is a type of immunotherapy that has been shown to promote durable responses in a minority of patients with metastatic, triple negative breast cancer expressing programmed death receptor ligand 1 (PD-L1), and only in combination with chemotherapy. In the breast expansion cohort of our Phase Ib trial (NCI-9844) we found that the combination of histone deacetylase inhibitor, entinostat, with dual ICI (anti-PD1 and anti-CTLA4), is safe, and led to a 25% objective response rate in heavily pretreated patients with metastatic HER2 negative breast cancer with expected rates of irAEs. In

addition, our preclinical studies support response in triple negative and HER2 positive mouse models of breast cancer. Evaluation of changes in the breast tumor microenvironment (TME) from these models revealed that decreased infiltration or suppression of myeloid derived suppressor cells (MDSCs) by entinostat is a potential mechanism of action. Here, we examined breast-to lung metastases from both HER2 positive and triple negative metastatic mouse models, Neu-N and 4T1, to gain a comprehensive understanding of changes to the tumor immune microenvironment within the metastatic niche induced by treatment with entinostat, and perpetuated following treatment combination with dual ICI. Single cell RNA sequencing of treated lung metastasis confirmed decreased granulocytic-MDSCs (G-MDSC) as seen in previous studies, and revealed significant shifts in C1q macrophages, metabolically activated macrophages, classic dendritic cells, activated and primed Th2 T cells, terminally differentiated T regulatory cells and some sub-populations of B cells. Multiparametric flow analysis was not concordant suggestive that functional changes are more likely contributing to mechanisms of response and decreased immune suppression. Entinostat treatment led to an increase in stemness in tumor cells and decreased mesenchymal gene expression. We then adapted cell circuit and CellChat analysis platforms to investigate cell interactions which revealed significant immune cell interactions affected by entinostat are MDSC- CD8-T cell, macrophage- CD8-T cell and NK- G-MDSC/ CD8-T cell interactions. Ligand receptor pair analysis then revealed signaling pathways controlling chemokine secretion, and cell adhesion are significantly decreased following treatment with entinostat and are preserved upon treatment with dual ICI. From this analysis, we are investigating 6 candidate targets on MDSCs and macrophages using ex-vivo suppression assays as compared to treatment with entinostat, to determine the contribution of these signaling axes in decreasing immunosuppressive function within the TME. We are also using multiplex immunohistochemistry to examine cellular interactions within breast-to-lung metastatic tumors. We will then validate findings in metastatic tumor samples from patients designated as responders from NCI-9844, treated with entinostat + dual ICI. Preliminary evaluation suggests a significant decrease in MDSC-CD8-T cell and Macrophage-CD8-T cell interaction in responders, supportive of our preclinical data. Overall, this investigation of breast-to-lung metastatic tumors reveals how entinostat decreases immune suppression via interference of MDSC and macrophage interaction with CD8-T cells as corroborated in patients who responded to treatment. Future studies will elucidate the molecular mechanisms of action and investigate the potential for identified targets as biomarkers of response and for potential as novel therapeutic targets to improve response rates in patients with advanced breast cancer.

P1-04-22: Loss of SMAD4 Drives Breast Cancer Invasion and Metastasis through E2F1-Mediated Activation of the PEG10-ERK Axis

Dan Shu, Shengchun Liu, Kang Li, Meiying Shen, Aishun Jin, Han Li, Xin Liu

Objective: Although SMAD4 mutations are rare in breast cancer, its loss is strongly associated with metastasis and poor prognosis. This highlights the need to elucidate the

mechanisms by which SMAD4 influences breast cancer progression. In this study, we examined the invasive and metastatic properties of SMAD4-deficient breast cancer cell lines, alongside transcriptomic changes in SMAD4 knockout (KO) models, with the aim of uncovering the molecular pathways through which SMAD4 regulates breast cancer recurrence and metastasis.
Methods: We analyzed SMAD4 expression across multiple bioinformatics platforms and in 102 clinical breast cancer samples. Using CRISPR/Cas9, we generated SMAD4-knockout cell lines and conducted both in vitro and in vivo assays to assess the impact of SMAD4 depletion on tumor growth and metastasis. RNA sequencing (RNA-seq) was employed to identify downstream targets and pathways influenced by SMAD4, while Cut&Tag-seq provided direct evidence of SMAD4's role as a transcriptional co-regulator controlling the expression of key target genes.
Results: SMAD4 was found to be significantly downregulated in breast cancer samples, with this downregulation correlating with adverse clinicopathological features and increased risk of recurrence and metastasis. Mechanistically, we discovered that SMAD4 suppresses tumor progression via the PEG10/ERK signaling axis. Disruption of PEG10/ERK signaling abrogated the pro-metastatic effects of SMAD4 loss. Further, we demonstrated that SMAD4 interacts with the transcription factor E2F1, enhancing its transcriptional activation of PEG10, which in turn activates ERK signaling and promotes breast cancer cell invasion and metastasis.
Conclusion: Our study position SMAD4 as a pivotal transcriptional co-regulator in breast cancer, with important implications for its role as a prognostic biomarker and tumor suppressor. We also underscore the critical contribution of the SMAD4-PEG10-ERK axis in driving breast cancer metastasis, providing potential therapeutic targets for intervention.

P1-04-23: Subpopulations of tumor-infiltrating lymphocytes features in ER-low breast cancer

Maxim Khoroshilov, Elena Kovalenko, Zarina Kadagidze, Tatiana Zabotina, Ekaterina Evdokimova, Yaroslav Zhulikov, Alexander Petrovskiy, Igor Vorotnikov, Mikhail Kiselevskiy, Elena Artamonova

Introduction: ER-low breast cancer (BC) is a special subgroup of tumors with the level of estrogen receptors (ER) in the range from 1% to 10% (total score according to IHC data – 3). Most often, either strong ER staining or its complete absence is determined, which of course makes it difficult to study cases with low ER expression. Overall, the prevalence of ER-low BC has ranged from 3% to 9%, however, due to the extremely high incidence of BC, the population of this subgroup is still of great importance. We analyzed the subpopulations of tumor-infiltrating lymphocytes (TILs) and tried to identify new predictive and prognostic factors to determine the immunological profile of this rare subgroup.
Materials and methods: This prospective trial included 90 patients (pts): 84 (93.3%) had 0-2 IHC scores according to Allred scoring and considered as triple negative BC (TNBC), 6 (6.7%) had 3 IHC scores and considered as ER-low. Both stromal and intratumoral

subpopulations of TILs was assessed with flow cytometry on a tumor sample obtained by core biopsy immediately before the start of neoadjuvant chemotherapy (NACT). All the pts received NACT with 4 cycles of dose-dense AC every 2 weeks (doxorubicin 60 mg/m2 + cyclophosphamide 600 mg/m2) then 12 cycles paclitaxel 80 mg/m2 + carboplatin AUC2 weekly in a N.N. Blokhin National Medical Research from 2018 to 2023.
Results: The level of TILs did not differ between the groups of TNBC (0.6%) and ER-low BC (0.8%, p=0.081). The analysis revealed a significant difference in the level of CD4+CD25+ activated lymphocytes: 8.0% in ER-low and 10.4% in TNBC (p=0.035). It is also worth noting quantitative, but not statistically significant differences in the level of NK cells (11.9% and 4.4%, respectively), NKT (11.1% and 9.3%, respectively) and B lymphocytes (4.6% and 2.0% respectively). Level of tumor infiltration with CD3+CD4+, CD3+CD8+, CD3+, CD8+, CD4+CD25highCD127−/low, CD3-CD19+, CD3-CD16+CD56+, CD3+CD16+CD56+, CD4+CD279+, CD8+CD279+, CD3-CD8+, CD3+HLA-DR+, CD3-HLA-DR+, HLA-DR+, CD8+CD28+, CD8+CD28-, CD8+CD28+/CD8+CD28-, CD4+/CD8+, 11b+28-, 11b+28+, 11b-28-, 11b-28+, CD8+CD4+, CD4+CD152+ lymphocytes subtypes did not differ significantly in the ER-low and TNBC groups. In the ER-low subgroup there were 16.7% of pathological complete responses (pCRs) versus 52.9% in TNBC (p=0.122).
Discussion: CD4+CD25+ and B-lymphocytes are known to be immunosuppressive and are important in terms of pCR reaching after NACT. It can be assumed that its level in ER-low tumors will be higher compared to TNBC, however, in our work, the data obtained do not agree with these deviations. The same applies to regulators of NKT cells, whose task is to regulate the immune response, both reducing and increasing the antitumor potential, including cytotoxic NK cells.

P1-04-24: Prognostic Value of Stromal Markers in Triple-Negative Breast Cancer: A Digital Image Analysis Approach

Zsófia Karancsi, Barbara Gregus, Tibor Krenács, Gábor Cserni, Ágnes Nagy, Klementina-Fruzsina Szőcs-Trinfa, Janina Kulka, Anna Mária Tőkés

Background: Triple negative breast cancers (TNBC), a heterogenous group of tumors represent about 15% of all breast cancers with limited biomarkers and treatment options. Tumor-stroma ratio (TSR) is a proven prognostic and predictive factor in various tumor types, including breast carcinomas, representing the stromal percentage in the most stroma abundant area of the tumor. The overall stromal ratio (OSR), which defines the stroma ratio of the entire tumor area on whole slide images (WSI) has scarcely been examined in the literature. Several studies suggest that changes in the extracellular matrix (ECM) composition and organization could promote tumor growth, but the results have not been consistent. The aim of our study was to investigate the prognostic value of stromal ratio and specific ECM proteins, including major structural components as type-I and type-III collagens as well as fibrillin-1. Understanding whether the expression of these proteins is associated with clinicopathological parameters and outcomes in the TNBC subtype offers valuable insight into the molecular mechanisms driving tumor development and metastasis.

We sought to determine if automated digital image analysis (DIA) methods could provide an objective approach for analyzing stromal ratio and ECM components on H&E and immunohistochemically (IHC) stained slides.
Methods: Our cohort included 101 female TNBC patients, primarily treated with surgery between 2005 and 2016. Representative H&E-stained WSIs were used to evaluate the TSR and OSR by two observers visually and through DIA. IHC was performed on tissue microarrays (TMAs) and scoring was determined both visually and through DIA for type-I collagen expression, type-III collagen expression and intensity, and fibrillin-1 expression and intensity. We employed the QuantCenter module of the SlideViewer program (v2.6; 3DHISTECH Ltd., Hungary), a DIA tool, to calculate the percentage of clusters representing the tumor, stroma, and background or cell-free area, as well as the intensity of the IHC staining. Statistical analyses were conducted using IBM SPSS statistics (v29 for Windows).
Results: The intra- and interobserver variability of the determination of TSR and OSR scores were good or excellent and significant ($r=.866-.979$, $p<.01$). The correlation between the visual and DIA assessed scores were good or excellent for both on the H&E and on the IHC-stained TMAs ($r=.927-969$), although only poor to moderate determining intensity of the IHC-staining ($r=.398-.566$). We found that high OSR correlates with worse overall survival, advanced pN categories, lower sTIL, lower mitotic index, and patient age ($p<.05$). TSR showed significant connections to the pN categories and mitotic index ($p<.01$). High type-I collagen (>45%), type-III collagen (>30%), and fibrillin-1 (>20%) expression levels were linked to significantly worse OS ($p=.004$, $p=.013$, and $p=.005$, respectively) and PFS ($p=.028$, $p=.025$, and $p=.002$, respectively) suggesting their roles in promoting tumor progression and metastasis. Multivariate analysis confirmed the independent prognostic value of high DIA OSR (HR=1.037, $p=.028$), type-I collagen (HR=3.075, $p=.01$), type-III collagen (HR=3.467, $p=.007$), and fibrillin-1 (HR=3.439, $p=.017$) for OS and type-I collagen (HR=2.725, $p=0.017$), type-III collagen (HR=3.825, $p=.011$), and fibrillin-1 (HR=3.815, $p=.018$) for PFS.
Conclusion: We identified promising extracellular matrix protein biomarkers that had not been previously examined in detail in TNBCs. Additionally, DIA proved to be a valuable tool in reliably separating the tumor tissue from its adjacent microenvironment in H&E-stained WSI for the objective measurement of TSR and OSR and to measure the expression of ECM proteins in IHC-stained samples.

P1-04-25: Fast and accurate detection of tumor-immune cell interactions with deep learning

Huiping Liu, Joshua Squires, Youbin Zhang, Yuanfei Sun, Kaiyu Liu, Andrew Hoffmann, David Scholten, Leonidas C Platanias, Yuan Luo, Carson Stringer, Massimo Cristofanilli, William J. Gradishar

Background: Our previous studies demonstrated liquid biopsy-derived circulating tumor cells (CTCs) not only serve as predictive biomarkers of therapy response and overall survival of breast cancer patients, but also drive new metastasis, especially by multicellular

CTC clusters with enriched stemness and up to 50 times higher metastatic potential than single CTCs (Cancer Discovery, 2019 and 2023). However, CTC detection remains challenging, and its characterization is limited due to the rare frequencies in blood cells and labor-intensive manual validations of CTC images analyzed by CellSearch and a few other methods.
Methods: Utilizing FDA-approved CTC CellSearch platform and advanced single-cell sequencing technologies for CTC and immune cell profiling, we have analyzed over 2,000 blood biospecimens longitudinally collected from patients with advanced breast cancer (N=445), including CTC images and CTC interactions with immune cells. Harnessing the power of machine learning and deep learning algorithms for CTC and immune cell image analyses, this study investigates the significance of CTCs, immune cells, and CTC clusters in predicting patient prognosis.
Results: By analyzing CellSearch raw images obtained from blood of breast cancer patients, we developed a python-based CTCpose analysis platform for cell feature analyses in connection with clinical relevance of various cell populations and intercellular communications. Our analysis automatically identified CTCs, immune cells, and CTC clusters differentiated by homogeneity or heterogeneity in cellular composition. By utilizing artificial intelligence (AI) algorithms, we extracted cellular features and classifications to identify different cell types and cell clusters at an accuray and sensitivity over 97%. Specifically, we found expression patterns of biomarkers such as cytokeratin, CD45, and DAPI to discern the spatial distribution and intensity within samples.
Conclusions: The study has explored the potential prognostic values of CTCs, immune cells, and CTC immune cell interactions by correlating their presence, abundance, and spatial information, with clinical outcomes. These outcomes may include patient survival, disease progression, and treatment response. By combining multidimensional data derived from cell morphology, biomarker expression, and spatial relationships, we aim to develop predictive models capable of stratifying patients into unique risk groups.

P1-04-26: THE USE OF IMMUNE CELL HEATMAPS IN UNRAVELLING THE TUMOR MICROENVIRONMENT IN INFLAMMATORY BREAST CANCER.

Christophe Van Berckelaer, Isaac De Decker, Chloe Vermeulen, Peter Van Dam, Steven Van Laere, François Bertucci, Mark Kockx, Gayathri R Devi, Christophe Van Berckelaer

Background: Inflammatory breast cancer (IBC) is a rare but highly aggressive subtype of breast cancer. The tumor microenvironment (TME) plays an important role in its clinical phenotype, evolution and outcome. Cytotoxic CD8+ T cells (Tcyt) are linked to a better prognosis, while CD163+ tumor-associated macrophages (TAMs) seem to influence the rapid tumor progression of IBC and correlate with an unfavorable prognosis. Usually, immune cells in the TME are evaluated on the whole slide, but the methods used may differ significantly. Moreover, not only the quantity, but also the spatial localization of immune cells seems to be important. Therefore, we analyzed the density of CD8+ and CD163+ cells after heatmaps were generated based on their localization. Focusing only on the densities of

hot spots and cold spots could increase standardization and replace a time-consuming evaluation of the whole slide. Our aim is to demonstrate the feasibility of this approach and evaluate the correlation of this heatmap with clinicopathological characteristics and outcome parameters.
Method: In this retrospective cohort study, data were collected as part of an international collaboration since 1996. We included 142 patients with IBC who received their initial diagnosis and started treatment between June 1996 and December 2016. First, consecutive FFPE slides were stained with validated antibodies and digitized for further evaluation and quality control. Next, an image analysis algorithm in Visiopharm marked DAB+ immune cells and localized them spatially with XY coordinates. We then generated heatmaps showing hot and cold spots as areas of highest and lowest density (using the 90th and 10th percentile) and finally calculated the overlap of the CD8 and CD163 hot spots.
Results: Most tumors were hormone receptor (HR) positive (60%, 85/142). The median sTIL score of this cohort was 12.5% (95% CI [1-80]) and 39% of the samples were PDL1 positive. Evaluation of the density in only the hot spots of both CD8 and CD163 showed a very strong correlation compared to the density of the whole slide (ρ= 0.91 and ρ= 0.92 respectively, P< .001).
The presence of CD163+ TAMs correlated with more aggressive disease characteristics, both when evaluated with hot spots (HS) and on the whole slide (WS): nodal involvement (HS: P= .005 & WS: P= .04), higher tumor grade (HS: P< .001 & WS: P= .005), HR negativity (HS: P= .02 & WS: P= .04) and PDL1 positivity (HS: P< .001 & WS: P< .001). In contrast, CD8+ Tcyt correlated only with PDL1 positivity and more sTIL, and there was also no difference in evaluation of the WS or HS.
Both pathological complete response (pCR) and disease-free survival (DFS) were evaluated in 108 patients that presented without metastatic disease at diagnosis and received neoadjuvant chemotherapy (NACT). Patients who achieved pCR after NACT had more CD8+ and CD163+ cells, regardless of whether evaluation was done using the WS (CD8: P= .02 / CD163: P= .006) or only the HS (CD8: P= .03 / CD163: P= .01).
Finally, DFS was evaluated after dichotomizing the immune parameters. CD163+ TAMs were associated with shorter DFS (HR: 0.58, 95% CI [0.34-0.99], P= .04). This was borderline not significant in the HS analysis (HR: 0.60, 95% CI [0.34-1.05], P= .07). Although the presence of CD8+ Tcyt was not associated with longer DFS, an increasing overlap of the HS of CD8 with the HS of CD163 was associated with shorter DFS (HR: 0.59, 95% CI [0.33-1.03], P= .06), indicating the importance of immune cell interactions.
Conclusion: Using heatmaps, we evaluated the density of CD8 and CD163 in both hot spots and the whole slide. There was a strong correlation between the two evaluations, proving the feasibility and reproducibility of this approach. Moreover, the presence of CD163+ TAMs was associated with more aggressive disease characteristics and worse prognosis in IBC, both when using hot spot or whole slide evaluation.

P1-04-27: Characterizing Tumor-Infiltrating Lymphocytes and Their Clinicopathological and Prognostic Significance in Triple-Negative Breast Cancer: an Analysis Focusing on Natural Killer Cells and Spatial Distribution

Eunkyung Han, Hye Yeon Choi, Hyun Jung Kown, Hee-Chul Shin, Eun-Kyu Kim, Koung Jin Suh, Se Hyun Kim, Jee Hyun Kim, So Yeon Park

Background: Triple-negative breast cancer (TNBC) is a heterogeneous disease with a poor prognosis and limited treatment options. The tumor microenvironment, particularly tumor-infiltrating lymphocytes (TILs), plays a critical role in prognosis and response to therapy. High TIL levels generally correlate with better outcomes in TNBC, yet specific immune cell subtypes and their spatial distribution remain poorly understood. Our study aimed to characterize TIL composition, correlate these findings with clinicopathological features and patient outcomes, and investigate impact of heterogeneity of TILs on prognosis of TNBC patients.
Methods: We analyzed 36 TNBC samples through PanCancer Immune Profiling using NanoString nCounter assays to identify differentially expressed immune-related genes in relation to TIL levels. Next, we evaluated protein expression of selected markers through immunohistochemical staining on tissue microarray using 155 TNBC samples. Clinicopathological features and survival data were correlated with TIL infiltration and its subsets, including CD4+, CD8+, CD56+, CD57+, Granulysin (GNLY)+, and Granzyme B (GZMB)+ TILs. To comprehensively assess the expression of cytotoxic T lymphocyte (CTL) and natural killer (NK) cell markers, CTL-NK score was devised based on CD8+, CD56+, CD57+, GNLY+, and GZMB+ TIL levels, and its association with survival was analyzed. Additionally, the heterogeneity of TIL infiltration within tumors was evaluated and correlated with outcome of the patients.
Results: Differential expression of gene analysis revealed significant upregulation of NK cell-associated genes including GNLY, KLRC2, and GZMB in TIL-high TNBCs. Immunohistochemical validation confirmed that TNBCs with higher TIL had more CD56+, CD57+, GNLY+, and GZMB+ TILs, not only in absolute number but also in proportion relative to CD4+ or CD8+ TILs. High TIL infiltration correlated with some favorable clinicopathological features of tumor, including lower T stage and absence of lymphovascular invasion. In survival analysis, high CTL-NK score was found as an independent prognostic factor for better disease-free survival (DFS). Furthermore, uniformly high TIL infiltration was linked to better DFS, whereas cases with heterogeneous TIL infiltration showed no difference in survival compared with those with uniformly low TIL infiltration.
Conclusion: Our study showed that NK cell-associated gene expression and protein levels differ significantly according to TIL levels, and CTL-NK score and distribution of TILs within tumor have a prognostic value. These findings underscore the importance of both NK cells and the spatial uniformity of TIL infiltration in influencing outcome of TNBC patients,

providing valuable insights for refining prognostic assessments and guiding immunotherapeutic approaches.

P1-04-28: Comparison of tumor immune microenvironment of TNBC with different treatment outcome with neoadjuvant chemotherapy: Spatial analysis using multiplex fluorescent immunohistochemistry

Jee Hung Kim, Inho Park, Su-Jin Shin, Heounjeong Go, Jiwon KO, Yangkyu Lee, Soong June Bae, Sung Gwe Ahn, Joon Jeong, Yoon Jin Cha

Background: Triple-negative breast cancer (TNBC) is known for its highly aggressive nature and poor prognosis. However, it has been noted to exhibit high immunogenicity compared to other breast cancer types, making it more responsive to immunotherapy. Recently, neoadjuvant chemotherapy (NAC) has become the standard treatment for early high-risk TNBC. Higher stromal tumor-infiltrating lymphocytes (TIL) predict increased pathologic complete response (pCR) and superior clinical outcomes in TNBC treated with NAC. Despite this general trend, high TIL does not always predict a favorable response, nor does low TIL always predict a poor response. This suggests that individuals with varying treatment outcomes might have different immune dynamics, even under similar TIL levels.
Objective: This study aimed to examine the tumor immune microenvironment (TIME) of pretreated TNBC samples that subsequently underwent NAC using multiplex immunofluorescence (mIHC). Our investigation explored the role of TIME in NAC response and elucidated differences in TIME among patients with similar TIL levels but varying treatment outcomes, as well as those with differing TIL levels but similar treatment responses.

Methods: We retrospectively collected medical records of 16 patients with stage II-III early TNBC treated with NAC at Gangnam Severance Hospital, Yonsei University, between January 2019 and August 2021. Two pathologists (SSJ and YJC) evaluated stromal TIL levels, tumor-stroma ratio, and PD-L1 (22C3) status (CPS). mIHC, including CK, CD4, CD8, CD20, and FOXP3, was performed for tumor cells (TC) and immune cells (IC). Spatial metrics, including the cellular densities of TC and IC, and cell-cell distances between IC, were analyzed.

Results: A total of 1,183,644 cells (761,976 TC and 421,668 IC) from sixteen patients (six pCR [4 high- and 2 low TIL] and ten non-pCR [4 high- and 6 low TIL]) were analyzed. There were no significant differences in baseline characteristics or IC densities between the pCR and non-pCR groups. In the pCR group, CD20+IC and CD8+IC were predominant IC subtypes, particularly in high TIL cases, whereas CD4+IC was the dominant fraction in the non-pCR group. Density plots of different IC types showed dense clustering of CD8+IC and CD20+IC near the TC in the pCR group. Regarding IC-IC interaction, the CD4 IC pair was the largest fraction overall. Within the pCR group, high TIL cases had a high proportion of CD20 IC pairs, whereas low TIL cases had IC pairs, including CD8+IC.

Conclusion: This study observed differences in IC composition and their distribution in pretreated TNBC samples based on pCR status and TIL levels. The findings suggest that tumoral CD8+IC and CD20+IC play crucial roles in determining the response to NAC in eTNBC. Particularly, significant infiltration of CD20+IC in high TIL conditions suggests the presence of B-T cell interaction.

P1-04-29: The expression patterns of the immune checkpoint molecules PD-1 and PD-L1 in the context of seroma development in breast cancer

Nina Ditsch, Nicole Pochert, Felicitas Schneider, Fritzi Schittek, Melitta Köpke, Udo Jeschke, Mariella Schneider, Aline Metz, Matthias Reiger, Claudia Traidl-Hoffmann, Christian Dannecker, Carl Mathis Wild, Ludwig Christian Hinske, Johanna Veh, Natalie Rohrmoser, Eva Leopoldsberger, Laura Bähner, Steffi Hartmann, Michael Untch, Maggie Banys-Paluchowski, Thorsten Kühn, Nina Ditsch

Background: Seroma formation is one of the most frequent complications after breast cancer (BC) surgery. One of the aims of the uni-center SerMa pilot study was to investigate the risk of patients for seroma development after mastectomy with or without implant reconstruction. The expression patterns of the programmed cell death protein 1 (PD-1) and its ligand (PD-L1) found in the tumor microenvironment (TME) of formalin-fixed paraffin-embedded (FFPE) tissue samples of BC patients were therefore of particular interest, since inhibitors against those molecules are currently used in BC treatment.
Methods: The checkpoint molecules PD-1 and PD-L1 were immunohistochemically stained in 80 FFPE tissue samples of patients of the SerMa pilot study cohort and positive cells were evaluated. PD-1 positive cells in the TME were examined and the presence (yes/no) was determined. To assess whether the tumor was positive or negative regarding PD-L1 expression, the immune cell (IC) score, combined positive score (CPS) and tumor proportion score (TPS) were assessed by pathologists. Cells isolated from aspirated seroma fluids (SFl) of a sub-cohort of 18 patients were analyzed using flow cytometry to identify CD3+ T cells and CD68+ macrophages with their PD-1 and PD-L1 expression.
Results: In 37 patients PD-1+ cells were detected in the TME and 15 out of the 80 were considered positive for PD-L1 (IC ≥1%; of those 4 had a CPS ≥10 and 3 a TPS ≥1%). Since we detected checkpoint molecules on our tissue samples, we were interested in their presence on cells of the SFl. We succeeded in measuring both PD-1 and PD-L1 on the surface of T cells as well as macrophages. Almost all analyzed SFl contained macrophages positive for PD-L1 (17 out of 18). In six out of the 18 SFl T cells were positive (>1%) for PD-1. In a next step, we compared the positivity of PD-1 and PD-L1 in cells of the SFl with the corresponding tissue samples (n=13). In three cases we found positive results for PD-L1 in both fluid and tissue, for PD-1 it was only 1 case. When comparing all patients with regard to negative or positive results for PD-1 and PD-L1 in tissue and SFl, there was no evidence of a significant positive or negative correlation.
Additionally, there was no significant difference in PD-1 and PD-L1 expression in the TME

between patients with and without seroma formation. However, dividing the cohort at the median age of 64 years we found significant differences between seroma developers and non-developers: the presence of PD-1+ cells in the TME of older patients (64 years and older) (p=0,032) as well as the CPS of younger patients (<64 years) (p=0,039) showed significance.
Discussion and Outlook: To the best of our knowledge, this is the first study showing PD-1 and PD-L1 expression on T cells and macrophages of SFl. However it is still unclear, whether there is a relation between the PD-1/PD-L1 positive tissue cells and the later emerging immune cells of the SFl, since the sub-cohort presented here is too small to draw any conclusions. Further research is needed to investigate the role of PD1/PD-L1 expressing immune cells in the context of seroma development in the bigger study cohort of the multi-center international SerMa study (EUBREAST 5). Our first results suggest that in older patients the presence of PD1+ cells in the TME decreased the risk of developing a seroma significantly while older age is associated with a higher risk for seroma formation.
Acknowledgements: The authors thank Prof. Dr. Bruno Märkl for the pathological evaluation of the tissue samples.

P1-04-30: Tumor-infiltrating lymphocytes around ductal carcinoma in situ on core needle biopsy can aid in the prediction of the presence of invasive carcinoma

Sawaka Yukishige, Hiroaki Inoue, Tomohiro Inui, Soichiro Sasa, Mariko Misaki, Kazumasa Okumura, Naoki Hino, Toru Sawada, Taeko Kawanaka, Miyuki Kanematsu, Masakazu Goto, Hiromitsu Takizawa

Background: Tumor-infiltrating lymphocytes (TILs) are immune cells that infiltrate tumors and their microenvironment and are associated with antitumor immune responses. TILs are reportedly useful in predicting the efficacy of chemotherapy and the prognosis of invasive breast cancer. However, there are few reports to date on TILs in noninvasive breast cancer; thus, the role of TILs is still unclear. Therefore, we decided to evaluate TILs around noninvasive carcinoma to determine whether it is possible to predict the presence of invasive carcinoma.
Methods: Our study included 212 patients diagnosed with ductal carcinoma in situ via core needle biopsy who underwent surgery from April 2014 to March 2022 at three hospitals, including our hospital. TILs were measured using needle biopsy specimens, and the percentage of lymphocytes in the stroma around noninvasive carcinomas was evaluated from 0% to 100% according to the measurement method of the International Immuno-Oncology Biomarker Working Group. We divided the percentage of TILs into two groups, high and low, with a cutoff value of 10% and examined their association with the presence of invasive areas in surgical specimens.
Results: The median patient age was 57 (30-88) years, and 66 (31%) surgical specimens showed invasive carcinoma. Of these, 152 (80%) were ER-positive and 40 (22%), HER2-positive (3+ by immunohistochemistry). There were three postoperative recurrences: two

in the axillary lymph nodes and one in the local skin. The average TIL values for the groups with and without tumor invasion were 11.1% and 7.5%, respectively, and tended to be higher in the group with tumor invasion (P =0.1517). When TILs were divided into low and high groups, 41 of 154 cases (27%) and 25 of 58 cases (43%), respectively, were found to have invasion. The high TILs group showed significantly greater invasion (p=0.0230). Univariate analysis in the presence of invasion showed significant differences in the high TIL group (HR: 2.09, 95%CI: 1.11-3.92, p=0.0230) and tumor diameter ≧14 mm on imaging (HR: 1.96, 95%CI: 1.01-3.83, p=0.0429). There was no significant difference in Ki-67≧30%, but this group tended to have greater invasion (HR: 2.16, 95%CI: 0.97-4.82, p=0.0626). Multivariate analysis using these three factors showed that a high TIL count was the most independent predictor of invasion (HR: 2.37, 95%CI: 1.12-5.04, p=0.0244).
Conclusion: These results suggest that the evaluation of TILs around noninvasive carcinoma on core needle biopsy may be predictive markers of invasion. TILs, along with other factors such as tumor size, may be used as predictive markers of invasion.

P1-05-01: Direct-to-Consumer “23andMe” Testing for Germline BRCA1 and BRCA2 Gene Variants among Arab Jordanians

Faris Tamimi, Hira Bani Hani, Baha' Sharaf, Yazan Talab, Suhaib Khater, Sarah Abdel-Razeq, Tamer Al-Batsh, Hanan Khalil, Mariam Al-Atrash, Hikmat Abdel-Razeq

Background: Direct-to-consumer genetic testing allows individuals to access their genetic information independently, without the involvement of healthcare providers or insurance companies. Recently, the FDA approved the updated “23andMe” for selected variants in BRCA1 genes for marketing. This updated test, which analyzes human saliva samples from individuals aged 18 and older, now includes 44 specific BRCA1/BRCA2 variants, adding 41 new variants to the previously authorized three common among Ashkenazi Jews. However, thousands of pathogenic variants have been reported in BRCA1 and BRCA2 genes.
The included 44 variants cover over 90% of cancer-related BRCA1 and BRCA2 variants in individuals of Ashkenazi Jewish descent, 30-40% in African Americans, people of Europeans descent, and Hispanics or Latinos and 5-35% in Asians. Given this diversity, it is crucial to assess the prevalence of these variants in various populations. This study aims to evaluate the prevalence of BRCA1/2 variants included in the “23and Me” panel in the Arab Jordanian population.
Methods: Between January 2016 and June 2024, breast cancer patients underwent genetic testing at King Hussein Cancer Center. We analyzed the genetic data of breast cancer patients who were identified with pathogenic or likely (P/LP) variants. Specifically, we assessed the frequency of this cohort's 44 FDA-approved BRCA1/2 variants.
Results: Among the 5,896 breast cancer patients tested, 635 (10.7%) were identified as having P/LP variants. Of those, 421 (66.3%) had P/LP variants in the BRCA1 and BRCA2 genes. The median age at diagnosis with breast cancer was 40 years (range: 19-84 years). 150 (23.6%) breast cancer patients carried P/LP variants in the BRCA1 gene, encompassing 64 different variants and 271 (42.7%) were found to have P/LP variants in the BRCA2 gene,

which included 88 different P/LP variants. Only 44 (10.45%) patients were found to have P/LP variants listed in the “23andMe” panel, including 16 patients with BRCA1 variants and 28 patients with BRCA2 variants.
Almost half of the cases in our patients involved 8 highly frequent BRCA1 variants and 7 highly frequent BRCA2 variants. Among those, only BRCA2 c.2808_2811del, reported in 12 cases, is included in the 23andMe genetic testing panel. Eight BRCA1 variants matched those reported by “23andMe” in 16 cases: c.68_69del (2 cases), c.1961del (1 case), c.3756_3759del (1 case), c.3770_3771del (1 case), c.4065_4068del (5 cases), c.4327C>T (1 case), c.5123C>A (1 case), and c.5266dup (4 cases). For BRCA2, 6 variants matched those reported by 23andMe in 28 cases: c.658_659del (3 cases), c.771_775del (2 cases), c.2808_2811del (12 cases), c.3170_3174del (1 case), c.3847_3848del (5 cases), and c.7480C>T (2 cases).
Conclusions: The 23andMe test potentially missing 89.55% of P/LP BRCA1/2 variants in Arab Jordanians. Including frequently reported variants from different world regions should be considered in direct-to-consumer genetic testing to improve test sensitivity.

P1-05-02: Medium chain fatty acids shift metabolism towards the de novo serine pathway fostering epigenetic plasticity and oxidative DNA damage

Mariana Bustamante Eduardo, Curtis W. McCloskey, Gannon Cottone, Shiyu Liu, Flavio R. Palma, Maria Paula Zappia, Abul B.M.M.K. Islam, Jason Locasale, Marcelo G. Bonini, Maxim V. Frolov, Elizaveta V. Benevolenskaya, Rama Khokha, Navdeep S. Chandel, Seema A. Khan, Susan E. Clare

Introduction: We have investigated the breast microenvironment to identify factors that promote Estrogen Receptor Negative Breast Cancer (ERneg BC) and that may be disrupted for prevention. To that end, we have identified a lipid metabolism gene signature associated with the risk of ERneg BC. To better understand lipid metabolism in the breast, we studied the effect of fatty acids (FA) on non-transformed breast epithelial cells and tissues. FA exposure alters histone methylation, affecting gene expression and increase flux through serine, one-carbon, glycine (SOG) and methionine pathways. The association of the serine pathway and ERneg BC was first observed over a decade ago. A SOG pathway gene signature is significantly correlated with ERneg status. We hypothesized that the metabolism of FA results in a metabolic shift toward the de novo serine synthesis pathway (SSP), which ultimately increases S-adenosylmethionine (SAM), altering histone methylation, profoundly changing gene expression and fostering ERneg oncogenesis.
Methods: Non-transformed MCF-10A cells were used for in vitro metabolic and epigenomic analyses. Cells exposed to the medium-chain FA octanoic acid (OA) were utilized for proteomics and U13C-glucose tracing. SAM, glutathione (GSH) and 2-hydroxyglutarate (2-HG) concentrations were measured following treatment with OA ± blockade of the serine pathway. Reactive Oxygen Species (ROS)-induced redox changes were monitored live cells. Comet assay was performed to detect DNA damage. CUT&RUN was performed for H3K4me3. Human breast tissue derived microstructures were utilized for genomic

analysis. Single-cell RNA-seq (scRNAseq) was performed in microstructures exposed to ± OA. Metabolic flux analyses was performed using Compass.
Results: 13C flux analysis revealed that OA led to increased flux to methylation. OA significantly increased the main methyl donor SAM, the antioxidant GSH via the transsulfuration pathway and the oncometabolite 2-HG after 15 min exposure. Blocking the first and rate limiting enzyme in the SSP, PHGDH, prevented these increases. Proteomics revealed the overexpression of PHGDH following OA exposure. Upon exposure to OA, scRNAseq analysis revealed increased expression of the SSP transcription factor (TF) ATF3 and the SSP genes PHGDH and PSAT1 in epithelial and non-epithelial clusters. Upon OA the proportion of three subtypes within the epithelial compartment increased: basal BSL1, Hormone sensing HS1 and luminal progenitor LP3. Compass, an algorithm to characterize cellular metabolic states, revealed flux greatly increased through the three enzymes of the SSP: PHGDH, PSAT1 and PSPH secondary to OA exposure in BSL1, LP3 and HS1 cells. H3K4me3 CUT&RUN revealed 661 differential peaks (FDR < 0.05) comparing OA to control. Motif analysis revealed an overrepresentation of binding sites for SSP TFs ATF3/4 ($p < 0.05$). After 5 min OA exposure, mitochondrial and nuclear ROS increased significantly ($p < 0.01$), peaking at 15 min. OA exposure triggered DNA damage likely due to ROS increase in the nucleus. Compass predicted an increase in GSH metabolism and ROS detoxification in BSL1.
Conclusions: Protein levels of PHGDH are elevated in 70% of ERneg BCs. This cannot be explained by gene amplification alone as PHGDH gene amplification is observed in only approximately 6% of all breast cancers. This suggests that there are mechanisms other than gene amplification that contribute to PHGDH dysregulation. One of those mechanisms may be the lipid induced metabolic shift toward the SOG and methionine pathways that we have identified. The increased SAM and 2-HG foster epigenetic phenotypic plasticity via altered histone methylation. ROS increase shortly after OA exposure and are controlled by antioxidant defenses (e.g. GSH), which favors the survival of specific cell subtypes with acquired DNA damage which likely facilitates malignant transformation.

P1-05-03: Serum and breast tissue biomarker changes induced by Atorvastatin in women at increased risk for breast cancer

Amanda Lanier, Johannes Fahrmann, Fatma Nihan Akkoc Mustafayev, Angelica Gutierrez, Powel H Brown, Banu Arun

Background: Breast cancer risk can be stratified using clinical models, genetic testing, and mammographic findings. These methods can identify those at high risk of breast cancer who might benefit from risk-reducing interventions. While Tamoxifen is highly effective at reducing the incidence of ER-positive breast cancers, there are no approved agents for reducing the risk of ER-negative cancers. Observational and preclinical evidence supports the study of statin drugs for breast cancer risk reduction.
Objective: This study aimed to investigate the effects of Atorvastatin treatment on serum and tissue biomarkers in patients at increased risk for breast cancer.

Methods: Women at increased risk for breast cancer were accrued prospectively into a biomarker modulation study at UTMDACC, Breast Medical Oncology High Risk Clinic. The study was approved by the IRB and all study participants signed informed consent. High risk was defined as having a previous history of DCIS, LCIS, or atypical hyperplasia, 5-year projected Gail risk >1.67 %, or lifetime risk >20 % calculated by clinical models. Patients were randomized to no treatment (n=15) or daily 10mg (n=16), 20mg (n=14), or 40mg (n=15) Atorvastatin for 3 months. Fasting blood and FNA biopsies were collected at baseline and study completion. Serum biomarkers were analyzed with ELISA (R&D Systems). The IGF1/IGFBP3 molar ratio was calculated using [IGF1 (ng/mL) x 0.13] / [IGFBP-3 (ng/mL) x 0.035]. The Wilcoxon matched-pairs signed rank test was used to determine significance. Lipidomic analyses were conducted on a Waters Acquity™ UPLC system with 2D column regeneration (I-class and H-class) coupled to a Xevo G2-XS quadrupole time-of-flight (qTOF) mass spectrometer under standardized operating procedures. Pre- and post-treatment serum lipids were compared in each treatment group. Paired t-tests with the Benjamini-Hochberg correction were used to determine significance. Results were also compared depending on menopausal status, BMI, and HMG-CoA Reductase genotypes. Tissue gene expression analyses will be conducted using the NanoString Breast Cancer 360 Panel.
Results: At baseline, IGF1 and IGFBP1 were significantly lower in participants with BMI>25 (p=0.017, 0.047), and the IGF1/IGFBP3 molar ratio was significantly lower in post-menopausal participants (p=0.025). Serum IGF1, IGFBP1, and IGF1/IGFBP3 molar ratio did not change significantly post-treatment. Serum IGFBP3 was decreased following treatment but was significant only in the 10mg treatment group (p=0.0034). Global changes in circulating lipids were seen following Atorvastatin treatment compared to no treatment. In the 40 mg treatment group, there was a significant reduction in several lipid subclasses, including glycosphingolipids, ceramides, and sphingomyelins, as well as reductions in selected phospholipids and triglycerides.
Conclusions: These results indicate that short-term treatment with Atorvastatin induced changes in circulating protein and lipid biomarkers. Further analysis on breast tissue will give greater insight into the effects of Atorvastatin treatment.

P1-05-04: Two years of experience of the first broad breast cancer program in Nuevo León, México

Dione Aguilar, Paulina Herrera Ríos, Sonia María Flores Moreno, Martin Lara Esqueda, Graciela Areli Lopez Uriarte, Carlos H. Burciaga Flores

Breast cancer is a complex disease that represents a significant health issue worldwide. Government involvement in oncology is mandatory, ensuring cancer prevention, early detection programs, and treatment for its population. Nowadays, to provide an optimal oncology treatment, a broad and multidisciplinary approach is needed. Unfortunately, this comes with a significant higher cost, leaving most patients in a difficult position. Public health program enhancements are required to provide a better outcome for the patients.

Mexico's public health system is complex, with different resources and coverage depending on federal and regional distribution and programs. Three federal health institutions hold up to 87% of the population, and private institutions only account for 2%. The remaining 11% of the population is often overlooked, depending on the regional government's efforts to ensure health coverage. Since 2022, the Nuevo León local government has raised the standard of care in public health in Mexico by implementing the first breast cancer program that includes whole coverage for diagnosis (including genetic testing for hereditary cancer), treatment, and risk reduction interventions.
In this abstract, we report the results of the first two years of experience in genetic testing and risk reduction interventions of a pioneer breast cancer program in Mexico. Patients identified in weekly multidisciplinary tumor board are referred to the clinical genetic service. After a clinical evaluation, 288/317 (90.85%) patients met the criteria for genetic testing according to current National Comprehensive Cancer Network guidelines. NGS multipanel allowed identification of at least one germline pathogenic variants (gPV) in 58 patients (20.3%). All patients received genetic counseling and followup.
The patients with gPV were analyzed by age and cancer type. Women younger than 50 had higher PV detection 49/240 (20.41%) than women older than 50 years 11/62 (17.7%). Regarding tumor type, we found that gPV were identified in around one-third of triple-negative breast cancer (TNBC) patients: 30/86 (34.88%). Finally, we evaluated the terminal efficacy of the program by the performance of risk reduction surgeries in the carriers. Risk reduction surgeries were recommended according to the type of gPV, age, parity, and clinical status of carriers. To date, 32 (83.7%) contralateral risk reduction mastectomies and 16 (40%) risk reduction salpingo-oopherectomies have been performed. The main reasons for incomplete coverage were patient decisions, age younger than 35 for oophorectomy, and advanced cancer diagnosis or palliative treatment. The experience gained in this model can be used as an example to replicate in other centers for the benefit of our oncologic patients.

P1-05-05: Genetic profile of pathogenic variants associated with breast cancer identified in a chilean inherited family oncological program

Karin Alvarez, Lagos JM, Cares C, Alanis M, Mariani V, Robin J, Lopez-Köstner F, Carvallo C, Silva R, Itriago L, Barajas O, Droppelmann N

Background: Hereditary breast cancer constitutes between 5-10% of total cases, whichare referred to oncological genetic counseling programs based on clinical criteria such as early onset, triple-negative, bilateral, male breast cancer, or family history of cancer(breast, ovarian, prostate or pancreatic cancer). Approximately 20-25% are attributable to pathogenic variants in the high-penetrance genes BRCA1 and BRCA2. However, with the application of multigene panels, testing for genes beyond BRCA1/2 has become more prevalent. The objective of this study is to identify the prevalence and spectrum of germline mutations in a Familial Hereditary Oncology Program in Chile.Methods: A total of 326 index cases were enrolled from Familial Hereditary OncologyProgram of Clinica Universidad de

los Andes between September 2020 to June 2024. Of these, 276 met clinical criteria for hereditary breast cancer, which were studied using a multigene NGS panel. The panel includes common hereditary breast cancer genes, such as homologous recombination repair genes and other DNA damage repair genes.Results: The detection rate of pathogenic or likely pathogenic variant was 17.4% (48/276).Among them, 16 patients (5.8%, 16/276) were identified as carrying BRCA1 mutation, 14 patients (5.1%, 14/276) as carrying BRCA2 mutation and 16 patients (5.8%, 16/276) as carrying non-BRCA germline variants detected in 8 genes: RAD51D (1.4%), MSH6(1.1%), BRIP1 (0.7%), CHEK2 (0.7%), PALB2 (0.7%), CDKN2A (0.4%), MUTYHheterozygous (0.4%) and NBN (0.4%). In addition, two patients (0.7%, 2/276) carrieddouble mutations in CHEK2-CDKN2A and BRCA2-CDH1. The most common variant was c.68_69del; p.(Glu23ValfsTer17) in BRCA1 present in three Ashkenazi Jewish patients. A novel mutation c.4614del; p.(Gln1538HisfsTer10) was identified in BRCA1. The majority of cases (26/48, 83%) were referred due to a personal history of breast cancer on average at 43.9 y.o., followed of ovary cancer at 52.7 y.o., prostate cancer at 63.3 y. Interestingly, the average age of diagnosis in non-BRCA carriers was later compared to BRCA2 and 1 (56 years, 48.9 years and 37.7 years, respectively). Significant differences were observed between the non-BRCA and BRCA1 groups (p=0.0022).Conclusions: Non-BRCA genes represent a third of the pathogenic/likely pathogenicvariants identified in patients with hereditary breast cancer, it is important to performmultigene panel to determine the hereditary susceptibility to cancer in our population and to identify who requires more specialized surveillance, demonstrating the relevance of a Familial Hereditary Oncology Program.

P1-05-06: The frequency of somatic mutations in the PIK3CA gene in Kazakhstani patients with metastatic HR+ HER2-negative breast cancer.

Mariya Dmitrenko, Dilyara Kaidar, Kaldygul Smagulova, Samat Kaldarbekov, Madina Orazalieva

Relevance: Up to 40% of HR+ HER2-negative breast cancer (BC) cases contain mutations in the PIK3CA gene and are a major cause of the development of hormone resistance. Activation of the PI3K protein (phosphatidylinositol-3-kinase) regulates proliferation and apoptosis, and somatic mutations in the PIK3CA gene can activate these processes. Information on the frequency and spectrum of PIK3CA mutations is important for determining the strategy of drug treatment. A combination of the selective PI3K inhibitor alpelisib and the estrogen receptor antagonist fulvestrant may be used as therapy for such tumors.
Objective of the study: To determine the frequency and spectrum of mutations in the PIK3CA gene in patients with “luminal HER2 (-) metastatic breast cancer in the Kazakh population.”
Materials and Methods: The presence of mutations in exons 7, 9, and 20 of the PIK3CA gene was determined in a sample of 320 tumor specimens from patients diagnosed with “luminal HER2 (-) metastatic breast cancer” who received antitumor therapy during the period of

2017-2023 at the Kazakh Institute of Oncology and Radiology. The age of patients ranged from 25 to 86 years, with a mean age of 65.6 years; all patients were women. Of the 320 patients, 183 (57.2%) were of menopausal age, 81 (25.3%) were perimenopausal, and 56 (17.5%) were premenopausal.
Patients with the luminal subtype “A” accounted for 134 (41.9±2.75)%, and those with the luminal subtype “B” accounted for 186 (58.1±2.75)%. Her2neu - 1+ was observed in 128 (40%) patients, and Her2neu – 0 in 192 (60%) patients. For patients with the luminal subtype “A”, 55 had Her2neu - 1+ and 79 had Her2neu – 0; for the luminal subtype “B”, 73 had Her2neu - 1+ and 113 had Her2neu – 0.
DNA extraction was performed using the GeneJET FFPE DNA Purification Kit from paraffin blocks. Amplification and detection of results were conducted using the PIK3CA Mutation Analysis Kit for Real-Time PCR (Entrogen), which includes the mutation spectra E542K, E545K, E545Q, H1047R, and H1047L.
Results: Among the 320 patients, 75 (23.4%) had various mutations in the PIK3CA gene, which is somewhat lower than global data. For example, according to cBioPortal, the mutation frequency of PIK3CA in breast cancer is 37% (1888/5129). The three most frequent missense mutations in the PIK3CA gene were p.H1047R - 36 (48%), mutation p.E542K - 22 (29.3%), and mutation p.E545K - 15 (20%). Another mutation, p.H1047L, was found in 2 (2.7%) cases, while the p.E545Q mutation was not detected in our sample.
PIK3CA mutations in the luminal subtype “A” were found in 33 (44%) cases, with Her2neu - 1+ status identified in 14 (42.4%) cases and Her2neu - 0 in 19 (57.6%) cases. In the luminal subtype “B” (n=42), Her2neu - 1+ was found in 18 (42.9%) cases, and Her2neu - 0 in 24 (57.1%) cases.
PIK3CA mutations were more frequently found in women of perimenopausal age - 43 (57.3%) cases, and in menopausal age - 32 (42.7%) cases. Among Kazakh nationality patients (179 in total), 35 (19.6±2.96%) were found to have the PIK3CA mutation.
Conclusions: The prevalence of PIK3CA mutations in the Kazakh population sample (n=320) was 23.4%, and the spectrum of PIK3CA mutations generally aligns with data from large international studies. PIK3CA mutations were somewhat more frequently found in patients of menopausal age (57.2%±2.76%), as well as in patients with the luminal subtype “B” Her2neu – 0. Among Kazakh women, the frequency of PIK3CA mutations was lower at 35 (19.6±2.96%) compared to women of other nationalities (28.4%).

P1-05-07: Expression of ATP6AP2 in clinical breast cancer and the prognostic and therapeutic value in ERBB2 subtype of breast cancer

Jia Tong, Amber X Li, Fiona Ruge, Tracey A Martin, Kefah Mokbel, Eleri Davies, Bo Dong, Wen G. Jiang

Background: ATP6AP2 (ATPase H+ Transporting Accessory Protein 2), also known as the Renin/Prorenin receptor (RR), is a crucial protein associated with ATPases, playing a vital role in cellular intracellular pH homeostasis, energy conservation, protein degradation, and intracellular signalling. While its functions in non-cancer cells are becoming clearer, its involvement in cancer remains poorly understood. This study aims to assess the expression of ATP6AP2 in human breast cancer, examining its clinical implications and potential therapeutic value, with a focus on hormone receptor status and molecular subtypes.
Materials and Methods: We evaluated ATP6AP2 transcript expression using quantitative transcript analysis and assessed protein expression via immunohistochemistry. Expression levels were correlated with clinical and pathological parameters, hormone receptor status, molecular subtypes, and patient outcomes. Additionally, we investigated the association between ATP6AP2 expression and patient response to targeted therapies.
Results: Breast cancer tissues exhibited significantly elevated ATP6AP2 levels compared to normal mammary tissues (p=0.0024). High ATP6AP2 expression was observed in ER-positive and ERBB2-positive tumours. Patients with high ATP6AP2 levels had significantly shorter overall survival (OS) (p=0.039, hazard ratio: 3.75, 95% CI: 1.09-12.9) and marginally shorter disease-free survival (DFS) (p=0.087). Notably, among ERBB2-negative patients, high ATP6AP2 expression was associated with significantly shorter OS (p=0.022), which was not observed in ERBB2-positive patients. No significant difference was detected between triple-negative breast cancer (TNBC) and non-TNBC patients. Furthermore, high ATP6AP2 expression in breast cancer correlated with resistance to anti-ERBB2 treatment (p=0.0086).
Conclusion: ATP6AP2 is aberrantly expressed in breast cancer tissues and is associated with poor survival outcomes, particularly in ERBB2-negative tumours. Its expression pattern also correlates with response to anti-ERBB2 treatment, suggesting its potential as a predictive biomarker in breast cancer therapy.

P1-05-08: Germline Mutations in Early Triple-Negative Breast Cancer Brazilian Patients

Giulia Zanetta, Giulia K. Zanetta, Izabela P. Ferreira, Hendrio R. Santiago, Flavia C. Balint, Monique C. Tavares, Luciana M. Leite, Felicia P. Cavalher, Solange M. Sanches, Vladmir C. C. Lima, Marcelle G. Cesca

Background: Triple-negative breast cancer (TNBC) is pathologically defined by the absence of hormonal receptors and HER2 expression. This subtype accounts for approximately 20% of all breast cancers and is known for its worse prognosis. The literature demonstrates a high association of TNBC with germline mutations in BRCA1 and other genes. With the

development of targeted therapies, this information impacts the therapeutic decision for these patients.
Methods: Retrospective, single-institutional, descriptive study, which recruited consecutive patients submitted to neoadjuvant chemotherapy for early TNBC between 2010 and 2023. Data was retrieved from medical records. The primary objective was to describe germline hereditary breast and ovarian cancer (HBOC) test results in this population.
Results: 394 TNBC patients were included. The median age was 44, and most were premenopausal women (64%). Two hundred sixty-two patients (66.5%) had a positive family history of cancer, and 242 (61.4%) underwent a germline HBOC test. A germline mutation was present in 128 patients (52.9% of the tests): 24.4% of tested patients (15% of all patients) had variants of uncertain significance (VUS) and 31% of pathogenic mutations (19% of all patients). The most prevalent VUS were in BRCA2 (N=9; 3.7%), ATM (N=8; 3.3%), BRCA1 (N=6 2.5%), and mismatch-repair genes (N=9; 3.7%). The pathogenic mutations prevailed in BRCA1 (N=45; 18.6%), BRCA2 (N=9; 3.7%), and RAD15C (N=6; 2.5%). Together, germline pathogenic mutations in BRCANESS genes were present in 68 patients (28.1% of all tests). Two patients had co-pathogenic mutations in CHEK2 and TP53. Considering the tested cohort, 21.1% of > 60-year-old patients and 27.8% of patients without a family history of cancer presented pathogenic germline mutations.
Conclusion: The high prevalence of pathogenic mutations in this cohort highlights the importance of germline tests and genetic counseling for TNBC patients, despite age or family history criteria.

P1-05-09: High prevalence of germline BRCA1/2 pathogenic variants in TNBC patients who achieve pCR: results from the TRINITY study.

Emmanouil Saloustros, Christos Christodoulou, Flora Zagouri, Ippokratis Korantzis, Ioannis Boukovinas, Anna Koumarianou, Angelos Koutras, Eleni Timotheadou, Giannis Mountzios, Loukas Kontovinis, Ioannis Binas, Alkistis Papatheodoridi, Eleni Zairi, Athanasios Kotsakis, Charalampos Athanasopoulos, Konstantinos Papazisis

Background: Several reports indicate that over 15% of triple negative breast cancer (TNBC) patients harbor germline BRCA1/2 pathogenic variants (PV). BRCA-associated cancers have distinct characteristics that may result in higher pathologic complete response (pCR) rates after neoadjuvant chemotherapy (NACT). We hypothesized that the population of TNBC patients who achieve pCR may be enriched with germline BRCA1/2 PV.
Methods: TRINITY is a retrospective, multicenter study, that enrolled patients with stage II–III TNBC who underwent surgery in Greece between 2016 and 2022. In this report we focused in the patient who received NACT and underwent BRCA1/2 germline genetic testing. We evaluate the prevalence of germline BRCA1/2 PV in the patients who achieved pCR and those with residual disease after NACT.
Results: Of the 230 enrolled patients in the study (10 centers), 113 (49.1%) received NACT. Median age was 52 years (range: 30.2-82.1). Of the patients with available data on family history, 45 (39.8%) reported breast cancer and 19 (16.8%) ovarian cancer family history.

Out of 113 patients, 61 patients had pCR and 52 incomplete response to NACT. BRCA1/2 data were available for 72 patients (63,7%): 45 and 27 patients from the pCR and residual disease group respectively.
More than half of the patients of the pCR group, 25 out of 45 (55.5%), had germline BRCA1/2 PV: 21 in the BRCA1 and 4 in the BRCA2. The prevalence of the PV in the patients with residual disease was 18,5% (5/27): 4 in the BRCA1 and 1 in the BRCA2. The age at diagnosis and the percentage of patients with family history didn't differ significantly in the two groups.
Conclusion: according to our study, the patients with TNBC that achieved pCR after NACT seems to have a high prevalence of germline BRCA1/2 PV. Genetic counseling and testing should be strongly recommended for these patients, despite the fact that they are not eligible for targeted adjuvant therapy.

P1-05-10: Investigating the Potential Role of Rare Germline Non-Coding Variants in Cancer Predisposition Genes in Patients with Triple-Negative Breast

Michela Palleschi, Alessandra Virga, Emanuela Scarpi, Eugenio Fonzi, Filippo Merloni, Samanta Sarti, Rita Danesi, Mila Ravegnani, Chiara Casadei, Marianna Sirico, Caterina Gianni, Roberta Maltoni, Sara Bravaccini, Daniele Calistri, Valentina Arcangeli, Valentina Zampiga, Ilaria Cangini, Erika Bandini, Francesca Mannozzi, Fabio Falcini, Ugo De Giorgi, Paola Ulivi, Gianluca Tedaldi

Current genetic screening for breast cancer predisposition is limited to the analysis of coding regions (exons) and intron/exon boundaries of BRCA1/2 genes. There is limited data on the prevalence and clinical significance of variants in the non-coding regions of these genes. Consequently, the majority of variants identified in these regions remain unclassified, and approximately 80% of germline BRCA1/2 tests are not considered in the daily management of patients with triple-negative breast cancer (TNBC).
Emerging evidence suggests that non-coding variants can impact cancer risk and response to treatment. This study aimed to investigate the prevalence of variants in the non-coding regulatory regions of BRCA1/2 and other breast cancer predisposition genes in TNBC patients selected based on age at cancer diagnosis and/or family history of cancer. Additionally, we sought to explore the functional role of identified variants of uncertain significance (VUS) through ongoing analyses.
We enrolled 144 TNBC patients who had previously tested negative for germline variants in the coding regions of BRCA1/2 and other cancer predisposition genes. Next-generation sequencing (NGS) analysis identified 635 rare variants in the non-coding regions of 28 selected genes involved in breast/ovarian cancer predisposition. In our TNBC cohort, we observed a higher prevalence of rare variants in the genes CDH1 (1.3%), STK11 (11.2%), ATM (10.7%), PTEN (7.40%), and PMS2 (5.04%).
Germline variants in BRCA2 were statistically significantly associated with worse overall survival (p-value=0.017). CDH1 rare variants were associated with the highest percentage

of non-pathologic complete response after neoadjuvant chemotherapy (p=0.0273). MLH1 and PALB2 rare variants were both associated with bilateral breast cancer (p=0.015 and p=0.0005, respectively). Rare variants of the ATM gene were associated with a positive family history (p=0.041).
Preliminary single nucleotide variant (SNV) data analysis showed that the most significant functional score for alterations were detected in the promoter of MSH6, potentially associated with chromatin effects. Further analyses are ongoing to elucidate the functional impact of these variants.
Due to the small sample size, these analyses should be considered exploratory, and larger studies are needed to confirm these findings and establish the clinical utility of screening for non-coding variants in TNBC patients.

P1-05-11: The timing of BRCA1/2 germline testing and patient's decision toward the risk-reducing mastectomy in breast cancer

Eunhye Kang, Hyerim Kang, Changhoon Lee, Min Jung Lee, Jinyoung Byeon, Ji-Jung Jung, Hong Kyu Kim, Han-Byoel Lee, Wonshik Han, Hyeong-Gon Moon

Background: BRCA1 and BRCA2 pathogenic variants significantly increase the risk of breast cancer. Risk-reducing mastectomy (RRM) is an option for these patients, offering substantial risk reduction. However, the decision to undergo RRM is complex and influenced by various factors. This study aims to analyze factors influencing RRM decisions in BRCA mutation carriers, with a particular focus on how the timing of BRCA testing affects the choice to undergo RRM.
Methods: We conducted a retrospective analysis of 499 breast cancer patients diagnosed with germline BRCA1/2 pathogenic variants at Seoul National University Hospital between 2005 and 2023. Exclusion criteria included patients with distant metastasis at the time of BRCA testing, those who underwent palliative surgery at initial diagnosis, patients who had already undergone contralateral total mastectomy at the time of BRCA testing, and those initially diagnosed with bilateral breast cancer.
Result: Of the 499 patients, 172 (34.4%) underwent RRM. Among the 262 patients who underwent BRCA testing before their initial breast cancer surgeries, 197 patients were aware of their BRCA mutation status prior to surgery, while for 65 patients, their BRCA test results became available after surgery. RRM rates were significantly higher in patients who knew their BRCA status before surgery compared to those whose results became available after surgery. (65.0% vs. 18.5%, p <0.001). Moreover, only 13.5% of patients who underwent BRCA testing after primary surgery subsequently underwent RRM.
In the subset of 68 patients diagnosed with contralateral breast cancer (CBC) during follow-up, RRM rates were higher among those aware of their BRCA status before surgery for CBC compared to those who learned results post-operatively (32.4%vs. 11.7%, p = 0.079). However, this difference was not statistically significant.
The results of the multivariate analysis showed that the timing of BRCA genetic testing emerged as a significant factor influencing the decision for RRM. Patients who underwent

testing before their initial surgery were 10.1 times more likely to undergo RRM compared to those tested after surgery (95% CI: 6.09-17.20). Additionally, BRCA1 mutation carriers were found to be 1.8 times more likely to undergo RRM than BRCA2 carriers (95% CI: 1.12-2.88). Additionally, patients who received neoadjuvant chemotherapy were 1.8 times more likely to undergo RRM compared to those who did not (95% CI: 1.07-2.84). In contrast, other factors including age at diagnosis, sex, family history of breast or ovarian cancer, personal history of ovarian cancer, and presence of bilateral breast cancer were not significantly associated with the decision to undergo RRM.
Conclusion: The timing of BRCA testing significantly influences decisions on risk-reducing mastectomy (RRM). This finding underscores the importance of considering genetic testing timing in breast cancer management. Clinicians should take this into account when planning BRCA testing to optimize patient decision-making regarding risk-reduction strategies.

P1-05-12: The 70-Gene Signature Assay vs. Traditional Clinical Risk Assessment: Impact on Adjuvant Chemotherapy Choices in Mexican Breast Cancer Patients

Diego Ontiveros Ramírez, Brizio Moreno Jaime, José Luis González Trujillo, Carlos Alberto Ramírez Alvarado, Paulina Martínez Valadez, Mario Alberto Ramírez González

Introduction: Breast cancer is the most frequent malignant neoplasm in mexican women; it is a complex disease with diverse clinical outcomes and multiple responses to treatment (1). Adjuvant systemic treatment decreases the risk of developing distant metastasis and death by approximately 30% in patients with node-negative breast cancer, but 70% of all patients on adjuvant therapy will experience toxicity without benefit from such treatment (2,3). Tools including St Gallen, NIH guidelines, risk calculators (PREDICT) or indexes such as the Nottingham Prediction Index are currently used as tools for administer adjuvant chemotherapy, although in certain populations the need for this therapy tends to be overestimated (5,6). The 70-Gene Signature Assay has shown a significant correlation with patient outcome. This tool was subsequently validated in several groups of patients in European countries and was approved by the Food and Drug Administration of the United States (7,8). Currently there is no study in mexican breast cancer patients, therefore, our study is the first on the signature of 70 genes in Mexico.
The 70-Gene Signature Assay was evaluated in Mexican breast cancer patients. An association was assessed between the 70-Gene Signature Assay with clinicopathological characteristics in these patients.
Methods: Forty eligible patients with breast cancer who underwent a 70-Gene Signature Assay test and had the result in their medical record were included. Data collection was performed from the clinical archive of the Hospital Angeles Leon, in the period from November 2012 to March 2023. The following criteria were considered: patients diagnosed with clinical stage I-II breast cancer, node-negative and had not received neoadjuvant therapy. Patients whose results were pending at the time of the study or those with a previous malignant neoplasm were not included. The concordance between the risk

predicted by the 70-Gene Signature Assay and commonly used clinicopathological guidelines (St. Gallen guidelines, National Institutes of Health [NIH] guidelines, the Nottingham Prognostic Index and the PREDICT tool) were assessed.

According to the St. Gallen guidelines, low clinical risk is defined as the sum of all the following criteria: estrogen receptor positive and/or progesterone receptor positive, a tumor size of 2 cm or less, a histologic grade 1, and an age of 35 years or older (9). The National Institutes of Health (NIH) guideline recommends that the low-risk group in the node-negative group have a tumor size of less than 1 cm and a favorable histologic subtype such as tubular and mucinous cancer (10,11).

The Nottingham Prognostic Index (NPI) is a prognostic measure that predicts operable survival of primary breast cancer. The NPI value is calculated based on tumor size, number of lymph nodes and tumor grade (11), The PREDICT program algorithm was developed from data of the East Anglia Cancer Registry and Information Centre (ECRIC) on patients with primary breast cancer treated in 1999-2003 and provides 5- and 10-year survival estimates with and without adjuvant systemic therapy (hormonal therapy, chemotherapy and trastuzumab) (13). The clinical low-risk group for this calculation was defined as patients with 10-year overall survival probabilities of at least 88% in ER-positive tumors and at least 92% if ER expression was observed in ER-negative tumors (13).

Statistical analysis was performed with SPSS version 15.0 (SPSS Inc., Chicago, USA). The p value was bilateral. Differences between the groups of interest were tested with Pearson's $\chi 2$ test or Fisher's exact test. A p value < 0.05 was considered statistically significant.

Results: Of the 44 eligible patients, 4 were excluded because of sampling failure (n = 4). A prognostic signature report was obtained for the remaining 40 patients. Twenty-five (62.5%) patients had a low-risk prognostic signature, and 15 (37.5%) patients had a high-risk prognostic signature. The mean age of eligible patients was 54.28 years ± 11.33 and the mean tumor diameter was 1.7 cm ± 0.9 cm. No significant differences in age, tumor size, histological grade, estrogen, or progesterone status were observed between the low-risk and high-risk groups according to the 70-Gene Signature Assay. Only histologic type was significantly different between groups p = 0.000. The mean tumor diameter was 1.80 cm (range, 0.9-4 cm) in the high-risk group and 1.64 cm (range, 0.2-3 cm) in the low-risk group (Table 1).

According to the St. Gallen criteria, 38 of 40 (95%) patients were at high risk, according to the NIH guideline, 34 of 40 (85%) patients were at high risk, according to PREDICT, 28 of 40 (70%) patients were at high risk and for the NPI, 16 of 40 (37.5%) patients were at high risk. (Table 2).

Discussion: The 70-Gene Signature Assay has been considered a powerful tool to predict metastasis or the outcome for breast cancer patients. Our analysis shows a notably proportion in the low-risk group (62.5% of the low-risk group, 37.5% of the high-risk group), these results differ from those reported in Korea, Japan and European populations for the low- risk group (13.9%, 20% and 19.6% respectively) and high-risk groups (86.1%, 80%, 80.4% respectively)(14). There were not statistically differences between age, tumor size, histological grade, estrogen, or progesterone receptors. Only the histological type was different between low and high-risk groups.

The clinical utility of the 70-Gene Signature Assay depends on its potential value in addition to using traditional prognostic factors. Therefore, we compared the signature's risk assessment to the clinicopathological risk assessment using the St. Gallen criteria, the NIH guidelines, PREDICT and Nottingham Prognostic Index. Overall, as compared with that of the clinicopathological risk guidelines, about two thirds of the patients were discordant with the 70-Gene Signature Assay. (Discordance of 67.5% compared to the St. Gallen criteria, 57.5% compared to the NIH guideline, 45% compared to PREDICT and 57.5% compared to the NPI). In a previous study, the discordant rate between the 70-Gene Signature Assay and other clinicopathological guidelines was 28.3-39% (15, 16). A discordant rate is not frequently mentioned in many of the earlier validation studies. However, a comparison between the 70-Gene Signature Assay and the clinicopathological guidelines suggests that this signature is a stronger predictor of disease outcome than the currently used clinicopathological guidelines (14).

As a result, these discordant rates imply that using this signature could lead to a significant reduction in the number of patients recommended for chemotherapy. Our findings show similar incidence in the low-risk group compared with European studies, this could implicate a cost and unnecessary cytotoxic treatment indicate in patient where classical clinicopathological risk assessment tools tend to overestimate the high-risk patients in Mexican population.

The limitations of this study were first the sample size, second there is not a follow-up evaluation to determine those patients who remains disease-free at 5 to 10 years. Further large-scale studies with a follow-up evaluation are required to assess whether the use of the 70-Gene Signature Assay can predict a prognosis for Mexican patients with breast cancer.

Conclusion: Our study is the first to evaluate the 70-Gene Signature Assay in Mexican breast cancer patients. The results show a higher proportion of patients classified as low-risk compared to traditional clinicopathological guidelines, which often overestimate the need for chemotherapy. The discordance rates suggest that the 70-Gene Signature Assay may offer more accurate risk assessment, potentially reducing unnecessary treatments. Although limited by sample size and lack of follow-up, these findings emphasize the value of integrating genomic tools with conventional methods to enhance personalized treatment. Future large-scale studies with follow-up are needed to confirm these results and fully establish the clinical utility of the 70-Gene Signature Assay in Mexican patients.

P1-05-13: Rates of Adherence to NCCN Breast Cancer Screening Recommendations among Unaffected Women with a Hereditary Breast Cancer Predispositionosition

Kathleen Vitale, Jandiss Vayansky, Sondra Swain, Emily Calahan, Rachelle Huziak, Melissa Bourdius, Trinity Sprague, Jewel Wasson, Maria Rhine, Darcy Thull, Phuong L. Mai

Background: Hereditary predisposition accounts for approximately 5-10% of all breast cancer cases. It is clinically important to identify individuals with a hereditary breast cancer predisposition early in order for appropriate cancer risk management to be implemented. Although cancer screening guidelines exist for the high- and moderate-penetrance breast cancer predisposition genes, limited data are available on the breast cancer screening adherence rates among these women. Here we describe our experience among unaffected women with a hereditary breast cancer predisposition who were seen in a breast cancer screening and prevention program.
Methods: Our cohort included patients with a pathogenic variant (PV) in a breast cancer predisposition gene who were seen in the Magee-Womens Breast Cancer Risk Assessment and Prevention Program for consultation regarding cancer risk management at least once between January 1, 2017 and December 31, 2022. We conducted a retrospective medical chart review to collect data on risk reducing mastectomy, screening adherence, and breast cancer diagnosis. Patients who had a breast cancer diagnosis prior to genetic testing being performed were excluded. Patients not pursuing risk reducing mastectomy were recommended to follow screening guidelines as suggested by the National Comprehensive Cancer Network (NCCN). Breast cancer screening was not recommended after risk reducing mastectomy. We evaluated adherence to the recommended breast cancer screening recommendation over the past 18 months (between January 1, 2023 to June 30, 2024). Numbers of screen-detected and interval breast cancer diagnoses were described.
Results: A total of 336 patients were identified, of whom 36 were excluded due to insufficient EHR data to determine screening adherence. Of the remaining 300 patients, age at initial encounter ranged from 19 to 65 years. The majority of patients had a PV in BRCA2 (109, 36.3%) and BRCA1 (85, 28.3%), the remaining genes include ATM (32, 10.7%), CHEK2 (31, 10.3%), PALB2 (23, 7.7%), TP53 (5, 1.7%), CDH1 (4, 1.3%), BARD1 (3, 1.0%), RAD51C (2, 0.7%), and RAD51D (1, 0.3%). Sixty-one patients underwent risk reducing mastectomy (age range 21-63 years) with 5 breast cancers diagnosed at the time of surgery (3 with a BRCA2 PV, 1 with a BRCA1 PV, 1 with a CDH1 PV). Sixteen patients had a screen-detected breast cancer (5 with BRCA1, 5 with BRCA2, 3 with ATM, 1 each with CDH1, CHEK2 and RAD51C). There were two interval cancers (both BRCA1). Screening adherence was evaluated for the remaining patients over an 18-month period from January 2023 to June 2024. MRI was not recommended for individuals who were pregnant/breast feeding, were at a weight incompatible with MRI, or have metal implants. Mammogram was not recommended for individuals who were pregnant, or were younger than the age at which mammogram should be started. Annual MRI was recommended for 208 and annual mammogram was recommended for 190, 183 were recommended to have both MRI and mammogram. 149 of the 208 (72%) patients for whom MRI was recommended had it done within the past 18 months, while 162 of the 190 (85%) patients had mammogram as recommended. Of the 59 patients who did not have MRI, 35 (59.3%) were up-to-date with mammogram.
Conclusion: In this population of patients with a hereditary predisposition to breast cancer, the majority of patients have adhered to breast cancer screening recommendations in the past 18 months. Rates of adherence to screening were high, and was higher for

mammogram than MRI. Coordinated high risk management provided in an established cancer screening clinic is effective in promoting adherence to cancer surveillance.

P1-05-14: OnTarget crofelemer diarrhea prophylaxis trial: responder analysis of patients with breast cancer receiving targeted therapy with or without chemotherapy

Pablo C. Okhuysen, Eric Roeland, Lee Schwartzberg, Hope Rugo, Enoch Bortey, James Bolognese, Stacey Tinianov, Kelly Shanahan, Pravin Chaturvedi

Background: Cancer therapy-related diarrhea (CTD) is a common adverse effect of targeted therapies (e.g., TKIs, CDK4/6 inhibitors), resulting in treatment modifications and poor clinical outcomes. Crofelemer is a chloride ion channel modulator of cystic fibrosis transmembrane conductance regulator. It is FDA-approved for HIV-associated diarrhea based on a responder analysis of the proportion of patients with improved diarrhea. Here, we present the prespecified responder analysis of the OnTarget study (NCT04538625) in the breast cancer subgroup receiving targeted therapies.
Methods: OnTarget was a randomized, multicenter, double-blind, placebo-controlled prophylactic trial evaluating crofelemer versus placebo in adults with solid tumors receiving targeted therapies. Patients were randomized to 125 mg of crofelemer twice daily or placebo for 12 weeks to prevent CTD. Diarrhea outcomes were captured using patient-reported outcomes (PROs). Key exclusions included immunotherapy, neratinib, irinotecan, colitis/ostomy/abdominal surgery ≤3 months, and any antidiarrheal or antibiotic use ≤7 days. The primary outcome was the mean weekly number of loose/watery stools (LWS) over 12 weeks. Secondary endpoints included the Patient Global Impression of Severity (PGIS) for gastrointestinal symptoms, and time to onset of durable response. Subgroup analyses for tumor types and targeted therapies were prespecified; anchor-based methods using PGIS determined optimal thresholds for the average number of weekly LWS for responders. The optimal cut-off values of the mean LWS per week to define responders were derived via receiver operating characteristics (ROC) curve analyses of PGIS anchors. Further, monthly responders met the cutoff for mean weekly LWS for at least 2 of 4 weeks per month. Since the time to onset of responder status does not address sustainable effects, continuous efficacy over the entire 3-month period was assessed per ordered categories (none, 1/3, 2/3, or 3/3 months) via ordered logistic regression. We analyzed the onset and sustained effect of treatment using response patterns that prioritized an early and durable response for each month. The patterns of the number of responding months were ranked from 0-8, with a rank of 8 designating a full responder for all 3-months. All p values are 1-sided.
Results: The OnTarget study enrolled 287 adults with 10 solid tumor types and 24 unique targeted therapies. The prespecified primary endpoint of the mean weekly LWS over 12 weeks was not met. Adverse events were similar in both arms. A total of 184 (64.1%) patients with breast cancer participated; median age 57 yrs [IQR: 48-65 yrs], 16.5% non-White); 96 (54.6%) received abemaciclib, 67 (38.1%) pertuzumab/trastuzumab, and 13

(7.4%) kinase inhibitors. PRO data was available for 176 patients with breast cancer. ROC analysis showed that weekly responders have ≤9 LWS/week in each week. Continuous responder efficacy analysis in patients with breast cancer having ≤9 LWS/week showed significant improvement with crofelemer over placebo (OR 1.77 [CI: 1.01-3.12]; p=0.0245). Patients with an ECOG performance status of 0-1 (n=170) showed improved response with crofelemer compared to placebo (OR 1.99 [95% CI: 1.11-3.56]; p=0.0104). Additionally, more patients with breast cancer receiving crofelemer (41/87; 47.1%) were responders for all 3 months compared to placebo (30/89; 33.7%) (OR 2.14 [95% CI: 1.10-4.14]; p=0.0123). Crofelemer had significantly faster onset and sustained efficacy compared to placebo (OR 1.80 [95% CI: 1.02-3.16]; p=0.021), including patients with ECOG status of 0-1 (n=170, OR 2.00 [95% CI: 1.12-3.56]; p=0.0095).
Conclusion: In this responder analysis of patients with breast cancer on targeted therapies, crofelemer CTD prophylaxis resulted in a greater proportion of monthly responders of diarrhea improvement compared to placebo, with better-sustained response in those with preserved functional status (ECOG 0-1).

P1-05-15: A real-world analysis of cancer prevention measures among individuals with hereditary breast and ovarian cancer (HBOC) syndromes and no personal history of malignancy.

Abby Hadley, Grayson Buning, Nicholas C. Henderson, Kara J. Milliron, Bailey B. Hulswit, Lauren E. Hipp, Versha A. Pleasant, James M. Rae, Melissa L. Pilewskie, Daniel F. Hayes, N. Lynn Henry, Sofia D. Merajver, Erin F. Cobain

Background: Strategies exist to decrease cancer incidence among individuals with HBOC syndromes. These include: 1) surgeries such as risk-reducing mastectomy (RRM) and risk reducing bilateral salpingo-oophorectomy (RRBSO) and 2) risk-reducing medications with selective estrogen receptor modulators (SERM) or aromatase inhibitors (AI). RRM decreases the incidence of breast cancer by >90%. RRBSO decreases ovarian cancer risk by >80%, may decrease breast cancer risk, and decreases mortality in individuals with BRCA1 and BRCA2 mutations. Use of 5 years of SERM or AI reduces risk of future breast cancer by 40-50% in individuals at high risk, but data regarding efficacy in individuals with HBOC syndromes are limited. To date, few studies have explored cancer risk reducing treatment decisions among individuals with hereditary cancer susceptibility without personal history of malignancy.
Methods: Individuals evaluated in the Breast and Ovarian Cancer Risk Evaluation Clinic (BOCREC) at the University of Michigan Rogel Cancer Center with pathogenic germline variants (PGVs) conferring increased cancer risk without personal history of breast, ovarian, pancreatic, or prostate cancer from 1/1/2012 to 1/1/2022 were eligible for analysis. Basic demographic information (age, sex, and race/ethnicity), pursuit of cancer risk reduction measures, and subsequent cancer diagnoses were recorded. A chi-squared test was used to compare rates of RRM among carriers of high penetrance versus moderate penetrance breast cancer susceptibility genes.

Results: 402 individuals were included in this analysis. The majority were female (80%) and white (91%; Not listed 5%; Asian 3%; Black 1%). The most common PGVs identified were in BRCA1 (32%, n=134) and BRCA2 (32%, n=133), followed by CHEK2 (16%, n=66), ATM (7%, n=30), PALB2 (4%, n=18), BRIP1 (3%, n=14), RAD51C/RAD51D (2%, n=8), Lynch Syndrome associated PGVs (1.2%, n=5), CDH1 (0.5%, n=2), TP53 (0.5%, n=2), CDKN2A (0.2%, n=1), and PTEN (0.2%, n=1). Of the 295 individuals eligible for RRM (female, PGV in breast cancer susceptibility gene), 108 (37%) underwent RRM. Of those who had a RRM, the average time to surgery following PGV diagnosis was 21 months (range 0.5-97 months). RRM was most common in the 40-49 age group (31%, n=35), closely followed by the 30-39 age group (30%, n=34). Only 13% of individuals had a RRM below age 30 (n=15) and 9% of RRMs occurred in individuals aged 60 or older (n=10). Likelihood of undergoing RRM was significantly greater for individuals with a highly penetrant breast cancer PGV (42% for BRCA1, BRCA2, PALB2, PTEN, TP53, CDH1) versus a moderately penetrant breast cancer PGV (21% for CHEK2, ATM, RAD51C/D) ($p = 0.002$). Among 116 individuals eligible for RRBSO (female, PGV in ovarian cancer susceptibility gene) 86% underwent RRBSO within the timeframe recommended. Of the 178 patients eligible for breast cancer risk-reducing medication (breast cancer PGV, female, age ≥ 35, no RRM), 80% (n=142) had a documented discussion regarding risks and benefits of SERM or AI at time of PGV diagnosis and 7 patients (3.9%, BRCA1 n=2, BRCA2 n=2, CHEK2 n=3) initiated therapy. Of the 402 patients analyzed, 41 (11%) were subsequently diagnosed with cancer during the follow up period, 51% (n=21) of which were breast cancer. Of those diagnosed with breast cancer, 57% were carcinoma in situ and 24% were stage I.
Conclusions: In this cohort, nearly 40% of unaffected females with hereditary breast cancer risk opted to undergo RRM. Approximately 1 in 5 individuals with moderate penetrance breast cancer PGVs opted for RRM despite insufficient evidence of benefit. Compliance with RRBSO among those with hereditary ovarian cancer risk was high. Uptake of risk-reducing medication (SERM or AI) was exceptionally low despite its potential to significantly decrease breast cancer risk. Additional research regarding efficacy of risk-reducing medication in those with hereditary breast cancer predisposition is needed.

P1-05-16: Differential ctDNA-based genomic features of Triple-Negative Metastatic Lobular Breast carcinoma: insights into a rare and poorly understood disease

Lorenzo Gerratana,Andrew A. Davis, Lorenzo Foffano, Carolina Reduzzi, Emily Podany, Arielle J. Medford, Marko Velimirovic, Katherine Clifton, Annika Putur, Laura Munoz-Arcos, Letizia Pontolillo, Rachel O Abelman, Caterina Gianni, Shaili Tapiavala, Elisabetta Molteni, Marla D Lipsyc-Sharf, Eleonora Nicolò, Eleni Andreopoulou, William J Gradishar, Fabio Puglisi, Cynthia X. Ma, Aditya Bardia, Massimo Cristofanilli

Background: Invasive lobular carcinoma (ILC) comprises 10-15% of all breast cancers (BC), predominantly presenting as low grade and hormone receptor positive (HRpos). Triple-negative ILC (TN-ILC) is rare, accounting for approximately 2% of all triple-negative BC

(TNBC) and 0.1% of all BC. Due to its rarity, TN-ILC is poorly understood and lacks well-established treatment standards. This study aims to investigate the genomic characteristics of TN-ILC through circulating tumor DNA (ctDNA) profiling within a large multi-center consortium.
Methods: The study analyzed a retrospective cohort of 750 patients (pts) with HER2 negative metastatic BC with ctDNA testing using the Guardant360 NGS panel within a large multicenter academic consortium. HR and HER2 status were defined based on the most recent biopsy. Associations across single nucleotide and copy number variations (SNVs and CNVs), histology, and HR status were tested by multinomial logistic regression in terms of Relative Risk Ratio (RRR), adjusting for significant clinical characteristics (i.e., lines of treatment, metastatic sites). Oncogenic pathway analysis was defined based on Sanchez-Vega F et al, Cell. 2018. Prognosis was analyzed for overall survival (OS) defined from the time of ctDNA collection.
Results: Among the 750 pts analyzed, the cohort consisted of TN-ILC (N:16, 2%), HRpos-ILC (N:91, 12%), TN-invasive ductal carcinoma (IDC) (N:186, 25%), and HRpos-IDC (N:457, 61%). In TN-ILC, the most frequently altered genes were PIK3CA (50%), TP53 (44%), ERBB2 (25%), and CDH1 (25%). Less frequent alterations included BRAF, ALK, ARID1A, MET, RB1, and SMAD4, each occurring in 12-19% of cases. PIK3CA (48%) and TP53 (39%) had a similar alteration frequency in HRpos-ILC, and ESR1alterations were also common (36%). Multivariable multinomial logistic regression, designed with TN-IDC as reference, investigated differences in oncogenic pathway alterations across histologies and subtypes. In TN-ILC, a significant association was observed for RAS SNVs (RRR = 7.9, p = 0.038) and PI3K SNVs (RRR = 4.32, P = 0.015). In HRpos-ILC, cell cycle CNVs (RRR = 0.3, P = 0.013) and P53 SNVs (RRR = 0.26, P < 0.001) had a significantly lower prevalence than in TN-IDC, while RAS SNVs (RRR = 4.94, P = 0.022) and PI3K SNVs (RRR = 2.6, P = 0.003) were more common. Single gene alterations were investigated across significantly altered pathways. PIK3CA SNVs were more common in TN-ILC (50%) compared to TN-IDC (16%), but similar in frequency to HRpos-ILC (42%) (P<0.001). PTEN SNVs were higher in HRpos-ILC (11%) than in TN-IDC and TN-ILC (respectively 0% and 6%). KRAS SNVs were more represented in HRpos- and TN-ILC (respectively 6% and 8%), with respect to TN-IDC (1%) (P= 0.017). TP53 SNVs were significantly more detected in TN-IDC (68%) than in HRpos and TN-ILC (respectively 44% and 35%, P<0.001). A similarly unfavorable outcome was observed for TN-ILC and TN-IDC (median OS 12 and 13 months, respectively), compared to their HRpos counterparts (median OS 31 and 33 months, respectively) (P<0.001).
Conclusions: Our study highlights distinct genomic features of triple-negative ILC detectable through ctDNA. These findings reinforce the need for improved understanding of TN-ILC to define personalized treatment options for this aggressive and rare subtype.

P1-05-17: Structural Variants Affecting CDH1 in Breast Invasive Lobular Carcinoma

Fresia Pareja, Arnaud Da Cruz Paula, Christopher J. Schwartz, Esra Dikoglu, Andrea M. Gazzo, Sophia Zelizer, Matteo Repetto, Dara S. Ross, Nadeem Riaz, Joshua Drago, Sarat

Chandarlapaty, Adrian Lee, Steffi Oesterreich, Hannah Y. Wen, Hong Zhang, Larry Norton, Edi Brogi, Britta Weigelt

Background: Invasive lobular carcinoma (ILC) is the most frequent special histologic subtype of breast cancer (BC). ILC displays a characteristic discohesive phenotype, caused by inactivation of CDH1 (E-cadherin) that plays key roles in cell-to-cell adhesion. CDH1 bi-allelic inactivation is due to loss-of-function CDH1 mutations associated with loss of heterozygosity of the wild-type allele (LOH) in most (~80%) cases. A subset of ILCs, however, lack CDH1 mutations despite displaying a lobular phenotype, and their molecular underpinning is yet to be determined. Here we sought to elucidate whether structural variants (SV) would be a mechanism of CDH1 genomic inactivation underpinning ILC.
Methods: We interrogated 4,376 primary and 5,105 metastatic BCs, previously subjected to clinical paired tumor/normal targeted sequencing using the FDA-approved MSK-IMPACT assay to identify BCs harboring SVs affecting CDH1. LOH was assessed using FACETS. The driver probability of fusion genes was examined using Oncofuse. A histopathologic examination of cases was conducted following the WHO criteria. Estrogen receptor (ER) and HER2 status were retrieved from medical records. E-cadherin expression was assessed by immunohistochemistry. Somatic genetic alterations of BCs harboring CDH1 SV were compared to those of ILCs with CDH1 loss-of-function mutations. Mutational signatures were inferred using SigMA in cases with ≥5 single nucleotide variants.
Results: We identified 21 BCs (6 primary and 15 metastatic BCs) harboring SVs in CDH1, encompassing out-of-frame fusion genes (n=6), out-of-frame intragenic deletions (n=5), in-frame intragenic deletions (n=5), out-of-frame duplications (n=4) and an out-of-frame intragenic inversion (n=1). The second CDH1 allele was affected in 71% (15/21) of cases in the form of LOH (n=12) or as somatic inactivating mutations (n=3). Three fusion genes (CDH1-RAD21, CDH1-TANGO6, CDH1-ZNF815P) were predicted to result in the loss of the cytoplasmic and/or transmembrane domains of E-cadherin, while the other three (SMPD3-CDH1 and two fusion genes affecting CDH1 and intergenic regions in chromosome 16 or 19) were predicted to lead to loss of CDH1 signal peptide, precursor and extracellular domains and the 5' regulatory region harboring the transcription start site. All 6 fusion genes were categorized as drivers by Oncofuse (median driver probability score=0.97; range, 0.84-0.99). Most BCs harboring CDH1 SVs exhibited a lobular phenotype (16/21; 76%), including pleomorphic ILC/ILC with pleomorphic features (n=8), classic ILC (n=6) and mixed ductal-lobular BCs (n=2), while 5/21 (24%) cases displayed a non-lobular histology. We observed loss of E-cadherin expression in 73% (11/15) of cases interrogated. Most BCs were of histologic grade 3/poorly differentiated (n=10) or grade 2/moderately differentiated (n=10). The majority were ER+/HER2- (12/20; 60%), followed by ER-/HER2- (6/20 (30%). Besides CDH1, the most frequently altered cancer genes in primary BCs harboring CDH1 SVs were PIK3CA and NSD3 (33%, each), while TP53 (40%), ESR1 (27%) and PIK3CA (20%) were the most frequently affected cancer genes in metastatic cases. Akin to ILCs with CDH1 mutations, most primary BCs with CDH1 SVs (66%) showed a dominant aging mutational signature, and most metastatic cases had a dominant aging (54%) or APOBEC (31%) mutational signature. We observed no differences in the repertoire of genetic alterations between primary and metastatic BCs harboring CDH1 SVs compared to primary

and metastatic ILCs harboring biallelic CDH1 mutations.
Conclusions: We demonstrate that CDH1 affecting SVs act as drivers of a subset of ILCs. Most of these SVs result in loss of E-cadherin protein expression and a lobular phenotype, akin to CDH1 mutations. ILCs harboring CDH1 SVs were enriched for aggressive histologic features and display a repertoire of genetic alterations resembling that of ILCs with CDH1 mutations. These findings support the notion that ILC is a convergent phenotype, driven by various molecular mechanisms that disrupt the cell-cell adhesion complex, including SVs affecting CDH1.

P1-05-18: Genomic Landscape in Advanced Breast Cancer Across Different Genomic Ancestries

Alejandro Rios Hoyo, Ethan Sokol, Jeffrey Ross, Maureen Pelletier, Neal Fischbach, Maryam Lustberg, Adriana Kahn

Background: The use of genomic profiling in advanced breast cancer (aBC) has recently increased, however, access disparities persist due to racial/ethnic inequities. This study evaluated aBC samples with comprehensive genomic profiling (CGP), stratified by HER2 and hormone receptor (HR) status, and examined genomic alterations across different genomic ancestries.
Methods: Hybrid-capture CGP targeting 324 genes was performed on advanced BC samples (FoundationOne®CDx). HER2 immunohistochemistry status was abstracted from pathology reports, and HER2 amplification status was obtained from CGP. Patients were classified according to genomic ancestry: African (AFR), South and East Asian (ASI), European (EUR), and Others (including Admixed American). Short variants (SV), copy number alterations (CNA), and rearrangements (RE) were extracted from CGP data.
Results:We analyzed 2083 aBC samples: HER2-positive (n=416), HR+HER2-negative (n=1140), and TNBC (n=527). Ancestry distribution was AFR (n=312), ASI (n=110), EUR (n=1447), and Others (n=214). In the HER2-positive subtype, the most frequent genomic alterations in the AFR group were SV in TP53 (75%), PIK3CA (39%), and ARID1A (8%); CNA in ERBB2 (96%), MYC (32%), and RAD21 (32%); and RE in CDK12 (5.6%). In the ASI group, the most frequent SV were in TP53 (79%), PIK3CA (62%), and ERBB2 (10%); CNA in ERBB2 (100%), RAD21 (34%), and MYC (31%); and RE in ATR (10%). In the EUR group, the most frequent SV were in TP53 (72%), PIK3CA (38%), and ARID1A (8%); CNA in ERBB2 (97%), RAD21 (29%), and MYC (22%); and RE in CDK12 (8%). In the Others group, the most frequent SV were in TP53 (64%), PIK3CA (45%), and ARID1A (11%); CNA in ERBB2 (98%), RAD21 (39%), and MYC (30%); and RE in BRCA1 (9%). In the HR+HER2-negative subtype, the most frequent genomic alterations in the AFR group were SV in PIK3CA (45%), TP53 (40%), and GATA3 (23%); CNA in RAD21 (26%), MYC (20%), and CCND1 (20%); and RE in NOTCH2 (5%). In the ASI group, the most frequent SV were in PIK3CA (56%), TP53 (40%), and ESR1 (20%); CNA in NSD3 (26%), FGFR1 (24%), and ZBF703 (24%); and RE in MAP2K4 (2%) and MYC (2%). In the EUR group, the most frequent SV were in PIK3CA (53%), TP53 (33%), and CDH1 (19%); CNA in CCND1 (23%), FGF19 (21%), and FGF3

(21%); and RE in NOTCH2 (1%). In the Others group, the most frequent SV were in PIK3CA (57%), TP53 (45%), and ESR1 (12%); CNA in RAD21 (23%), MYC (19%), and CCND1 (18%); and RE in NOTCH2 (3%). In the TNBC subtype, the most frequent genomic alterations in the AFR group were SV in TP53 (95%), PIK3CA (15%), and RB1 (11%); CNA in RAD21 (35%), MYC (35%), and MCL (15%); and RE in RB1 (5%) and SPEN (4%). In the ASI group, the most frequent SV were in TP53 (88%), PIK3CA (15%), and RB1 (15%); CNA in MYC (15%), NSD3 (12%), and FGFR1 (12%); and RE in RB1 (4%) and SPEN (4%). In the EUR group, the most frequent SV were in TP53 (90%), PIK3CA (25%), and PTEN (12%); CNA in RAD21 (23%), MYC (23%), and PTEN (9%); and RE in EZH2 (2%). In the Others group, the most frequent SV were in TP53 (91%), NF1 (12%), and RB1 (7%); CNA in MYC (37%), RAD21 (21%), and PTEN (14%); and RE in NF1 (3.5%) and EZH2 (3.5%). Conclusions: The distribution of genomic alterations is consistent across breast cancer subtypes, regardless of genomic ancestry. These findings highlight the critical need for equitable genomic testing access for all patient populations.

P1-05-19: Circulating Tumor DNA as a Prognostic Biomarker for CDK 4/6 Inhibitor Therapy in Metastatic Breast Cancer

Luis Chinea, Julia Maués, Christine Hodgdon, Hannah Chang, Isaac S. Chan

Background: Cyclin dependent kinase (CDK) 4/6 inhibition in addition with endocrine therapy (ET) is first line therapy for patients with hormone receptor-positive (HR+), HER2 non-amplified, metastatic breast cancer (mBC). Recognizing which patients are going to benefit from treatment and identifying which patients acquire resistance are still poorly understood. Molecular alterations in CCNE1, MYC, and RB1 from breast tissue samples have been associated with resistance to CDK4/6 inhibitor therapy. Circulating tumor DNA (ctDNA) offers a unique noninvasive method to capture mBC heterogeneity and treatment response. Studies have used ctDNA to monitor for emergence of mutations and monitor dynamic response to treatment in HR+ mBC. Here, we test the hypothesis that CCNE1, MYC, and RB1 can be detected in ctDNA and utilized as a biomarker to predict response to CDK4/6 inhibitor therapy. Methods: In this study, we analyzed a subset of patients from the Dallas Metastatic Breast Cancer Study comprised of patients with HR+, HER2 non-amplified, mBC who underwent treatment with a CDK4/6 inhibitor (palbociclib, ribociclib, abemaciclib) and ET, became resistant to therapy, and had ctDNA testing (n=102). Commerical testing results through Tempus xF and FoundationOne Liquid CDx, which detects cancer-relevant genetic alternations, were obtained and analyzed. The data was collected from multiple hospitals within a single academic medical center starting with the initial ctDNA collection from 2019 to 2024. 13 patients had ctDNA collected before the start of therapy, 84 patients had ctDNA collected after progression, and 5 patients had ctDNA collected before therapy and after progression. Results: 88 of 102 patients did not have CCNE1, MYC, or RB mutations present had a median progression-free survival (mPFS) of 13.5 months. Among the remaining 14 patients, two had CCNE1 alterations with a mPFS of 5.5 months: one had ctDNA collected before treatment and one had ctDNA collected after

progression. Three patients had MYC alterations with a mPFS of 19 months: one had ctDNA collected before treatment and after progression, and two had ctDNA collected after progression. Nine patients had RB1 alterations with a mPFS of 7 months: four had ctDNA collected before treatment and after progression, and five had ctDNA after progression. Of the patients that had both timepoints collected, one patient had acquired a MYC alteration at time of progression. Four patients had acquired RB1 alterations at time of progression. Among patients with RB1 mutations (n=9), 3 had loss of function mutations, 1 had a missense mutation, 1 had low coverage region, 5 had multiple single nucleotide variants (SNVs) and among these, 2 had splice site variants. Conclusion: There is an urgent need to develop predictive biomarkers that capture real-time changes in tumor biology. Tissue analyses from patients resistant to CDK4/6 inhibitors have demonstrated a 14%-28% expression of CCNE1, 16% of MYC mutations, and 9%-10% expression of RB mutations. In our study, we observe a lower rate of detection in ctDNA of each gene. This result suggests that correlation between tissue mutations and detectable ctDNA mutations may not occur in a linear fashion. This analysis further suggests that new research is needed to identify other mutations detected in ctDNA which could predict CDK4/6 inhibitor resistance beyond CCNE1, MYC, and RB. Broadening our understanding of other correlative mutations in ctDNA with therapy resistance could allow for improved clinical implementation. Our study was limited by the small sample size and lack of consecutive ctDNA collection. Further studies are needed to determine the temporal and dynamic changes of acquired tumor mutations detected through ctDNA and the predictive value of specific mutations on outcomes.

P1-05-20: Validation of the HER2 Activation Response Predictive Signature (HARPS) as a Predictive Biomarker for HER2+ Therapy Response in the Neoadjuvant Setting

Emanuel Petricoin, Julia D. Wulfkuhle, Rosa I. Gallagher, Mridula A. George, Coral Omene, Deborah Toppmeyer, Niloofar Ramezani,, Gregory Riedlinger, Lance A. Liotta, Shridar Ganesan

Background: Not all patients with breast cancer identified HER2+ by standard IHC and FISH assays benefit from HER2-targeted therapy, suggesting these assays are not optimized to predict response to HER2-targeted agents. We previously reported results from the I-SPY2 TRIAL wherein we identified a HER2 Activation Response Predictive Signature (HARPS) as a novel functional phosphoprotein-based measurement of HER2 activity in the baseline pre-treatment biopsy sample that is based on HER2 Y1248 and EGFR Y1173 co-phosphorylation (p). HARPS predicted neoadjuvant response to a variety of anti-HER2 agents in tumors classified as HER2+ and TNBC (PMID: 34741023; 32914002). Moreover, we found that activation of the PLK1 pathway through pFADD S194 predicted non-response to HER2 therapy (PMID: 38086377) in HER2+ patients. Based on this observation, we investigated the HARPS signature and PLK1 pathway activation as predictive biomarkers of response in a blinded and independent study set of pre-treatment tumor biopsy samples obtained from

women with HER2+ BC disease who received HER2-targeted neoadjuvant therapy.
Methods: Reverse phase protein microarray (RPPA) analysis of Laser Capture Microdissected (LCM) -enriched tumor epithelium was performed on FFPE tumor biopsies from patients with HER2+ BC (N=38; 31 HR+/7 HR-) under CAP compliance (#7223012). Anti-HER2 therapy consisted of Trastuzumab (T) + Pertuzumab (N=35), T alone (N=2), TDM-1 (N=1), pCR outcomes were kept blinded. Quantitative measurement of total HER2, pHER2 Y1248, pEGFR Y1173 and pFADD S194 was made. Previously described HARPS +/- cutpoints were imputed onto the pHER2 and pEGFR data and a pCR prediction (HARPS+ = pCR Yes (Y) vs HARPS- = pCR No (N)) was made on a subset (N=26) of patients whose tumors had the lowest and highest HARPS scores. After unblinding, ROC-based optimization of HARPS was performed on the full study set (N=38). Association between quantitative individual protein values, HARPS +/- determination and pCR was assessed using uncorrected, non-parametric t-tests and Fisher's exact tests.
Results: 14 tumors from the blinded set were determined to be HARPS-. After unblinding, 12 did not achieve pCR after therapy and 2 patients had pCR (12/14, 86% NPV). 12 tumors from the blinded set were determined to be HARPS+. After unblinding, 8 were pCR Y and 4 were pCR N (8/12, 67% PPV). There was a significant association (p=0.009) between the blinded outcome call vs the actual outcome. Independent analysis of pHER2 Y1248, pEGFR Y1173 and total HER2 were all found to positively predict pCR in the full study set (p=0.005, p=0.006 and p=0.009, respectively). pFADD S194 levels trended with non-response (p=0.09). A ROC-optimized HARPS signature applied to the full study set of 38 tumors correctly identified 11/14 pCR Y (80% PPV) and 20/24 pCR N (83% NPV). There was no significant association of misclassification based on HR status or HER2 treatment type.
Conclusions: The robustness and generalizability of the previously described HARPS signature to predict response to HER2 therapies was validated in a blinded independent study set of FFPE HER2+ tumors (HR+ and HR-). Response prediction of HARPS was independent of type of HER2 therapy and HR status. Moreover, we verified that PLK1 activation was a negative predictor of response and that PLKi inhibitors should be explored as a bona fide candidate for combination with HER2 inhibitors for HARPS- patients who will not respond to current anti-HER2 therapy regimens. Our results justify rigorous evaluation of HARPS as a reflex test for women with HER2+ disease in prospective clinical trials for HER2 therapy escalation/de-escalation.

P1-05-21: Prognostic implications of oncogenetic pathway alterations in advanced male breast cancer

Dario Trapani, Sachin Kumar Deshmukh, Sharon Wu, Joanne Xiu, Daniel L. Abravanel, Priya Jayachandran, Nancy U. Lin, Giuseppe Curigliano, Philip Spanheimer, Milan Radovich, Stephanie L. Graff, Maryam Lustberg, George W. Sledge Jr, Sara M. Tolaney, Jose P. Leone

Background: Male breast cancer (MaBC) represents a rare entity, accounting for only 1% of all BC cases. In a previous work, we reported that MaBC recapitulates a unique mutational repertoire, harboring a distinct immune and genomic landscape across BC clinical subtypes.

However, prognostic implications of pathway alterations in MaBC have not been reported before, leaving uncertainty regarding their significance and clinical actionability in MaBC, and similarity with female BC (FeBC) counterparts. In this work, we analyzed the prognostic implication of single gene alterations on MaBC-related survival.
Methods: 17,759 breast tumors were tested by next-generation sequencing (NextSeq; WES, NovaSeq) and whole-transcriptome sequencing (NovaSeq; Caris Life Sciences, Phoenix, AZ). Real world overall survival (OS) was obtained from insurance claims and calculated from treatment start to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q<0.05$).
Results: Of 17,759 BC patients, there were 226 (1.3%) MaBC and 17,533 (98.7%) FeBC. In FeBC, GATA3 mutations (MT) were associated with better OS post-endocrine therapy (mOS: 49.6 vs. 43.1 months, HR 0.83, 95% CI 0.71-0.9, $p<0.01$) compared to GATA3 wild type (WT); whereas in MaBC, GATA3-MT was not associated with survival post-endocrine therapy (mOS: 54.8 vs. 60.8 months, HR 1.4, 95% CI 0.63-3.2, $p=0.39$) compared to GATA3-WT. The presence of TP53 mutations was adversely associated in FeBC, with a trend in MaBC. Poorer outcomes in TP53-MT vs WT were observed in FeBC patients post-endocrine therapy (FeBC: ΔmOS 25.2 months, HR 1.7, 95% CI 1.6-1.7, $p<0.01$ vs MaBC: ΔmOS 16.3 months, HR 1.08 95% CI 0.43-2.7, $p=0.85$), with CDK4/6 inhibitor (FeBC: ΔmOS 18.2 months, HR 1.7, 95% CI 1.6-1.9, $p<0.01$ vs MaBC: ΔmOS 19.5 months, HR 1.35, 95% CI 0.46-2.7, $p=0.57$) and in the post-chemotherapy setting (FeBC: ΔmOS 18 months HR 1.3, 95% CI 1.3-1.4, $p<0.01$ vs MaBC: ΔmOS 34 months HR 1.7, 95% CI 0.93-3.4, $p=0.07$). Additionally, CDH1, BRCA2 and PIK3CA mutations appeared to have no prognostic role in both MaBC and FeBC. The proportion of HR+/HER2- subtype was 72.12% in MaBC and 54% in FeBC. The results in the HR+/HER2-MaBC subgroup were consistent with those reported from the overall cohort. The number of HR+/HER2- MaBC with mutations in ESR1 (n=7), AKT1 (n=2), PTEN (n=8), mTOR (n=0), CDK4 (n=0), Rb1 (n=2), as well as other cancer susceptibility genes were very infrequent.
Conclusions: MaBC may recapitulate a unique tumorigenic trajectory that differs from FeBC, as suggested by the dissimilar prognostic significance of selected genomic alterations. These data warrant further confirmation toward the goal of understanding sex-defined differences in BC and potential for tailored therapeutic strategies.

P1-05-22: Targeting human Endoplasmic reticulum oxidoreductin 1-Lα in novel therapy for triple negative breast cancer.

Asaka Wada, Yoshihiko Hirohashi, Goro Kutomi, Daisuke Kyuno, Hiroaki Shima, Toshihiko Torigoe

Background: Triple negative breast cancer (TN breast cancer) has a poor prognosis and few therapeutic targets, and the development of novel therapies is desirable.Human endoplasmic reticulum oxidoreductin 1-Lα (hERO1-Lα) is an oxidase that exists in the endoplasmic reticulum and its expression is augmented under hypoxia. hERO1-Lα has a role

in the formation of disulfide bonds of secreted proteins and cell-surface proteins. We reported that hERO1-Lα is present in high levels in various types of tumors, and is a poor prognostic factor of TN breast cancer. We have focused on hERO1-Lα as a novel target molecule in TN breast cancer. In this study, we demonstrated that hERO1-Lα expression is involved in epithelial to mesenchymal transition (EMT), which is a process related to cancer metastasis and invasion, and analyzed its molecular mechanism. In addition, we investigated the effect of ERO1-Lα inhibitor (ERO1-Lα-I) on distant metastasis inhibition and anti-tumor effect for clinical application.

Materials and Methods: We generated MDA-MB-231 cells with hERO1-Lα knockdown (KD) using shRNA against hERO1-Lα, and with ERO1-Lα overexpression（OE） transfected with human hERO1-Lα cDNA. EMT changes in cells were analyzed by observation of cell morphology and western blotting (WB), and the same analysis was performed with the addition of ERO1-Lα-I (EN460). Cell motility was evaluated by scratch assay and invasive ability was evaluated by cell invasion assay. Since hERO1-Lα regulates the production of secreted proteins, we searched for EMT-related factors by comparing the results of cytokine arrays and ELISA using culture supernatants from each cell line. MCF7 with culture supernatant from OE cells was evaluated for induction of EMT using WB. The hERO1-Lα KD cells were transplanted into NOD/SCID mice and evaluated for distant metastasis. We also evaluated the anti-tumor and distant metastasis inhibitory effects of ERO1-Lα-I treatment and tumor pathology in NOD/SCID mice transplanted with TN breast cancer cell lines.

Results: EMT was suppressed in the hERO1-Lα KD cells and the ERO1-Lα inhibitor-added cells in WB, while it was enhanced in the OE cells. Cell motility and invasive ability were significantly suppressed in the hERO1-Lα KD cells ($p < 0.05$).Leukemia inhibitory factor (LIF), which has been reported to be involved in EMT, was detected relatively strongly in the culture supernatant of OE cells using cytokine arrays and was considered as a candidate molecule. ELISA showed a correlation between hERO1-Lα expression and LIF secretion. MCF cells with OE cells culture supernatant containing LIF showed EMT.Lung metastases were significantly suppressed in mice transplanted with the hERO1-Lα KD cells ($p < 0.001$) . Tumor growth was significantly suppressed in mice in the ERO1-Lα inhibitor group without toxicity ($p < 0.05$) .

Conclusions: hERO1-Lα suppression and hERO1-Lα inhibitors suppressed EMT of tumor cells, and LIF was identified as an EMT-related factor involving hERO1-Lα. Inhibition of hERO1-Lα suppressed distant metastasis, and addition of inhibitors showed antitumor effects. These results indicate that hERO1-Lα is involved in tumor growth and metastasis and may be a candidate for a new molecular targeted therapy for TN breast cancer.

P1-05-23: An observational cohort study of Multiplex8+: a spatially informed assay that uses multiplexed RNA-FISH guided laser capture microdissection followed by total RNA-sequencing

Evan Paul, Barbora Huraiová, Natália Matyašovská, Daniela Gábrišová, Soňa Gubová, Tomáš Ondris, Michal Gala, Liliane Barroso, Helena Ignačáková, Natália Valková, Fresia Pareja, Jakob N. Kather, Pavol Čekan

We previously developed and validated a breast cancer (BCa) diagnostic test called mFISHseq on a retrospective cohort of 1,082 FFPE breast tissues. The test utilizes a multiplexed RNA-FISH panel consisting of estrogen (ESR1), progesterone (PGR), and HER2 (ERBB2) receptors and Ki67 (MKI67) to characterize regions of interest that are subsequently captured by laser capture microdissection for total RNA-SEQ. Here, we report the results from 53 patients that underwent a research use only (RUO) version of the test called Multiplex8+, which provides information about the four main BCa biomarkers, intrinsic molecular and TNBC subtypes, prognostic risk, and expression of 40 genes and 28 gene signatures that inform about cancer hallmark pathways and treatment response to chemotherapies as well as targeted therapies (e.g., immunotherapy, CDK4/6 inhibitors, and antibody drug-conugates (ADCs)). Three patients had two specimens (primary and metastatic tumor specimens) processed yielding a total of 56 patient specimens, which consisted of hormone receptor positive (HR+)/HER2− (n=11), HR+/HER2+ (n=9), HR−/HER2+ (n=4), and HR−/HER2− (n=30) as determined by IHC. Two patients had unavialable IHC data. The median age at surgery was 46 yrs and the patients comprised various node statuses (negative=17, positive=18, unavailable=21), tumor sizes (pT1=22, pT2-4=17, unavailable=17), and grades (G1=1, G2=16, G3=30, unavailable=9).
Multiplex8+ showed high agreement with 90.5% of IHC reported results. Agreement was highest for HER2-ERBB2 (96.4%) followed by PR-PGR (92.7%), ER-ESR1 (85.5%), and Ki67-MKI67 (85.3%). Most discordant results for hormone receptors were in gray zone areas for IHC (i.e., ER/PR low ≤10%) and Multiplex8+ classified them as negative. Notably, two patients were classified as basal-like by intrinsic subtyping (both mesenchymal (M) TNBC subtype) and had high expression of proliferation, immune, and/or angiogenesis signatures. Another patient was classified as HER2 overexpressed and had elevated HER2 amplicon signatures and low luminal pathway signatures. This suggests that Multiplex8+ reflected the underlying tumor biology better than IHC.
Follow up data for 20 patients revealed insights into the ultility of genes and gene signatures in predicting risk of relapse and response to treatment. Multiplex8+ was correct in predicting treatment sensitivity or resistance in 77% (17/22) of instances, which spanned chemotherapy, endocrine, anti-Her2, and novel targeted therapies. For example, one metastatic TNBC patient who had an excellent response to bevacizumab had two heterogeneous regions dissected using LCM and both regions had high levels of a hypoxia/inflammation/angiogenesis signature previously shown to predict sensitivity to bevacizumab. This patient also had high TACSTD2 and TOP1 the antigen and payload targets of the ADC, sacituzumab govitecan (SG). Notably, after progressing on bevacizumab, this patient responded well to SG, highlighting the value of this test in predicting response

to more than one line of therapy. Another patient with metastatic HR+/HER2− BCa had a low (neo)adjuvant chemotherapy response signature as well as a high E2F4 signature that was previously shown to predict resistance to aromatase inhibitors and sensitivity to CDK4/6 inhibitors. Indeed, this patient had a poor response to aromatase inhibitors and chemotherapy, relapsing 2 months after surgery, but then had a beneficial response to CDK4/6 inhibitors. These examples, and other patient vignettes that will be discussed, demonstrate the clinical potential of Multiplex8+ by providing unique insights for each patient that could identify potential treatments (including subsequent lines of therapy) and explain why prior treatments performed poorly.
The specimens in this observational study were obtained with the patients informed consent and the study was approved by the Ethics Committee of the Bratislava Self-Governing Region (Ref. No. 05320/2020/HF).

P1-05-24: Biomarkers and Spatial Determinants of SHR-A1811 Efficacy in Neoadjuvant Treatment for HER2-Positive Breast Cancer

Zhi-Ming Shao, Ding Ma, Lei-Jie Dai, Xiang-Rong Wu, Cheng-Lin Liu, Shen Zhao, Hang Zhang, Li Chen, Yi Xiao, Ming Li, Yi-Zhi Zhao, Lin Yang, Tong Zhou, Jun-Jie Li, Wen-Tao Yang, Yi-Zhou Jiang

Background: The emergence of next-generation anti-HER2 antibody-drug conjugates (ADCs), such as T-DXd and SHR-A1811, represents a breakthrough in HER2+ breast cancer treatment. However, identifying factors that influence treatment response and pinpoint suitable candidates for these ADCs remains challenging.
Methods: We conducted a translational study on the neoadjuvant SHR-A1811 monotherapy arm in phase II FASCINATE-N trial (NCT05582499) to identify potential biomarkers for SHR-A1811 in HER2+ breast cancer. The first-stage analysis included the first 60 patients completing neoadjuvant treatment and surgery, of whom all were included in this translational study.
We performed multiomics profiling using baseline biopsy samples if they were adequate. A total of 48 patients had genomic data, 39 had transcriptomic data, 60 had computational pathology (CP) data based on whole slide images of paired H&E-stained and HER2 IHC-stained slides, and 21 had Xenium single-cell in situ spatial imaging.
We also developed an interpretable SHR-A1811 efficacy prediction model using multi-model integration and a voting classifier based on clinicopathological and CP features.
Results: In 60 patients included in the first stage analyses, 37 (61.7%) achieved pathological complete response(pCR). When stratified by hormone receptor (HR) status, the pCR rate was 48.10% (13/27) for HR+ patients and 72.72% (24/33) for HR- ones.
No difference in mutation or copy number were found between tumors of different efficacy. Transcriptomic analysis hinted that in the HR- subgroup, immune microenvironmental factors were associated with efficacy (upregulation of HLA molecules in pCR), whereas in the HR+ subgroup, tumor cell-associated factors played a more significant role (i.e., higher estrogen-related genes in non-pCR, including PGR, AREG, and GREB1). This hypothesis was

supported by further analysis.
Specifically, in the HR- subgroup, CP analysis showed significantly higher proportion of immune cells in pCR patients (P=0.0046), which were not observed in the HR+ subgroup (P=0.38). Xenium data further identified specific immune cell types and revealed that the T cells, particularly cytotoxic T cells, were the vital cell group that showed largest difference (P=0.0058), as is verified by higher CD8 IHC intensity (P=0.00031). Spatially, CP analysis found that pCR patients also showed higher mixture of immune cells and tumor cells, exhibiting a more immune infiltrated landscape. Xenium further found stronger antigen presentation between tumor cells and cytotoxic T cells in pCR patients, while non-pCR ones showed higher PD-L2–PD1 interaction.
In the HR+ subgroup, non-pCR diseases showed a clustering rather than even distribution of HER2-strong-positive tumor cells (P=0.016). This might result from the luminal-like molecular feature in non-pCR patients, as is supported by higher PGR and CCDN1 in non-pCR tumor cells in Xenium data and stronger PR staining in IHC tests.
In addition, we developed a practical model capable of predicting neoadjuvant treatment responses of both SHR-A1811 and based on clinicopathological features and pathological images (training set AUC = 0.95, 95% CI: 0.89-1.00; test set AUC = 0.86, 95% CI: 0.76-1.00).
Conclusions: Overall, our findings suggested the potential mechanism underlying tumor's response to SHR-A811. The investigation into biomarkers, particularly their spatial distribution, may enhance the prediction and identification of patients who are more likely to respond favorably to the treatment of SHR-A1811 and the related ADCs. Our study also indicated potential strategies to promote the efficacy of SHR-A811 with the combination of immunotherapy or endocrine therapy.

P1-05-25: Improving the Specificity and Sensitivity of Digital 3D Mammography using serum, plasma and saliva derived proteomes and mathematical modeling

Kurayi Mahachi, Wendy Pelton, Angela Toepp, Alessandra Luchini, Lance Liotta, Richard Hoefer

Digital 3D mammography is currently the most utilized screening tool used to identify early-stage breast cancer. Mammograms are scored using the BI-RADS categories (Breast Imaging Reporting and Data System). Categories IV and V mammograms are associated with a significant risk of breast cancer, mandating a biopsy and a pathologic diagnosis. Image guided percutaneous needle biopsy diagnoses cancer in about 25% of these BIRADS IV, V abnormalities emphasizing the lack of specificity and sensitivity of 3d Digital Mammography in diagnosing early-stage breast cancer. The poor positive predictive score subjects 75% of these patients with benign radiographic abnormalities to the potential anxiety, cost and harms of an unnecessary tissue biopsy. We studied 150 patients with BIRADS IV, and V mammographic abnormalities with serum, plasma and saliva obtained just prior to image guided biopsy. Hydrogel affinity nanoparticles were used to harvest and concentrate low abundance proteins, and the proteins were then identified by mass

spectrometry. Candidate peptides were identified, and these markers were verified in blinded confirmation. We developed and validated a statistical model to differentiate between cancer and non-cancer cases using a combination of proteomic and microbial biomarkers. Biomarkers were identified through bivariate analysis to find those with significant differences in abundance between cancer cases and controls. Additionally, lasso feature selection was employed to pinpoint the biomarkers most strongly associated with the cancer outcome. The model was constructed by comparing three distinct models using maximum likelihood estimates and Akaike information criterion, with the most parsimonious model selected for final analysis. K-fold cross-validation was used to ensure the model's robustness, and a receiver operating characteristic (ROC) curve analysis yielded an area under the curve (AUC) of 0.82, indicating strong overall predictive accuracy. To determine risk categories, we identified thresholds using spline analysis and calibration models. Splines were applied to the predicted probabilities to detect significant changes in cancer likelihood, and calibration curves were used to fine-tune the threshold. This process identified a 0.5 probability cut-off, which was used to categorize predictions into low and high likelihood of cancer. Confusion matrices were then employed to evaluate model performance at this threshold. The model demonstrated high sensitivity (92%), effectively identifying true positive cases, but had a lower specificity (45%), indicating a higher rate of false positives. Despite challenges such as handling factor levels and missing values, the model, which incorporated nine significant biomarkers (seven proteomes and two microbes), proved valuable for identifying high-risk patients. The model's high sensitivity potentially makes it a useful tool to guide the clinical decision to biopsy a mammographic abnormality or follow it clinically with additional interval follow-up imaging. An accurate risk marker can potentially reduce unnecessary invasive biopsies. To enhance clinical utility, future work should focus on improving specificity to reduce false positives and validating the model with larger, more diverse datasets to increase its generalizability and practical application.

P1-05-26: MammaPrint Genomic Signature, Molecular Subtype Characteristics and Outcomes of HER2-Low Early Breast Cancer (EORTC10041 / BIG 03-04 MINDACT Trial)

Gustavo Werutsky, Marcia Graudenz, Rafaela Gomes, Giuseppe Viale, Emiel J T Rutgers, Martine Piccart, Coralie Poncet, Laura J. van 't Veer, Fatima Cardoso

Background: HER2-low breast cancers (BC) are heterogeneous with different degrees of HER2 expression and hormone receptor (HR) status. Recent developments in anti-HER2 antibody–drug conjugates (ADCs) open new therapeutic options for HER-low BC. We aim to further characterize HER2-low BC using genomic assay and molecular subtype and its association with clinical outcome.
Methods: In this exploratory analysis of the MINDACT trial (EORTC 10041/BIG 3-04) we selected HER2-low tumors (i.e. HER2 1+ or 2+ non-amplified) tested by immunohistochemistry (IHC)/-ISH and with available HR status (Estrogen and

Progesterone receptor) both accessed by central pathology review. HER2 expression was evaluated with the HercepTest kit (Dako polyclonal). Molecular subtype by BluePrint classified patients in Luminal A (blueprint luminal AND MammaPrint (MP) low risk), Luminal B (blueprint luminal AND MP high risk), HER2-enriched and Basal. Genomic risk was defined using 70-gene signature using MP. Association of molecular subtype and genomic risk with distant metastasis free survival (DMFS) was evaluated. DMFS were adjusted for chemotherapy and endocrine therapy administration.
Results: From a total of 5929 enrolled patients in MINDACT with central pathology review, 2320 (39.1%) patients were classified as HER2 low, 1505 (64.9%) were HER2 1+ and 815 (35.1%) had HER2 2+/-ISH negative tumors. Median age at diagnosis was 55 years, 1675 (72.2%) of tumors had ≤ 2cm, 1400 (60.4%) were grade 2, 1830 (78.9%) had lymph-node negative disease and 2186 (94.2%) were HR (ER and/or PgR) positive. HER2-low tumors molecular subtype distribution was: 1574 (67.8%) Luminal A, 554 (23.9%) Luminal B, 25 (1.1%) HER2 enriched and Basal 167 (7.2%). Genomic risk classified HER2-low as MP low risk 1589 (68.4%) vs. 731 (31.5%) high risk (p<.0001). Molecular BC subtype distribution according to HER2-low score 1+ vs. 2+ were: Luminal A 1116 (74.2%) vs 458 (56.2%), Luminal B 272 (18.1%) vs 282 (34.6%), HER2 enriched 14 (0.9%) vs 11 (1.3%) and Basal 103 (6.8%) vs. 64 (7.9%), respectively (p<.0001). Genomic risk distribution according to HER2-low score 1+ vs. 2+ were: low risk 1125 (74.8%) vs 464 (56.9%) and high risk 380 (25.2%) vs. 351 (43.1%), respectively (p<.0001). Median follow-up was 108.5 months (95% CI, 107.8 - 109.3). The HER2-low 5-year DMFS according to genomic risk was 96.5% (95% CI, 95.6-97.4) in MP low vs. 92.5% (95% CI, 90.5-94.4) in MP high risk (HR 1.9 [95% CI, 1.4-2.5], p<.0001). The HER2-low 5-year DMFS according to molecular subtype was 96.5% (95% CI, 95.5-97.4) for Luminal A, 92.8% (95% CI, 90.7-95.1) for Luminal B, 88% (95% CI, 76.1-100) for HER2 enriched and 92.6% (95% CI, 88.7-96.7) for Basal (p<0.0001). In the multivariable analysis, age > 50 years (HR 1.34, [95% CI, 1.0-1.8], p=0.0490), lymph node positive (HR 1.75, [95% CI, 1.2-2.4], p=0.0003) and genomic high risk (HR 2.02, [95% CI, 1.5-2.7], p<0.0001) were independently associated with worse DMFS.
Conclusions: In the MINDACT trial exploratory analysis most HER2-low tumors were HR positive, Luminal A BC molecular subtype and Low MP genomic risk. However, HER2-low BC is not a uniform biological entity with an enrichment of Luminal B and High MP genomic risk in the HER2 2+ score subset. In addition, this analysis demonstrated that clinical outcome of HER2-low early BC is associated with MP genomic risk. The MINDACT trial exploratory analysis, using a central pathology review and long-term follow-up, shows that HER2-low BC has heterogeneous molecular profile, genomic risk and clinical outcomes and thus these results may influence future clinical trials with new agents for the treatment of HER2-low early BC.

P1-05-27: Analytical comparison of tissue-based next-generation sequencing assays for the detection of PIK3CA, AKT1, and PTEN tumor alterations in breast cancer

Xiaodun Li, Alexander Yarunin, Benjamin Chaffey, Manisha Maurya, Peter Stewart, Fionn Corr, Efstratios Efstratiou, Kirsty Trewellard, David Gonzalez

Background: Next-generation sequencing (NGS) testing in patients with advanced breast cancer (ABC) enables genomic biomarker interrogation, potentially guiding clinical management. Results from the CAPItello-291 Phase 3 randomized trial led to the approval of the first-in-class pan-AKT inhibitor capivasertib in combination with fulvestrant as a treatment option in patients with hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative ABC, with one or more PIK3CA/AKT1/PTEN tumor alterations following disease progression on/after prior aromatase inhibitor therapy. PIK3CA/AKT1/PTEN alterations are present in approximately 50% of all HR-positive/HER2-negative breast cancers and also in around 30% of all triple-negative breast cancers (TNBC). This study aimed to analytically compare the ability of commercially available tissue-based NGS assays to detect PIK3CA/AKT1/PTEN tumor genomic alterations in breast cancer samples.
Methods: Formalin-fixed, paraffin-embedded tumor samples collected from patients with TNBC were analyzed at three different sites using the following commercial NGS assays in accordance with the manufacturers' instructions: AVENIO Tumor Tissue CGP (Roche), TruSight Oncology 500 (Illumina), oncoReveal Core LBx (Pillar Biosciences), Oncomine Comprehensive Assay v3 (ThermoFisher Scientific), AmoyDx HANDLE Classic (Amoy Diagnostics), and SOPHiA ExtHRS (SOPHiA GENETICS). Detection of single nucleotide variants, insertions/deletions, and copy number variants in PIK3CA, AKT1, and PTEN approved by the FDA as genomic alterations which determine eligibility for treatment with capivasertib in combination with fulvestrant in patients with HR-positive/HER2-negative ABC was recorded and compared. Positive percent agreement (PPA), negative percent agreement (NPA), and overall percent agreement (OPA) were calculated for all assays. AVENIO Tumor Tissue CGP was used as the reference assay, as the content is broadly comparable to the FDA-approved FoundationOne CDx assay.
Results: Overall, 45 samples were processed, and all samples were included in the final analysis. PPA, NPA, and OPA for any alteration(s) (PIK3CA, AKT1 or PTEN) versus AVENIO (reference) were: TruSight: 86.0%, 100.0%, and 86.7%; oncoReveal: 81.4%, 100.0%, and 82.2%; Oncomine: 81.4%, 100.0%, and 82.2%; AmoyDx: 86.0%, 100.0%, and 86.7%; SOPHiA: 88.4%, 100.0%, and 88.9%. There was 100.0% PPA, NPA, and OPA for both PIK3CA and AKT1 between TruSight, Oncomine, AmoyDx, SOPHiA and AVENIO. For oncoReveal, PPA, NPA, and OPA were 100.0%, 94.1%, and 97.8% for PIK3CA and 100.0%, 100.0%, and 100.0% for AKT1 alterations, respectively. For PTEN alterations, PPA, NPA, and OPA per assay versus reference were: TruSight: 58.8%, 96.4%, and 82.2%; oncoReveal: 17.6%, 100.0%, and 68.9%; Oncomine: 35.3%, 100.0%, and 75.6%; AmoyDx: 47.1%, 100.0%, and 80.0%; SOPHiA: 58.8%, 100.0%, and 84.4%. Lower agreement for PTEN alterations was due to differences in gene coverage and ability of some assays to detect complex PTEN genomic

alterations, such as large rearrangements and copy number variations.
Conclusions: All assays evaluated demonstrated good concordance with the AVENIO Tumor Tissue CGP test, especially for detecting capivasertib treatment eligible alterations in AKT1 and PIK3CA. Further improvement on detection of PTEN structural and copy number alterations is needed for some assays in order to maximise patient identification for capivasertib in combination with fulvestrant. These data can help clinicians make informed decisions regarding suitable diagnostic tests to determine patient eligibility for breast cancer therapies.

P1-05-28: Immune related adverse events are associated with better event free survival in a Phase I/II Clinical Trial of Durvalumab Concomitant with Neoadjuvant Chemotherapy in Early-Stage TNBC

Alejandro Rios Hoyo, Jiawei Dai, Thomas Noel, Kim Blenman, Tristen Park, Lajos Pusztai

Immune-related adverse events (irAE) during neoadjuvant immune checkpoint inhibitor therapy and chemotherapy are associated with improved outcomes in triple negative breast cancer. This analysis included patients from a phase I/II single arm clinical trial at Yale Cancer Center and its regional care centers was conducted from December 2015 to December 2020. Eligible patients were adults 18 years and older with clinical stages I–III, TNBC for whom systemic chemotherapy was indicated. Patients received durvalumab concomitant with nab-paclitaxel and dose dense doxorubicin-cyclophosphamide. Durvalumab was not administered postoperatively. We examined the association between developing an irAE with pathologic complete response (pCR=ypT0/is, ypN0), residual cancer burden (RCB), event-free survival (EFS) and overall survival (OS). Sixty-seven patients were eligible for toxicity and efficacy analysis, 27 had irAEs of any grade, 13 had multiple irAEs. Median follow up was 61 months (range 6.8-94.03 months). The most frequent irAEs were dermatologic (n=14), endocrine (n=13), and gastrointestinal (n=5). Patients who experienced irAEs achieved a pCR or RCB 0-1 rate of 58% and 73%, respectively, compared to 42% and 55% in those without irAEs (p=0.309 and 0.19). Development of irAE was also associated with significantly improved EFS (HR: 0.25; 95% CI 0.09-0.66; p=0.024), and a trend for improved OS (HR: 0.42; 95% CI 0.14-1.27; p=0.17). Patients with more than one irAE had no EFS events. Development of irAE was associated with a numerically improved pCR rates, lower RCB, and significantly higher EFS in patients treated with neoadjuvant immune checkpoint therapy plus chemotherapy.

P1-05-29: The Nanomechanical Phenotype of Lobular Breast Cancer

Marko Loparic, Sara Nizzero, Mariam Gachechiladze, Tobias Appenzeller, Leonie Briner, Rosemarie Burian, Sabine Schädelin, Simone Muenst-Soysal, Tatjana Vlaijnic, Ellen Obermann, Sophie Dellas, Serafino Forte, Zlatko Marušić, Ahmed Jizawi, Yitian Xu, Lee B. Jordan, Colin A. Purdie, Philip R. Quinlan, Chandandeep Nagi, Karla A. Sepulveda, Gregory

Zaugg, Papa Diogop Ndiaye, Philipp Oertle, Vittorio Cristini, Alastair M. Thompson, Marija Plodinec

Background: Recent research has spotlighted lobular cancer as a distinct histological phenotype, potentially revolutionizing treatment paradigms. Invasive lobular carcinoma (ILC) is identified by a specific morphological feature, notably the "Indian file" arrangement of discohesive breast cancer cells. Frequently, these cancers are estrogen receptor positive, though they can appear within any molecular subtype of breast cancer. Emerging evidence indicates that, within the same molecular subtype, ILC leads to less favorable outcomes compared to invasive ductal carcinoma (IDC). These outcomes include higher rates of metastatic disease, lower response rates to both neoadjuvant and adjuvant treatments, and decreased overall and disease-free survival. Such findings strongly support reclassifying ILC as a distinct entity, advocating for a paradigm shift in therapeutic approaches. Mechanistic Insights into ILC The development of ILC is mechanistically linked to the loss of E-cadherin, a crucial epithelial cell-cell adhesion molecule. This loss is directly associated with changes in cell nanomechanical compliance and tumor microenvironment nanomechanical remodeling. This study presents the first clinically integrated, functional characterization of ILC tissues at the nanomechanical level, providing new insights into the physical properties of ILC and offering novel avenues for clinical management.

Methods: This investigation utilized data from a single-center, blinded, prospective study aimed at measuring the multiparameter nanomechanical signature of breast cancer. Conducted between 2016 and 2019, the clinical study included 588 fresh breast biopsy samples from 545 suspected breast cancer patients. Samples were measured using the AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) investigational device within a routine clinical setting at the Breast Clinic, University Hospital Basel (Switzerland). Patients who underwent clinically indicated breast biopsy and consented to participate were eligible for the study. Biopsies were collected before treatment, and patients are being followed up to collect long-term responses for up to 10 years. Core needle biopsies from 125 invasive breast cancer patients were selected for nanomechanical profiling of ILC and IDC, including 12 pure ILC and 113 pure IDC cases. The nanomechanical signature integrated analysis was performed using the proprietary ARTIDISNet software platform.

Results: This study presents the first comprehensive nanomechanical signature of ILC compared to IDC, including stiffness, adhesion, and dissipation profiles and their association with other known clinico-histopathological aggressive features. The specific mechanical nature of ILC was confirmed through spatial analysis of multiplex imaging from several lobular breast cancer patients. This characterization supports the investigation and definition of ILC as a unique nanomechanical subtype of breast cancer.

Conclusion: The loss of E-cadherin in ILC is directly related to the loss of cell-cell adhesions, epithelial-mesenchymal transition, cell invasion, migration, and metastasis, all of which are mechanical aspects of ILC pathogenesis. This study presents the first integrated characterization of the nanomechanical phenotype of ILC, which will be further validated in the ongoing multicenter ANGEL clinical trial, currently enrolling over 2700 patients in the

USA over the next three years. Understanding and fully characterizing the mechanical nature of ILC has the potential to revolutionize clinical management of this unique disease.

P1-05-30: A statistical model for integration of on-treatment circulating tumor DNA dynamics and prediction of outcomes in patients with ER+/HER2- metastatic breast cancer

Mitchell Elliott, Jesús Fuentes-Antrás, Sasha Main, Aaron Dou, Elizabeth Shah, Emily Van de Laar, Caroline M. Weipert, Amar Das, Eitan Amir, Michelle B. Nadler, Celeste Yu, Hal K. Berman, Lillian L. Siu, Philippe L. Bedard, David W. Cescon, Christopher Pretz

Background: There is growing evidence that on treatment circulating tumor DNA (ctDNA) dynamics are a sensitive measure of treatment response in metastatic ER+/HER2- breast cancer (mBC). Questions remain about the approach to interpreting serial ctDNA tumor fraction (TF) measurements and how temporal evolution relates to clinical outcomes. Herein, we demonstrate a statistical joint modeling (JM) approach that combines longitudinal ctDNA and time-to-event data. This approach generates dynamic predictions which continually re-assesses a patient's event risk as ctDNA dynamics evolve, providing adaptive information that could potentially aid in decision making around treatment efficacy and risk for progression.

Methods: JM was applied to a single institution cohort of ER+/HER2- patients with mBC who underwent prospective collection of plasma while receiving endocrine therapy (ET) and CDK4/6-inhibitors (CDK4/6i). Plasma samples were collected pre-treatment and regularly on-treatment (mostly around the time of restaging CT). Samples were analyzed using the Guardant Infinity assay, a tumor-agnostic genomic and epigenomic platform. Patients with at least three plasma samples available were included in the model. To meet model assumptions, ctDNA TF values were logit-transformed. A hierarchical cubic spline random effects sub-model was utilized to capture the longitudinal ctDNA data and a cox-proportional hazard sub-model was used for the time-to-event data. Dynamic predictions for patient-specific progression-free survival (PFS) and overall survival (OS) curves were generated, which were continually updated as additional longitudinal ctDNA information was added. Baseline covariates were incorporated into the JM and are used to directly inform patient-level predictions. All results are displayed graphically.

Results: In total, 49 ER+/HER2- mBC patients with 279 ctDNA time points were used in the analysis. Baseline covariates included: patient age (median=62 years), CDK4/6i drug used [Palbociclib (71.4%) vs Ribociclib or Abemaciclib], histology [ductal (81%) vs lobular or mixed histology], current line of therapy [1 (75.5%) vs 2 or more], and prior adjuvant treatment [no (57.1%) vs yes]. Interrogation of various JM indicated that the patient's estimated current TF has a significant relationship with both OS and PFS (respective p-values <0.0001). This result is directly observable in the dynamic predictions, where increasing TF trends are indicative of a poorer PFS while decreasing TF trends show

improved outcomes. Each patient's unique combination of baseline covariate values informs PFS or OS predictions.

Conclusions: Here we demonstrate that complex longitudinal genomic data can be modeled successfully and leveraged to provide patient-specific prognostic estimates. This approach is in contrast to prognostication based on biomarker analysis of a baseline sample or the examination of TF changes between two set time points, which do not account for the continual evolution of dynamic biomarkers, such as TF, and how this evolution modifies outcome. This proposed statistical approach provides an opportunity to integrate serial biomarker results with patient information to enhance prognostic accuracy. The adaptive patient-level dynamic predictions generated by this model has the potential to improve the clinical utility of TF and longitudinal monitoring for clinical decision-making and should be studied and validated in additional clinical cohorts.

P1-06-01: Efficacy and Safety of Camrelizumab Combination Therapy in Triple-Negative Breast Cancer: A Systematic Review and Meta-Analysis

Moazzam Shahzad, Umar Akram, Muhammad Kashif Amin, Zain Ali Nadeem, Obaid Ur Rehman, Muhammad Ahmed Raza, Aimen Nadeem, Rutaab Kareem, Maheen Zahid, Hamza Ashraf, Haider Ashfaq

Background: Triple-negative breast cancer (TNBC) has an aggressive clinical course with a high recurrence rate and risk of metastasis. Camrelizumab, a humanized monoclonal anti-PD-1 antibody, has shown promising prognostic outcomes for patients with TNBC by restoring T cell activation. This systematic review and meta-analysis aimed to evaluate the efficacy and safety of Camrelizumab combination therapy in women with TNBC.
Methods: Following PRISMA guidelines, a literature search was carried out on PubMed, Embase, Scopus, Cochrane, and ClinicalTrials.gov from inception until March 2024 using the keywords "Camrelizumab", "Anti-PD1", "Immune Check Point Inhibitors", "Breast Neoplasms", "Breast Cancer", "Breast Carcinoma". The initial search yielded a total of 10,282 articles, out of which 9 studies comprising women with histologically confirmed TNBC who were administered Camrelizumab were included in this review. We performed a meta-analysis using the "meta" and "metasens" packages via RStudio. Proportions were pooled using a random-effects model. Between-study heterogeneity was assessed using Cochrane Q χ^2 statistics and Higgins I^2 statistics. The evaluation of study quality was carried out using the "National Heart, Lung, and Blood Institute (NHLBI) Study Quality Assessment Tool for Before-After (Pre-Post) Studies with No Control Group." The protocol of this systematic review is registered with PROSPERO under the identifier CRD42024521992.
Results: A total of 397 patients with TNBC were included in the study. 116 patients had a T0 - T2 and 29 patients had a T3-T4 breast cancer stage before the start of the intervention. Camrelizumab was combined with Nab-paclitaxel, Apatinib, and Famitinib in 4, 3, and 2 studies, respectively. The pooled overall response rate was 58% (199/334, $P<0.01$, $I^2=94\%$). The pooled one-year survival rate was 71% (114/161, $P=0.12$, $I^2=49\%$). The

pooled stable disease and progressive disease at the last reported follow-up were 25% (71/271, P<0.01, I^2=85%) and 11% (31/242, P<0.01, I^2=79%), respectively. The most frequently reported adverse event was neutropenia in 166/277 (66%), followed by leukopenia 207/381 (59%), fatigue 173/406 (51%), Aspartate aminotransferase (AST) elevation 137/363 (39%), Alanine aminotransferase (ALT) elevation 130/363 (37%), and asthenia 37/115 (32%).
Conclusion: Our meta-analysis affirms that Camrelizumab combination therapy has shown promising results in terms of overall response rate and the one-year survival rate. Further research with large-scale randomized clinical trials is warranted to generate robust results.

P1-06-02: Remote functional cognitive rehabilitation in Breast Cancer Patients, a single center retrospective study

Einav Nili Gal-Yam, Sharon Harel, Rachel Kizony, Maya Ben-Yakov, Beatrice Shaham, Galia Barkai

Background: The number of breast cancer survivors is increasing substantially. About 15-50% of them cope with cognitive and executive functions difficulties that are related to decreased daily participation in meaningful activities and quality of life. Initial results point to the feasibility and efficacy of rehabilitation programs which focus on enhancing self-management abilities and executive functions, aiming to improve breast cancer survivors' participation in meaningful activities. Nevertheless, programs which are delivered remotely to improve accessibility to care are scarce. We report the results of a remote functional-cognitive occupational therapy rehabilitation in a single center.
Methods: Twenty-eight breast cancer patients were treated upon referral from their treating oncologists. Baseline evaluations were conducted in the clinic utilizing Montreal Cognitive Assessment (MOCA) and Trail Making Test (TMT-A and TMT-B). Personal treatment goals (meaningful activities, e.g: "organize a weekly schedule") were chosen and rated by each patient for perceived performance and satisfaction on a scale of 1(low) to 10(high) before and after the intervention, with the Canadian Occupational Performance Measurement (COPM). Improvement of two points or more in the COPM is considered as clinical meaningful.
The intervention included 8-12 sessions using videoconferencing. The first session aimed at promoting knowledge on the effects of cancer and its treatment on functional cognition and encouraging self-efficacy. The functional cognitive treatment was comprised of bottom-up sessions which utilized digital worksheets and gamified activities to improve cognitive skills, such as memory and executive functions. Additionally, top-down sessions focused on meta-cognitive strategies to enhance self-management for coping with daily life challenges, identified in the COPM. Additionally, self-practice exercises were provided to the patients.
Results: Between12/2021 to 01/2024, 28 breast cancer patients underwent the intervention and were included in this analysis. Twenty-six were breast cancer survivors on active follow-up and 2 were metastatic breast cancer patients who were in remission. 19/28 (68%) patients previously underwent chemotherapy treatment and 17/28 (60%)

patients were on endocrine treatment. Mean age was 50.4±11.2 (range 34-75). Twenty five patients (90%) completed at least 8 remote sessions. Mean MOCA score at baseline was 27.5±1.9, indicating intact general cognition. Baseline mean TMT scores were 39.5±12.6 seconds for TMT-A (20 (71%) below 50 percentile) and 83.5±39.6 seconds (14 (50%) below 50 percentile) for TMT-B. These results reflect a decrease in visual attention and executive functioning respectively. Mean COPM scores post intervention were significantly higher compared to the scores pre intervention for both perceived performance (pre = 4.2±1.6; post=7.0±1.2; p<.001) and satisfaction (pre = 3.0±1.8; post=6.7±1.8; p<.001). Out of 28 patients 21(75%) reported improvement in at least 2 or more points in performance and satisfaction of 2 activities.

Conclusions: Remote functional cognitive rehabilitation is feasible and beneficial in breast cancer patients who report cognitive impairment following medical therapy and should be integrated into the standard care. Our study is limited by its retrospective nature and short term follow up. We are now conducting a prospective randomized controlled trial with extended evaluations and a longer follow up.

P1-06-03: Concurrent GLP1R-agonist use with chemoimmunotherapy for early-stage triple-negative breast cancer: A potential detrimental effect

Bethania Santos

Introduction: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have emerged as a key class of drugs for treating type 2 diabetes mellitus (T2DM) and obesity, two of the most prevalent metabolic disorders globally. These drugs act by stimulating the GLP-1 receptor (GLP-1R), which enhances insulin secretion and exerts multiple metabolic benefits. Endogenous GLP-1 is rapidly degraded by dipeptidyl peptidase 4 (DPP4), limiting its plasma half-life to approximately 2 minutes. This rapid degradation led to the development of DPP4 inhibitors (DPP4i), which prevent GLP-1 inactivation and prolong its effects, thereby improving glycemic control in T2DM patients. GLP-1R was initially identified in the endocrine pancreas, but subsequent research revealed its expression in intraepithelial lymphocytes and immune cells, suggesting potential implications in immune modulation. Despite their widespread use and benefits in metabolic diseases, recent evidence suggests that GLP-1 receptor agonists and DPP4 inhibitors may also influence cancer biology. Current research suggests that these drugs might have paradoxical effects on cancer therapy, potentially altering the efficacy of immunotherapeutic approaches such as anti-PD-1 and anti-PD-L1 treatments. Furthermore, GLP-1R activation in tumor cells activates key signaling pathways, such as PI3K-AKT and MEK-ERK1/2, which regulate processes including anti-apoptosis, inflammation suppression, cell growth, autophagy, angiogenesis, and proliferation. This suggests that GLP-1R activation may not only undermine the efficacy of immunotherapy but also promote tumor cell survival and expansion, potentially accelerating cancer progression. This study aims to investigate the impact of GLP-1RAs and DPP4i exposure on pathological complete response (pCR) rates for patients with early-stage triple negative breast cancer (TNBC) receiving neoadjuvant chemotherapy with immunotherapy.
Methods: Patients with early stage TNBC diagnosed between July 1, 2021, and December 31, 2023 who subsequently received the KEYNOTE-522 regimen were identified through three institutional databases. Patients taking GLP-1RAs and DPP4i at breast cancer diagnosis and throughout the neoadjuvant period, either alone or in combination with other diabetes or obesity medications, were identified. Patients who started or stopped GLP-1RAs/DPP4i therapy during neoadjuvant chemoimmunotherapy administration were excluded. Bivariate analyses were conducted to determine if there were significant differences in pCR rates between GLP-1RAs/DPP4i users and non-users. Group comparisons were made using the Chi-square test for categorical variables and the two-sample t-test for continuous variables. IHC staining for GLP1R was performed on human TNBCs.
Results: Among the 347 eligible patients identified, 25 (7.2%) were using GLP-1RAs or DPP4i. The pCR rate for those receiving GLP-1RAs or DPP4i was 28% (7/25) vs. 63.66% (205/322) between those using other classes of diabetes medication or no medications, respectively (p=0.0006). The pCR rate among those using other classes of diabetes medications was 60% (27/45). There was no significant difference between the two groups

(GLP-1RAs/DPP4i-exposed vs not) by age, body mass index (BMI), or T stage. In univariate analysis, age younger than 50 years, grade 3 disease, BMI of ≥30, and the absence of diabetes had improved pCR rates ($p<0.1$). In multivariate analysis, grade, age, BMI, and diabetes were significant predictors of pCR [OR (95% CI): 2.15 (1.05, 4.40), 2.02 (1.15, 3.56), 1.85 (1.08, 3.20), and 2.31 (1.13, 4.75), respectively; $p<0.05$]. GLP1R was detected in tumor cells and infiltrating immune cells in human TNBC specimens (n=100). Ongoing spatial transcriptomics of pre and post treatment tumor specimens from patients taking GLP1R-agonists with neoadjuvant chemotherapy will be presented.

Conclusion: We observed significantly lower pCR rate among patients taking GLP-1RA/DPP4i during neoadjuvant chemotherapy for TNBC. These effects were not observed with other diabetic medications. Detection of GLP1R expression in TNBC specimens indicates there are direct and indirect effects of agonists to the GLP1 pathway on tumor immunity and response to chemotherapy that detrimentally affect response rates. Use of GLP-1RA/DPP4i use may need to be carefully considered during breast cancer therapy.

P1-06-04: Psychological stress and its correlations to patients with acute lymphedema after breast cancer surgery

Li-Chen Tang,Li-Ping Ge

Introduction: Breast cancer patients are commonly affected by lymphedema and psychological problems. This study aimed to determine the incidence and determinants of anxiety and depression in patients with lymphedema after breast cancer surgery.
Materials and Methods
The study enrolled 1,613 patients who underwent curative breast cancer surgery during 2023 in Shanghai Cancer Hospital, Fudan University, Shanghai, China. Descriptive analysis and logistic regression were conducted in the study by using SPSS 26.
Results: Among all the patients, 363 (22.50%) cases were identified as acute lymphedema. Anxiety was identified in 500 (31.0%) breast cancer patients after surgery and depression was detected in 21.2% of patients in the overall cohort.
Acute lymphedema was the significant impact factor for anxiety in breast cancer patients (OR = 1.57, 95%CI: [1.04 to 2.38], P=0.033). Subgroup analysis observed that in the acute lymphedema group, a longer period of hospital stay (OR = 0.51, 95%CI: [0.30 - 0.88], P=0.017) and invasive disease (OR = 0.39, 95%CI: [0.19-0.78], P=0.0008) were related to less anxiety; lymph-vessel invasive disease was related to increased anxiety (OR= 5.97, 95%CI: [1.15 – 30.97], P=0.03). On the other hand, menopause (OR = 0.72, 95% CI=0.56 - 0.94, P=0.014), and the length of hospitalization (OR = 1.30, 95% CI=1.00-1,68, P=0.047) were the factors influencing depression in all breast cancer patients. Among acute lymphedema group, lymphnode surgery (OR = 8.52, 95%CI: [1.56 - 48.23], P=0.014) was the impact factor to depression.
Conclusion: Psychological stress and acute lymphedema may have the crucial impact on breast cancer patients after surgery.

P1-06-05: Efficacy of using "cold caps" or "scalp cooling systems" with the DigniCap system in Uruguayan patients receiving chemotherapy for the treatment of early-stage breast cancer (Digni-T-Uy: DigniCap Trial Uruguay)

Dahiana Amarillo, Melanie Garcia, Maria Clara Rodriguez, Maria Guerrina, Noelia Strazzarino, Bruno Borrelli, Valeria Lemes, Natalia Camejo, Mauricio Cuello, Cecilia Castillo, Gabriel Krygier

Background: Alopecia is a generally transient adverse effect of chemotherapy treatment in patients with early-stage breast cancer, causing significant emotional impact and occasionally rejection of therapies. Although it is usually reversible, it can take months to resolve, amplifying the psychological effect of the treatment. Strategies such as cold caps or scalp cooling systems have emerged in recent years, aiming to prevent or limit this adverse effect, and have shown promising results. This prospective observational study aimed to describe our experience with the DigniCap system (DCS).
Methods: This is a prospective observational study in patients who started scalp cooling with DCS while undergoing chemotherapy for early-stage breast cancer. From March 2022 to June 2024, 50 consecutive early-stage BC patients who received anthracycline and/or taxane-based treatment were enrolled, subject to local Ethics Committee approval. Efficacy was defined as the "successful prevention" of hair loss, with a maximum Dean score of ≤ 2 (hair loss ≤ 50%). Safety, tolerance, successful prevention of hair loss as determined by the patient's perception, and quality of life were also evaluated.
Results: Hair loss of 50% or less (Dean score of 0-2) was seen in 27 (67.5%) of 40 patients. Complete preservation of the hair (G0) was observed in 6 pts (15%), G1 in 14 pts (35%), and G2 in 7 pts (17.5%). The most frequent scalp cooling-related symptoms were headache (72.5%), scalp pruritus (62.5%), neck pain (50%), and coldness (45%). Overall, 20% (n = 8) of patients discontinued DCS because of unsatisfactory hair preservation (n = 4, 10%) and cold discomfort (n = 4; 10%). The quality of life of patients who had successful treatment was not significantly affected.
Conclusions: Our results confirmed and reinforced previous evidence that scalp cooling with DCS is safe and effective for reducing chemotherapy-induced alopecia during CT with anthracycline and/or a taxane-based regimen.

P1-06-06: Oral cyclophosphamide-induced hemorrhagic cystitis from metronomic Cyclophosphamide/Methotrexate/5-Fluorouracil for treatment of synchronous bilateral breast cancer – A case report

Jina Yun, Grace Baek, Arianne Duong, Dane Fritzsche, William Gwin

Introduction: Cyclophosphamide/methotrexate/5-fluororuracil (CMF) has been used for the treatment of early-stage breast cancer since the 1970s. Cyclophosphamide, a main component of the CMF regimen, is an alkylating agent with potential to cause hemorrhagic

cystitis. This side effect is thought to be dose-dependent, with incidence up to 12-41% reported with doses of 150 – 200 grams. The risk of cyclophosphamide-induced hemorrhagic cystitis is very low with CMF, due to the low dose used in this regimen. At these doses of oral cyclophosphamide in CMF, intravenous (IV) hyperhydration or supportive care with mesna is not recommended. At the Fred Hutchinson Cancer Center, metronomic CMF (mCMF) is utilized in the adjuvant setting, where smaller doses are administered weekly for patients who may not tolerate higher doses of chemotherapy in traditional CMF. Cho and colleagues demonstrated similar efficacy and more tolerable side effect profile when compared with traditional CMF as well. The following report presents a patient with cyclophosphamide-induced hemorrhagic cystitis while receiving therapy with mCMF for the treatment of her breast cancer.

Case Report: In April 2021, a 46-year-old female was diagnosed with cT2 cN0 cM0 estrogen receptor (ER)-/ progesterone receptor (PR)-positive, human epidermal growth factor receptor (HER)2-negative IDC of the right breast in addition to cT1b cN0 cM0 ER-positive, PR-negative, HER2-negative IDC of the left breast. Her past medical history included ulcerative colitis status post ileostomy, history of Stevens-Johnson syndrome with sulfa drugs, and mucinous cystadenoma of the ovary status post total abdominal hysterectomy and bilateral salpingo-oophorectomy. In June 2021, the patient presented to the Fred Hutchinson Cancer Center for initiation of adjuvant systemic therapy with mCMF. Her regimen consisted of cyclophosphamide 60 mg/m2 by mouth once daily, methotrexate 15 mg/m2 given intravenously once weekly, and 5-fluorouracil 300 mg/m2 given intravenously once weekly. She began treatment in July 2021, and her total dose of oral cyclophosphamide was 125 mg daily. Prior to week 11 of treatment, the patient reported persistent dysuria, urinary urgency, and hematuria. Despite several emergency department visits, antibiotic usage, and non-pharmacologic supportive care, she continued to have urinary symptoms. Ultimately, she was diagnosed with cyclophosphamide-induced hemorrhagic cystitis, confirmed by cystoscopy and cytopathology. The cyclophosphamide was discontinued at this time and the patient had received a total of 9.4 grams of oral cyclophosphamide over a 75-day period. With the resolution of her cystitis, adjuvant chemotherapy with only methotrexate and 5-fluorouracil was resumed 37 days after her last methotrexate and 5-fluouracil infusions and 30 days after her last dose of oral cyclophosphamide.

Discussion: To date, there are four case reports of cyclophosphamide-induced hemorrhagic cystitis in patients with breast cancer. Two patients received capecitabine and oral cyclophosphamide while two patients received docetaxel and intravenous cyclophosphamide, all receiving cyclophosphamide at higher doses than the patient described in this case report. This case is the first to describe cyclophosphamide-induced hemorrhagic cystitis with adjuvant mCMF with oral cyclophosphamide at the lower dose of 60 mg/m2. The exact etiology of this adverse effect in this patient remains unclear; some hypothesized patient risk factors include reported nightly administration technique and her history of ulcerative colitis requiring ileostomy leading to inadequate oral hydration and bladder voiding and reduced fluid absorption, respectively.

P1-06-07: APOE4 impairs the cardiac stress response to doxorubicin through defective M2 macrophage activation and tissue repair transcription pathways

Nanette Bishopric, Harshul Pandit, Adam Ikeda, Kyle Korolowicz, G. William Rebeck, Olga Rodriguez, Marc E. Lippman, Nanette H. Bishopric

Background: The human apolipoprotein E (APOE) gene has three major allelic variants: APOE3, APOE4, and APOE2. Carriers of the APOE4 allele are at high risk for Alzheimer's and other neurodegenerative disorders and exhibit elevated oxidative stress in the central nervous system. Recently, we observed that mice expressing the human APOE4 allele are predisposed to cardiac damage induced by doxorubicin (DOX), a potent and widely used breast cancer therapeutic. How APOE4 contributes to oxidative stress-related tissue damage remains poorly understood.
Objective: To identify mechanisms of APOE4-mediated vulnerability to DOX cardiotoxicity.
Methods: C57Bl/6 mice (5-8 mo and 14-18 mo, male and female) with human APOE3 or APOE4 homozygous knock-in (=APOE3 and APOE4, respectively) received a single IP injection of saline (Control) or DOX (10 mg/kg) and monitored between 3-45 days afterward. Cardiac function was quantitated using echocardiography (Vevo 3100) at baseline and during the study. TUNEL assays were used to identify apoptotic cells. Collagen was imaged by Masson's Trichrome staining. Myocardial protein and RNA were extracted from the left ventricle and subjected to immunoblotting, IHC, real-time PCR, and RNASeq. Transcriptomic data were analyzed using Gene Set Enrichment Analysis (GSEA) for pathway analysis and CIBERSORTx for deconvolution of myocardial immune cell subtypes.
Results: At baseline, no difference in cardiac function was observed between the 2 mouse lines. Following DOX treatment, APOE4 mice had greater declines in left ventricular ejection fraction, heart weight, and more myocyte apoptosis compared with age-matched APOE3 mice (all $p<0.05$). APOE4 also conferred more age-associated myocardial collagen and cardiomyocyte apoptosis than APOE3, and higher myocardial levels of 4-HNE (4-hydroxy-2-nonenal), an oxidative stress byproduct. Surprisingly, APOE4 mice had a marked reduction in immunoglobulin production and age-dependent IgG deposition in the myocardium compared with both APOE3 and wt mice ($p= 0.002$, E4 vs. E3 at 17 mo). The transcriptomic analysis confirmed defective activation of TGF-beta, TNF-alpha, Myc, and p53 pathway genes in APOE4 mice after DOX, as well as a defective tissue repair response. In APOE3 myocardium, mRNAs encoding neuregulin (Nrg1), a key cardiac survival/repair factor, and multiple cardiac-specific contractile proteins were induced at d3 after DOX; this response was markedly attenuated in APOE4 mice. CIBERSORTx analysis for 22 distinct immune cell types showed an increase in activated M2 macrophages after DOX in APOE3, but not in APOE4 mice. Western and immunohistochemical analyses confirmed increased CD206, a specific M2 macrophage biomarker, in APOE3 but not in APOE4 mice after DOX ($p<0.05$.) Of note, M2 macrophages increased with age in both wt and APOE3 mice, but not in APOE4 mice ($p<0.05$, E3 vs. E4, 17 mo.).
Conclusion: Our results suggest that the APOE4 allele may confer increased vulnerability to DOX-induced and age-mediated cardiac damage through specific impairment of post-injury

repair responses involving M2 macrophage polarization and activation. Whether this is related to known APOE allelic differences in lipoprotein transport or innate immunity functions remains to be determined, as does potential relevance to chemotherapy and other types of cardiac injury in humans.

P1-06-08: Quantifying Treatment Tolerability in Real-world Breast Cancer Practice: A Pragmatic Approach Utilizing Patient-Reported Outcomes (PROs)

Emelly Rusli, Aaron Galaznik, Debra Wujcik

Background: Treatment tolerability in cancer care, historically assessed by the clinician, is moving towards incorporating patients' voices to capture how they feel and function during treatment1-3. Women undergoing breast cancer (BC) treatment often experience debilitating symptoms and decreased quality-of-life (QoL). Routine symptom monitoring and patient-reported outcomes (PROs) may enhance the understanding of tolerability from patients' perspectives. Measurement of patient-reported tolerability (PRT) for thyroid cancer was recently published by Brose et al (2024)4. This study aimed to adopt this method to explore PRT in breast cancer using PROs collected in real-world clinical practice.
Methods: Study participants included patients who enrolled in Carevive PROmpt®, a remote symptom monitoring (RSM) platform, and received BC treatment between 9/2020 and 5/2024. Patients completed at least one weekly PRO survey that included treatment bother, measured by a single item FACT-GP5 ("I am bothered by side effects of treatment"), and were followed from baseline survey completion until last survey completion or end of study period (whichever was earliest). Treatment data (name, start, and end dates) were sourced from the electronic medical record or entered directly into the platform by the care team. Treatment tolerability was defined as the degree of treatment bother and was classified into two categories: 1) high treatment bother (HTB), defined as response 3 ("Quite a bit") or 4 ("Very much") and 2) low treatment bother (LTB), defined as response 0 ("Not at all"), 1 ("A little bit"), or 2 ("Somewhat") to the single item FACT-GP5 on a given survey. PRT was calculated as the proportion of surveys with HTB per patient per regimen. Persistent HTB was defined as reporting HTB 76-100% of the time. Results were analyzed by stage (Early vs. Metastatic), biomarker (HER2-/HR+, HER2+, TNBC), therapy type, and PRO assessment time (weeks 1-4 vs. weeks 5+).
Results: A total of 299 patients were included in the study. Median age was 55, 85% White, 21% metastatic, 14% TNBC, with median follow-up of 10 weeks. Average number of treatment regimens per patient was 1.2 (SD=0.5, Median=1). About 44% of patients (n=132) reported HTB at least once. Incidence rate of HTB was 6.46 per 100 patients per week. Most patients (79%) experienced HTB </=50% of the time, yet 21% experienced HTB 51-100% of the time on treatment. More patients in the metastatic group appeared to report persistent HTB (13.8%) than in the early-stage group (7.9%). Similarly, more patients with TNBC type reported persistent HTB than other biomarkers. When examined by therapy type, the proportion of patients with persistent HTB ranged from 6-13%.

Prevalence by PRO assessment time showed a higher percentage of patients experiencing persistent HTB at week 5 or later than during weeks 1-4 (8.4% vs 6%, respectively). Further exploration by stage showed the proportion of persistent HTB appeared to increase from weeks 1-4 (5.1%) to week 5 or later (8.4%) in the early-stage group while the proportion was more consistent in the metastatic group (9.4% vs. 9.8%, respectively). Conclusions: This study utilized PROs to quantify treatment tolerability in women receiving BC therapy in the real-world clinical practice. Nearly half of women reported HTB at least once during treatment and 1 in 5 reported persistent HTB. A closer look showed more patients with metastatic disease and TNBC reported persistent HTB, and bother was higher at week 5+ versus week 1-4. PRT provides the means to quantify tolerability and track longitudinal changes, which gives important insights into BC treatment experience. Future studies should focus on factors that impact tolerability, symptoms that are most persistent over time, and healthcare resource utilization associated with HTB.

P1-06-09: Importance of Assessing Thyroid Dysfunction in Breast Cancer Patients Undergoing Pembrolizumab-based Neoadjuvant Chemotherapy

Byeongju Kang, Jung Eun Choi, Moohyun Lee, Ho Yong Park, Jin Hyang Jung, Soo Jung Lee, Su Hwan Kang, Jin Gu Kang, Sun Hee Kang, Jihyoung Cho, Yee Soo Chae, Soo Jung Lee, In-Hee Lee, Keon Uk Park, Hyera Kim, Jeeyeon Lee

Introduction: Pembrolizumab is a novel immunotherapy agent that improves oncological outcomes in various cancer types. Although there are minor immune-related adverse events (irAEs) when used alone, various irAEs have been reported when it is combined with chemotherapy. The aims of this study were to investigate irAEs that occurred after neoadjuvant chemotherapy (NAC) with pembrolizumab based on the KEYNOTE-522 regimen for triple-negative breast cancer (TNBC) and to identify fatal irAEs that should be corrected before surgery under general anesthesia.
Methods: Between 2022 and 2024, a total of, 71 cases from 81 patients who completed NAC with pembrolizumab based on KEYNOTE-522 regimen (wP/Cab and pembrolizumab followed by AC and pembrolizumab) followed by surgery were reviewed based on their medical records. All irAEs that occurred were investigated and classified into five categories: systemic, gastrointestinal, respiratory, musculoskeletal, and endocrine. Underlying diseases that existed before the diagnosis of breast cancer or complications that occurred after surgery were excluded.
Results: The mean age of the patients was 49.62 (SD, ±10.6) years, and the stages at diagnosis were as follows: IIA (n=23, 32.4%), IIB (n=22, 31.0%), IIIA (n=14, 16.2%), IIIB (n=1, 1.4%), and IIIC (n=11, 15.5%). After NAC with pembrolizumab, the pCR rate was 49.3% (35/71)
Fifty-three patients (62.2%) experienced adverse events, and the number of adverse events were as follows: 1 (n=11, 20.8%), 2 (n=20, 37.7%), and ≥3 (n=22, 41.5%). Gastrointestinal symptoms were the most common (n=46, 86.8%), and dermatologic symptoms were the second most common (n=31, 58.5%). Among fatal irAEs, including colitis and pneumonitis,

they occurred in 11 patients (20.8%) and 2 patients (3.8%), respectively. There was no case of hepatitis, myocarditis, or hypophysitis as fatal irAEs after NAC and pembrolizumab for TNBC. Among these irAEs, thyroid disorders (n=16, 22.5%) were the most common adverse event after skin rash and nausea. Of the patients with thyroid disorders, 3 experienced fatal dysfunction. Their surgeries were delayed for an average of 8.5 weeks to correct the thyroid imbalance before they could safely undergo general anesthesia. The remaining patients, who did not experience such complications, were able to undergo surgery after an average of 5.2 weeks.
Conclusion: The irAEs that occurred after NAC with pembrolizumab in TNBC were varied and included some that were severe enough to affect the timing of surgery under general anesthesia. Thyroid dysfunction, in particular, should be evaluated and corrected during the neoadjuvant chemotherapy to prevent delays in surgery.

P1-06-10: Long-term Cardiovascular Risks in Breast Cancer Survivors with Diabetes

Sixten Harborg, Martin Magnusson, Olle Melander, Jonas Manjer, Signe Borgquist

Purpose: Examine the association between diabetes and long-term cardiovascular outcomes in breast cancer survivors enrolled in the Malmö Diet and Cancer Study (MDCS).
Methods:The MDCS enrolled 17,035 Swedish women from 1991 to 1996. We identified female MDCS participants diagnosed with invasive breast cancer between 1991 and 2014 and followed them until the first occurrence of a cardiovascular event (CVE), death, emigration, or December 31, 2020. Participants with prevalent breast cancer (N=576), carcinoma in situ (N=105), bilateral breast cancer (N=21), or metastatic disease at diagnosis (N=15), were excluded. Cardiovascular outcomes were ascertained through the Swedish National Patient Register and cause of death registries. CVE was defined as having an event of myocardial infarction, heart failure, or stroke. Diabetes information was obtained from six national and regional registries and treated as a time-varying variable. Survivors with diabetes before breast cancer diagnosis were exposed from the date of diagnosis, while those diagnosed after breast cancer were exposed from the date of diabetes diagnosis. We fit Cox regression models to compute hazard ratios (HRs) with 95% confidence intervals (CI) for CVEs and cardiovascular mortality comparing breast cancer survivors with and without diabetes and stratified by adjuvant cancer therapies. Sensitivity analyses were conducted for the subgroup of survivors with incident diabetes after breast cancer diagnosis.
Results: Among the 1,099 breast cancer survivors followed for a median of 10.7 years, 87 had diabetes before breast cancer diagnosis, and 116 were diagnosed after breast cancer diagnosis. During follow-up, 255 CVEs occurred, and 92 survivors died from cardiovascular disease. Survival analysis showed that breast cancer survivors living with diabetes had an increased risk for CVEs (HR 1.44, 95% CI 1.05-1.99) compared with breast cancer survivors without diabetes. Stratifying by adjuvant chemotherapy, we found that survivors who received chemotherapy had a substantially higher risk for CVEs (HR 2.34, 95% CI 1.16-

4.72). When only considering survivors with incident diabetes after breast cancer diagnosis, the risk for CVEs was increased (HR 1.54, 95% CI 1.00-2.39) again specifically for chemotherapy-treated individuals (HR 3.46, 95% CI 1.24-9.66). Additionally, the risk of cardiovascular mortality was increased in survivors living with diabetes (HR 2.23, 95% CI 1.38-3.60). No differences were observed for the association with CVE when analyses were stratified for adjuvant endocrine therapy or radiation therapy.
Conclusion: Diabetes is associated with an increased risk of long-term cardiovascular events and cardiovascular mortality in breast cancer survivors. The risk is particularly pronounced in survivors with incident diabetes following breast cancer diagnosis and among survivors treated with chemotherapy. These findings underscore the importance of cardiovascular monitoring and management in breast cancer survivors, particularly those who develop diabetes during follow-up. Early detection and treatment of post-breast cancer diabetes could potentially mitigate these cardiovascular risks.

P1-06-11: Intravenous Iron in Early-Stage Breast Cancer Patients Receiving Neoadjuvant Chemotherapy

Jules Cohen, Meghana Rao

Background: Early-stage breast cancer patients frequently demonstrate iron deficiency with or without anemia because of recurrent menstrual losses during their premenopausal years. It is not uncommon to remain iron deficient after menopause due to failure to replete whole body iron stores with diet alone. Chemotherapy induces anemia through its suppressive effects on the bone marrow and hematologic recovery can be impeded by iron stores insufficient to manufacture new red blood cells. Available data suggests that intravenous (IV) iron supplementation is safe in cancer patients and that anemia in cancer patients is associated with an increase in all-cause mortality. We are conducting a retrospective study to understand the effect of IV iron supplementation on efficacy and toxicity in early-stage breast cancer patients receiving neoadjuvant chemotherapy. We hypothesize that IV iron supplementation can improve rates of pathologic complete response (pCR) and improve our ability to administer standard neoadjuvant chemotherapy regimens by maintaining patient quality of life and reducing need for dose modifications and treatment delays.
Objective: To identify the effect of IV iron supplementation on the efficacy and toxicity of neoadjuvant chemotherapy in early-stage breast cancer patients.
Methods: We are analyzing efficacy endpoints (pCR, 3 year invasive disease-free survival, etc.) and toxicity endpoints (dose reductions, dose delays, hemoglobin decreases, hemoglobin recovery, etc.) in a retrospective cohort of breast cancer patients receiving neoadjuvant chemotherapy. Patients will be divided into three major groups: (1) iron deficient (ferritin <100) receiving IV iron, (2) iron deficient not receiving IV iron and (3) not iron deficient (ferritin >100) not receiving IV iron. pCR rate will be evaluated across the entire cohort and subdivided by luminal (ER-positive), triple negative and HER2-positive subtypes. We will further analyze the absolute and relative changes in hemoglobin levels

over time; the incidence of dose reductions and dose delays; and the effects on patient quality of life as evidenced in the medical record before, during and after the course of neoadjuvant chemotherapy.
Results: We anticipate that iron deficient patients with or without IV iron supplementation will manifest a pCR rate no worse than non-iron deficient patients but that there will be better tolerability and fewer dose reductions or dose delays in patients receiving IV iron supplementation. At best, patients receiving IV iron will demonstrate a pCR rate superior to patients not receiving IV iron, possibly regardless of whether it is indicated (ferritin <100) or not (ferritin >100).
Conclusions: Iron deficiency, with or without anemia, is common in women with early-stage breast cancer receiving neoadjuvant chemotherapy. Available data suggests that IV iron is safe during cancer chemotherapy and may improve efficacy and minimize side effects to these toxic drugs commonly known to cause myelosuppression. If we demonstrate that patients receiving IV iron have improved pCR rates and decreased dose reductions and dose delays, this could have a practice-changing effect on supportive care interventions administered during neoadjuvant chemotherapy for early-stage breast cancer.

P1-06-12: Efficacy and safety of the addition of prophylactic atropine to patients with metastatic triple-negative breast cancer treated with sacituzumab govitecan: a Spanish multicenter real-world study

María José Echarri, Marta Santisteban, Juan David Cárdenas

Background: Sacituzumab govitecan (SG) is a first-in-class trophoblastic antigen-2 (Trop-2)-directed antibody–drug conjugate (ADC) composed of a humanized monoclonal antibody (hRS7 IgG1κ) that recognizes Trop-2 and SN-38, a topoisomerase I inhibitor which is covalently attached to the antibody by a hydrolysable linker and results in DNA damage leading to apoptosis and cell death.
SG showed a significant and clinically meaningful improvement in progression-free survival (PFS) and overall survival (OS) compared with single-agent chemotherapy among patients with pretreated advanced triple negative (TN) and luminal HER2 negative breast cancer (BC) in the ASCENT1 and TROPiCS-022 trials, respectively.
SN-38 can cause early-onset diarrhea through parasympathetic stimulation and delayed diarrhea via intestinal epithelial damage, inflammation, and dysbiosis. In clinical trials, the safety profile of SG was manageable, with febrile neutropenia (4.8%), diarrhea (3.9%), neutropenia (2.6%) and pneumonia (2%) being the most frequently reported serious adverse reactions3, causing dose reductions and treatment discontinuations.
Atropine is a muscarinic acetylcholine receptor antagonist that suppresses the parasympathetic effects of SN-38. Premedication with atropine sulfate in treatments such as SG could improve the management of severe diarrhea associated with cholinergic syndrome.
Objective: To evaluate the efficacy and safety of the use of prophylactic atropine to prevent diarrhea in advanced metastatic BC patients treated with SG.

Case series: Here, we describe 17 female patients with a median age of 50 years (29-72) and histologically confirmed TN (13) and HR+/HER2- unresectable locally advanced mBC (4) who were treated with SG and prophylactic atropine according to the approved indications in Spain. At baseline, most of the patients had ECOG score of 1 (52.9%) or 2 (35.3%), positive germline BRCA 1/2 mutations (11.8%), PDL1+ (82.1%), and visceral metastasis 41.2%, central nervous system (CNS) 17.6%, and both 64.7%.
According to the efficacy results, the median lines of therapy was 3 (range 1-9), with a median duration of response of 4 months (2-12). We observed a clinical benefit rate of 64.7%, defined as the percentage of advanced cancer patients who achieved complete remission (5.9%), partial remission (41.2%) and stable disease (17.6%). Median progression-free survival was 5 months.
The main treatment-related adverse events were any grade (64.7%) or grade 3-4 (23.5%) neutropenia, and diarrhea (58.8% grade 0; 35.3% grade 1; and 5.9% grade 2; without grade 3-4), 17.6% of the patients required a dose reduction. No discontinuations due to treatment-related adverse events were observed.
Conclusions: We observed a similar median progression-free survival to that observed in the ASCENT trial. Adding atropine to SG led to a higher proportion of subjects without diarrhea (58.8%) compared to ASCENT (30.2%), with no subjects presenting grade 3-4 diarrhea. These finding suggested that adding atropine to patients treated with SG might be beneficial for reducing diarrhea while maintaining the efficacy of the treatment.

P1-06-13: Financial Toxicity and Quality of Life in Breast Cancer Patients at a Safety Net Hospital

Bayle Smith-Salzberg, Joshua Feinberg, Pasang Sherpa, Vijaya Natarajan, Ashley Anderson, Mukuhi Nganga, Fleure Gallant, Jonathan Klein

Introduction: Financial toxicity (FT) is the burden faced from out-of-pocket expenses related to cancer treatment, including direct cost of treatments, lost income, and travel expenses. Studies suggest increased FT is associated with decreased quality of life (QOL) and, possibly, worse survival. Patients from potentially marginalized groups including non-English speakers or patients with low socioeconomic status may be particularly vulnerable to FT. Maimonides Medical Center (MMC) is a safety net hospital in Brooklyn, NY, that treats many such patients. Here we present preliminary data from a prospective, longitudinal study of FT in breast cancer (BC) patients at MMC.
Methods: All patients undergoing curative-intent treatment for BC at MMC were eligible. We collected demographic and clinical data from patients' electronic medical records. FT was

assessed via the total score on the validated Comprehensive Score for Financial Toxicity (COST) version 2 questionnaire and QOL was assessed via the summary score of the EORTC Quality of Life Core-30 questionnaire and EORTC question 30: "How would you rank your overall quality of life in the past week?" The EORTC summary score was calculated according to the scoring manual and does not include question 30. EORTC summary score is out of a maximum of 100, with a higher score indicating better QOL. COST is scored out of a maximum of 44, with a higher score indicating better financial well-being (FWB).
In the study, patients complete questionnaires at baseline (i.e. prior to treatment start) and 6 months later, with optional collection at 3, 9, and 12 months. Preliminary data presented here were collected at baseline. Data analysis was performed using SPSS (version 29.0, IBM Corp.) and R (version 4.4.1, R Core Team). Descriptive statistics, Pearson correlation, ANOVA, and Spearman's rank correlation analyses were performed. All p values are reported from 2-sided tests, and the results were deemed statistically significant at $p < .05$.
Results: Thirty-seven patients were included in this analysis. Mean age at diagnosis was 57 (SD: 10). 13 patients (35%) did not speak English. Six patients (16%) identified as Asian, 18 (49%) as Black, 8 (22%) white, and 5 (13%) declined to answer. Twenty patients (54%) reported household income of less than $60k per year, 8 (22%) reported more than $60k, and 9 (24%) declined to answer. Fourteen patients (38%) had private insurance coverage, 9 (24%) Medicare, and 13 (35%) Medicaid. Six (16%) patients had DCIS, 21 (57%) had stage T1 BC, 5 (14%) had T2-3 BC, 4 (11%) had node-positive BC and 1 (3%) had bilateral BC.
At baseline, mean COST score among all participants was 22 (SD: 10). The mean EORTC summary score was 83 (SD: 17). For EORTC question 30, patients responded on a 7-point Likert scale where 1 indicates "very poor" QOL and 7 indicates "excellent" QOL. No patient marked 1 or 2, 2 (5%) marked 3, 10 (27%) marked 4, 7 (19%) marked 5, 9 (24%) marked 6, and 9 (24%) marked 7.
Better FWB measured via (higher) COST score positively correlated with better overall QOL via both EORTC summary score ($\rho = 0.47$; $p = 0.004$) and EORTC question 30 ($\rho = 0.39$; $p = 0.017$). There was a statistically significant association between higher COST score and patients with household incomes >$60k ($p = 0.002$). Early-stage (DCIS or T1) was also associated with higher COST score ($p = 0.047$). There was no difference between the COST scores of patients of differing age, insurance type, language, or ethnicity ($p > 0.05$).
Conclusion: Worse FT at baseline is associated with lower QOL in BC patients, underscoring the importance of financial burdens for cancer patients. Patients with lower household incomes and those with more advanced disease experience worse FT even before initiation of treatment. Further work including longitudinal data collection will help inform our understanding of how FT develops over the course of treatment and help develop future interventions to screen for and mitigate the effects of FT.

P1-06-14: The relevance of carbon footprint in enviro-logistical analysis in breast cancer trials

Stefan Lukac, Michael Hiete, Wolfgang Janni, Sibylle Loibl, Visnja Fink, Elena Leinert, Kristina Veselinovic, Henning Schäffler, Davut Dayan, Sabine Heublein, Florian Ebner

Background: The consequences of environmental pollution in oncology are well known and should be addressed. Clinical trials in breast cancer typically compare different therapeutic strategies regarding their effect on survival endpoints such as overall survival, disease-free survival, or patient-reported outcomes like quality of life (QoL). Both endpoints relate to the patients' quantitative (time) and qualitative (QoL) benefits, but they do not reflect the patients' time burden caused by the treatment and the associated environmental burden that can ultimately negatively affect the achieved benefit.
Methods: In the ongoing MyTime study (DRKS00033577) during the neoadjuvant treatment of early breast cancer and the PADMA trial (NCT03355157) in the metastatic setting, an enviro-logistical analysis is included to evaluate the logistical burden on the patient and the consequent ecological burden on the environment. Therefore, we propose the clinically relevant key principles of carbon footprint and enviro-logistical analysis that could be incorporated in future breast cancer trials.
Results: First, according to different treatment schemes, the necessary number of contacts with the healthcare system should be recorded as a primary variable. Its relevance lies in the logistical analysis of the patients' burden from the treatment. The related parameters to the number of contacts include the time spent on necessary contacts (time burden of the patient due to the therapy) and the climate impact in CO2 equivalents caused by the means of transport. Second, a material evaluation based on the material and energy consumption necessary for the application of the therapy should be assessed using carbon footprinting or streamlined life-cycle assessment methodology. Consequently, the additional therapy-triggered CO2 equivalents are included, and the carbon footprinting is completed. By including the time burden on patients and the consequent environmental burden from transport, materials, and energy consumed, beneficial information for comparing treatment options holistically can be acquired.
Conclusions: In summary, while the primary goals will remain survival and QoL, for treatment options with equivalent effectiveness, the enviro-logistically optimal one could be selected to reduce patients' burden and environmental pollution, thereby avoiding secondary negative factors affecting outcomes. Therefore, the enviro-logistical approach should be included in clinical trials.

P1-06-15: Multi-Site Real World Data of Patient Reported Outcomes from Patients with Breast Cancer on Immunotherapy or Antibody Drug Conjugates using the Carevive PROMPT™ Web-Based Platform

Kim Blenman, Mariya Rozenblit, Adriana Kahn, Mateo Montalvo Campana, Danielle S. Lee, Alice Wnuk, Jessica Robitaille, Cassidy Lockwood, Kelley Messina, Mya Davis, Renelle Gee, Suzanne Johnson, Emelly Rusli, Julie Scott, Aaron Galaznik, Maryam Lustberg

Introduction: Immunotherapy and antibody drug conjugates are quickly becoming the backbone of treatment regimens for breast cancer. However, these therapies do present with appreciable treatment emergent adverse events that are variable and difficult to predict in individual patients. Patient reported outcomes (PROs) are critical for

understanding the patient experience and kinetics of treatment emergent adverse event. Therefore, providing tools for patients to capture these events outside of a clinical visit is critical.
Methods: The Patient Reported Outcomes mobile web-based platform, Carevive PROmpt™ was used to collect symptom and wellness data once per week for at least 12 weeks using validated psychometric tools (PRO-CTCAE (symptoms), FACT-GP5 (treatment bother), PROMIS 4a (physical function), ECORTC QLQ C30 (quality of life)). Descriptive statistics are shared from 97 patients with breast cancer who were treated with immunotherapy (atezolizumab, pembrolizumab) and/or an antibody drug conjugate (ado-trastuzumab emtansine (T-DM1), fam-trastuzumab deruxtecan-nxki (T-Dxd), sacituzumab govitecan-hziy (sacituzumab)) as standard of care. The following 16 symptoms were measured: anxiety, constipation, cough, decreased appetite, diarrhea, fatigue, general pain, insomnia, mouth/throat sores, muscle pain, nausea, numbness/tingling, rash, sadness, shortness of breath, and vomiting. The number of patients reporting an individual symptom was divided by the total number of patients each week to generate a percentage positive value for each symptom for each week. The median percentage and interquartile range (IQR) of each symptom over the evaluation period is reported. Data was used from multiple centers.
Results. Fifty-two (54%) triple negative, 8 (8%) HR-HER+, 17 (17%) HR+HER2+, 19 (20%) HR+HER2-, and 1 (1%) unknown subtype were included in this analysis. The majority of patients, 56 (58%), were clinically early-stage. The remaining patients were metastatic (32 (32%)) or unknown stage (10 (10%)). Fifty-two (54%) patients were treated with immunotherapy plus chemotherapy regimens and 34 (35%) were treated with antibody drug conjugates, including 18 (18%) T-DM1, 15 (15%) T-Dxd, and 2 (2%) sacituzumab. Eleven (11%) patients were treated with an immunotherapy and antibody drug conjugate during the study period. Sixty-one (63%) were < 55 years of age, 29 (30%) were <45 years of age, and 18 (19%) were less than 40 years of age. The race and ethnicity distributions were 64 (66%) White, 19 (20%) Black or African American, 3 (3%) Asian, 2 (2%) American Indian or Alaska Native, 4 (4%) Hispanic/Latine, and 9 (9%) Other/Unknown. The highest reported symptoms over a 32-week period were fatigue (median 6.70% (IQR 21.65%)), muscle pain (median 4.12% (IQR 10.31%)), anxiety (median 3.09% (IQR 9.28%)), sadness (median 2.06% (IQR 6.09%)), and mouth/throat sores (median 2.06% (IQR 3.09%)). The highest reported symptoms were reported starting within the first week of reporting and were often reported in at least 50% of the timepoints for each patient that reported the symptom. There were no appreciable differences between reported symptoms from patients with metastatic versus early-stage disease.
Conclusions: The onset and duration of treatment emergent adverse events can be assessed for individual patients. This information will facilitate earlier interventions for symptom management of individual patients. However, a limitation is that although the questionnaires were sufficient to alert clinical care teams of potential toxicity in general, they were not specific to toxicities associated with immunotherapies or antibody drug conjugates. Therefore, an opportunity area for the field is to create more specific or tailored PROs for immune toxicities associated with immunotherapies, antibody drug conjugates, and cell-based therapies.

P1-06-16: Tumor Immune Micro-Environment (TIME) Effect of Cryoablation in Triple-Negative Breast Cancer - It was the best of TIMES…

Flavia Sardela de Miranda, Dalia Martinez-Marin, Rachel L. Babcock, Geetha Pryia Boligala, Nicholas Wagner, Elizabeth Jeffery, Rebecca Joseph, Omar Barakat, Reshad S. Ghafouri, Maria F. Mahecha, Karla Daniele, Kevin Pruitt, Sharda P. Singh, Michael W. Melkus, Rakhshanda Layeequr Rahman

Background: Cryoablation of breast cancer (BC) is an out-patient procedure, less invasive than surgery, cost-efficient and may provide the added benefit of anti-tumor immunity. Cryoablation has been approved for small (≤1.5 cm) low-risk (hormone receptor positive) breast tumors and is currently being investigated for high-risk breast cancers (HER2+ and TNBC). Cryoablation uses ultrasound to guide a cryo-probe into the tumor and, through a series of freeze thaw cycles, kills the tumor and induces necrosis. The tumor remains in the patient and renders it "hot" promoting immune cell infiltration while preserving tumor associated antigens (TAA) to generate an immunogenic response. Our pre-clinical reports show cryoablation results in lower rates of tumor recurrence and metastasis with increased TILs at distant tumors. Using a murine model for TNBC cryoablation, we evaluated the immune response following cryoablation compared to surgical resection to identify early mechanism of the abscopal effect and potential biomarkers for cryoablation efficacy.
Methods: We used a syngeneic TNBC mouse model with an intact immune system to better understand cryoablation and the abscopal effect utilizing a distant tumor for immune response read out. BALB/c mice were orthotopically transplanted with 1x106 cells of the highly metastatic TNBC 4T1-12b-luciferase expressing cell line into the fourth and ninth mammary fat pad on left and right sides. Tumor growth and metastasis were monitored by palpation, caliper measurements and the in vivo imaging system (IVIS) for luminescence during the course of the experiments. At 2 weeks post-transplantation, the left tumor was treated by either resection or cryoablation. IVIS imaging showed complete tumor cryoablation at 24-hrs. One-week later the mice were sacrificed, necropsied for metastasis and tissues evaluated by flow cytometry for the anti-tumor immune response.
Results: The cryoablated tumor had significant infiltration of immune cells (naïve CD4+ T cells and myeloid cells) for tissue damage control and clean-up which allows for de novo TAA presentation. In addition, there was a significant increase in migratory cDC1s (CD103+/XCR1+) in the tumor draining lymph node (TDLN) as well as the spleen (secondary lymphoid tissue). In examining the distant abscopal tumors, cryoablation of the primary tumor resulted in significantly smaller abscopal tumors and changes in TIME with increased activated CD8+ ICOS+ T cells compared to resection. Differentially expressed gene analysis of bulk tumors (cryoablation abscopal vs. resection abscopal) showed increased anti-tumor changes with upregulation of tumor suppressor genes (Stat6 and Nlrp12) and T and NK cell cytotoxicity (Prf1 – perforin) and downregulation of metastatic (Cx3cr1) and angiogenesis and immunosuppression (Cxcl2) genes. STRING analysis for gene pathway ontology showed several immune processes to be involved including immune system process, cell activation, cytokine production, and cell surface receptor signaling pathways. GSEA (gene set enrichment analysis) plot analysis identified significant changes for

hallmark genes in the Inflammatory response, IL2-Stat5 Signaling, and IL6-Jak-Stat3 signaling.
Conclusion: Our results suggest that cryoablation enhances the myeloid response playing an early role in generating the anti-tumor immune response and potentially influences the TIME at distant tumors. We found increased infiltration of migratory cDC1 (CD103+/XCR1+), potent antigen presenting cells (APC) critical for effective anti-tumor CD8+ T cell priming, in the cryoablated TDLN and spleen. This dendritic cell population also has the ability to "cross-dress"/pass antigens to other APCs, making cDC1s a potential target for immune modulation to increase anti-tumor immunity enhancing the abscopal effect.

P1-06-17: Inhibition of oncogenic PTK6 kinase enhances immune response against triple negative breast cancer via EMT reversal

Hanna Irie, Ibuki Harada, Criseyda Martinez, Koichi Ito, Eunjee Lee, Jun Zhu

Background/Rationale: PTK6/Brk, a non-receptor tyrosine kinase, is highly expressed in approximately 40% of triple negative breast cancers (TNBC). Higher levels of PTK6 expression are associated with worse patient outcomes. PTK6 is a driver of oncogenic growth, survival, invasion, epithelial-mesenchymal transition (EMT), chemotherapy resistance and metastasis. Recent studies have reported an association between PTK6 expression and an immunosuppressive microenvironment in patient breast cancers. Therefore, in addition to tumor cell-intrinsic oncogenic functions, PTK6 may play a critical role in shaping the tumor immune microenvironment which could modulate sensitivity to chemo/immunotherapy of TNBC. Inhibition of PTK6 could therefore suppress TNBC tumor growth and metastasis via dual (cell autonomous and microenvironmental) mechanisms.
Methods. Genetic and pharmacological approaches were used to downregulate/inhibit PTK6 in immunocompetent and immunodeficient mouse models of TNBC (MMTV-myc, 4T-1). The effects of PTK6 shRNA expression, as well as treatment with a validated PTK6 kinase inhibitor (P21d), on TNBC tumor growth were monitored. For studies using immunocompetent models, immune populations (tumor-infiltrating and systemic) were analyzed by flow cytometry and immunofluorescence.
Results: MMTV-myc or 4T-1 tumor-bearing, immunocompetent mice were treated with P21d, a validated small molecule inhibitor of PTK6 kinase activity. P21d treatment significantly inhibited tumor growth and increased tumoral infiltration by activated, cytotoxic immune cells (CD8+ T cells, NK cells). These effects were phenocopied by PTK6 shRNA or SNAIL shRNA expression, both of which also promote EMT reversal. Interestingly, the effects of P21d and PTK6 shRNA treatment on tumor growth were discordant when these same tumors were grown in immunodeficient mice; PTK6 shRNA, but not P21d treatment, inhibited TNBC growth. These results indicate that P21d's inhibitory effect on tumor growth is reliant on immune modulation and that this immune regulation is PTK6 kinase-activity dependent. These results also suggest that there are kinase activity-independent mechanisms that are important for tumor growth control by PTK6. The importance of immune modulation in P21d-dependent triple negative tumor

inhibition was reinforced by the fact that co-treatment of tumors with CD8 T cell or NK cell-depleting antibodies nearly completely abrogated P21d's effects on tumor growth. We identified CXCL10 as a mediator of P21d treatment-induced tumoral immune cell infiltration and tumor growth inhibition.
Summary/Conclusion: Our studies highlight novel tumor immune microenvironmental functions of PTK6 oncogene in TNBC. PTK6 inhibition leads to recruitment and activation of cytotoxic T and NK cells that are critical for TNBC growth inhbition. Ongoing studies will determine whether these functions can be leveraged to enhance efficacy of immunotherapies currently used in the care of patients with TNBC.

P1-06-18: Variation of CCR7 Immune Cell Receptor Expression by Nodal Burden in Patients with Invasive Breast Cancer

Jennifer Chen, Gong, Megumi Kai, Lei Huo, Wendy A. Woodward

Background: CCR7 is a G-protein coupled immune cell receptor differentially expressed on breast cancer cells to mediate trafficking toward lymphatic vessels. Current understanding of CCR7 expression profile in relation to patient and tumor characteristics is lacking. We aimed to characterize CCR7 expression and correlate expression patterns with clinicopathologic factors and outcomes in patients with invasive breast cancer.
Methods: Surgical resection samples were obtained from patients diagnosed with invasive breast cancer from 2006-2016. Tissue microarray (TMA) was prepared with immunohistochemical staining of samples in duplicates. CCR7 staining was scored by two expert breast pathologists for staining pattern (membranous vs. cytoplasmic), percentage (0-100% in 10% increments), and intensity after normalizing for background staining (range 1-3+). Chi-squared and one-way ANOVA tests were used to compare CCR7 staining patterns between groups. Pearson correlation coefficient was used to measure relationships between staining parameters and Kaplan Meier analysis was used for survival estimates
Results: In total, 217 patients were included. The median age at diagnosis was 56.0 (IQR 48.0-64.0) with 62.7% (136) White, 17.1% (37) Hispanic, 14.3% (31) Black, and 4.1% (9) Asian, and 4 (1.8%) Other patients. Up to 61.5% (88/143) of the cohort had clinical AJCC stage II-III disease and majority had ductal (85.7%, 186), grade 2 or higher (87.1%, 189), HER2-negative disease (81.1%, 176). Receptor subtypes consisted of 56.2% (122) HR+/HER2-, 24.4% (53) triple negative, 15.7% (34) HR+/HER2+, and 2.8% (6) HR-/HER2+. LVI was present in 30.4% (66) of patients and 28.6% (62) of patients received neoadjuvant chemotherapy prior to surgical resection. Overall, majority of patients had diffuse (100%) membranous and cytoplasmic expression of CCR7 (90.3%, 196). Up to 6.9% (15) had mixed membranous and cytoplasmic expression (< 100%) while 1.4% (3) had only cytoplasmic expression and 1.4% (3) had no CCR7 expression altogether. Cytoplasmic CCR7 staining positively correlated with membranous CCR7 for both percentage and intensity ($p < 0.01$ for both, $r = 0.647$ and 0.503, respectively). Staining intensity tended to be higher for membranous (median 3+) compared to cytoplasmic CCR7 expression (median 2+). Nodal burden was a key contributor to both membranous and cytoplasmic CCR7 staining

intensity. Patients with higher clinical and pathologic nodal burden demonstrated significantly increased membranous CCR7 staining intensity (3+: 75% for cN3c vs. 44.1% for cN1, p = 0.021 and 80% for pN3 vs. 55.3% for pN0, p = 0.015). Similarly, higher pathologic nodal status, greater clinical and pathologic tumor size, and higher overall pathologic stage were significantly associated with increased cytoplasmic CCR7 staining intensity (all p < 0.05). There were otherwise no differences in CCR7 staining pattern and intensity by age, race, tumor grade, histology, presence of lymphovascular invasion, clinical nodal status, and receptor subtype. Overall survival and progression-free survival did not vary by cytoplasmic and membranous CCR7 staining intensity (OS: p = 0.241 and 0.369, PFS: p = 0.898 and 0.147, respectively).
Conclusion: In this cohort of patients with invasive breast cancer, CCR7 is highly prevalent and expression pattern varied significantly with extent of nodal disease. Given its association with nodal burden, CCR7 may serve as a promising therapeutic target for patients with invasive breast cancer, particularly among those with locally advanced disease.

P1-06-19: Circulating Cytokine Profiles Associated with Differential Stromal Tumor Infiltrating Lymphocyte (sTIL) Levels in ER-positive Early Breast Cancer

Noel Blaya Boluda, Esmeralda García-Torralba, Esther Navarro Manzano, Miguel Pérez Ramos, Elisa García Garre, Esperanza Guirao, Alberto García-Romero, Pilar de la Morena Barrio, Ana Fernández Sánchez, Alicia de Luna Aguilar, Francisco García Molina, Elena García-Martínez, Francisco Ayala de la Peña

Background: Luminal breast cancer (BC) is associated with a lower level of tumor immune response, but recent results from trials with neoadjuvant immunotherapy (IT) and translational studies suggest that some subgroups of luminal BC might be sensitive to IT. The significance of the relation between the immune peripheral and the immune tumor compartments is not yet well understood and might be relevant for the search of new predictive immune biomarkers. Blood levels of cytokines partially reflect immune and inflammatory activation and might be related to differential immune response levels in the tumor. The aim of this study was to determine if certain profiles of blood cytokines are related to stromal lymphocytic infiltration (sTIL) in early luminal BC treated with neoadjuvant chemotherapy (NCT).
Methods: We analyzed pre-treatment plasma levels of 29 cytokines in a prospective single-center cohort of women with estrogen receptor (ER)-positive BC treated with NCT (2012-2017). Cytokine levels were analyzed using bead-based multiplex assays and Luminex technology. Pre-treatment sTIL (percentage) were measured in the diagnostic core biopsy following validated standard methods. For statistical analysis, preprocessing of plasma cytokine values included log transformation, assignment of half the limit of detection to non-detectable values, treatment of outliers and imputation of missing values with an iterated random forest algorithm. The correlation between cytokine levels and sTIL was

analyzed with Spearman's Rho, and those cytokines with stronger correlations were included in a multilinear regression model. Partial least squared-discriminant analysis (PLS-DA) was additionally performed to identify the association of cytokine levels with high sTIL infiltration (dichotomous sTIL with a 10% cut-off); performance was assessed with AUC (area under the cuve) of the ROC (receiver-operating characteristic) curve. R version 4.2.3 was used for statistical analysis and data visualization.
Results: A total of 63 patients with ER-positive breast cancer were studied. Median age: 49 (range: 31-76); 39.7% grade III; 33.4% stage III; 39 patients ER+/HER2- (61.9%) and 24 ER+/HER2+ (38.1%). The mean sTIL infiltration was 15% (SD, 16.6); 32 patients were categorized as sTIL-low (≤ 10%) and 22 as sTIL-high (>10%). A higher correlation with sTIL was found for pre-NCT levels of IL-15, TNFα, MICA, MICB, CD27, HVEM, and PDL2. A multilinear regression model for sTIL as a continuous variable only included plasma PD-L2 (coefficient 19.72; 95%CI: 5.81, 33.62; p=0.006) and BTLA (coefficient: -7.66; 95%CI:-15.85, 0.53; p=0.06). In the optimized model obtained by PLS-DA for sTIL, two principal components (PCs) explained 52% of cytokine variation and had an AUC=0.82 for classification between sTIL-low and sTIL-high. The first PC was exclusively formed by pre-treatment PD-L2, further confirming its association with tumor lymphocytic infiltration.
Conclusions: In ER-positive early BC, baseline levels of circulating PD-L2 are associated with stromal TIL, exemplifying the interactions between the peripheral immune compartment and the immune response in the tumor microenvironment. Further research is needed to better understand the potential role of PD-L2, a PD-1 ligand, in modulating immune-related mechanisms of response to neoadjuvant treatment.

P1-06-21: The Ral GTPases regulate the TNBC secretome to drive growth and metastasis.

Jonathan Spehar, Prathik Chakravarthy, Dillon Richardson, Reena Shakya, Zaibo Li, Daniel Stover, Gina Sizemore, Steven Sizemore

Breast Cancer (BC) is the most common cancer and leading cause of cancer associated mortality in women worldwide, with TNBC patients have the highest mortality compared to other subtypes. Ras-Like Protooncogene A (RalA) and Ras-Like Protooncogene B (RalB) are small GTPases that are known to regulate growth and metastasis in several cancers. Our group and others have identified the Rals as molecular drivers of TNBC, however the roles of these GTPases in BC is poorly understood. The goal of this study was to investigate the contributions of RalA and RalB in TNBC.
We found that silencing RalA or RalB in the MDA-MB-468 (468) TNBC cells reduced primary tumor growth in NSG mice. To better recapitulate human disease, we utilized two genetically engineered mouse models of TNBC. First, we found in the MMTV-Cre; MMTV-PyMT spontaneous TNBC tumor model that loss of Rala significantly reduces primary tumor growth while loss of Ralb increases growth, with no changes in tumor initiation or mammary gland development. Then we tested loss of Rals in the Brca1; Trp53 mouse model, which form TNBC tumors phenotypically similar to human TNBC when given and

intraductal injection of adenoviral-Cre. Here we find that loss of Ralb significantly increases primary tumor growth with no changes in tumor initiation.
To understand how the Rals regulate tumorigenesis, we looked closer at the 468 tumors and cells. In the 468 model we found no differences in proliferation or apoptosis, leading us to test the tumor-microenvironment (TME) to explain the reduction in tumor growth. Using Masson's Trichrome staining, we found increased collagen deposition in the 468 tumors upon depletion of either Ral. Staining for blood vessels using CD31 revealed depletion of RalB, and not RalA, reduced stromal and intertumoral blood vessel density. We then tested for macrophage infiltration and find a reduction of either Ral increases overall macrophage infiltration and specifically M1-like macrophages. Depletion of RalA also reduced recruitment of M2-like macrophages compared to control or RalB depleted cells. To find what factors lead to the differences in the TME, we performed a human secreted protein array on conditioned media from the 468 shRal cells and confirmed significant results via ELISAs. We found the Rals promote secretion of the angiogenic factor ANGPT1 and interleukins CXCL1-3. Western blot on intracellular protein showed no changes in expression of ANGPT1, revealing that changes in secreted protein are not due to altered expression from sh depletion.
These results show that the Rals influence protein secretion that alters tumor angiogenesis and collagen dynamics to promote tumor microenvironment changes that aid TNBC growth and metastasis.

P1-06-22: Challenging the paradigm for NK cell activation

Isabella Terrazas, Isaac S. Chan

Breast cancer (BC) is the most common cancer in women and metastatic disease accounts for most BC-related deaths. Immunotherapy, which is currently focused on activating T cells, has revolutionized cancer care but results have been mixed for patients with metastatic BC. Natural killer (NK) cells are critical members of the innate immune system with potent anti-cancer and anti-metastatic properties and provide a potential new immunotherapy for BC patients. However, these therapies are quite nascent and improving them requires a mechanistic understanding of how NK cell cytotoxicity is regulated. NK cell cytotoxic response is typically described as being regulated by a variety of activating and inhibitory receptors whose activity depends on specific ligands on cancer cells; yet we still do not fully understand what causes NK cells to lose their anti-cancer properties in BC. Many studies characterizing NK activating or inactivating receptors in the context of cancer describe the activity of each receptor independently. However, we and others have found that these activating and inactivating receptors are not exclusively expressed. In a recent study we found intratumoral NKs have high gene and protein expression of a prominent inhibitory receptor, NKG2A, in breast tumors. We found as many as 95% of BC patients' NK cells were NKG2A+. We further sought to characterize the NKG2 receptor family by measuring expression of activating receptor NKG2D because BC patients with higher NKG2D+ NK cells have improved outcomes. Surprisingly, we found 100% of NKG2A+ NKs from healthy donors were also NKG2D+. The temporal and spatial regulation of the co-

expression of these receptors has not been defined in the context of BC.
NK cells were characterized through flow cytometry from whole blood samples from patients with BC. Using a dataset we previously published, which contains single-cell transcriptomic profiling of a very large cohort of breast tumors, we validated which BC cell lines are most resistant to NK cell killing. Healthy human NKs were cocultured with these lines and BC death and NK cell receptors were measured via flow cytometry. To test the function of NK cell receptors, during coculture, an antibody blockade for both NKG2A and NKG2D or their known ligands were added. This included MICA/B and ULBP1-6 for NKG2D and HLA-E for NKG2A. Post coculture, IFNg from the media were measured using an ELISA. Using a coculture system with NKs and cancer cells, we characterized the phenotypic and functional significance of NKG2D and NKG2A, an activating and inhibitory receptor, respectively. Phenotypically, in BC patients we have found that the receptor expression varies based on disease status. For example, NKs from a patient with ductal carcinoma were 48% double positive while NKs from a patient with invasive lobular carcinoma is 98% double positive. Next, we defined the 24-hour sensitivity or resistance of BC cell lines to NK cell cytotoxicity using primary NK cells isolated from healthy human donors. Compared to an established NK-sensitive erythroblast cell line, K562s, BT474 in coculture with NK cells had ~25% death, whereas K562 cells in coculture had 80% death, confirming that BT474s are more resistant to NK cell killing. We then tested functional blockade of both NKG2D and NKG2A on NK cells in coculture with BT474s and found IFNg secreted in the media increased by 2.5-fold compared to blocking receptors individually. When testing double positive NK function in coculture with NK cells from healthy donors, NKG2A+NKG2D+ cells had an 8.9-fold IFNg increase when cocultured with BT474, compared to NKG2D+ NK cells. Adding HLA-E, the natural ligand for NKG2A did not significantly change IFNg production. These results suggest NK cell function requires both NKG2D and NKG2A signaling. Identifying how these receptors function in tandem will clarify how NK cells respond specifically to BC. Ultimately, this could aid development of targeted BC NK cell immunotherapies.

P1-06-23: Extracellular matrix in Young Onset Breast Cancer – A dynamic niche as a therapeutic target

Lohita Krishna Kanyadhara, Srinath B S, Sulakshana Srihari, PS Hari, DurgaDevi Veeraiyan, Vikas Choudhary, Wude Ewunetu Zeleke, Savitha S. Sharma, Megha Sarvothama, Keerthi Shetty, Ramray Bhatt, Mallar Banerjee, Pooja Advani, Aruna Korlimarla

Background: Breast cancer (BC) incidence in young women is on the rise as reported over the last decade and presents with aggressive features and high metastatic rates. Young Breast Cancer (YBC), as defined by ESMO would be <=40 years of age, has worse prognosis and is postulated to represent a distinct pathological entity compared to older breast cancer (OBC). In our prior analysis with YBC, we had analyzed TCGA breast cancer data for differential gene expression between the young and older breast cancers (>60y), and the most significant set of genes pointed to those coding for the Extra Cellular Matrix (ECM)

(n=98 for <=40 and n=493 for >60 FDR <0.05). The ECM is a highly dynamic 3D network of structural and bioactive macromolecules secreted in part by cancer associated stromal cells such as fibroblasts (CAFs), known to prime the pre-metastatic niche in the breast environment. We thus hypothesized that progression of YBC could be associated with age-related expression differences in ECM associated genes due to remodeling and reactivation of the paracrine pathways, highlighting its relevance in metastasis of BC.
The aim of this study was to analyze gene expression differences of ECM degrading and ECM processing genes which seem to be associated with YBC. We also aim to examine the role of ECM remodeling in YBC using patient-derived primary culture models of tumour-cells and cancer associated fibroblasts (CAFS) to understand the metastasis pattern.
Methods: This study was conducted at Sri Shankara Cancer Hospital and Research Center, Bangalore after obtaining Institutional Ethical Committee approval. In-silico analysis of TCGA-BRCA, RNAseqV2 was conducted with clinical data. A set of ECM associated 17 gene panel of collagens, laminins and matrix metalloproteinases was established using differentially expressed genes from the TCGA RNA seq findings. This gene set was tested on a 55 primary retrospective FFPE specimens of YBC and a control group of 35 OBC using q-RT-PCR. A patient-derived primary culture was established and differentially separated for CAFs.
Results: 55 YBC (≤40years) and 32 OBC (≥60 years) with complete clinical information were included in the study. Median age of YBC and OBC was 37 and 67 years respectively. Although discontinuous in series, 44% were hormone receptor positive, 34% were Triple negative and 22% were HER2 expressing in the YBC. In OBC they were 75%, 12.5% and 12.5% respectively. Median tumour size was 3cm in both groups. Interestingly we found expression levels of ECM degrading genes to be significantly higher in YBC ($p<.05$) A comprehensive score generated based on combined score of 4 genes showed a significant association with an event of distant metastasis at a median follow up of 24 months. We also found that this score was not significantly associated with molecular subtypes of breast cancer showing age as an independent factor ($p=0.21$) Patient derived primary culture from biopsy of YBC and an OBC is established, and CAFs isolated. Identification of CAF secretome and validation of select markers with Immunohistochemistry to support our findings is underway

Conclusion: Our work suggests ECM changes in YBC play a significant role in creating a supportive microenvironment for cancer cell aggressiveness. More investigations of YBC tumour cell and CAF secretome using primary culture models are underway. This could pave ways to understand role of ECM in progression to metastasis leading to possibilities for novel therapeutic interventions. A large validation study with collaborators at Mayo Clinic is underway.

P1-06-24: Single-cell RNA sequencing reveals the role of HSPA1B+ immune cells in breast cancer microenvironment remodeling during neoadjuvant chemotherapy

Zihan Zhai

Background: Advanced breast cancer is still a major problem of cancer treatment in the world, and the overall prognosis is poor. The application of neoadjuvant chemotherapy (NAC) provides a new strategy for the treatment of locally advanced breast cancer and chemotherapy sensitive tumors. However, some patients are still facing the problem of NAC resistance. Studying the mechanism of NAC immune regulation may solve the problem of drug resistance. In this study, we aimed to clarify the characteristics of TME in primary tumor specimens before and after NAC. By analyzing the potential mechanisms of NAC resistance, we tried to find potential targets to prevent breast cancer progression and overcome NAC resistance.
Methods: Thirteen patients initially diagnosed with primary invasive breast cancer were recruited for this study. The standard neoadjuvant chemotherapy strategy was performed for 6 cycles. Tumor tissues were collected using core needle biopsies before NAC and through surgical excision after NAC. Single-cell RNA sequencing was used to analyze the tumor microenvironment in PCR and Non-PCR samples. The scRNA-seq data were used to analyze ligand-receptor-mediated intercellular communication at the molecular level via the CellPhoneDB tool. Moreover, paired formalin-fixed paraffin-embedded (FFPE) blocks were obtained before and after NAC and subjected to immunohistochemical staining for further analysis.
Results: Using a scRNA-seq protocol with unique transcript counting, cells were classified into breast epithelial cells, smooth muscle cells, T/NK cells, mast cells, fibroblasts, plasma cells, endothelial cells, myeloid cells, and B cells. Given that NAC can promote the reshaping of specific immune cell subpopulations, B cells were reclustered and annotated as 6 subgroups. The results showed that HSPA1B+ immune cells increased in the Non-PCR group, consistent with the immunohistochemical staining results. Interestingly, the TNF pathway was identified as a common pathway in HSPA1B+ immune cells, thus promoting inflammatory responses.
Conclusions: HSPA1B is upregulated in breast cancer tissue and is associated with poor prognosis in breast cancer patients. HSPA1B+ immune cells act on endothelial cells and cancer-associated fibroblasts (CAFs) by secreting pro-inflammatory cytokines (TNF), promoting chronic inflammation in the tumor microenvironment, and affecting the efficacy of NAC. Targeting HSPA1B may be a new strategy to prevent breast cancer progression and overcome treatment resistance.

P1-06-25: B7-H3 (CD276): A Metabolic Switch for the Survival of Breast Cancer Brain Metastasis

Asad Ur Rehman, Jaewon Lee, Ranjana Kanchan, Parvez Khan, Mahek Fatima, Mohd Ali Abbas Zaidi, Md Arafat Khan, Laiba Anwar, Jesse Cox, Sidharth Mahapatra, Surinder K. Batra, Brad St. Croix, Juan A. Santamaria-Barria, Mohd Wasim Nasser

Introduction: Up to 30% of cancer patients will have brain metastasis (BrM) at the time of their death, particularly those with lung cancer, breast cancer (BC), and melanoma. The prognosis for BCBrM patients is poor, with limited treatment options, highlighting the need to understand how cancer cells develop BCBrM. High immune cell infiltration in BrM suggested immunotherapies as a treatment promise, but they have been largely unsuccessful in BCBrM. This failure could be due to other immune checkpoints, such as B7-H3 (CD276), and the deranged metabolism that metastasized BC cells adapt to survive in the brain. These cells rely on oxidative phosphorylation (OXPHOS) and need more energy than normal brain cells, which are growth restricted and rely on glucose as their main source of energy. We hypothesize that targeting CD276-mediated metabolic reprogramming in BCBrM will mitigate BCBrM and improve therapeutic outcomes.
Methods: We performed in-silico dataset analysis and RNA sequence profiling on BCBrM CD276 Scr and knockout (KO) cells. Analysis was done using in-vitro and in-vivo experiments to ascertain the significance of CD276 in causing BCBrM. Metabolic perturbations were studied using metabolomics and Seahorse assays to unravel the mechanism of CD276 driving BCBrM. Furthermore, to evaluate CD276 as a therapeutic target, we used a CD276 antibody-drug conjugate (ADC), m276-SL-PBD, with a pyrrolobenzodiazepine (PBD) payload, which was administered intraperitoneally against macro-metastases implanted intracranially in mice and studied for tumor progression and survival.
Results: In-silico data analysis revealed B7-H3 (CD276) as a potential candidate target in BCBrM. CD276 was overexpressed in cancer cells, tumor-associated stromal cells, and tumor vasculature in most solid cancers, but was almost undetectable in normal tissues. CD276 expression was consistently elevated in BrM tissues and in BC cell lines metastasizing to the brain. Consequently, we observed that CD276 KO BCBrM cells lost migration potential, as assessed by trans-well migration ($p<.05$) and failed to create BrM lesions in NSG mice intracardially injected with MDA-MB231Br CD276 KO cells (BrM variant of MDA-MB231; $p<.001$). The immune-centric role of CD276 has been previously recognized, but lately its role in regulating metabolism is emerging, so we investigated if CD276-mediated metabolic changes could be driving BrM. Transcriptomic analysis revealed that CD276 KO cells have decreased expression of asparaginase synthetase (ASNS), among the top three downregulated genes, including its transcription factor ATF4 as well. We postulated that their downregulation could be due to decreased glutamine (Gln) metabolism. Effectively, we found that CD276 could be regulating glycolytic and OXPHOS. Seahorse analysis of oxygen consumption rate (OCR) in CD276-KO BCBrM cells, showcased their shift from OXPHOS ($p<.0001$). CD276 KO also significantly decreased glucose uptake by cancer cells leading to energy crisis and colony formation assay showed decreased

proliferation of CD276 KO cells. The reduced glucose uptake by cancer cells will be available to the immune cells, that showed increased infiltration in fully immunocompetent C57BL/6 mice injected with syngeneic E0771Br CD276 KO cells as compared to E0771Br CD276 Scr. Therefore, targeting Gln metabolism and, subsequently, OXPHOS through CD276 in BrM cells will be novel and could attenuate BCBrM by creating a metabolic crisis that can be leveraged to enhance immunotherapy. Finally and expectantly, we observed that m276-SL-PBD ADC treatment decreased BCBrM and improve survival in preclinical mouse models. Conclusions: Data suggest CD276 is critically involved in BrM and make cancer cells switch towards OXPHOS metabolism for survival and growth in a glucose-restricted brain microenvironment. Our results identify m276-SL-PBD ADC has the potential to enter early phase clinical trials for BCBrM patients.

P1-06-26: The optimal cut-off point for Tumor-Infiltrating Lymphocytes (TILs) in Triple-Negative Breast Cancer (TNBC)

Petr Krivorotko, Sheyda Abdullaeva, Tatiana Semiglazova, Anna Artemyeva, Asel Kudaybergenova, Valentina Zagoruiko, Tatiana Kudriashova, Olga Ponasenko, Vladislav Semiglazov, Vladimir Semiglazov

Introduction: TILs are promising, inexpensive biomarker with prognostic and predictive potential in triple-negative breast cancer. There is no consensus on the appropriate cutoff point to define high and low TILs. Therefore, we aimed to evaluate the prognostic value of TILs in an independent TNBC cohort and to determine an appropriate cut-off point by which to stratify TILs scores into prognostically significant categories.
Methods: The study included information on 140 patients with I-III stage TNBC and estrogen receptors <10%. Tumor tissue samples at baseline biopsies were evaluated the histological type, HER2 expression, estrogen expression levels, Ki-67 and TILs. The pathological response was evaluated according to the ypTNM, Miller—Payne, and RCB classifications. According to the criteria of the International Working Group, the classification of TILs into low (< 10%), intermediate (≥ 10% to ≤ 40%), and high (> 40%) levels was performed. When analyzing TILs in the main subgroups, we used a binary division of TILs into high level (TILs > 40%) and low (TILs ≤ 40%). The differences between groups were assessed using the Chi-square test. The correlation was analyzed with Spearman correlation test. Event-free survival (EFS) was estimated by the Kaplan-Meier method and Cox regression analysis.
Results: The average level of TILs in biopsy specimens before NACT was 29.3±23.1%. Low levels of TILs (<10%) were defined in 21% of cases, intermediate levels (≥10% to ≤40%) in 55% of cases, and high levels (>40%) in 24% of cases. Using the two-tiered system, low TILs (≤40%) were defined in 76% and high TILs (>40%) in 24% of cases. The level of TILs was correlated with histological grade (R=0.187; p=0.027) and estrogen receptor expression level (R=0.211; p=0.012). There were no significant differences depending on the level of TILs and other pathological parameters. When assessing EFS depending on the level of TILs across three cohorts, the 3-year rates were 64%, 65%, and 95% for low, intermediate, and

high levels of TILs respectively. No significant differences in EFS were found between the low and intermediate levels of TILs (HR=0.386, 95% 0.10- 1.44, p=0.156). Using the two-tiered system, 3-year EFS in patients with high TILs levels was 95% versus 65% in the low TILs group (HR=0.119, 95% 0.02 - 0.88, p=0.037).
Conclusion: Stromal TILs are an important prognostic biomarker in TNBC. Using a cutoff of 40%, high TILs are significantly associated with longer EFS.

P1-06-27: Role of MARCKS in regulating the tumor microenvironment in inflammatory breast cancer

Maroua Manai, Pascal Finetti, Nadia Bayou, Yoldez Houcine, Wissal Ben Taher, Balssem Mosbahi, Rihab Benhassen, Jeannine Donahue, Valerie Fraser, Carolina Reduzzi, Maha Driss, Hamouda Boussen, François Bertucci, Massimo Cristofanilli

Background: Inflammatory breast cancer (IBC) is a rare and aggressive form of breast cancer, accounting for 1-3% of cases and more frequent in North of Africa (7-11%). A major challenge in treating IBC is the lack of specific therapeutic targets. Myristoylated Alanine-Rich C Kinase Substrate (MARCKS) was found overexpressed and associated to poor prognosis in IBC vs. non-IBC (nIBC). As a an activator of inflammation in different types of cancer, our study aimed to evaluate in vitro and in clinical samples the role of MARCKS in inflammation and tumor microenvironment in IBC samples compared to nIBC. Methods: Using siRNA; we knocked-down MARCKS expression in IBC (SUM149) and nIBC (MDA-MB-231) cell lines, then evaluated the inhibitory effect on migration, invasion and mechanism of action in both single and co-culture with M2 macrophages. Inflammation was induced by LPS in vitro, and the clinical relevance of protein expression of MARCKS, CD163, CD68, LPS and NFkB was assessed in a large series of IBC vs. nIBC patients using immunohistochemistry (IHC).

Results: Using IHC, our results showed that in IBC samples only, the presence of M2 macrophages (CD163) was associated with obesity and that obese patients presenting M2 macrophage infiltration had a poorer 5-years overall survival. We also found an overexpression of NFκB in IBC patients correlated to MARCKS and M2 macrophages infiltration. We also showed in vitro that MARCKS-knockdown impaired cell migration and invasion in SUM149 (IBC) compared to MD-MB-231 (nIBC) cells. Furthermore, using western blot, only in IBC, MARCKS inhibition regulated several proteins involved in IBC inflammation and tumor microenvironment (TME) particularly NFκB and EGFR known to be directly implicated in IBC aggressiveness with better regulation of the different pathways in co-culture with macrophages M2.

Conclusions: Our study suggests an important role of MARCKS as a potential target modulating the TME and inflammation in IBC that needs further investigation using in vivo models.

P1-06-28: Assessment of the immune microenvironment of the breast cancer PAM50 Subtypes – a deconvolution approach

Lilly Anne Torland, Jürgen Geisler, Youness Azimzade, Linn Buer, Jon Lømo, Øystein Garred, Inger Øynebråten, Astri Frafjord, Alexandre Benoit Corthay, Andliena Tahiri, Marianne Lyngra, Kristine Sahlberg, Vessela Kristensen, Xavier Tekpli

Background: Breast cancer is a heterogeneous disease with many drivers involved I disease progression. Diagnosis and treatment decisions are guided by clinical, pathological, and molecular markers. The PAM50 subtypes which include Luminal A, Luminal B, Normal-like, Basal-like and HER2-enriched, are associated with different tumour phenotypes and overall survival.
In breast cancer, immune infiltration influences treatment response and disease outcome. In estrogen receptor negative and basal-like breast cancers a higher degree of immune cell infiltration has been associated with improved survival and enhanced responses to treatment. The recruitment of different immune cell types has different effect on the tumor growth and sensitivity to treatment Understanding the function and phenotypes of immune cell types in breast tumors may allow to better map which immune cell types may explain subtype specific tumor pathogenesis.
Aim and method:
Using two deconvolution algorithms, CIBERSORT and xCell, we aim at investigating whether the PAM50 subtypes have different immune microenvironment landscapes. We used 15 independent publicly available breast cancer cohorts with transcriptomics available for which, we inferred tumor immune cell infiltration. To experimentally assess the association between breast cancer subtypes and immune microenvironment, stained was performed on 80 tumors spanning the PAM50 subtypes for marker genes defining 6 minor immune cell types.
Results: Unsupervised clustering of the CIBERSORT scores inferring for the quantity of 22 immune cell types in the tumor and xCell scores predicting for the presence of 64 cell types showed that the immune microenvironment was strongly correlated with the molecular PAM50 subtypes. We also found differences in the immune microenvironment of Luminal A and B subtypes, which are considered close in lineage, with the Luminal A subtype showing higher infiltration of mast cells while and Luminal B‘s higher infiltration of regulatory T cells. The HER2-enriched exhibits a microenvironment with high amount of plasma cells and neutrophils. Finally, Basal-like tumors have in general higher immune infiltration characterized by of natural killer cells, cytotoxic T cells and dendritic cells.
Conclusion: Our findings show that the PAM50 subtypes may have overall differences in their immune microenvironment landscape which could be taken in consideration when explaining response to therapy or prognosis.

P1-06-29: Targeting NRP1 reduces triple-negative breast cancer lung metastasis and improves immunotherapy efficacy

Zhuxi Duan, Qun Lin, Yu Shi, ,Jinpeng Luo, Jieer Luo, ,Xiaolin Fang, Chang Gong

Metastasis is the leading cause of death in breast cancer, with approximately 90% of breast cancer-related deaths attributed to complications arising from metastasis. Lung metastasis is with a significantly poor prognosis and a 5-year overall survival (OS) rate of only 16.8% in breast cancer. Among all subtypes, triple-negative breast cancer (TNBC) shows the highest propensity for lung metastasis, accounting for 36.9% of all metastatic TNBC cases and contributing substantially to TNBC mortality. A key challenge in clinical practice is the inability to accurately predict lung metastasis at an early stage, leading to delayed treatment. In this study, single-cell RNA sequencing (scRNA-seq) was conducted on samples from TNBC patients without distant metastasis (n=3) and those with lung metastasis (n=3). scRNA-seq guided both in vivo and in vitro experiments, identifying NRP1 as a critical gene promoting lung metastasis. Mechanistically, NRP1 binds to the CLH1 protein, facilitating cell secretion via vesicles. The oxygen-rich lung environment inhibits CLH1-mediated vesicle secretion, thereby stabilizing membrane-bound NRP1 expression and promoting breast cancer lung metastasis.Furthermore, lung-tropic subcutaneous TNBC immunosufficient models displayed a significant increase in immunosuppressive cells (such as Treg cells and M2 macrophages) and PD-1+CD8+ T cells within the lung microenvironment. Combination therapy with anti-PD-1 and anti-NRP1 was found to reduce lung metastases and improve immune function. To screen the target population for this combined therapy, we integrated scRNA-seq data with The Cancer Genome Atlas (TCGA) breast cancer prognosis data and constructed a 6-gene predictive model for TNBC patients. This model facilitates the identification of individuals with lung-tropic metastasis potential who are likely to benefit from combined anti-NRP1 and anti-PD-1 treatments. In conclusion, our study demonstrates that screening for populations likely to benefit from and targeting NRP1 for treatment could effectively mitigate breast cancer lung metastasis, enhance the breast cancer immune microenvironment, and improve the efficacy of immunotherapy.

P1-06-30: Use of decellularized tumor and adipose tissue to model triple negative breast cancer

Marcus Moody

Triple-negative breast cancer (TNBC) constitutes 10-15% of all breast cancers, is associated with poor patient prognosis, and has a higher propensity for metastasis compared to other breast cancer subtypes. It is characterized by the absence of estrogen and progesterone receptors and the expression of human epidermal growth factor receptor 2 (HER2). Due to the lack of actionable markers, there is a need to develop novel targeted therapies for TNBC. While traditional cell culture techniques offer insights, current preclinical models inadequately replicate the native tumor and tumor microenvironment (TME), leading to loss of preclinical validation in clinical trials. Thus, there is a demand for more sophisticated 3D models capable of mimicking mechanical and biochemical signals present in the TME. The studies performed here aim to determine the translational potential of decellularized tumor and breast adipose tissue for use as 3D in vitro tumor models.
To assess the effects of tumor-specific decellularized ECM (dECM) on tumor growth in vivo,

a TNBC cell line was seeded on dECM derived from a pre-neoadjuvant chemotherapy TNBC tumor and implanted in SCID/beige mice. This was compared to TNBC cells injected with VitroGel. Tumors were detected at 4 weeks in the VitroGel injected TNBC cells and at 8 weeks in the dECM seeded group. The dECM seeded TNBC cells demonstrated slower tumorigenesis than the VitroGel injected TNBC cells. Upon tumor and organ harvesting, TNBC cells were isolated from tumors in both groups and RNA-Sequencing was performed.

Results: demonstrated that TNBC cells had changes in gene expression associated with ECM regulation, epithelial-mesenchymal transition (EMT) and cellular attachment between the injected control and dECM tumors. Specifically, ECM associated collagens and integrins COL6, COL8, ITGA7 and ITGA9 were significantly upregulated in the dECM group compared to the injected control. Cell attachment and immune response genes, CD6, CD8, HLA-DMB and HLA-DOA, were also significantly upregulated in the dECM seeded TNBC cells.
Due to the suggested impact of tumor-derived dECM on TNBC transcriptome, dECM tumor scaffolds were next optimized breast dECM for in vitro use. For this, dECM scaffolds derived from breast adipose tissue were lyophilized and homogenized into a powder. The resulting dECM powder was then used to generate tumor spheroids with different dECM concentrations, which were evaluated for spheroid formation, shape and cell death. Whereas control spheroids self-assembled within 24 hours without the need for centrifugation, the dECM spheres needed additional manipulation for aggregation and spheroid formation was observed at 48 hours. Preliminary histology showed that cells in dECM spheroids with higher amounts (50ug) of dECM were heavily concentrated on the outer edge of the sphere and had more irregular circularity than lower (10ug) dECM concentrations and control spheres. However, all groups showed significant compactness over a 7 day period. These observations suggest that dECM powder affects sphere formation and growth, and further characterization of dECM spheroid formation and structure is in progress. These initial findings support the use of breast tumor dECM as appropriate models for medium throughput models of TNBC in vitro.

P1-07-01: The Semi-Dry Dot-Blot Kit Can Detect Lymph Node Metastases in Breast Cancer Regardless of Neoadjuvant Chemotherapeutic Effects

Yuki Hara, Ryota Otsubo, Rin Yamaguchi, Ayako Fukushima, Eiko Inamasu, Yukutake Aki, Momoko Akashi, Sayaka Kuba, Susumu Eguchi, Keitaro Matsumoto

Background: The accurate diagnosis of sentinel lymph node (SLN) metastasis is important in breast cancer. We developed a new detection kit for lymph node (LN) metastases using the semi-dry dot-blot (SDB) method, which visualizes the presence of cancer cells by washing sectioned LNs with cytokeratin (CK)-19. Compared with the permanent histological diagnosis of 924 LNs to distinguish macrometastases that are larger than 2.0 mm in diameter, the SDB kit demonstrated 94.4% sensitivity, 96.2% specificity, and 95.6% accuracy in identifying macrometastases in patients who did not receive neoadjuvant chemotherapy (NAC). Recently, adjuvant treatment strategies considering efficacy of NAC, known as the residual disease-guided approach, have been used in human epidermal

growth factor receptor 2 (HER2)-positive and triple-negative (TN) breast cancer. However, it is unclear whether NAC affects the diagnostic ability of SDB kits for LN metastases with cancer cell degeneration. This study aimed to determine whether the SDB kit could correctly diagnose LN metastases in patients receiving NAC.
Methods: Sixty patients (101 LNs) who received NAC and underwent surgery between May 2022 and March 2024 at Nagasaki University Hospital were enrolled. The target number of patients was assumed to be 60 (120 LNs). Eligible LNs were all excised SLNs in patients without clinical LN metastasis, and two dissected axillary LNs in patients with pre-chemotherapeutic clinical LN metastasis. Micrometastases and isolated tumor cells (ITCs) were diagnosed when the tumor cells were larger than 0.2 mm but not 2.0 mm, and not more than 0.2 mm in the greatest extent. Non-macrometastasis was defined as LN status, including micrometastases, ITCs, and negative status. Diagnoses based on the SDB kit were compared with the permanent pathological diagnoses. Primary endpoints were the sensitivity, specificity, and accuracy of the SDB kit for distinguishing macrometastases from non-macrometastases.
Results: Among the 60 patients, the subtypes were hormone receptor-positive/HER2-negative (luminal) in 15 (25.0%), HER2 in 29 (48.3%), and TN in 16 (26.7%). The pathological complete response rates were 20% (3/15) for luminal, 48.3% (14/29) for HER2, and 43.8% (7/16) for TN. Twelve (11.9%) and 89 (88.1%) LNs were assessed as macrometastases and non-macrometastases, respectively, using permanent section examination with hematoxylin and eosin staining. Non-macrometastases included three micrometastases (3.0%) and one case of ITCs (1.0%). The SDB kit correctly diagnosed 11 of the 12 LN macrometastases and all of the LN non-macrometastases. The sensitivity, specificity, and accuracy of the SDB kit were 91.7%, 100%, and 99.0%, respectively. One false-negative case was caused by sparse residual swollen tumor cells with a long diameter of 2.1 mm.
Conclusion: This study revealed that the SDB kit could detect LN metastases in breast cancer, regardless of NAC effects. Therefore, we plan to conduct a multicenter prospective study to expand the use of the SDB kits in the diagnosis of LN metastasis in patients receiving NAC.

P1-07-02: Alteration of HER2 status following neoadjuvant chemotherapy in breast cancer: a clinicopathological analysis focusing on HER2-low status

Hyun-Jung Sung, Hyun Jung Kwon, Hee-Chul Shin, Eun-Kyu Kim, Koung Jin Suh, Se Hyun Kim, Jee Hyun Kim, So Yeon Park

Background: Human epidermal growth factor receptor 2 (HER2) status can undergo alteration following neoadjuvant chemotherapy (NAC) in breast cancer. This study aimed to investigate the alteration of HER2 status after NAC in breast cancer and its impact on clinical outcomes of patients, focusing on HER2-low status.
Methods: We retrospectively reviewed 1,063 breast cancer patients who received NAC

followed by surgery between 2013 and 2020. Using paired samples of 670 patients with residual disease, HER2 discordance rate between pre- and post-NAC samples, the relationships between HER2 discordance and clinicopathological characteristics, and clinical outcomes of the patients were analyzed.
Results: As a whole, HER2-low status before NAC was associated with a lower pathological complete response rate and higher Residual Cancer Burden (RCB) class, compared with HER2-zero and HER2-positive status. However, in subgroup analysis by hormone receptor (HR) status, no statistical differences were found in chemo-responsiveness between HER2-low and HER2-zero breast cancers. Following NAC, the overall HER2 discordance rate was 21.2% ($\kappa = 0.676$). The most common type of alteration was zero-to-low (10.8%) conversion, followed by low-to-positive (3.4%) conversion. HER2 discordance was significantly associated with lower HER2 levels and HR positivity before NAC, as well as lymphovascular invasion, higher ypT stage, lymph node metastasis, and higher RCB class in residual disease after NAC. In further analyses, HER2-zero-to-low conversion showed an association with HR positivity and low histologic grade. In multivariate logistic regression analyses, HR positivity and higher RCB class were identified as independent predictive factors for HER2 discordance. In survival analyses, HER2 discordance revealed a worse prognostic impact on disease-free survival of the patients, particularly within HR-positive subgroup, which remained statistically significant on multivariate Cox regression analysis. However, no survival differences were found between patients with HER2-zero-concordant and those with zero-to-low conversion.
Conclusion: Given the prognostic implications of HER2 discordance, which primarily involves zero-to-low conversion, and the therapeutic benefits of newly developed antibody-drug conjugates in HER2-low breast cancer, HER2 status should be re-evaluated in surgical resection specimens following NAC, especially in cases showing HR positivity and high RCB class.

P1-07-03: Improved Standardization and Accuracy of HER2 Score with AI support in Breast Cancer: Large Multicenter Study

Savitri Krishnamurthy, Stuart Schnitt, Anne Vincent-Salomon, Elena Provenzano, Rita Canas-Marques, Laurent Arnould, Gaetan Mac Grogan, Elisabeth Shearon, Derek Welch, Pranil Chandra, Piotr Borkowski, Sabine Declercq, Joseph Loane, Anu Gunavardhan, Luca Di Tommaso, Vitor Krauss, Jeanne Thomassin, Marie Brevet, Maya Grinwald, Dana Mevorach, Sevde Etoz, Raz Ziv, Shai stein, Giuseppe Mallel, Judith Sandbank, Chaim Linhart, Manuela Vecsler

Objective: HER2 expression is a key prognostic and treatment-influencing factor in breast cancer and is assessed for all invasive breast carcinoma (BC). As with all immunohistochemistry (IHC) staining, visual interpretation of HER2 expression is subjective, which leads to intra- and inter-pathologist variability. This study aims to evaluate the clinical utility (concordance, accuracy, and user feedback) of artificial intelligence (AI)-aided HER2 scoring solution on whole slide digital images of HER2 IHCs of

breast samples.
Methods: The cohort included biopsies and excisions from 1,997 patients from 12 US, EU, and UK clinical laboratories, including academic medical centers and reference/private laboratories. HER2 slides of diverse BC subtypes from primary and metastatic tumors were stained with anti-HER2 antibody (4B5, VENTANA) at each laboratory and scanned with different scanners (Leica GT450DX, Philips UFS, Aperio AT2). This observational two-arm multi-reader study compared the performance of 26 pathologists ("readers") on HER2 scoring (each reviewed 50-200 slides) unassisted vs. aided by AI HER2 solution (Ibex Breast HER2®), which detects the invasive tumor area and on slide control, classifies tumor cells based on their staining pattern, and derives a slide-level HER2 score by applying 2018 ASCO/CAP guidelines. Both study arms were compared to ground truth (GT), established as majority score of three breast pathologists ("experts") who reviewed the slides manually.
Results: Experts' overall inter-observer agreement on all HER2 scores was 73.9% (95%CI: 72.6%,75.2%) and for 0/1+/2+/3+ was 80.8%/ 66.2%/ 63.7%/ 94.3%, respectively. Readers' overall inter-observer agreement was significantly higher when assisted by AI, 87.5% (85.9%,89.0%) vs. 74.3% (72.3%,76.3%) without AI, $p < 0.05$. Moreover, reader's accuracy for all HER2 scores (agreement with GT) was significantly higher with AI 80.9% (79.7%,82.2%) vs without AI, 76.6% (75.2%,77.9%) ($p < 0.05$).
For 0/1+ vs 2+/3+ cutoff, readers with AI showed significantly higher inter-observer agreement 93.1% (91.8%,94.2%) vs. without AI 86.8% (85.2%,88.3%), $p < 0.05$, and significantly higher accuracy, 91.9% (91.0%,92.8%) with AI vs 88.8% (87.7%,89.8%) ($p < 0.05$) without AI.
For the HER2-low cutoff of 0 vs. 1+/2+/3+, readers with AI showed significantly higher inter-observer agreement of 95.0% (93.9%,95.9%) vs. 88.8% (87.3%,90.2%), $p < 0.05$, with slightly higher accuracy (89.8% (88.8%,90.7%) with AI vs 88.5% (87.4%,89.4%) without AI).
The standalone automatic AI solution demonstrated high accuracy for HER2 scoring of 89.4% (88.0%,90.7%), and 91.2% (89.8%,92.3%) for the respective clinical cutoffs of 0 vs. 1+/2+/3+, 0/1+ vs. 2+/3+.
Feedback from reader pathologists' user survey indicates an increased confidence in their HER2 scoring accuracy and consistency. Additionally, 77% of the pathologists expressed a preference for HER2 scoring supported by AI over manual scoring.
Conclusions: This study reports a large multi-site validation of a fully automated AI solution for HER2 scoring in BC. Pathologists supported by AI showed significant improvements in HER2 scoring consistency, evidenced by inter-reader agreement, and accuracy overall and for other clinical cutoffs. The AI solution demonstrated high accuracy and generalizability to multiple different laboratories (pre-analytics and staining protocols) and scanners. AI solutions, such as the one investigated here, could be used as decision-support tools for pathologists in routine clinical practice, enhancing the reproducibility and consistency of HER2 scoring, thus enabling optimal treatment pathways and improved patient outcomes.

P1-07-04: Re-evaluation of a novel diagnostic kit which uses the semi-dry dot-blot method combined with an automatic reader to detect breast cancer metastases in sentinel lymph nodes: A multi-center prospective study

Ryota Otsubo, Yuki Hara, Aya Tanaka, Ayako Fukushima, Eiko Inamasu, Momoko Akashi, Michi Morita, Sayaka Kuba, Fujiko Kaseida, Shigeki Minami, Hiroshi Yano, Masayuki Baba, Hiroaki Shima, Kosho Yamanouchi, Katsunori Yanagihara, Masahiro Nakashima, Rin Yamaguchi, Susumu Eguchi, Keitaro Matsumoto

Background: The semi-dry dot-blot (SDB) method, a diagnostic procedure for detecting lymph node (LN) metastases using an anti-cytokeratin (CK) antibody, is based on the theory that epithelial components, such as CK, are not found in normal LNs. Thus, metastases are diagnosed based on the presence of CK in the lavage fluid of sectioned LNs. We developed a prototype kit which uses the SDB method and a newly created anti-CK19 antibody with a borderline CK 19 absorbance of 60 milliabsorbance (mABS) to distinguish macrometastases. We then prospectively evaluated 924 sentinel LNs and 94 macrometastases using a mass-produced SDB kit which was equivalent to the prototype kit. In a prospective clinical study, the sensitivity and specificity of the kit for detecting macrometastasis was 68.1% and 99.9%, respectively, with a borderline CK19 absorbance of 60 mABS. This was not sufficient for clinical application. However, when the analysis was conducted using a borderline CK19 absorbance of 11.9 mABS, the sensitivity and specificity was 94.7% and 98.3%, respectively. Therefore, we established a new borderline for the mass-produced SDB kit and conducted a multicenter prospective study to evaluate its performance.
Methods: We obtained 527 sentinel LNs dissected between August 2023 and May 2024 at six institutions in Japan. Patients who received neoadjuvant chemotherapy or endocrine therapy were excluded. The LNs were sliced at 2-mm intervals and washed with phosphate-buffered saline. Cells suspended in the lavage fluid of sliced LNs were centrifuged and lysed. The extracted protein was applied to the SDB kit to diagnose LN metastasis using absorbance as evaluated by an automatic reader. The washed LNs were blindly examined using intraoperative and permanent histological examinations. Diagnoses based on the SDB kit were compared with those made by permanent histological examination of the LNs. The primary endpoints were sensitivity, specificity, and overall agreement of the SDB kit for distinguishing macrometastasis from non-macrometastasis.
Results: Forty-seven of the 527 LNs were assessed as macrometastases on histological examination, 14 as micrometastases, and 466 as negative. Using a borderline CK absorbance of 11.9 mABS for detecting macrometastasis, the sensitivity and specificity of the SDB kit and its overall agreement with permanent histological examination was 89.4%, 94.6%, and 94.1%, respectively. Furthermore, the kit with automatic reader yielded a diagnosis within approximately 20 minutes at a cost of less than $30 for the SDB kit and less than $3,000 for the automatic reader.
Conclusions: Using the kit to diagnose LN metastasis was fast, accurate, and cost-effective.

The kit was also useful for distinguishing macrometastases and will be sufficient for clinical application.

P1-07-05: Association of BMI variations with response to neoadjuvant chemoimmunotherapy for early-stage triple-negative breast cancer

Bethania Santos

Introduction: Increased body mass index (BMI) has been associated with improved response to immune checkpoint inhibitors (ICIs) in multiple cancer types. This phenomenon has been attributed in part to obesity, higher adipose tissue composition in the breast and/or metabolic syndrome leading to T-cell dysfunction. However, BMI may vary during neoadjuvant therapy due to dietary changes, toxicity of therapy or psychosocial factors including anxiety and stress. This study aims to investigate the impact of BMI variation on pathological complete response (pCR) for patients with early-stage triple negative breast cancer (TNBC) receiving neoadjuvant chemotherapy with immunotherapy.
Methods: Patients with early-stage TNBC diagnosed between July 1, 2021, and December 31, 2023, were identified through two institutional databases. All patients received the KEYNOTE-522 regimen. Based on their baseline BMI, patients were categorized as obese (BMI ≥30) or non-obese (BMI <30). The chi-square test of independence was used to assess whether a significant association exists between BMI variation categories, greater than 1 point vs. 1 point or less (7lb/3Kg) and pCR status (achieved vs. not achieved). Univariate and multivariate analyses were performed using logistic regression to identify factors associated with pCR.
Results: Among the 264 patients identified, the median age was 52.9 years, the average BMI was 28.3, and 119 (45.1%) were obese. In univariate analysis, a BMI of ≥30 at baseline was associated with an improved rate of pCR ($p < 0.1$). In multivariate analysis, patients with a BMI ≥30 had improved pCR rates [OR (95% CI): 1.85 (1.08, 3.20), $p < 0.05$]. An unbiased selection of 38 patients from our cohort was analyzed to determine if BMI variation between the beginning and end of neoadjuvant treatment impacts outcomes. Among patients with a BMI variation > 1 point, 78.95% (15 out of 19) achieved a pCR, while among patients with a BMI variation < 1, only 21.05% (4 out of 19) achieved a pCR. A chi-square test of independence indicated a statistically significant difference between the two groups ($\chi^2 = 12.9240$, $p = 0.002$).
Conclusion: These findings highlight the importance of considering BMI variation as a factor in treatment outcomes. Nutritional status, changes in diet and physical activity during treatment can influence BMI variation. Intrinsic differences in tumor biology might influence both BMI variation and response to treatment. More aggressive tumors might cause more weight loss, which could be linked to the high activity of the immune response. Further understanding these factors should help to interpret the results and improve treatment outcomes. Larger, prospective studies are needed to confirm these results.

P1-07-06: Adjunctive statistical standardization of quantitated adjuvant HER2 and very low statistically standardized HER2 in CCTG MA.27

Judith-Anne Chapman, Jane Bayani, Sandip SenGupta, John M.S. Bartlett, Tammy Piper, Mary Anne Quintayo, Shakeel Virk, Paul E. Goss, James N. Ingle, Matthew J. Ellis, George W. Sledge, G. Thomas Budd, Manuela Rabaglio, Rafat H. Ansari, Richard Tozer, David P. D'Souza, Haji Chalchal, Silvana Spadafora, Vered Stearns, Edith A. Perez, Karen A. Gelmon, Timothy J. Whelan, Catherine Elliott, Lois E. Shepherd, Bingshu E. Chen, Karen J. Taylor

Background: We proposed adjunctive statistical standardization of quantitated ER and PgR to improve inter-laboratory comparability of biomarker results and therapeutic management of breast cancer. Adjunctive statistical standardization of quantitated HER2 is used here; we also examined the effects on outcome of ultra-low HER2 and very low statistically standardized HER2.
Methods: We utilized CCTG MA.27 (NCT00066573), an adjuvant phase III trial of exemestane versus anastrozole in postmenopausal women with ER+ and/or PgR+ tumors. IHC HER2 HSCORE and % positivity (%+) were centrally assessed by machine image quantitation, and statistically standardized to mean of 0, standard deviationn (SD) of 1 followig Box-Cox variance stabilization transformations of 1.) natural logarithm (ln with addition of 0.1 to 0 HSCOREs and 0 %+), 2. square root. Additionally, centrally assessed FISH HER2 and CEP17 values were used to define ASCO/CAP categorizatiion. Post hoc, the effects of ultra-low HER2 , IHC 0 with (0,10%] 1+ stain, were examined. The primary endpoint was distant disease-free survival (DDFS) at the longest trial follow-up of median 4.1 years. Survival was described with Kaplan-Meier plots and tested with the univariate Wilcoxon (Peto-Prentice) test statistic. We examined cut-points at standard deviations about mean of 0 (<-1; (-1,0]; (0,1]; >1). Cox multivariant regressions were adjusted for age, T and N stage, grade, lymphovascular invasion, treatment, baseline patient demographics, ER and PgR; 2-sided Wald tests had nominal significance if $p<0.05$.
Results: Of 7576 women accrued to MA.27, 2900 women had ER, 2726 had PgR, and 2680 had HER2 results; 2325 had all three biomarkers for multivariant investigations. Twenty-five women received received herceptin with only one experiencng a DDFS event. ASCO/CAP categorization significantly differentiated univariate DDFS (p=0.01). Image analysis identified 57% of IHC 0 to have ultra-low HER2. Five-year DDFS for IHC 0 without stain was 92% [95% CI (90,95); N=864] which was similar to that for ultra-low HER2 of 96% [95% CI (94,97); N=1143]. Statistical standardization did not significantly differentiate univariate DDFS (p=0.08-0.27). DDFS for ln standardized values <-1.0 (HSCORE, or %+ <0.1) was similar to that with standardized values >1.0 (HSCORE >19, or %+ >14): for HSCORE <1.0, 5-year DDFS was 92% [95% CI (85.98); N=88] vs for >1.0, 92% [95% CI (89,95); N=577]; for %+, 5-year DDFS was 91% [95% CI (85,98); N=102] vs >1.0, 92% [95% CI (89,95); N=613].
In multivariant assessments with ASCO/CAP guideline and statistically standardized data, both ER (p=0.65-0.94) and HER2 (p=0.20-0.97) were not significantly associated with the DDFS primary endpoint in models with PgR; while higher PgR had significantly better DDFS (p<.003) in models with ER and HER2.

Conclusions: ASCO/CAP HER2 guidelines significantly differentiated univariate DDFS although not values of IHC 0 and ultra-low HER2, with <10% weak stain. Statistical standardization did not differentiate univariate DDFS. Image quantitation identified very small numbers of 1+/2+/3+ intensity stained nuclei. DDFS was similar for any intensity of low ln(HER2) stain (<1 SD below the mean) compared to any intensity of higher HER2 stain (>1 SD above the mean), although we offer caution in assessment of ultra-low, or very low, HER2 stain due to the dynamic range of the HER2 assay. Neither ASCO/CAP nor standardized HER2 had multivariant significance in these hormone receptor rich patient tumors. The adjunctive statistical standardization of ER, PgR, and HER2 performed here is similar to that mandated for clinical practice by the World Health Organization for BMD.

P1-07-07: Secretory Carcinoma: Clinical, Pathological and Molecular Insights into a Rare Breast Cancer Subtype

Andrea Vethencourt, Irene Blázquez, Andrea Vethencourt, Jan Bosch-Schips, Fara Brasó-Maristany, Blanca González-Farre, Esther Sanfeliu, Maria Neus Fullana, Anna Petit, Carla Valentí, Laura López-Vilaró, Felip García Hernández, Ivonne Vázquez de las Heras, Teresa Soler, Sonia Pernas

Introduction: Secretory carcinoma of the breast (SCB) is an exceptionally rare subtype of breast cancer , accounting for only 0.02% to 1.5% of all breast cancers. Initially described as juvenile breast carcinoma, most cases are now also described in adults. Diagnosis of SCB requires an experienced breast pathologist due to its rarity and histological overlap with other subtypes. Although SCB generally has a favorable prognosis, some cases result in fatal metastatic disease. This study aims to elucidate the clinical, pathological, and molecular characteristics of SCB. Methods: This study includes 9 patients diagnosed with SCB from 2015 to 2022 at the Institut Catala d'Oncologia (ICO)-Hospital Universitari de Bellvitge (HUB) and 5 additional Spanish centers. Each diagnosis was reviewed by two expert breast pathologists. Comprehensive analysis was conducted on clinical data, histopathological diagnoses, immunohistochemical profiles, NTRK positivity (assessed with EPR17341 clone) and translocation status by fluorescence in situ hybridization (FISH), and PAM50 molecular subtype using the nCounter platform. Results: A total of 15 SCB tumors from 9 patients were analyzed, with 4 patients providing paired primary and relapsed tumor samples. The median age at diagnosis was 64 years (range 45-78). Median tumor size was 1.7 cm (range 0.6-9.5 cm). Estrogen receptor (ER) positivity was detected in 44.4% of tumors, albeit with weak intensity; all tumors were HER2-negative. The mean Ki67 index was 7.15% (range 1-22%). Histologically, four patients had moderately differentiated (G2) tumors, and five had well-differentiated (G1) tumors. Positive regional lymph nodes were found in 23.23% of cases. All tumors exhibited NTRK positivity and rearrangements by FISH. During a median follow-up period of 172 months (range 48-480), 5 patients experienced recurrences, with one patient succumbing to pleural metastasis. PAM50 molecular subtype analysis revealed that 6 of 9 primary cases (66.6%) were normal-like, while 4 cases (44.4%) were basal-like. All recurrence samples (3/3, 100%) were basal-like. Review of normal-like cases ruled out

normal breast tissue involvement. Conclusion and Future Directions: This comprehensive analysis of SCB advances our understanding of this rare breast cancer subtype and suggests new hypotheses for targeted molecular approaches and disease-agnostic tools. The indolent nature and low proliferation rates of SCB likely contribute to its normal-like molecular classification. However, specific tailored molecular techniques are still warranted to accurately detect SCB cases with aggressive behavior. Additionally, a next-generation sequencing (NGS) mutational analysis (TS0500) will be conducted to identify specific genetic markers in such cases. Keywords: Secretory carcinoma of the breast, NTRK, PAM50 molecular subtype.

P1-07-08: LUMINAL BREAST CANCER HER 2 AMPLIFIED IS A DIFFERENT

Ronald Limon, Zaida Morante Cruz, Edith Claros, Pedro Vega, Carolina Henostora, Mario Gianella, Wara Cortez, Ara Cortez, Denize Ramirez, Claudia Sitic, Neyza Espinoza, Isabel Jorges, Iris Otoya, Cindy Calle Carreno, Jorge Sanchez, Carlos Antelo

Background: Breast cancer with overexpression of Her 2 represents approximately 15-20% of alll breast cancers diagnosed in women worldwide. The group of patients with HR(+) and Her2(+) overexpressed (triple positive breast cancer) represent 65% of cases that belong to the HER2 tumor group. In Latin America as in the rest of the world the management of this luminal Her2(+) tumors based on anti-hormonal therapy and anti-Her2 therapy as neoadjuvant, adjuvant and metastatic disease. we aimed to identify differences between Luminal BC patients with Her2 IHC 2+ vs 3+.
Methods: We identified medical records of patients with luminal Her2(+) BC diagnosed at INSTITUTO NACIONAL DE ENFERMEDADES NEOPLASICAS (LIMA-PERU) and ONCOBOLIVIA (SANTA CRUZ - BOLIVIA) between2015-2022. we only included patients with confirmed diagnosis of breast cancer ER(+) PgR(+) and Her2overexpressed. The exclusion criteria were: Patients without confirmation of HER2 status by immunohistochemistry of FISH techniques; patients who have discotinued therapy whitout any reason or those who have not received anti-HER2 therapy. Statistical analysis comparisons between HER 2 IHC 2(+) vs 3(+) groups were made using chi-squared Fisher`s exact, or Wilcoxon rank-sum tests as appropiate univariate logistic regression assessed the association between HER 2 status and pathological complete response (pCR). Kaplan- Meier survival analysis was performed to evaluate overall survival (OS) by HER 2 IHC scorea whit survival curves compared using the long-rank test. All analyses used R; eith statistical significance set al $p<0.05$
Results: We found 58 patients who met the study criteria; 87.9% reported with HER2+ IHC(3+). Overall median age was 44.5 years (IQR 40.0-47.0). Most patient had T2 tumors (n=27,46.6%) and cN1 nodal involvement (n=43,74.1%). Tumors classified as G3 (n=29,59.2%) were the most frequent. HR status showed that 89.7% of patients were ER+ and PgR+ and Ki 67 proliferation index had a median of 40% (IQR 25-50). Most common chemotherapy treatment was AC - TH (n=25,42.1%). Regarding treatment response 25.5% of the HER2 + IHC 3+ group achieved pCR; However most patients in HER 2 IHC 2+ and IHC 3+ had a partial response (66.7% and 74.4% respectively). In our cohort we did not find

Her2 scores as a predictive variable for pCR(IHC 2+ vs IHC 3+, OR=0.69, 95% CI=0.12-5.39, p=0.7) and for OS (p=0.3)
CONCLUSION. In conclusions we found no significant differences in pCR or OS between LUMINAL HER 2+ / IHC2+ (amplified) vs IHC 3+ patients. Larger studies are needed to further explore the potential prediction of treatment response in these subgroups and the importance of the luminal component in the response to anti-Her2 treatments.

P1-07-09: Development and validation of Residual tumor Burden calculator specific for Inflammatory breast carcinoma (IBC) to predict outcome (R-IBC)

Savitri Krishnamurthy, Roland L Bassett Jr., Azadeh Nasrazadani, Rachel M Layman, Bora Lim, Susie Xinying Sun, Megumi Kai, Naoto Ueno, Debu Tripathy, Vicente Valero, Anthony Lucci, Wendy Woodward, MDACC Inflammatory Breast Cancer Team

Background: Inflammatory breast carcinoma (IBC), a rare and aggressive variant of breast carcinoma, is a distinct clinicopathological entity characterized by lymphovascular tumor emboli in skin of the breast. Residual cancer burden (RCB) trained and validated in non-IBC is not optimal for using in IBC because it does not take into consideration pathologic features of IBC such as skin involvement and lymphovascular invasion or important features such as proportion of lymph nodes involved and extranodal extension. We sought to develop and validate a residual tumor burden calculator specific for IBC (R-IBC) using pathological features after neoadjuvant chemotherapy in combination with clinical features to predict progression-free survival (PFS) and overall survival (OS) .
Methods: We used 415 IBC patients (training set, 332 [80%]; test set, 83 [20%]) to develop and validate R-IBC score. A univariate Cox proportional hazard regression analysis was used to evaluate pathological features- tumor size, residual tumor cellularity (RTC), proportion of lymph nodes (PLN) with metastatic tumor, presence of residual lymphovascular invasion (LVI) in skin/breast, skin involvement, extranodal extension (ENE), and largest size of lymph node metastasis, for predicting each survival outcome separately. The significant pathological features were included in a multivariate model to identify factors to be utilized for building the R-IBC score. For PFS, the raw R-IBC score was calculated as R-IBCraw = (0.8668 x RTC) + (1.0646 x PLN) + (0.5894 x ENE). The score was then scaled from 0 to 10 as follows: R-IBC = 10 x R-IBCraw/max(R-IBCraw). Clinical features- age, race, clinical stage, clinical N category, ER/PR/HER2 status, were evaluated using univariate followed by multivariate analysis to identify significant factors to be combined with R-IBC for predicting outcome. Performance of R-IBC score alone and a final model including R-IBC score combined with clinical features was assessed by implementing the area under the receiver operating characteristic curve (AUC-ROC). The process was repeated for OS.
Results: Clinical features for training and test sets were: mean ages 59/58 years, clinical stage III 77%/73%, clinical stage IV 22.9%/25.9%, clinical T4d 100%, ER+ and PR+ 54.2%/54.5%, HER2+ 26.5%/38.7%, and triple-negative status 19.3%/6.8%. Pathological

features in the training and test sets were: residual tumor size 4.07 cm/4.1 cm, RTC 10.9%/11.8%, PLN 0.3/0.2, ENE 35.7/41.5%, lymphovascular invasion 40.1%/45%, skin involvement 26.6%/28.9%, pathologic complete response (PCR) 27.7%/29.8%, and non-PCR 72.3%/70.2%. The univariate Cox regression analysis identified all pathological features evaluated in the training dataset to be significant for inclusion into R-IBC score. Multivariate analysis identified RTC, PLN, and ENE alone to be significant for calculating R-IBC score (0-10). The calculated R-IBC score showed strong correlation with increasing risk of death or disease progression in patients with higher scores. Clinical nodal (N) category and triple-negative status were identified as significant clinical features that could be combined with R-IBC score for developing the final model. The AUC from the full model for the test set was 0.780 and 0.783 for PFS and OS ; the AUC of R-IBC score alone was 0.717 and 0.710 for PFS and OS .
Conclusion: The developed and validated R-IBC is the first IBC prediction calculator. R-IBC uses RTC, PLN, and ENE as key pathological features after NC in predicting outcome of IBC. Clinical N category and triple negative status could be combined with R-IBC for added predictive ability. Large-scale validation of R-IBC is warranted to enable consideration of incorporating the IBC specific calculator for predicting outcome of IBC patients in clinical practice and research.

P1-07-10: Clinicopathologic Characterization of Hormone-Receptor Positive, HER2 Null, Ultralow, and Low Breast Carcinoma in the Metastatic Setting

Raza Hoda, Patrick J McIntire

Background: The landscape of HER2-directed therapy is evolving at a rapid rate. Patients with hormone receptor (HR)-positive and human epidermal growth factor receptor 2 (HER2) Low (IHC 1+ or 2+/ISH-) and HER2 Ultralow advanced (IHC 0 with membranous staining in <10%) demonstrate clinically meaningful progression-free survival improvement with HER2-directed antibody drug conjugates (e.g. trastuzumab deruxtecan). Studies are limited on the clinical and pathological features of patients with HR+ /HER2 Ultralow and Low metastatic breast carcinoma. Herein, we provide the prevalence of HER2 Low, HER2 Ultralow, and HER2 Null status across MBC and characterize eligible patients and their tumors of a one-year retrospective review from our institution.

Methods: We retrospectively assessed rates of HER2 Null, HER2 Ultralow, and HER2 Low in patients with MBC who underwent biopsy at Cleveland Clinic from 1/1/2023 to 12/31/2023. Clinical and pathologic variables were recorded for patients with HR+/HER2 Ultralow; limited clinical and pathological parameters for patients with HR+/HER2 Low, HR+/HER2 Null, HR+/HER2 amplified, HR-/HER2-amplified, and HR-/HER2- breast carcinoma [‘triple-negative’ breast carcinoma (TNBC)] were recorded with detailed review forthcoming. Results of ER, PR, and HER2 testing on primary and metastatic tumor samples were reviewed in the electronic medical record. Patients without ER, PR, and HER2 testing

performed on metastatic tumor sample were excluded. HR+ disease was considered immunoreactive for estrogen or progesterone receptor in ≥1% of invasive tumor-cell nuclei. Glass slides of all HER2 IHC 0 cases were jointly assessed by two expert breast pathologists and scored as "HER2 Ultralow" (incomplete and is faint/barely perceptible and membranous staining in <10%) or "HER2 Null" (absence of any membranous staining) by consensus.

Results: A total of 130 patients were included in the study. All patients were women, and median age at time of MBC diagnosis was 67 years (mean, 65 years, range: 47-86 years). Common sites of MBC sampled included bone (n=73; 56.2%), liver (n=24;18.5%), lung (n=10; 7.7%), and soft tissue (n=8; 6.2%). Seventy (53.9%) patients had HR+/HER2 Low MBC, 21 (16.2%) had HR+/HER2 Ultralow MBC, and 8 (6.1%) had HR+/HER2 Null MBC. Twenty (15.4%) patients had metastatic TNBC, 8 (6.1%) had HR+/HER2+ MBC, and 3 (2.3%) had HR-/HER2+ MBC. Amongst the 21 patients with HR+/HER2 Ultralow MBC, the median age at time of MBC diagnosis was 68 years (mean, 68 years; range, 46-86 years). A majority of these cases (n = 9 of 17 primary cases available; 53%) demonstrated invasive carcinoma of no special type histology. Oncotype DX recurrence score (RS) was obtained in 5 cases, with 4 cases showing RS of 11-25 and 1 case showing of RS >25. Sixteen (76%) of 21 patients with HR+/HER2 Ultralow MBC received cytotoxic chemotherapy, and all patients received endocrine therapy. The median number of lines of therapy for MBC was 2 (range, 1-5). Median clinical follow-up time since time of primary breast carcinoma diagnosis was 89 months (mean, 94 months; range, 3-317 months). Twelve (57%) of 21 patients with HR+/HER2 Ultralow MBC had partial response or stable disease on therapeutic regimen, while 3 (14%) showed progression of disease and 6 (29%) died of disease.

Conclusions: Our one-year single-institution retrospective study shows a majority of MBC are HR+/HER2 Low, followed by a smaller proportion of HR+/HER2 Ultralow, indicating a large population of patients who may show benefit with HER2-directed antibody drug conjugates. Further comparison between patient cohorts will be performed to identify potential differences in clinical characteristics and pathologic variables, including HR and HER2 status of primary tumor, primary tumor histology and grade, and Oncotype DX RS.

P1-07-11: Evaluating the Correlation Between FISH and NGS in Assessing ERBB2 Alterations in Breast Cancer

Viktor Smirnov, Polina Turova, Vladimir Kushnarev, Gleb Khegai, Sheila T. Yong, Anna Butusova, Nikita Kotlov, Konstantin Chernyshov

Introduction: Fluorescence in situ hybridization (FISH) is the gold standard for evaluating ERBB2 amplification in breast cancer (BC) when HER2 status is equivocal by immunohistochemistry, per ASCO guidelines (15–20% of cases). Next-generation sequencing (NGS) can confirm the HER2 status of BC samples and, in turn, help reduce the

incidence of equivocal samples. Here, we examined the correlation between FISH and NGS in annotating HER2 status of BC samples and evaluated the clinical utility of NGS as a support tool for improving analysis outcomes.
Methods: The BostonGene internal breast cancer (total n=358, FISH annotation=124) and TCGA-BRCA (total n=972, FISH annotation n=285) cohorts were assessed together for ERBB2 expression via RNA sequencing and ERBB2 mutation and amplification via DNA sequencing. High ERBB2 gene expression was set at >8.5 log2(TPM+1)1. For NGS, Gain was defined as an increase of one gene copy relative to sample ploidy, while Amplification referred to an increase of two or more gene copies compared to sample ploidy. Samples were assessed for FISH positivity (+) per ASCO/CAP guidelines.
Results: There was substantial agreement between FISH and NGS analysis for both cohorts combined (Cohen's kappa=0.57). All FISH+ samples had significantly higher ERBB2 expression (n=71, median (med)=8.8) than all FISH- samples (n=338, med=6.6, U-statistics (stats), p<0.001). Among the FISH+ samples, 53% (n=37) had high ERBB2 expression. Samples with amplification as shown by NGS had significantly higher ERBB2 expression (n=35, med=9.6) than non-amplified samples (n=335, med=6.6, U-stats, p<0.001). High ERBB2 expression was observed in 31% (n=23 of 74) of samples with ERBB2 gain or amplification. FISH+ samples with ERBB2 gain had significantly higher ERBB2 expression (n=14, med=10.5) than FISH- samples (n=13, med=7.9, U-stats, p<0.001).
NGS also detected 23 unique ERBB2 mutations, among which 18 were classified as missense, 4 as frameshift, and 9 as gain-of-function. Interestingly, 20 non-amplified samples with ERBB2 mutation exhibited significantly higher ERBB2 expression (med=7.4) than non-amplified samples with wildtype ERBB2 (n=999, med=6.9, U-stats, p=0.004).
Conclusion: Our study demonstrated substantial agreement between FISH and NGS (Cohen's kappa=0.57) in evaluating HER2 status in BC, highlighting NGS as a viable support tool for assessing HER2 status, particularly in equivocal cases. First, NGS reliably detected significantly higher ERBB2 expression in FISH+ samples than in FISH- samples. Next, it detected ERBB2 mutations in non-amplified samples that were not covered by FISH. Since these mutations may be associated with increased ERBB2 expression, they are clinically relevant and warrant further study. Last but not least, NGS detected focal ERBB2 amplifications and gains at a higher resolution than FISH. While associated with varied FISH results, these events consistently concurred with higher ERBB2 expression, reflecting the heterogeneous nature of HER2 amplification in BC that FISH does not take into account. The ability of NGS to identify these nuanced genomic alterations yields valuable insights into the tumor biology and potential resistance mechanisms of BC that are crucial for designing personalized treatment strategies and improving patient outcomes.

P1-07-12: Comprehensive characterization of invasive mammary carcinoma with lobular features: Integrating morphology and E-cadherin immunochemistry pattern

Aeree Kim, Taesung Jeon, You-Na Sung, Jaewon Oh, Jungsuk Ahn, Ji-Yun Lee

Introduction: Breast cancer treatment prioritizes molecular subtypes over histologic types. However, considering the unique biologic behavior of invasive lobular carcinoma (ILC), its diagnosis is crucial for patient management. In this study, we reviewed breast cancer, with a particular focus on investigating the E-cadherin staining patterns and lobular morphology of cases that were misclassified in the original reports.
Materials and Methods: A comprehensive review was conducted on 481 cases diagnosed with invasive breast carcinoma of no special type (IBC - NST) or ILC through biopsy, in which E-cadherin staining was also performed. Subsequently, these cases were categorized into six groups based on a combination of tumor morphology (ductal / lobular) and E-cadherin expression pattern (membranous / loss / aberrant).
Results: In 211 cases (43.8%), an E-cadherin pattern indicating ILC (loss & aberrant) was observed alongside lobular morphology, representing 5.52% of all breast cancer biopsies during the relevant period. 181 cases (37.6%) showed membranous pattern with ductal morphology, 4 (0.8%) were mixed IBC-NST and ILC, and 85 (17.7%) exhibited discordance between morphology and E-cadherin. Notably, of 58 cases reviewed as ILC due to aberrant pattern, only 15 (25.9%) had initial diagnosis of ILC. Among 58 cases showing membranous pattern with lobular morphology, only 2 were diagnosed as ILC in the original reports. Similarly, despite the presence of ductal morphology, 17 cases (63%) exhibiting either loss or aberrant pattern were initially diagnosed as ILC.
Conclusion: Despite the E-cadherin expression pattern being recognized as a 'desirable' diagnostic criterion for ILC in the WHO blue book, real-world practice tends to depend on E-cadherin results, even in the presence of evident lobular morphology. Especially, aberrant pattern was often interpreted as membranous pattern, leading to misdiagnoses of IBC-NST. Additionally, cases showing discordance between morphology and E-cadherin patterns were observed in 85 cases (17.7%), highlighting the need for molecular clarification of these discrepancies.

P1-07-13: Adipocyte size in relation to clinical factors, mammographic density and quantitative histologic metrics in ductal carcinoma in situ (DCIS).

Charlotta Mulder, Mathilde Almekinders, Renaud Tissier, Petra Kristel, Esther Lips, Marjanka Schmidt, Jelle Wesseling

Background: Ductal carcinoma in situ (DCIS) is a non-obligate precursor to invasive breast cancer, but distinguishing patients with harmless from potentially hazardous ductal carcinoma in situ (DCIS) remains a challenge. Consequently, a cornerstone of DCIS research is finding prognostic biomarkers. One such recent biomarker is adipocyte hypertrophy, which has been shown to be predictive of iIBC in post-menopausal women with primary DCIS 1. Little is known about the correlation between adipocyte size and clinical factors, mammographic breast density and other tissue composition metrics conferring risk of breast cancer.
Methods: Using the digital pathology software program HALO®, we automated the

adipocyte detection pipeline by building a machine learning algorithm for tissue segmentation, whereafter individual adipocytes were characterized using the vacuole module version 3.2.2. The correlation between the automated adipocyte measurement and the pathologist's generated measurement was assessed for 249 patients. Thereafter, archival hematoxylin and eosin- stained breast biopsy and excision specimens were retrieved from 700 women diagnosed with primary DCIS between 2000 and 2020 treated at the Netherlands Cancer Institute. These slides were digitized whereafter the machine-learning algorithms were applied to retrieve adipocyte size, proportion of epithelial cells, stromal cells and fibroglandular tissue. Radiology reports were obtained to extract mammographic BI-RADS density. Age at diagnosis, weight, length and menopausal status were extracted from electronic patient records. Associations between adipocyte size and clinical factors, BI-RADS density and tissue metrics were investigated using multivariable linear regression models.
Results: The median age at primary DCIS diagnosis was 55 years (interquartile range (IQR): 49.0 -63.0) and most DCIS lesions were grade 3 (40.9%). The median BMI was 24.1 (IQR: 21.9 - 27.1). The majority of women were post-menopausal (47.8%) and had dense breasts, whereby 40.6% had heterogeneously dense breasts and 13.7% had extremely dense breasts 2. Furthermore, there was good concordance between the automated adipocyte measurements in comparison to the pathologist's measurement with an intraclass correlation coefficient of 0.96 (95% CI = 0.95-0.97). In December, we will present the associations between adipocyte size and the clinical factors, mammographic breast density and tissue composition metrics.
Conclusion: Adipocyte hypertrophy has been shown to be predictive of iIBC in post-menopausal women with primary DCIS. This biomarker can be confidently measured with machine learning algorithms. This study will elucidate the associations between adipocyte size and clinical factors, mammographic breast density and other tissue composition metrics.

P1-07-14: MutL loss in ER+ breast cancer promotes pro-tumorigenic macrophage polarization that aids migration capacity

Megha Raghunathan, Aloran Mazumder, Sabrina Carrell, Daniel Lozano, Nindo Punturi, Svasti Haricharan

The Mismatch Repair (MMR) pathway, a crucial tumor suppressor mechanism, is dysregulated across cancer types. We previously identified the loss of the MutL complex of the MMR pathway, as a key factor inducing resistance to endocrine therapy in Estrogen Receptor positive (ER+) breast cancer patients. Preliminary data previously generated in

the lab supports a role for MutL loss in promoting metastasis of ER+ breast cancer. A mammary-specific knockout mouse model for MLH1, a principal component of MutL, created in the Haricharan lab develops aggressive mammary tumors that metastasize to multiple organs. To unveil the mechanism by which MLH1 loss triggers metastasis, an unbiased RPPA and RNA-Seq was conducted which revealed cytokine secretion in the immune system as a distinctive signature of MLH1- ER+ breast cancer cells. The tumor secretome, particularly cytokines, can manipulate macrophage plasticity to skew polarization states towards either an anti- or pro- metastatic phenotype. Secreted cytokine levels altered by MLH1 loss were identified in multiple ER+ breast cancer cells lines from concentrated conditioned media. Additionally, in vivo experiments with xenograft MLH1- ER+ tumors in nude mice, revealed an elevated number of CD206 expressing tumor-promoting M2 macrophages in the tumor microenvironment. Furthermore, MLH1- ER+ breast cancer cells grown in the presence of macrophages exhibit an increase in their migratory capacity. Our preliminary data strongly indicate that loss of MLH1 alters the ER+ breast cancer secretome and alters macrophage maturation, suggesting a role for MLH1 in immunomodulation supporting metastatic progression. Investigation of this new role will uncover key tumor-intrinsic drivers of “cold” tumor immune microenvironment profiles and present unique opportunities for therapeutic interventions to convert them into “hot” profiles, thereby improving ER+ breast cancer patient outcomes.

P1-07-15: Tumor size reduction and overall survival improvement in HER2-overexpressing cancer patients vaccinated with HER-Vaxx, a B-cell peptide-based vaccine, plus standard-of-care chemotherapy

Joshua Tobias, Michael Kundi, Erika Garner-Spitzer, Christoph C. Zielinski, Marina Maglakelidze, Zoran Andric, Zoran Petrovic, Ivan Nikolic, Dinara Ryspayeva, Lurie Bulat, Rajnish Nagarkar, Tanuj Chawla, Leslie Mi Ok Chong, Bonnie Nixon, Nicholas J. Ede, Sharon Yavrom, Ursula Wiedermann

Purpose: Overexpression of HER2 has been observed in several types of cancers, including in 10-30% of breast and gastric/gastroesophageal tumors. We have previously identified three peptides representing B cell epitopes on HER2 extracellular domains, comprising trastuzumab’s binding site. In a Phase I study including patients with metastatic breast cancer, vaccination with the single peptides conjugated to virosome particles induced humoral and cellular immune responses, as well as an excellent safety profile. For the clinical efficacy evaluation, a hybrid peptide based on the three single peptides was generated and conjugated to the carrier protein CRM197 (toxoid of diphtheria toxin). In conjunction with the Th1/Th2-deriving adjuvant Montanide, the formulated vaccine compound, HER-Vaxx, was evaluated in HER2-overexpressing gastric cancer patients from countries where trastuzumab is not the first line of treatment. In a dose escalation Phase Ib trial, HER-Vaxx was shown to be safe, and the higher doses were associated with increased antitumor effect and progression-free survival. Thus, the recently completed randomized open-label, multicenter phase 2 HERIZON trial (NCT02795988) was conducted to compare

vaccination with HER-Vaxx plus chemotherapy, and chemotherapy alone.
Methods and Patients: Patients (n=36) with HER2-overexpressing gastric/gastroesophageal junction (GEJ) cancer naïve to anti HER2 therapy, were vaccinated with HER-Vaxx plus chemotherapy (n=19) using the recommended Phase 2 dose (50µg), or treated with standard-of-care chemotherapy (n=17). The study evaluated overall survival (OS; primary endpoint), safety, progression-free survival (PFS) and clinical response (secondary endpoints), and vaccine-induced, HER2-specific antibody levels in serum and their correlation with tumor response rates (exploratory endpoints).
Results: A 40% OS benefit (hazard ratio [HR]: 0.60; median OS: 13.9 months; 80% (2-sided) confidence interval [CI]: 7.52-14.32) was observed in vaccinated patients compared to OS of 8.31 months (80% CI: 6.01-9.59) in chemotherapy-alone patients. No additional toxicity due to HER-Vaxx was observed. A 20% PFS difference was obtained for the vaccination arm (HR: 0.80; 2-sided 80% CI:0.467, 1.381). Highly significant HER2-specific IgG and IgG1 antibody responses, particularly after 3 or more doses of HER-Vaxx were induced (P<0.001 vs. controls), which significantly associated with tumor reduction (IgG, P=0.001; IgG1, P=0.016), inhibition of phosphorylation of the intracellular HER2-signalling pathways, and mediation of antibody-dependent cellular cytotoxicity. An association between increased vaccine-induced antibodies and decreased levels of immunosuppressive FOXP3+ Tregs was also shown.
Conclusions: In gastric/GEJ cancer patients, HER-Vaxx plus standard chemotherapy improves OS, the vaccine-induced immune responses are significantly associated with tumor size reduction, and a favorable safety profile compared to standard-of-care chemotherapy alone is exhibited. This study suggests a possible inclusion of HER-Vaxx as first line treatment modality in HER2-overexpressing cancers.

P1-07-16: Real-World Duration of Sacituzumab Govitecan-hziy Treatment in Patients with Metastatic Triple-Negative Breast Cancer

Fred Kudrik, Vikram Gorantla, Rushir Choski, Debra Patt, Anupama Vasudevan, Erin Alwon, MS, Dawn Brenneman, Mike Gart, Prateesh Varughese, Brandon Wang, Lisa Morere, Simon Blanc

Background: The objective of this study was to determine the duration of Sacituzumab Govitecan-hziy (SG) treatment in patients with Metastatic Triple-Negative Breast Cancer (mTNBC) stratified by granulocyte colony-stimulating factor (GCSF) treatment.
Methods: This retrospective, observational study included US adult patients with mTNBC who received SG treatment (any line) between January 1, 2020 and July 1, 2023 in the community oncology setting. Patients were followed until January 4, 2024. The study utilized real-world structured electronic health data from the Integra Connect PrecisionQ de-identified database. Primary prophylactic GCSF usage was defined as GCSF being received on or after the initial date of SG administration but before neutropenia diagnosis. Secondary prophylactic/treatment GCSF usage was defined as GCSF received on or after the initial date of SG administration and on or after the date of neutropenia diagnosis.

Neutropenia was defined as neutrophils <1500 cells/mL. Duration of treatment was calculated as absolute duration utilizing start and stop dates documented in the data.
Results: A total of 337 patients were included in this study. The median (IQR) age at first treatment was 58.3 (49, 67) years. Of these patients, 219 (65%) were White, 57 (17%) were Black/African American, and 6 (2%) were Asian. The median (IQR) time from initial breast cancer diagnosis to the first SG administration was 3.3 (1, 6) years. ECOG status at SG initiation was unknown in 35 (10%) patients. Of the patients with ECOG status data at SG initiation, 93 (28%) were ECOG 0, 164 (49%) were ECOG 1, 38 (11%) were ECOG 2, 5 (1%) were ECOG 3, and 2 (1%) were ECOG 4.
Overall, 202 (60%) mTNBC patients treated with SG received a concomitant GCSF agent. Of patients who received GCSF, 98 (49%) received a long-acting GCSF agent, 102 (50%) received a short-acting GCSF agent, and 2 (1%) received both a long-acting and short-acting GCSF agent. Of the 202 patients who received GCSF, 92 (46%) received primary prophylactic GCSF and 110 (54%) received secondary prophylactic/treatment GCSF. Among the 92 providers who used a primary prophylactic GCSF, 34% treated with a short-acting GCSF and 65% treated with a long-acting GCSF; the remaining 1% treated with both short- and long-acting GCSF agents. In contrast, among the 110 providers who used a secondary prophylactic/treatment GCSF, 65% used a short-acting GCSF, 35% used a long-acting GCSF, and 1% used both short- and long-acting GCSF agents.
The median (IQR) duration of SG therapy was 137 (71, 239) days for those who received GCSF and 85 (44, 188) days for those who did not receive GCSF. The median (IQR) duration of SG treatment was similar among patients who received primary prophylactic GCSF (134 [65, 241] days) and secondary prophylactic/treatment GCSF (139 [71, 239] days). The median (IQR) duration of SG treatment was 155 (72, 246) days for patients who received long-acting GCSF agents and 134 (71, 224) days for those who received short-acting GCSF agents.
Conclusions: This descriptive study found that more patients with mTNBC on SG treatment received secondary prophylactic/treatment GCSF rather than primary prophylactic GCSF. Patients who received a GCSF appeared to have a longer median duration of SG treatment than those who did not. Further research, including both structured and curated data, is needed to better understand the reasons behind these differences.

P1-07-17: Mitotically-associated long noncoding RNA (MANCR): A novel long noncoding RNA that promotes genomic stability and cellular proliferation in Triple Negative Breast Cancer

Janine S. A. Warren, Bodhisattwa Banerjee, Jonathan A. R. Gordon, Prachi N. Ghule, Janet L. Stein, Gary S. Stein, Jane B. Lian, Peter A. Kaufman

Background: While recent advances have improved outcomes for Triple Negative Breast Cancer (TNBC), it continues to have a poor prognosis. Long non-coding RNAs are among a recent class of epigenetic regulators that function in the nucleus to support the stability of cells and maintain the fidelity of chromatin interactions. Our laboratory discovered the long

noncoding RNA MANCR (LINC00704) as being upregulated in human breast cancer. Furthermore, our work demonstrated that MANCR is enriched in TCGA breast cancer patient samples that are not estrogen or progesterone receptor positive. We also demonstrated that the 10-year survival in this TCGA analysis is substantially worse in patients with high MANCR expression. More recently, we have found MANCR to be aberrantly expressed in TNBC cells, and these cells are highly dependent on MANCR to retain their tumorigenic characteristics.
Methods: Functional in vitro studies in MDA-MB-231 TNBC cells used short antisense nucleic acids (GapmerRs) to knockdown MANCR. For in vivo studies, TNBC cells were injected into the mammary fat pad of mice, allowing tumor formation, and subsequent treatment with 2 nmol/g of a negative control or MANCR targeting GapmeR. We also identified genome interaction sites at single nucleotide resolution by chromatin isolation by RNA purification sequencing (ChIRP-seq) to determine the mechanism of MANCR activity in TNBC cells.
Results: We now demonstrate that MANCR knockdown promotes DNA damage and decreases cell proliferation, migration, anchorage-independent colony formation, transwell invasion, and cellular survival. Additionally, in vivo targeting of MANCR drastically inhibited tumor growth over time and the end-point tumor mass. The MANCR GapmeR treatment also inhibited the ability of TNBC cells to circulate and disseminate to distant organs in vivo. After performing ChIRP-seq in the MDA-MB-231 cells, we identified 1206 genome-wide binding sites that exhibit MANCR interactions, of which 48% are intergenic and 52% are in genic regions. Furthermore, many MANCR ChIRP peaks were found to overlap with fragile sites in the genome, indicating MANCR provides stability to these sites.
Conclusions: These data suggest that targeting MANCR has therapeutic potential for patients with “MANCR-high” TNBC tumors by disrupting genome stability. Indeed, our in vivo studies demonstrate that “MANCR-high” TNBC tumors require MANCR to rapidly grow and promote disease progression. Significantly, many of the MANCR-chromatin interactions identified were found in intergenic regions and overlap with fragile sites within the genome. Collectively, these data strongly indicate that MANCR stabilizes the TNBC genome, and disrupting genome stability by targeting MANCR has therapeutic potential.

P1-07-18: Testing the Rac/Cdc42 inhibitor MBQ-167 in ex vivo cultures of Hispanic TNBC tissue

Anamaris Torres-Sanchez, Nilmary Grafals-Ruiz, Ailed M. Cruz-Collazo, Maria Dos Santos-Torres, Viviana Negron, Victor Carlo, Suranganie Dharmawardhane

Triple-negative breast cancer (TNBC) is a deadly form of breast cancer that is a health disparity in the US because the incidence of TNBC is tripled in African American women compared to Caucasian women. In Puerto Rico, where the admixture consists of Spanish, native Caribbean (Taino), and African American, more younger women present with TNBC at an advanced stage, when the tumor has already metastasized to distant sites, thus reducing their survival to ~10%. Since the absence of estrogen/progesterone (ER/PR)

receptors and human epidermal growth factor receptor (HER2) limits targeted therapy for TNBC, novel targeted therapies are required. To fill this critical need for targeted therapy for advanced cancer, our group developed MBQ-167 as a specific inhibitor of the homologous metastasis drivers Rac and Cdc42, which are risk factors for advanced breast cancer patient survival. MBQ-167 inhibits Rac/Cdc42 activation by GTP loading and the activation of their downstream effector P21-activated kinase (PAK) by phosphorylation at an IC50 of ~100nM. Consequently, MBQ-167 reduces TNBC tumor growth and abolishes metastasis without toxicity in animal models. In addition to inhibiting cancer cell survival and migration, MBQ-167 reduces immunosuppressive myeloid cells and upregulates cytotoxic T cells in the tumor microenvironment (TME). Therefore, we have initiated a Phase 1 clinical trial to determine the safety of MBQ-167 in advanced Puerto Rican breast cancer patients (NCT06075810). Immunohistochemistry (IHC) of breast cancer tissues from Puerto Rican breast cancer patients demonstrate that Rac and Cdc42 are expressed at all stages of the disease and that the levels of phospho (P)-PAK are high in advanced breast cancer. The objective of this study is to determine the efficacy of MBQ-167 in Puerto Rican TNBC patient tissues using an ex vivo drug testing platform. Treatment naïve TNBC patient tissues (>2cm lesion) were collected immediately following surgical resection from the Auxilio Mutuo Cancer Center Hospital, San Juan PR, under IRB 1487543-6. Tissue slices (2mm) were incubated in 0-1000nM MBQ-167 for 24-48h in ex vivo culture. Tissue slices were fixed for H&E staining and IHC, immunostained for KI-67 and Cyclin D for proliferation, and p-PAK for MBQ-167 efficacy. Results (N=5) show that hematoxylin-stained invasive ductal carcinoma cells were reduced upon MBQ-167 treatment. When tissues were stained with antibodies to p-PAK (1,2,3)T423 or Cyclin D, positive p-PAK and Cyclin D staining were prominent in the vehicle but not in the MBQ-167 treated tissue. Therefore, MBQ-167 is effective as a targeted therapeutic in advanced breast cancer tissues. The results of this study promise to directly address the dynamics of Rac/Cdc42 inhibitor therapy in Puerto Rican TNBC patients and forward Phase 2 trials for this novel therapeutic in advanced breast cancer patients. This study was supported by the US Army Breast Cancer Research Program (BCRP) HT9425-23-1-0166 (to SD), 5R25GM061151-21 (ATS), and NIH NCI 5R25CA240120-05 (MDT).

P1-07-19: Old Medicine, New Application: Therapeutic Potential of the Second-Generation Antihistamine Aerius as a N-WASP Inhibitor in Breast Cancer Metastasis

Rhiannon Yannan Yu, Q Ping Dou, Elyas Khan, Wen G. Jiang, Tracey A. Martin

Background: Aerius (desloratadine) is a second-generation antihistamine commonly prescribed to alleviate allergy symptoms. Recently, there has been growing interest in repurposing existing drugs for cancer therapy, leveraging their known safety profiles and mechanisms of action. Thus, Aerius has emerged as a candidate for targeting metastatic pathways in cancer. N-WASP, a key protein involved in actin polymerisation, plays a crucial role in cell motility and invasion. By facilitating cytoskeletal reorganisation, N-WASP

enables cancer cells to migrate and invade distant tissues, making it a significant target for therapeutic intervention. Understanding and disrupting the pathways that contribute to metastasis can lead to improved treatment strategies and better clinical outcomes for patients with advanced breast cancer.
Methods: Utilizing two breast cancer cell lines, MDA-MB-231 and MCF-7, along with HECV, an endothelial cell line, comprehensive in vitro biological assays included cytotoxicity tests, cell growth assay, Electric Cell-substrate Impedance Sensing (ECIS), wound scratch assay, immunofluorescence, qPCR and western blotting were conducted to discern Aerius's effects on cell proliferation, adhesion, motility, and its specific impact on N-WASP protein expression at both the mRNA and protein levels and its downstream events. Molecular docking was carried out by computer-assisted modelling to model the interaction between N-WASP and Aerius at the atomic level.

Results: Aerius demonstrated a significant inhibitory effect on cell proliferation in all three cell lines tested. When Aerius (at ? concentration for ? hours) was used in MDA-MB-231 cells, proliferation decreased by 51.76% ($P<0.0001$), while in MCF-7 cells, it decreased by 39.23% ($P<0.0001$), and in HECV cells, it reduced by 16.78% ($P=0.0004$). Furthermore, Aerius markedly impaired cell adhesion and migration in the ECIS assay. Wound healing assay revealed a 10.73% reduction in migration rate in MDA-MB-231 cells ($P<0.0001$), 35.89% reduction in MCF-7 cells ($P= 0.0014$), and 10.73% reduction in HECV cell lines ($P= 0.2367$) under the experimental conditions, indicating diminished motility.
Importantly, Aerius treatment led to a significant downregulation of N-WASP protein expression. Immunofluorescence assays and Western blot analysis confirmed these results. Additionally, qPCR results indicated the treatment of Aerius did not regulate the N-WASP mRNA expression, as it did not show any significant change compared with the untreated group, this suggests that the mechanism of action likely occurs at the post-transcriptional, translational or post-translational level. Finally, molecular docking revealed that Aerius had a binding profile with multiple amino acids of key domains of N-WASP protein.
These results highlight Aerius' multi-faceted inhibitory effects on key processes involved in breast cancer metastasis, including cell proliferation, adhesion, and migration, primarily through the downregulation of N-WASP protein expression.
Conclusion: Aerius shows significant promise in inhibiting N-WASP protein expression, thereby disrupting critical processes necessary for breast cancer metastasis. These results propose a new therapeutic application for Aerius, beyond its conventional use as an antihistamine, potentially offering a dual-purpose treatment strategy for managing metastatic breast cancer. Further clinical exploration is warranted to validate these findings and assess their therapeutic potential in a clinical setting.

P1-07-20: Mechanism of miR-221-3p/PARP1 regulating the progression of triple-negative breast cancer through the NF-κB pathway

Qianqian Lei, Ye Hong, Kegui Weng, Yanyan Long, Min Ying, Jing Chen, Mengyu Hu, Deqing Liu

Purpose: The underlying mechanisms driving the occurrence and progression of triple-negative breast cancer (TNBC) necessitate comprehensive elucidation. Our previous findings have demonstrated a significant association between low expression of miR-221-3p and unfavorable prognosis in TNBC patients, wherein it exerts inhibitory effects on TNBC cell proliferation and metastasis by negatively regulating PARP1. Prior studies have suggested that PARP1 facilitates TNBC progression through modulation of the NF-κB pathway. This study aims to elucidate the role of the miR-221-3p/PARP1/NF-κB axis in TNBC progression.
Materials and Methods: We established MDA-MB-231 cell lines with either overexpression or downregulation of PARP1 by plasmid transfection. Transcriptome sequencing and KEGG(Kyoto Encyclopedia of Genes and Genomes) pathway enrichment analysis were employed to identify differentially expressed genes and associated signaling pathways in the various cell lines. The effect of PARP1 on the expression of NF-κB pathway-related molecules was validated through analysis using the TCGA (The Cancer Genome Atlas) database, Real-time PCR(Polymerase Chain Reaction), and Western blot techniques. Additionally, miR-221-3p modulation by miRNA mimic or inhibitor was performed to elucidate its role in regulating the NF-κB pathway via targeting PARP1. Cell proliferation and migration abilities in TNBC cells were assessed using CCK8 assay and Transwell chamber.
Results: KEGG pathway enrichment analysis revealed significant alterations in the expression of molecules related to the NF-κB signaling pathway between cell lines with differential PARP1 expression. Subsequent analysis of the TCGA database demonstrated that high expression of NF-κB signaling pathway-related molecules, particularly the NFKB1 gene, was predominantly enriched in cells overexpressing PARP1. In vitro experiments confirmed a substantial increase in both NFKB1 gene and protein levels in PARP1-overexpressing cells compared to the control group. In contrast, the knockdown of PARP1 exerted an opposite effect, thus establishing a positive correlation between PARP1 and NFKB1. Additionally, miR-221-3p exhibited a negative correlation with NFKB1. Furthermore, we observed that downregulation of PARP1 attenuated the regulatory effect of miR-221-3p on NFKB1 and improved outcomes for TNBC. In contrast, the upregulation of PARP1 exerted an opposite effect.
Conclusion: PARP1 exhibits a positive correlation with NFKB1, while miR-221-3p demonstrates a negative correlation with NFKB1. The regulatory role of miR-221-3p in TNBC proliferation and migration, as well as the modulation of NFKB1 expression, is mediated through its targeting of PARP1. The miR-221-3p/PARP1/NFKB1 axis plays a crucial role in regulating the progression of TNBC cells.
Keywords: triple-negative breast cancer, miR-221-3p, PARP1, NF-κB signaling pathway

P1-07-21: Efficacy of CDK4/6 Inhibitor Abemaciclib in Metastatic Triple-Negative Breast Cancer

Chuling Zhuang

Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype with the lowest 5-year survival rate among different subtypes. Although TNBC is less frequently diagnosed in U.S. women compared to the HR+/HER2- subtype, it remains as the second most common breast cancer subtype (13.6%) in the most recent five years. However, there is still an unmet need to develop effective treatment for TNBC due to the lack of actionable drug targets and high resistance rate. Cell cycle dysregulation is a common cancer hallmark. By targeting key regulators of cell cycle progression, multiple cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors have achieved clinical benefits with FDA approval to treat HR+/HER2- advanced and metastatic breast cancer. Interestingly, our datamining of two public breast cancer patient datasets (TCGA and GEO) consistently showed that the CDK4/6 signaling pathway was significantly more enriched in TNBC patients, compared to luminal and HER2-enriched breast cancer patients. After stratifying patients based on CDK4/6 gene activation signature scores into high (CDK4/6-high) and low (CDK4/6-low), we observed that high CDK4/6 activation signature is significantly correlated with a shorter time to develop overall metastasis, as well as, site-specific metastasis to bone, lung, or brain. It is noteworthy that CDK4/6-high TNBC patients have significantly shorter metastasis-free survival, with a median of 20 months, while that of CDK4/6-low TNBC patients is substantially extended with a median of 51 months. Immunohistochemistry staining of tissue microarray of 46 pairs of human primary and metastatic breast tumor samples validated our findings in datamining as CDK4/6 positivity is increased in lymph node metastases compared to matched primary tumors, and it is the highest in TNBC patients in both primary (6/9, 67%) and lymph node metastasis (7/9, 78%) tissue samples. Western blot analysis of a panel of breast cancer cell lines showed that the CDK4/6 signaling pathway is activated in the majority of TNBC cell lines. Next, we investigated the efficacy of Abemaciclib, an FDA-approved CDK4/6 inhibitor, and demonstrated that it is effective in inhibiting the proliferation of TNBC cell lines, with a half maximal inhibitory concentration (IC50) of 5.6-9.6 μM. Abemaciclib also effectively induced apoptosis of TNBC cells as indicated by increased PARP cleavage and Annexin V staining positivity. Additionally, TNBC cells treated with Abemaciclib exhibited significantly inhibited migration, invasion, and mammosphere formation abilities. Using an intracardiac inoculation mouse model, we found that systemic administration of Abemaciclib treatment significantly reduced overall TNBC metastatic burden and brain metastases. Collectively, these findings suggest a promising utility of CDK4/6-targeted therapy in treating metastatic TNBCs.

P1-07-22: Phase I Study of B7-H3 Specific Chimeric Antigen Receptor (CAR) T Cell Therapy in Patients with Triple-Negative Breast Cancer

Yara Abdou, Barbara Savoldo, Natalie S. Grover, Gianpietro Dotti, Felicia Cao, Catherine J. Cheng, J. Kaitlin Morrison, Jonathan S. Serody, Lisa A. Carey, E. Claire Dees

Background: Triple-negative breast Cancer (TNBC) accounts for 15-20% of all breast cancers, among which it has the worst prognosis and limited therapeutic options. B7-H3, a type I transmembrane protein, is expressed in 75% to 85% of breast cancer, with the

highest expression found in TNBC. Preclinical studies have demonstrated significant anti-tumor activity of B7-H3 CAR-T cells in cell lines and patient-derived xenograft (PDX) models. Preliminary data from an ongoing phase 1 clinical trial of B7-H3 CAR-T cells for patients with relapsed ovarian cancer (NCT04670068) at our institution has shown a tolerable safety profile. Additionally, the implementation of an inducible Caspase 9 safety switch aims to mitigate the risk of severe complications such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS), enhancing the clinical application potential of B7-H3 targeted CAR-T cell therapy in TNBC. Based on these premises, we will conduct the first phase 1 study of B7-H3 CAR-T cells in patients with previously treated metastatic TNBC to establish the safety of this novel treatment modality and identify a recommended dose for further study in this population of patients with poor prognosis and unmet clinical need.
Methods: This is a Phase I, single-center, open-label study designed to evaluate the safety of escalating doses of CAR T cells targeting the B7-H3 antigen, incorporating an inducible caspase 9 safety switch (iC9-CAR.B7-H3 T cells) in patients with previously treated metastatic TNBC. The study utilizes a modified 3+3 dose-escalation design, starting with a dose of 1 × 106 transduced cells/kg. Patients with TNBC who meet eligibility criteria will undergo leukapheresis for the collection of cells to manufacture iC9-CAR.B7-H3 T cells. During the time period necessary to manufacture the iC9-CAR.B7-H3 T cells, patients will be allowed to receive standard-of-care bridging therapy at the discretion of their local physician. Eligible patients will then receive lymphodepletion chemotherapy with cyclophosphamide (300 mg/m2) and fludarabine (30 mg/m2) administered intravenously for three consecutive days, followed by the infusion of iC9-CAR.B7-H3 T cells. The primary objective is to evaluate the safety and tolerability of iC9-CAR.B7-H3 T cell administration. Safety assessments will include monitoring for adverse events, graded according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. Secondary objectives include identifying the recommended Phase II dose (RP2D), determining the objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Patients will be monitored for 15 years post-treatment completion in accordance with guidelines for gene transfer studies. This extended follow-up will evaluate the long-term safety and persistence of the genetically modified T cells. The trial is currently enrolling patients, NCT06347068.

P1-07-23: Matrix Metalloproteinase-7 regulates the process of pulmonary metastasis in triple-negative breast cancer cells

Ji Su Kim

Background: Organ-specific metastasis is a phenomenon where certain types of cancer preferentially metastasize to specific organs. This process is determined by a variety of factors such as the molecular traits of tumor cells, the microenvironment of target organs, and the interactions between tumor cells and the immune system. Understanding the molecular mechanisms regulating the organ-specific metastasis is crucial for developing

targeted therapies for metastatic breast cancers.
Methods: We established patient-derived xenograft (PDX) models of triple-negative breast cancer (TNBC), which exhibited the repetitive metastasis patterns either to lung or liver. Four TNBC PDX models, which repeatedly developed lung metastasis, were analyzed by performing RNA sequencing of their primary tumor and lung metastatic tumor tissues to characterize the gene expression features associated with lung metastasis. Control and MMP7 overexpression vectors were transfected into MDA-MB-231 and MDA-MB-468 cells, and transwell assay was performed to assess the role of MMP7 in cell migration and invasion in vitro. Furthermore, an in vivo orthotopic mouse model was established by injecting control and MMP7-overexpressed MDA-MB-231 cells into the fourth mammary fat pad. Experimental metastasis models were established via spleen injection to induce liver metastasis and tail vein injection to induce lung metastasis.
Results: Matrix metalloprotease-7 (MMP7) is one of the genes found to be consistently upregulated in lung metastatic tumors compared to primary tumors, based on RNA sequencing data. MMP7 overexpression in TNBC cell lines increased the migration and invasion in vitro. In addition, MMP7-overexpressed MDA-MB-231 cells showed significantly increased tumor growth in vivo in terms of tumor weight and volume. Moreover, there was no statistically significant difference in an experimental liver metastasis model while MMP7 significantly increased the metastasis in an experimental lung metastasis model.
Conclusion: In our TNBC PDX models, MMP7 was significantly upregulated in the lung metastasis tissues when compared to that of primary tumors. MMP7 upregulation was associated with increased cancer cell migration, invasion, and tumor growth, and MMP7 selectively promotes lung metastasis in TNBC. Further understanding of the biologic functions of MMP7 in TNBC can provide insights into the organ-specific metastasis to the lung.

P1-07-24: Induced Electric Fields Restrict Breast Cancer progression and metastasis via Immune Microenvironment Regulation

Manish Charan, Travis Jones, Nandini Acharya, Vish V. Subramaniam, Ramesh Ganju, Jonathan W Song

Breast cancer is the leading cause of cancer-related deaths in women across the globe. TNBC is a significant cause of mortality among breast cancer subtypes due to its aggressive nature and limited treatment options compared to other subtypes. Therefore, the development of safer and more effective therapies is urgently required. We found that alternating (100 kHz), and low intensity (<1 mV/cm) induced electric field (iEF) inhibits tumor growth and metastasis in an orthotopic TNBC model. Non-contact iEF treatment can be delivered safely and non-invasively in vivo via a hollow, rectangular solenoid coil. Furthermore, we discovered that iEF treatment significantly enhanced the anti-tumor immune responses. In particular, it enhances anti-tumor immune activity in both the primary tumor and distant lung metastases. Notably, iEF treatment decreases the exhaustion of CD8+ T cells and reduces the infiltration of immunosuppressive immune cells

in the tumor microenvironment, creating a less hospitable environment for cancer progression. Moreover, iEF treatment reduces the formation of lung metastases by promoting the enrichment of CD8+ T cells while suppressing immunosuppressive Gr1+ neutrophils in the lung microenvironment. We further observed that iEFs inhibit the ability of cancer cells to undergo epithelial-to-mesenchymal transition, thereby decreasing their metastatic potential. Furthermore, these findings suggest that iEFs could be a promising strategy to enhance overall anti-tumor immunity against aggressive and metastatic breast cancers. Taken together, the utilization of iEF technology could revolutionize current treatment paradigms for metastatic breast cancer.

P1-07-25: E3 ubiquitin-protein ligase RNF40 promotes triple-negative breast cancer progression and metastasis by promoting TRIM28 expression and stabilizing TWIST1 protein

Junjiang Fu, Chunli Wei, Jingliang Cheng, Jiewen Fu

Breast cancer (BC) is the common tumor in women globally and were approximately 2.3 million new cases of breast cancer and approximately 685,000 dead patients worldwide in 2020. In China, approximately 416,371 new female BC patients were reported in 2020, constituting 18.41% of new female cases in women worldwide. By 2040, the burden of BC is predicted to increase to over 3 million new patients and over 1 million dead patients each year. Triple-negative breast cancer (TNBC), a pathological subtype of BC defined by the lack of receptor expression for estrogen, progesterone, or epidermal growth factor receptor 2 accounts for 15~ 20% of all types in BC, is a metastatic and intractable cancer with limited treatment options. RNF40 is a RING finger E3 ubiquitin ligase containing multiple coiled-coil domains and a C-terminal RING finger motif engaging in protein-DNA and protein-protein interactions. RNF40 acts as a tumor suppressor or oncogene to play major epigenetic roles in cancer development, progression, and metastasis, highlighting the essential functions. However, the role and mechanism for RNF40 in TNBC is unclear. In this study, we found that RNF40 promotes TNBC progression and metastasis both in vitro and in vivo. Mechanistically, RNF40 epigenetically upregulated TRIM28 expression via histone modification including H3K4me3 in the TRIM28 promoter region, thereby further stabilized TWIST1 protein, highlighting its regulatory effects on EMT-inducing transcription factors (EMT-TFs) and TNBC progression and metastasis. Moreover, TRIM28 upregulated RNF40 expression in TNBC cells in a feedback loop manner. Clinically, RNF40 expression is positively associated with both TRIM28 and TWIST1 protein levels in most of tumor tissues compared with matched healthy tissues. Altogether, we identified novel RNF40/TRIM28/TWIST1 and EMT pathways as potentially valuable molecular targets for TNBC progression.

P1-07-26: Annexin A6 modulates the secretion of pro-inflammatory cytokines and exosomes via membrane fusion with SNAP 23 in triple negative breast cancer

Nobelle Sakwe, Portia Thomas, Josiah Ochieng, Amos M. Sakwe

The role of Annexin A6 (AnxA6) in the secretion of pro-inflammatory cytokines (PICs) and exosomes in triple negative breast cancer cells remains to be fully elucidated. However, understanding how AnxA6 influences or whether it is involved in the secretion of PICs and exosomes is still debatable. PICs are largely known to be secreted into the cancer microenvironment through exocytosis. Moreover, previous studies have reported the involvement of PICs in drug resistance and metastasis during exocytosis. We had previously shown that AnxA6 is secreted as a component of extracellular vesicles and that breast cancer cells secrete annexins via the exosomal pathway. Here, we examined the secretory function of AnxA6 in monocyte chemoattractant protein 1 (MCP-1) and interleukin 8 (IL-8) cytokines that contribute to triple negative breast cancer (TNBC) progression and we show that the secretion of cytokines and exosomes is AnxA6-dependent. AnxA6 upregulation in TNBC cells promotes increased extracellular vesicles (EVs) secretion. We equally show that cholesterol loading into EVs may also be AnxA6-dependent and that lapatinib-induced upregulation of AnxA6 leads to increased cytokine secretion in MDA-MB-468 lapatinib-resistant (LAP-R) cells. Furthermore, we demonstrate that lapatinib-induced upregulation of AnxA6 expression in EVs in MDA-468 LAP-R cells also leads to increased cholesterol accumulation. SNAP 23 interacts with AnxA6 for increased secretion through fusion of vesicles with plasma membrane. Together, these data not only suggest that PIC, exosome secretion, and cholesterol enrichment is AnxA6-dependent, but also provide evidence that induced AnxA6 upregulation triggered by chronic lapatinib treatment will lead to increased PIC secretion in the cells, which is bad for TNBC progression and poor patient outcome.

P1-07-27: Triple-negative breast cancer with bone marrow involvement and response after use of antibody-drug conjugate (ADC)

Sophia Freitas, Rafael Silva, Thales Silva, Bianca Carnevalli, Danillo Souza, Aumilto Junior, João Victor Oliveira

Introduction: Breast cancer is the most common malignancy in women. Among the histological profiles, the triple-negative subtype is the most aggressive and has the worst prognosis. It has high recurrence rates and frequently spreads to the brain and viscera. Bone marrow infiltration is a rare type of metastasis. In this context, antibody-drug conjugates (ADC) were developed in the attempt to offer a more stable and less toxic treatment, and have been demonstrating significant therapeutic improvement in these patients.
Case report: R. V. B., female, 60-year-old patient, previously healthy, ECOG 0, was diagnosed in 2018 with luminal breast carcinoma (HER-2 0, negative PDL-1, negative BRCA), and was treated with neoadjuvant AC-T regimen (doxorubicin and cyclophosphamide followed by

paclitaxel), with pathological partial response. In January 2024, the patient developed bone recurrence (S1, T12 e L5) and underwent a bone biopsy with diagnosis of a triple-negative breast carcinoma (TNBC), which led to the beginning of treatment with two weekly cycles of paclitaxel. In April 2024, the patient was admitted again to the hospital due to severe pancytopenia (hemoglobin 4,0/leukocytes 1900/platelets 48.000) and underwent blood transfusion, followed by the interruption of chemotherapy. Hematological evaluation recommended the execution of myelogram, which confirmed the bone marrow neoplastic involvement. Therefore, the antibody-drug conjugate (ADC) sacituzumab-govitecan (SG) was prescribed on April 12th, 2024. Surveillance CT scanning performed in June 2024 showed partial response in bone and bone marrow; laboratory results showed complete recovery of hematological series. The patient is currently using SG, with good clinical evolution.

Discussion: Bone marrow involvement in breast cancer is rare and is linked to a worse prognosis, generally associated with the occurrence of bone metastases. Conventional chemotherapy has been usually chosen as the main treatment for TNBC, but it is less effective and significantly reduces quality of life due to its adverse effects, making ADCs an excellent option. ADCs are composed of a monoclonal antibody, a cytotoxic agent and a linker between them. After the binding to a specific antigen on the surface of malignant cells and subsequent internalization, the conjugate releases its cytotoxic payload to kill them. The selective delivery of the drug to a specific target cell reduces the minimum effective dose, because it increases the amount of drug that reaches the tumor, while reducing the amount of drug that reaches non neoplastic tissues. More than 50 ADCs are being studied, such as SG and glembatumumab-vedotin, which have already been approved for breast cancer.

In the case reported, the patient was diagnosed with triple-negative breast carcinoma, with diffuse bone marrow involvement, and started the use of ADC (SG). This treatment was based on ASCENT trial, which demonstrated the increase of progression-free survival (PFS) (5,6 months, compared with PFS of 1,7 months with chemotherapy of physician choice) and of overall survival. The patient showed satisfactory response in radiological and laboratory tests, as well as improvement in the hematimetric levels and quality of life.

Other similar cases were reported by the literature, with positive responses to the use of SG and disitamab-vedotin (RC48) in patients with advanced breast cancer and bone marrow infiltration, resulting in the increase of hemoglobin levels without need of further blood transfusions.

Conclusion: Although the metastatic TNBC has a median overall survival of less than two years, the use of ADCs is a good therapeutic option for patients with bone marrow involvement and other visceral metastases. Additional randomized trials are needed to prove this benefit with a satisfactory sample.

P1-07-28: Real-World Study on Efficacy and Safety of SG Alone and Combined with Immunotherapy in Metastatic Triple Negative Breast Cancer Patients

Jingze Liu, Linxiaoxiao Ding, Tianzhu Long, Zouxiang Chen, Yangyang Cai, Simin Luo, Hongna Lai, Xiujuan Gui, Jie Chai, Ying Wang, Jianli Zhao

Introduction: Triple negative breast cancer (TNBC), characterized by the absence of estrogen receptor, progesterone receptor, and HER2 expression, is known for its aggressive behavior, high recurrence rate, and challenging prognosis. Sacituzumab Govitecan (SG), an antibody-drug conjugate targeting human trophoblastic cell surface antigen 2 (Trop-2), has shown promising efficacy in treating metastatic TNBC (mTNBC). Despite these advancements, there remains a significant lack of clinical research comparing SG alone versus SG combined with immunotherapy. This study seeks to address this gap by evaluating the efficacy and safety profile of SG plus immunotherapy compared to SG alone in mTNBC patients.
Methods: Retrospective data from metastatic triple negative breast cancer (mTNBC) patients treated with Sacituzumab Govitecan (SG)-based therapies were collected to assess both efficacy and safety outcomes. Clinicopathological data, premedication details, treatment efficacy metrics, and incidences of treatment-related adverse events (AEs) were rigorously analyzed across three distinct treatment cohorts: SG alone, SG combined with immunotherapy, and SG combined with immunotherapy in conjunction with anti-angiogenic therapy. Statistical methods were employed to evaluate and compare outcomes among these groups.
Results: Between January 8, 2023, and May 6, 2024, a cohort of 39 patients with metastatic triple-negative breast cancer (mTNBC) underwent treatment with SG-based therapies at the Breast Cancer Center of Sun Yat-sen Memorial Hospital. Among them, 28 patients received SG monotherapy, while 6 patients were treated with a combination of SG and PD1 monoclonal antibody (pembrolizumab/carrilizumab). Additionally, 5 patients received SG in combination with PD1 monoclonal antibody and anti-angiogenic therapy (Apatinib). Our findings indicate that compared to SG monotherapy, SG combined with immunotherapy showed a higher objective response rate (41% vs. 54%). Notably, the combination of SG with PD1 monoclonal antibody and anti-angiogenic therapy exhibited a trend towards even higher ORR (60%). Similarly, SG combined with Immunotherapy achieved a superior disease control rate compared to SG alone (62% vs. 81%). Moreover, the combination therapy group demonstrated improved progression-free survival rates compared to SG monotherapy, with a 3-month PFS rate of 73% versus 40% and a 6-month PFS rate of 34% versus 21%. Importantly, the incidence of treatment-related adverse events of grade 3 or higher did not increase with the addition of immunotherapy to SG compared to SG alone ($P < 0.05$). Interestingly, in contrast to adverse events reported in the ASCENT study, our data showed a reduced incidence of grade 3 or higher neutropenia (8%) with premedication using rhG-SF prior to SG treatment, with no occurrences of febrile neutropenia.
Conclusion: Our findings suggest that combining SG with immunotherapy enhances efficacy compared to SG alone in mTNBC patients, with minimal increase in treatment-related

adverse events. This combination therapeutic approach holds promise for future clinical applications, pending validation through well-designed clinical trials. Additionally, our data indicate that implementing preconditioning measures like rhG-SF may effectively reduce neutropenia incidence, offering a potential strategy for managing adverse events associated with SG in mTNBC patients.

P1-07-29: Single cell RNA sequencing of triple negative breast cancer patient-derived xenograft model identifies AK1 as a key regulator of breast cancer metastasis

Woohang Heo, Sieun Yang, Dakyung Lee, Rokhyun Kim, Jong-Il Kim, Hyeong-Gon Moon

Triple-negative breast cancer (TNBC) is a subtype of breast cancer that carries a higher risk of distant metastasis, particularly to the lung and liver. However, cancer cells within a tumor mass are heterogeneous characteristics, with different gene expressions playing various roles in tumor growth and metastasis. This heterogeneity makes it challenging to identify the specific cancer cells and genes that control the metastasis of TNBC. Therefore, we plan to investigate this through single-cell RNA sequencing of PDX models to study the specific cancer cells and genes involved in the metastasis of TNBC.
We established PDX models by obtaining tumor tissues from 26 triple-negative breast cancer patients and transplanting them into the mammary fat pads of immunodeficient mice. We classified the 26 TNBC PDX models based on their in vivo metastasis capacity and the clinical outcomes of the corresponding patients. Non-metastatic PDX models were characterized by the lack of distant metastasis development in either mouse experiments or clinical follow-up data (n=5). PDX models were defined as metastatic models when they developed distant metastasis in both mice and humans (n=4). We performed single-cell RNA sequencing on the nine PDX tumors and observed significant differences in gene expression of cancer cells between the metastatic and non-metastatic PDX models. Following the single-cell RNA sequencing data analysis, we identified the relevance between the high expressed genes in cells of the metastatic PDX models and TCGA clinical data. We identified four genes (AK1, HIST1H1C, MUCL1, SCGB2A2) that were significantly upregulated in metastatic PDX tumors and correlated with poor clinical outcomes in TCGA data. We conducted immunohistochemistry on proteins encoded by these genes to validate their effectiveness as metastasis markers at the protein level. We identified that among these four proteins encoded by the genes increased in metastatic PDX tumors, AK1 and HIST1H1C proteins were significantly expressed in metastatic PDX tumor tissues. Because there was no dramatic difference in the expression of the HIST1H1C protein between metastatic and non-metastatic PDX tumors, we focused on AK1 in our study. AK1, adenylate kinase 1, is a major isoform of the AK enzyme that catalyzes the nucleotide phosphoryl exchange reaction 2ADP ↔ ATP+AMP in the cytoplasm. AK is necessary for the functioning of organisms, including growth, differentiation, motility, and metabolism. In breast cancer, however, the role of AK1 in cancer progression and metastasis is unknown. Therefore, we studied the function of AK1 in TNBC using stable AK1 knockdown cell lines and AK1

overexpression cell lines. Surprisingly, we identified the downregulation of cell proliferation in both AK1 knockdown cells and overexpression cells, but trans-well migration and invasion capacity were upregulated in AK1 knockdown cells while AK1 overexpression cells had decreased migration and invasion capacities compared to control cells.
In brief, AK1 which was discovered by single cell RNA sequencing of TNBC PDX models is the potential regulator of TNBC metastasis regulating cancer cell migration, invasion and proliferation.

P1-07-30: Phase II adaptive TONIC2 trial to dissect immunomodulatory capacity of doxorubicin or cisplatin induction followed by anti-PD1 in mTNBC

Marleen Kok, Veerle Geurts, Olga Isaeva, Manon de Graaf, Sara Balduzzi, Leonie Voorwerk, Ferry Lalezari, Michiel de Maaker, Nina Abbott, Iris Nederlof, Noah Greenwald, Thomas van Brussel, Mi He, Elisa Champanhet, Maksim Chelushkin, Ingrid Mandjes, Martine Heuver-Mes, Koen van de Vijver, Inge Kemper, Roberto Salgado, Hugo Horlings, Ton Schumacher, Lodewyk Wessels, Diether Lambrechts, Michael Angelo, Marleen Kok

Introduction: Anti-PD1 in metastatic triple negative breast cancer (mTNBC) results in modest response rates but can lead to durable responses. Immunomodulatory strategies inducing a more inflamed tumor microenvironment (TME) could enhance response to anti-PD1. The TONIC1 trial explored immune induction strategies in relation to likelihood of response to PD1 blockade. Translational data of TONIC1 and the clinical data according to a pick-the-winner design identified low-dose doxorubicin and cisplatin as promising immune induction strategies [Voorwerk et al, Nat Med 2019]. Here, we present the randomized phase II TONIC2 study independently validating the benefit of using low-dose doxorubicin or cisplatin as induction therapy before the start of anti-PD1 (NCT04159818).

Methods: The non-comparative, phase II TONIC2 trial, using Simon's two-stage design, randomized patients with mTNBC to nivolumab (nivo) with either 2-week low-dose doxorubicin induction (15mg, weekly) or no induction. After completing recruitment of these cohorts, next cohorts randomized to nivo without induction or with 2-week cisplatin induction (40mg/m2, weekly). Primary endpoint was progression-free survival (PFS). Metastatic lesion biopsies were taken at baseline, after induction and on nivo for bulk RNA-Seq, single-cell RNA-Seq and tissue imaging (MIBI, 37 markers), to assess the induction effects on the TME.

Results: Among 97 randomized patients, 92 were evaluable for efficacy analyses (n=22 received doxorubicin followed by nivo, n=35 cisplatin followed by nivo, n=35 started directly with nivo without induction). The ORR was 20% in the control arm, 9% in the arm with doxorubicin induction and 9% in the arm with cisplatin induction. Median PFS (iRECIST) was 5.29 weeks (5.00 - 18.71) for patients in the doxorubicin arm, 5.86 weeks

(5.14 - 17.00) in the cisplatin arm and 8.71 weeks (5.57 – 12.57) in the control arm. Median OS was similar across arms.
The immunomodulatory effects of induction treatments on the TME were studied among all patients included in cisplatin, doxorubicin or control arms in TONIC1 and 2 (doxorubicin n=39, cisplatin n=48, no induction n=47). The control arm for postinduction comparisons consisted of patients who had a 2-week waiting period instead of induction treatment in TONIC1. The immunosuppressive Myc pathway decreased upon nivo compared to baseline in the doxorubicin induction arm (FDR<0.25). Immune checkpoints TIGIT and 4-1BB increased upon nivo after doxorubicin induction. Upon doxorubicin induction, deltas in PD-L1 CD8+ T cells, GLUT1+ CD8 T cells and HLADR+ CD4+ T cells were higher than in the control arm based on tissue imaging using MIBI. In addition, the delta of granulocyte to cancer cell ratio was lower in the doxorubicin arm.
Upon induction with cisplatin, we observed an increase in IFNα response (FDR<0.25). The differential gene expression profile of postinduction biopsies showed increased levels of immune checkpoint molecules, MHCI and MHCII, cytokines and T cell markers compared to baseline. Upon nivo after cisplatin induction, we observed an increase in IFNγ, inflammatory response pathways and IL6 signaling compared to baseline (FDR<0.25). Detailed translational analyses, including single-cell RNA-Seq, and outcomes in relation to PDL1 expression will be presented at the meeting.

Conclusion: Although exploratory results in the TONIC1 trial suggested a more favorable response rate upon nivo after induction with low-dose doxorubicin or cisplatin, these immune inductions did not result in significantly higher ORR/longer PFS in the independent and larger TONIC2 trial. In-depth translational analyses revealed modest but some favorable changes in the TME after induction with doxorubicin and cisplatin that could be important for future trial design.

P1-08-01: Aligning of cancer-associated collagens inhibits metastasis

Girdhari Rijal, Kimberly Hernanendez, Caitlyn Nguyen

Collagen with its networks is one of extracellular matrix (ECM) proteins that establishes the suitable microenvironment, necessary for the mechano-physiological function, to the cells (both normal and cancerous). In addition, certain collagen aligners and cross-linkers are necessary for the formation and the stabilization of extracellular matrix (ECM)-networks in both normal and abnormal tissues. Complexities of ECM proteins in tumor microenvironment (TME) challenge to reveal a cell-source of a specified protein aligner. For example, asporin (ASPN), a collagen aligner. It is interesting that TNBC cells express ASPN insignificantly. TNBC tissue shows positive for ASPN because of its expression by cancer associated fibroblasts (CAFs) in a tumor tissue. It is therefore important to understand the role of such a functional protein in a tumor.
We have noticed that the ECM networks in the normal tissue is stabilized with the regular collagen fibers with their standard networks through the collagen linkers, establishing the normal size pores throughout the ECM tissue scaffolds for the normal function. However,

the ECM established by TNBC cells is stiffer because of the bundling of collagen fibers, instead of crosslinking, supporting for the migration of TNBC cells.
Here, we studied the expression of ASPN from CAFs and MDA-MB-231 (MM231), and evaluated the role of ASPN in collagen alignment and crosslinking. Result showed that collagen becomes stiff with its deranged fibers with large-size pores in absence of ASPN similar to the outer TNBC core where cancer cells dominate the area, while aligned collagens cross-link and establish small-size pores in the network in the presence of ASPN similar to the inner TNBC core where CAF cell dominate the area. ASPN realigns collagen and helps establish the networks, inhibiting cancer metastasis.

P1-08-02: HIF-1-dependent expression of integrin β3 incorporated into extracellular vesicles promotes metastasis of breast cancer cells to the brain

Yongkang Yang

Brain metastasis is a major cause of breast cancer (BC) mortality, but the cellular and molecular mechanisms have not been fully elucidated. BC cells must breach the blood-brain barrier in order to colonize the brain. Here, we determined that integrin β3 (ITGB3) expression mediated by hypoxia-inducible factor 1 (HIF-1) plays a critical role in metastasis of BC cells to the brain. Hypoxia induces HIF-1-dependent expression of ITGB3, which is required for BC cell migration and invasion. Knockdown of HIF-1a or ITGB3 expression impairs the colonization of BC cells to brain after injection into the cardiac left ventricle of mice. Mechanistically, ITGB3 protein expressed by BC cells was incorporated into extracellular vesicles (EVs). The ITGB3+ EVs associated with brain endothelial cells, augmented vascular endothelial growth factor (VEGF)-dependent signaling via VEGF receptor 2 in brain-derived endothelial cells, and increased endothelial permeability to facilitate transendothelial migration of BC cells and metastatic colonization of the brain.

P1-08-03: Clinical Distribution and Impact of Biomarker Triads Consisting of either Quantified HER2 or EGF Receptor with ER and PR Proteins and Expression of Their Cognate Genes

Michael Daniels

Background: Development of novel therapeutics, e.g., antibody-drug conjugates (ADCs) and escalation/de-escalation therapy, prompted this study to ascertain clinical use of triads of ER/ESR1, PR/PGR, HER2/ERBB2, and EGFR/ERBB1 for predicting cancer behavior by quantifying proteins and their cognate gene expression. IHC of biomarkers, despite use in cancer management, faces multiparametric issues that ASCO/CAP Guidelines for ER/PR and HER2 seek to standardize. Our study avoids these issues by quantifying protein biomarkers and their cognate genes to associate with disease-free survival (DFS) and overall survival (OS). Laser capture microdissection (LCM) was employed to explore the molecular

landscape of each breast carcinoma. Methods: Clinical studies were conducted in silico on retrospective, de-identified data from IRB-approved databases. ER/PR proteins were quantified by FDA-approved tests (13,966 results from radio-ligand binding (LBA/NEN-DuPont) and 4,408 from enzyme immunoassays (EIA-Abbott), each expressed as fmol/mg cytosol protein. Of these, 1,194 biopsies had clinical outcomes. HER2, expressed as HNU/mg membrane protein, was quantified (504 by ELISA (NEN/Oncogene Sci.) and 901 by EIA (TRITON), with 189 having clinical outcomes. EGFR was quantified in 894 biopsies by radio-ligand competition assay, with 137 having clinical outcomes. Distributions of biomarker triads and relationships to DFS and OS were assessed for 123 patients. ER/PR status was compared across assay platforms, combined with HER2 or EGFR proteins. Analyses conducted on the Frontera supercomputer at TACC using R version 4.0.3 identified the quantile at which ERBB2 and ERBB1 gene expression predicts ER+/PR+ and ER-/PR- clinical outcomes using Cox regressions for PFS and OS. P-values of each Hazard Ratio (HR) were ranked with the top genes identified after adjusting for multiple comparisons. Results: Most carcinomas exhibited ER+/PR+ status regardless of assay platform. There was excellent agreement in ER-/PR- status distribution between assays. Neither ER nor PR levels were related to HER2 or EGFR levels, nor were HER2 and EGFR levels interrelated. Of 1,405 specimens, 9% were triple-negative breast cancer (TNBC) with HER2, while 41% were triple-positive (TPBC), compared to 6% TNBC and 34% TPBC with EGFR in the biomarker triad. Biopsies with TNBC profiles were associated with decreased DFS but not OS. HER2+ status was significantly associated with lower risk of death in the ER+/PR+ group (HR=0.44, p=0.05) but not with DFS (HR=0.56, p=0.23). EGFR+ status did not correlate significantly with either DFS (HR=2.03, p=0.23) or OS (HR=1.59, p=0.33) in the ER+/PR+ group. Microarray results of LCM-procured carcinoma cells of 247 primary breast biopsies were obtained for ~22,000 genes. The four biomarkers' cumulative relative frequency distribution analyses and triad permutations were examined. Cox regressions contrasted hazard ratios among ER/PR/HER2 and ER/PR/EGFR groups and their gene expression triads. Interaction models did not show significant effects, indicating no additional prognostic value beyond that of individual biomarkers. Conclusions: Patients with triple-positive gene expression triads (ESR1+/PGR+/ERBB2+ or ESR1+/PGR+/ERBB1+) exhibited better survival outcomes than triple-negative patients. Although HER2 protein presence in breast carcinoma predicts response to HER2-targeted therapy, lack of significance in interaction models suggests that HER2 or EGFR's prognostic value may be largely independent of ER/PR protein status. Frontera supercomputer analyses revealed differences in gene expression profiles between ER+/PR+ and ER-/PR- carcinomas and DFS. These unique findings with LCM-procured cells highlight the complex interplay of biomarkers and cognate gene expression in breast cancer and underscore the importance of quantifying ER and PR protein status in guiding treatment and predicting outcomes.

P1-08-04: Efficiency of Low-Viscosity Culture for TNBC Organoid Establishment and Drug Screens

Xavier Bittman-Soto, David C. Boyd, J. Chuck Harrell

Three-dimensional (3D) cell culture models, such as patient-derived xenografts (PDX) and PDX-organoids (PDXO), emerge as invaluable tools for exploring the complexities of disease, including the unique features of tumors. By accurately mimicking numerous aspects of the original tissue, such as growth rate, migration, and drug sensitivity, these models provide key insights for advancing drug discovery and development. Triple-negative breast cancer (TNBC) presents significant clinical challenges due to its aggressive nature, propensity for early metastasis, and limited treatment options. This study compared several 3D culture methods, including scaffold-free (suspension) and scaffold-based (low viscosity and domes) systems to evaluate the establishment and proliferative capacity of PDXOs from VCU patients of diverse genetic ancestry. We found that incubation in a scaffold-free environment overnight, followed by a low-viscosity culture system, reduced the time for organoid development, enhanced proliferative rate, and increased viability compared to higher-viscosity domes. The low-viscosity culture proved to be the most efficient for viability studies, drug screens, and expansion in vitro. Time-lapse imaging highlighted the diverse behavior among tumor cell samples, which has allowed for the development of a morphological classification system of organoids and cell aggregates. Importantly, the proliferative rates of the low-viscosity cultures were more similar to mammary tumors which provides confidence that therapeutic inhibitor studies will more effectively translate to in vivo systems and clinical trials. In conclusion, this study provides valuable insights into various 3D culturing systems for more efficient studies with TNBC organoids.

P1-08-05: The mechanism of FOXO3a in coping with oxidative stress to promote TNBC progression

Manqing Cao

Triple-negative breast cancer (TNBC) is an aggressive type of breast cancer associated with poor prognosis and limited treatment options. FOXO3a is an important transcription factor participating in many important biological process. It has been reported that FOXO3a expression is associated with lymph node metastasis and poor disease-free survival in TNBC. We also found that overexpression of FOXO3a in MDA-MB-231 cells could promote lung metastasis of by tail vein injection in vivo. However, the mechanism of FOXO3a in TNBC progression remains unclear. Here, we found that FOXO3a was highly expressed in nuclear of TNBC tissues than that in peritumor tissues by immunohistochemistry staining. FOXO3a enhances the invasion and motility of TNBC cells by transwell assays. RNA-sequencing combined bioinformatic analysis suggest that FOXO3a is closely related to adhesion pathway and PI3K/AKT pathway. Considering FOXO3a could translocate to nuclear to activate downstream signaling pathway under oxidative stress. Therefore, we further showed that FOXO3a could activate FAK/PI3K/AKT pathway under oxidative stress

to promote TNBC progression. Collectively, our research showed that the expression of nucleus FOXO3a was related to the progression of TNBC, and FAK/PI3K/AKT pathway participate in the role of FOXO3a in promoting the progression of TNBC. FOXO3a may serve as a prognostic biomarker and a potential therapeutic target for TNBC.

P1-08-06: Real-world outcomes and care utilization related to pregnancy in hormone receptor-positive breast cancer survivors

Julia Ransohoff, James Dickerson, Rebecca M. Lewinsohn, Ingrid Luo, Mina Satoyoshi, Rachael Chavez, Amanda J. Wheeler, Su-Ying Liang, Pragati Kenare, Victor Ritter, Lidia Schapira, Esther M. John, Allison W. Kurian

Background: Premenopausal women diagnosed with curable hormone receptor (HR)-positive breast cancer (BC) are typically treated with 5-10 years of adjuvant endocrine therapy (ET) which often impacts family planning. Prospective data from the POSITIVE trial suggest that pausing ET after 2 years to pursue pregnancy, delivery, and breastfeeding is safe in a selected population with high rates of ET resumption. We hypothesized that in real-world practice, resumption of ET and imaging surveillance would be lower than in the POSITIVE trial.
Methods: We used the Oncoshare dataset, which integrates electronic medical records (EMR) from two healthcare systems with California Cancer Registry (CCR) data, to study women diagnosed with stage 0-III HR-positive BC between 1994 and 2020 who became pregnant after BC diagnosis. We characterized time to pregnancy; ET utilization, total duration, pause, and resumption patterns; imaging surveillance patterns; and BC-specific survival and recurrence rates for women treated at a community practice (Sutter Health/Palo Alto Medical Foundation) or an academic hospital network (Stanford University Healthcare). Clinical and sociodemographic variables were derived from the CCR. ET prescription, pregnancy, and radiographic data were obtained via automated EMR data extraction and manual chart review. Characteristics were described using counts, percentages, medians, and interquartile ranges (IQR) and compared using a Fisher's exact test or Wilcoxon rank-sum test where appropriate.
Results: At a median follow up of 9.1 years, 105 women had at least one pregnancy following a BC diagnosis. The median age at diagnosis was 32.9 years (IQR: 30.3-35.4) and 98 women had at least one live birth, with 122 total live births recorded. Following BC diagnosis, 27 (25.7%) women never started ET, 20 (74.1%) of whom attributed this to a desire for pregnancy. Among the 78 (74.2%) women who ever initiated ET, tamoxifen use was most common (N=45, 91.8%) before 2015 and utilization of ovarian suppression-based regimens became more frequent after 2015 following publication of the SOFT/TEXT trials (N=12, 42.9%; $p<0.001$, Fisher's exact test). The median time from ET initiation to pause for pregnancy was 25.5 months (IQR 15.3-47.4) and from ET pause to delivery was 24.7 months (IQR 16.5-47.1). Following delivery, 31 (39.7%) patients did not resume ET and 62 (62.6%) did not resume surveillance imaging. Among 100 patients without disease recurrence at two years, 39 had resumed ET after treatment interruption. Only thirteen

patients resumed both ET and surveillance imaging. Among those who resumed ET after delivery, median time to resumption was 6.3 months (IQR 3.0-19.0); median time to surveillance imaging resumption was 9.3 months (IQR 3.5-18.5). Breastfeeding status was not associated with time to imaging resumption (p = 0.508, Wilcoxon rank sum test). BC-specific survival was 94.5% (95% CI: 88.7%-100%), with a 5.7% (N=6) three-year recurrence rate.
Conclusions: Among early-stage HR-positive BC survivors treated in community and academic practice who became pregnant after BC diagnosis, ET guideline adherence was notably lower than in the POSITIVE trial (39% vs 73% resumption rate). Resumption of imaging surveillance was also low; a substantial fraction of patients (n=32, 41.0%) were not taking ET or undergoing radiographic surveillance 5 years post-diagnosis, though we cannot rule out the possibility of patients seeking care elsewhere. Despite this, BC-specific survival with long-term follow-up in a real-world setting was high and short-term recurrence rates were comparable to those seen in POSITIVE (5.7% vs 7.9%). Confirmatory studies, encouragement of optimal adherence and follow-up, and longer-term data collection on recurrence and survival are indicated.

P1-08-07: Time Interval Between Diagnosis and Treatment of Early Breast Cancer and the Impact of Health Insurance Coverage in Latin America: A Sub Analysis of the LATINA Breast Study (LACOG 0615 / MO39485)

Gustavo Werutsky, Paula Cabrera-Galeana, Heloisa Resende, Henry L. Gomez, Rosa Vasallo Veras, Miriam Raimondo, Ricardo Elías Brugés Maya, Maria del Rosario Vidal, Cynthia Villarreal-Garza, Yeni Nerón, Ana María Donoso, Fernanda B. Damian, José d'Oliveira Couto Filho, Felipe Cruz, Isabel Alonso, José Bines, Victoria Costanzo, Tomás Reinert, Juan Manuel Donaire, Adriana Elizabeth Borello, Eduardo Cronemberger, Luis Enrique Fein, Marcela Urrego, Enrique Alanya, Jorge Luis Soriano García, Saul Campos-Gomez, Eduardo A. Richardet, Hugo Castro-Salguero, Diego Gómez, Angel Hernández, Carlos Farfan, Ronald Rodríguez, Rafaela Gomes de Jesus, Carlos Barrios

Background: Breast cancer (BC) is the most common type of cancer among women in Latin America. Evidence shows that delays in starting treatment, i.e. neoadjuvant chemotherapy or surgery, for early BC are associated with increased rates of relapse and mortality. Several factors have been associated with treatment delays such as socioeconomic status, health insurance type, age, racial/ethnic groups, educational level and rural residence among others. This study aimed to evaluate median days between diagnosis to first treatment and factors associated with delays in treatment initiation in patients diagnosed with early BC in Latin America.
Methods: This sub-analysis included patients with stage I-III BC from the LATINA Breast (NCT04158258), a prospective, observational study that included patients diagnosed with BC between February 2020 to August 2022 in 31 centers from 10 countries in Latin America. Time interval was calculated from the BC biopsy date to the date of the first treatment administered, i.e. surgery or neoadjuvant chemotherapy or endocrine therapy. A

multivariable logistic regression model was applied to evaluate factors associated with treatment delays of > 60 days after diagnosis.
Results: From a total of 3275 patients included in the LATINA Breast registry, 2768 (84.5%) were diagnosed with stage I-III BC and were included in this sub-analysis. A total of 2516 patients (90.8%) had available information on the date of the diagnostic biopsy and initial treatment. Overall, the median number of days from diagnosis to first oncologic treatment was 55 days (IQR 28-97) and of them 1159 (46.1%) patients had >60 days from diagnosis to first treatment. Time interval from biopsy to treatment according to clinical stage were 46 days (IQR 20-99) for stage I, 57 days (IQR 28-99) for stage II, and 56 days (IQR 32-91) for stage III, (p=0.1578). Time interval from diagnosis to treatment according to first treatment received were 58 days (IQR 34-92) for neoadjuvant treatment and 46 days (IQR 19-99) for surgery, (p =0.2300). Time interval from diagnosis to treatment per country were: Argentina 48 days (IQR 8-88), Brazil 87 days (IQR 50-130), Chile 34 days (IQR 19-63), Colombia 67 days (IQR 33-101), Cuba 14.5 days (IQR 6-18), Dominican Republic 77 days (IQR 58.5-105.5), Guatemala 20.5 days (IQR 12-56), Mexico 34 days (IQR 22-47), Peru 46 days (IQR 19-84) and Uruguay 27 days (IQR 0-37). The time interval from diagnosis to treatment was higher in women treated in the public health system, 60 days (IQR 30-104) versus the private system, 45 days (IQR 24-77), (p <0.0001). Factors significantly associated with delays of >60 days from diagnosis to treatment were age >50 years (OR 1.41, 95% CI 1.15-1.74, p=0.0011), Black or African American/Brown (OR 3.3, 95% CI 1.15-1.74, p=0.0011), educational level illiterate/incomplete school (OR 1.42, 95% CI 1.06-1.89, p=0.0011) and public health insurance (OR 2.18, 95% CI 1.66-2.86, p<.0001).
Conclusion: This analysis of the LATINA Breast study demonstrates that the median time from diagnosis to first treatment of early BC in Latin America is 55 days. Time intervals are variable among different countries likely reflecting differences in access to fragmented health care systems. Although in many countries, patients seem to be treated within an acceptable timeframe (<60 days), there is still a large population with long delays. Older patients, Black/African Americans/Brown, those with lower educational level and those treated within the public health care system, not surprisingly, had the longest timelines potentially impacting disease outcomes in these populations.

P1-08-08: Real-world efficacy of immediate subsequent lines of therapy after trastuzumab deruxtecan (T-DXd) in patients with metastatic breast cancer (MBC) – retrospective study from the nationwide Flatiron database

Paolo Tarantino, Do Lee, Julia Foldi, Pamela R. Soulos, Cary P. Gross, Tess O'Meara, Thomas Grinda, Adrienne G. Waks, Eric P. Winer, Nancy U. Lin, Ian E. Krop, Sara M. Tolaney, Sarah Sammons, Maryam Lustberg

Background: T-DXd represents an established treatment option for patients with HER2+ and HER2-low MBC, with relevant activity also shown in HER2-ultralow MBC. No clinical trial data is available to guide treatment after progression on T-DXd. We aimed to produce real-world data to understand the performance of treatment regimens commonly

administered after T-DXd.
Methods: We conducted a retrospective observational study using the nationwide Flatiron Health electronic health record-derived deidentified database. We included patients with MBC who initiated T-DXd between 12/2019 and 9/2023 and who received an additional line of non-T-DXd anticancer treatment immediately following T-DXd. Tumors were categorized as HER2+ if positive at any timepoint before T-DXd, hormone receptor (HR)+/HER2- or HR-/HER2- (i.e. triple-negative) if never HER2+. Real world progression-free survival (rwPFS) and overall survival (OS) for post-T-DXd treatments were estimated using the Kaplan-Meier method.
Results: We identified 633 patients who received a systemic therapy post T-DXd: 352 (56%) with HER2+, 222 (35%) with HR+/HER2- and 59 (9%) with HR-/HER2- MBC. Median age was 58 years, 62.9% of the patients were White, 73.9% were treated in the community setting and 31.0% had de-novo MBC. Median prior lines were 4 in each subgroup (range: 1, 15) and 75% (n=475) had experienced progression while on T-DXd.
Outcomes with post-T-DXd treatments were significantly more favorable for patients with HER2+ MBC. Median rwPFS was 4.3 months (mo) for HER2+, 3.0 mo for HR+/HER2- and 2.7 mo for HR-/HER2- MBC ($p<0.001$), with similar outcomes when restricting to patients with prior progression on T-DXd (rwPFS: 3.9 mo for HER2+, 2.7 mo for HR+/HER2-, 2.7 mo for HR-/HER2- MBC, $p<0.001$). Median OS was 12.6 mo for HER2+, 8.1 mo for HR+/HER2- and 4.8 mo for HR-/HER2- MBC ($p<0.001$).
Of note, treatment patterns after T-DXd were heterogenous, and outcomes significantly differed by the specific treatment regimen administered ($p<0.001$).
Among patients with HER2+ MBC, the most commonly administered post-T-DXd regimens and median rwPFS were: tucatinib, trastuzumab and capecitabine (n=95, 27.0%) with a rwPFS of 4.7 mo; endocrine treatment (ET)-based regimens (n=57, 16.2%) with a rwPFS of 4.4 mo; chemotherapy + anti-HER2 antibodies (n=56, 15.9%), with a rwPFS of 5.0 mo; anti-HER2 antibodies +/- tyrosine kinase inhibitors (n=34, 9.7%), with a rwPFS of 7.3 mo; T-DM1 (n=27, 7.7%), with a rwPFS of 4.1 mo; and sacituzumab govitecan (SG, n=16, 4.6%), with a rwPFS of 2.3 mo.
Among patients with HR+/HER2- MBC, the most commonly administered post-T-DXd regimens and median rwPFS were: SG (n=66, 29.7%) with a rwPFS of 2.5 mo; ET-based regimens (n=46, 20.7%) with a rwPFS of 3.2 mo; taxanes (n=20, 9.0%), with a rwPFS of 3.8 mo; capecitabine (n=18, 8.1%), with a rwPFS of 5.8 mo; and eribulin (n=16, 7.2%), with a rwPFS of 5.9 mo.
Among patients with HR-/HER2- MBC, the most commonly administered post-T-DXd regimens and median rwPFS were: SG (n=13, 22.0%) with a rwPFS of 3.0 mo; eribulin (n=9, 15.3%) with a rwPFS of 1.8 mo; multiagent chemotherapy (n=8, 13.6%), with a rwPFS of 2.2 mo; experimental/off label regimens (n=6, 10.2%), with a rwPFS of 1.9 mo; and anthracyclines (n=4, 6.8%), with a rwPFS of 2.8 mo.
Across all the 633 patients receiving a post-T-DXd treatment, those that received SG (n=95) experienced shorter rwPFS than those receiving a different regimen (2.7 vs 3.9 mo, $p=0.001$).
Conclusions: In a large real-world database, outcomes of post-T-DXd treatments

significantly differed by MBC subtype and type of regimen administered. The use of SG immediately after T-DXd was associated with relatively short rwPFS (≤3 mo) across subtypes, suggesting some degree of cross resistance among topoisomerase 1 ADCs.

P1-08-09: REAL-WORLD OUTCOMES COMPARING 3-MONTHLY WITH MONTHLY GOSERELIN IMPLANT IN PREMENOPAUSAL WOMEN WITH BREAST CANCER

Kelly E. McCann, Noran Osman, Joan Cannon, Lonnie Brent, Yuexi Wang, Dudith Pierre-Victor, Jon Tepsick, Prithviraj Vikramsinh Mandora, Vincent Miller, Nancy Martin, Virginia G. Kaklamani

Background: Goserelin 10.8 mg 3-monthly implant has been compared with goserelin 3.6 mg monthly in clinical trials. The 3-monthly implant is more convenient to clinicians and patients as it reduces office visits. Although goserelin 10.8 mg is not currently approved for breast cancer (BC) by the U.S. FDA, clinical trials demonstrated it to be non-inferior to 3.6 mg monthly implant in premenopausal HR-positive BC patients. However, real-world studies comparing goserelin 10.8 mg 3-monthly implant with goserelin 3.6 mg monthly implant are scarce. This study aimed to compare real-world treatment outcomes among BC patients treated with goserelin 3.6 mg and goserelin 10.8 mg.
Methods: Women aged 18-55 years without evidence of postmenopausal status at initial BC diagnosis and exposed to goserelin 3.6 mg or 10.8 mg post-BC diagnosis in the ConcertAI Patient360™ dataset were included in the study. Inverse probability treatment weighting (IPTW) was used to ensure the comparability of baseline demographic and clinical characteristics between the two cohorts. The primary outcome was the real-world disease-free survival (rwDFS) rate at 12 months to assess the non-inferiority of 3-monthly goserelin 10.8 mg vs. monthly goserelin 3.6 mg, and the non-inferiority margin was set at -15% between treatment groups based on published oncology clinical trials. No non-inferiority testing was carried out for other endpoints. Weighted Kapan-Meier analysis was used to characterize rwDFS, overall survival (rwOS), and time to treatment discontinuation (rwTTD) for patients who received 3-monthly goserelin 10.8 mg and monthly goserelin 3.6 mg.
Results: A total of 575 patients received goserelin 3.6 mg and 123 received goserelin 10.8 mg. Post-IPTW, the 3.6 mg cohort had a median age of 41 years, 70.3% white; 68.3% infiltrating ductal carcinoma histology, 41.7% ECOG 0-1, and 61.0% early stage BC at treatment, and the 10.8 mg cohort had a median age of 42 years, 69.9% White, 70.2% infiltrating ductal carcinoma histology, 36.4% ECOG 0-1, and 61.0% early stage BC at treatment. The 12-month rwDFS rates were 76.6% for the 3.6 mg cohort and 79.2% in the 10.8 mg cohort, with a treatment difference of 2.65% (95% CI: -1.75%, -7.04%), supporting the non-inferiority of goserelin 10.8 mg to 3.6 mg at the -15% margin. The rwTTD rates, reported as the proportion of patients on goserelin treatment at 12 months and 24 months for goserelin 3.6 mg vs.10.8 mg, were 39.6 % vs. 51.2% and 23.1% vs. 32.4%, respectively. The median rwDFS and median rwOS were not reached at the 60-month follow-up. The

rwDFS rates at 3-years and 5-years for goserelin 3.6 mg vs. 10.8 mg were 61.5% vs. 63.4% and 55.8% vs. 46.9%, respectively. The rwOS rates at 1-year, 3-years, and 5-years for goserelin 3.6 mg vs. 10.8 mg were 92.9% vs. 97.4%, 81.3% vs. 86.2%, and 69.0% vs. 67.4%, respectively.
Conclusions: This real-world analysis indicates that 3-monthly goserelin 10.8 mg is non-inferior to monthly 3.6 mg among premenopausal BC women in terms of 12-month rwDFS rate. This finding may support the use of the goserelin 10.8 mg 3-monthly implant as an alternative treatment option for this patient population.

P1-08-10: Germline BRCA1 and BRCA2 testing, Genetic Counseling and Adjuvant Therapy Patterns in Early Breast Cancer Patients

Mokica Izano, Kaitlyn Kane, Yao Yuan, Monika A Izano, Hina Mohammed, Anna Berry, Arelis Hernandez, Daniele Morgan, Frank M. Wolf, Tinamarie Bauman, Hafsah Jamil, Anastasia Kathrens-Gallardo, Robert Maganini, Ida Nool, Qixin Li, Xiaoqing Xu, Stella Redpath, Luis Campesato, David Chiu, Kathryn Emily Mishkin, Jennifer Hayes

Background: The U.S. FDA approved adjuvant Poly (ADP-ribose) polymerase-inhibitors (PARPis) for patients (pts) with high-risk human epidermal growth factor receptor 2 - negative (HER2-) early breast cancer (eBC) harboring pathogenic/likely pathogenic germline BRCA1/2 variants (gBRCAm) in early 2022. Subsequently, best practice guidelines recommended germline testing of pts with HER2- eBC to identify candidates for adjuvant PARPis. Yet, inequities may exist in who receives testing and subsequent treatment. We describe real-world practice patterns around gBRCA1/2 testing, genetic counseling, and adjuvant treatment for eBC to inform interventions that may improve patient care.
Methods: Pts with HER2- eBC (stages I-III) diagnosed between January 2018 and July 2022 at six sites of a community health system in the midwestern U.S. were followed through February 2023. Demographics, clinical characteristics, testing, treatment, and genetic counseling data were extracted from the electronic health records by oncology data specialists. Descriptive statistics are reported.
Results: Median (IQR) age of the 966 pts included in the study was 64 (53, 73). 954 (99%) pts were female and 12 (1.2%) pts were male. 668 (69%) pts were White, 67 (6.9%) pts were Black, 113 (12%) pts were Asian, 92 (9.5%) pts were Hispanic, and 26 (2.7%) pts were other/unknown race/ethnicity. Median (IQR) social vulnerability index score was 0.41 (0.21, 0.63). 506 (52%) pts received gBRCA testing, ranging from 29% - 73% across the six sites. Testing proportions were higher in pts <65 years (yr) old at diagnosis [67% vs 37% ≥65 yr], pts with a family history of breast cancer vs. without (65% vs 53%), and pts with a family history of ovarian cancer vs. without (77% vs. 58%). 55% (71) of TNBC pts and 48% (435) of HR+/HER2- pts were tested. 48% of pts with a <26 Oncotype Dx score were tested compared to 40% of pts with ≥26. Of the 506 tested, 15 (3%) were gBRCAm (8 TNBC, 7 HR+), 10 of whom had early (<50 yr) eBC onset. Results were available for 53% of pts prior to definitive surgery and for the majority (72%) of tested pts prior to adjuvant treatment.

45% (432) of the study population were both referred to and completed genetic counseling. 95% of pts who completed genetic counseling received gBRCA testing; only 18% of pts who did not complete counseling were tested. 9% (90) of pts were referred but failed to complete genetic counseling, and 46% (444) were never referred during follow-up. Of the 432 pts receiving counseling, the majority (63%) were counseled by nurses and 8% were counseled by certified genetic counselors. The tested proportion was lower in pts counseled by medical oncologists (83%) than those counseled by certified genetic counselors (100%), nurses (97%) or surgeons (93%).
A greater proportion of gBRCA-tested pts received adjuvant chemotherapy than those untested (20% vs 6%). A greater proportion of TNBC pts received adjuvant chemotherapy compared to HR+ pts (25% vs 12%), as expected.
Conclusions: Despite clinical guidelines recommending that all patients with TNBC and certain patients with HR+ BC should receive genetic testing, 48% of pts were not tested, with marked variability across sites within the same healthcare system (27-71%). When received, genetic counseling positively influenced testing rates. Although gBRCA status influences surgery and adjuvant treatment decisions, results were available for only 53% of pts prior to definitive surgery and only 72% of pts prior to adjuvant treatment, highlighting the need to improve the timely delivery of testing results to allow for appropriate treatment selection. These results will inform a Quality Improvement project with the objective of increasing guideline concordant gBRCA testing and referrals to genetic counseling, ensuring timely testing results to inform surgical and systemic treatment decisions.

P1-08-11: Incidence and Factors Predicting Survival in Inflammatory Breast Cancer: An Updated SEER Analysis

Malak Alharbi, Jayasree Krishnan, Kriti Ahuja, Mengyu Fang, Han Yau, Zunariah Shah, Riya Patel, Arya M. Roy, Shipra Gandhi

Introduction: Inflammatory breast cancer (IBC) is an aggressive type of breast cancer (BC) accounting for 1-5% of all BC cases and contributes to 8-10% of BC deaths. IBC is usually diagnosed at locally advanced or metastatic stage. It occurs more frequently in younger women, although the exact incidence is unknown. We examined the overall incidence of IBC from 2010 -2021, the age-adjusted incidence among those younger than 40 years and incidence among different racial groups. Additionally, we evaluated the factors predicting overall survival (OS) in IBC patients diagnosed between 2010-2021.
Method: We identified patients diagnosed with IBC from 2010 – 2021 using Surveillance, Epidemiology, and End Results (SEER) database and examined the incidence rate (IR) per 1000,000 in overall population, age-adjusted IR for those< 40 years (y), and IR by race: White, Black, Asian/Pacific Islander (API), American Indian/Alaska Native (AI/AN). Data on baseline demographic (age, gender, race), clinicopathologic (clinical TNM stage, grade, tumor subtypes) and treatment characteristics (chemotherapy (CT), radiation therapy (RT), surgery (Sx)) were abstracted. Frequencies of IBC subtypes were summarized by hormonal status: hormone receptor positive (HR+), HER2+, triple negative IBC (TNBC). Univariate and

multivariate cox-proportional hazard regression was conducted to analyze the factors predicting survival in IBC.
Results: A total of 1245 patients were included, the majority 99.8% (n=1422) were females, and 71% (n=1014) White, 18% (n=258) Black, 10% (n=135) API, and 1% (n=16) AI/AN. The median age at diagnosis of the cohort was 60 y (range: 20-85 y). 32% were diagnosed with HR+/HER2-, 22% with TNBC, 16% with HR-/HER2+, and 16% HR+/HER2+ IBC. The IR of IBC has decreased over the years, from 2.1 per 1000,000 in 2010 to a most recent IR of 1.3 in 2021. Age-adjusted IR also decreased, where people less than 40 y had an age-adjusted IR of 0.5 in 2010, and a most recent IR of 0.3 in 2021.
When analyzing IBC IR trends by race, we found a decreasing trend among all racial groups, except for AI/AN where we found a variable trend with initial decline until 2014 followed by steady increase in IR with peak value of 1.2 in 2021. The overall IBC IR in 2021 was 1.2 among Blacks and AI/AN, 1 among White, and 0.5 among API. Notably, in younger patients (<40 y), Black and AI/AN had the highest age-adjusted IR of 0.5 and 0.6 respectively in 2021.
Multivariate analysis showed that patients diagnosed with IBC at age younger than 60 y (median age of study cohort) had a worse OS than those diagnosed at an age older than 60 y (HR 1.18, 95%CI: 1.02-1.38, P= 0.02). Compared to White, Black patients had worse OS (HR 1.13, 95%CI: 1.09-1.58, P= 0.004), While AI/AN patients had a better OS (HR 0.30, 95%CI: 0.09-0.94, P=0.03). Compared with TNBC subtype, non-TNBC tumors were associated with improved OS. [HR-/HER2+ (HR 0.43, 95%CI:0.34-0.55, P=0.00), HR+/HER2- (HR=0.48, 95%CI:0.40-0.58, P=0.00), and HR+/HER2+ (HR 0.37, 95%CI: 0.29-0.47, P= 0.00)]. Moreover, patients who were treated with CT (HR 0.50, 95%CI: 0.41-0.61, P=0.00) and Sx (HR 0.58, 95%CI: 0.33-0.48, P=0.00) had better OS than those who did not. Interestingly, no significant association was noted between survival and receipt of RT (HR 0.89, 95%CI: 0.74-1.06, P=0.20).
Conclusion: The incidence of IBC has decreased over the past decade. Black women regardless of their age and AI/AN younger continue to have a higher incidence of IBC. The prognosis of IBC remains poor, especially among Black, those diagnosed at age younger than 60 y and TNBC subtype. Chemotherapy and surgery seem to improve OS in IBC. Larger studies are needed to explore the potential risk factors for IBC among different races.

P1-08-12: Clinical characteristics and survival outcome of patients with early discontinuation of first-line (1L) cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i) therapy for HR+/HER2- advanced breast cancer: a nationwide, real-world study

Martina Pagliuca, Alexandre Lolivier, Benjamin Verret, Barbara Pistilli, Michelino De Laurentiis, Antonio Di Meglio, Stefan Michiels, Fabrice André, Stephanie Foulon

Background: The combination of CDK4/6i and endocrine therapy (ET) is the standard-of-care 1L for patients with for Hormone Receptor-positive/HER2-negative (HR+/HER2-) advanced breast cancer in France since 2017. The aim of the present analysis was to

describe the real-world use of CDK4/6i for the 1L therapy in patients with HR+/HER2- advanced breast cancer, and to evaluate the overall survival (OS) in patients with early discontinuation of 1L treatment.
Methods: Retrieving data from the French National Health Data System (Système National des Données de Santé - SNDS), we identified patients ≥18 years old with HR+/HER2- advanced breast cancer who were started on 1L treatment with CDK4/6i plus ET from March 23, 2018 to December 31, 2021. Cohort characteristics at diagnosis and outcomes were described overall and by duration of CDK4/6i therapy, namely less than 6 months (defined as early discontinuation for any reason) and at least 6 months. Furthermore, we provide additional descriptive data among patients <50 and ≥50 years of age, and by endocrine sensitivity (i.e, endocrine resistant, defined by relapse during or <12 months after completion of adjuvant ET, and endocrine sensitive if relapsed >12 months or if endocrine naïve). A landmark survival analysis was conducted for OS from CDK4/6i therapy initiation, using the Kaplan-Meier method.
Results: As of December 31st, 2022, our cohort accounted for 34054 patients having received 1L treatment with CDK4/6i plus ET. Median age was 68 years (interquartile range, IQR 57-76), and 98.7% were women. Overall, mean time to treatment discontinuation (TTD) was 17.7 months (95% Confidence interval - CI 17.5-17.8), and 2-years OS was 74.6%.
Patients with early discontinuation accounted for the 25.1% (n=8565) of our cohort (among them, 85.5%, concurrently discontinued CDK4/6i and ET). Among patients who discontinued treatment early and among those who responded to 1L CDK4/6i therapy for at least 6 months, median age was 69 years (IQR 58-79) and 67 years (IQR 57-75), 10.6% and 12.9% were younger than 50 years, 98.0% and 99.0% were women, 29.4% and 26.2% were defined as endocrine resistant. Mean TTD was 3.1 months (95% CI 3.0-3.2) and 22.6 months (95% CI 22.4-22.7) among patients who discontinued treatment early and among those who responded to 1L CDK4/6i therapy for at least 6 months, respectively. 2-years OS was 39.2% and 85.8% in groups with early discontinuation of CDK4/6i treatment and without early discontinuation, respectively (Hazard Ratio - HR 3.91, 95% CI 3.75-4.09; p<.0001).
In the overall cohort, 12.3% (n=4202) were younger than 50 years. Mean TTD was 18.9 months (95% CI 18.5-19.4) and 2-years OS was 82.7% in this group, whereas TTD was 17.5 months (95% CI 17.3-17.7) and 2-years OS was 73.4% in patients ≥50 years. In addition, 27.1% (n=9210) patients were defined as endocrine resistant. Mean TTD was 16.7 months (95% CI 17.9-18.2) and 2-years OS was 72.9% in this group, whereas TTD was 18.0 months (95% CI 16.4-17.0) and 2-years OS was 75.2% in the endocrine sensitivity group.
Conclusions: While considering the limitations of a real-world analysis, the present study showed that approximately 1-in-4 patients newly diagnosed with HR+/HER2- advanced breast cancer discontinued the standard 1L CDK4/6i therapy early, within the first 6 months of treatment, and that patients with early discontinuation had worse 2-years OS compared to those without early discontinuation. This study suggests a potential unmet clinical need in the real-world setting, and identifies a population at worse prognosis, warranting further research to identify patients with HR+/HER2- advanced breast cancer who may benefit from a different 1L strategy than the combination of CDK4/6i and ET.

P1-08-13: 1000 Patient Prospective Inflammatory Breast Cancer (IBC) Registry Demonstrates Advances in Outcomes for IBC.

Azadeh Nasrazadani, Rebecca Tidwell, Megumi Kai, Rachel M Layman, Bora Lim, Vicente Valero, Sadia Saleem, Anthony Lucci, Michael Stauder, Susie Xinying Sun, MDACC Inflammatory Breast Cancer Team, Wendy Woodward

Background: Inflammatory breast cancer (IBC) is an aggressive yet rare subtype of invasive breast carcinoma with historically poorer outcomes as compared to non-IBC subtypes. Large studies are limited by the low incidence of IBC. An updated comprehensive analysis of outcomes inclusive of more recent advances in breast cancer management is presented.
Methods: Comprehensive clinicopathologic data was collected on patients enrolled to the MD Anderson Cancer Center (MDACC) IBC Registry (N=1,000; 12 patients excluded for lacking IBC criteria; 27 excluded with secondary IBC). All Stage IV patients were considered for Stage III standard chemotherapy followed by modified radical mastectomy and post-mastectomy radiation for local regional control based on response. Patient and disease characteristics are presented with descriptive tabulations. Comparisons between subgroups utilized chi-square tests. Overall survival (OS) was estimated by Kaplan-Meier methods and median times are reported with 95% confidence intervals. Comparisons utilized log rank tests.
Results: Among the N=961 patients evaluated for this study: 88% had invasive ductal carcinoma, 3.2% had invasive lobular carcinoma, and 5.3% had mixed invasive ductal lobular carcinoma. 8.7%, 81.3%, and 8.0% were black, white, or other, respectively, with 11.8% reporting Hispanic ethnicity. 20.2% were normal or underweight and 10.4% had never been pregnant. 13.3% of cases were hormone receptor positive (HR+) HER2 positive (HER2+), 20.3% were hormone receptor negative (HR-) HER2+, 32.7% were HR+HER2 low/negative (HER2-), and 33.7% were HR-HER2-. 49.7% of patients were postmenopausal and 48.8% were pre-menopausal. At time of diagnosis, 66.6% of patients were diagnosed at clinical Stage III, 33.4% had de novo metastatic disease, and only 5.0% had node negative disease. 83% of patients had <3 months from symptom development to diagnosis. The proportion of patients with <3 months from symptom development to diagnosis increased and the incidence of Stage IV de novo disease decreased over the period of the study (p=NS for each); however, since the pandemic, time from symptoms to diagnosis increased, but not as high as before 2015. Pathologic complete response (pCR) was achieved in 23.7%, 53.7%, 6.9%, and 23.6% of patients with HR+ HER2+, HR- HER2+, HR+ HER2-, and HR- HER2- IBC who underwent surgery, respectively. pCR rates increased over time from 35% before 2010 to 58% since 2021 for HER2+ patients (p = 0.07). Median OS of all patients was 5.5 (5.0, 6.9) years and was longer among patients who were pre-menopausal (p=0.05), HER2+ (p<0.01), or Stage III vs IV (p<0.01).
By subtype, OS at 5 years in patients diagnosed with Stage III vs Stage IV IBC was 80.5% vs 78.5% in HR+HER2+ (p = NS), 87.1% vs 62.1% (p = 0.001) in HR-HER2+, 59.9% vs 35.9% (p <0.001) in HR+HER2-, and 38.6% vs 9.8% (p <0.001) in HR-HER2-; metastasis developed in 29.4%, 29.8%, 43.1%, and 57.4% of Stage III patients, respectively.
Conclusions: Time to diagnosis and de novo metastasis presentation decreased over time,

reflecting the importance of timely diagnosis, while pCR rates after neoadjuvant chemotherapy (NAC) increased over time in the setting of evolving NAC regimens. Prognosis of IBC remains overall significantly poorer relative to non-IBC reflecting unmet needs for more effective therapies in this field.

P1-08-14: The occurrence of immune-related adverse events and overall survival among breast cancer patients receiving pembrolizumab

Xiaocao "Haze" Xu, Yu-Cheng Chang, Yu Chang, Cho-Hung Chiang, Shuwen Lin

Objectives: Immune-related adverse events (irAEs) have been associated with a better response and overall survival (OS) in patients with lung cancer or melanoma receiving immune checkpoint inhibitors (ICIs). The relationship between the occurrence of irAEs and survival outcomes of breast cancer patients receiving ICIs, in particular pembrolizumab, is unclear.
Methods: We conducted a retrospective, propensity score-matched cohort study using the TriNetX Analytics Network database, which contains de-identified data from over 120 participating healthcare institutions. We included all adult female breast cancer patients who were treated with pembrolizumab. We excluded patients who received hormonal or endocrine therapies. We defined irAEs as events that occurred within 12 weeks of ICI initiation. Patients who died before 12 weeks were excluded. This was designed to avoid immortality bias. We identified irAEs as cutaneous, gastrointestinal, pulmonary, or endocrine-related irAEs using a combination of International Classification of Diseases (ICD)-10 codes and irAE-directed therapies. The primary outcome was the 1-year OS following the initiation of pembrolizumab. Patients with or without irAEs were matched based on predetermined variables including age, race, breast cancer-directed therapy, and the Charlson Comorbidity Index.
Results: We identified 2552 patients with breast cancer who received pembrolizumab eligible for inclusion. The mean age was 55.5 ± 14.3. Over the 1-year follow-up period, 150 patients died, resulting in a 1-year OS of 93.5%. There were 778 (30.5%) cutaneous irAEs, 188 (7.4%) gastrointestinal irAEs, 103 (4.0%) pulmonary irAEs, and 101 (5.5%) incident endocrine irAEs within 3 months of ICI therapy. In the propensity score-matched analysis, patients with cutaneous irAEs had a higher 1-year OS (96.1 vs. 93.5%; log-rank p = 0.021) than those who did not have cutaneous irAEs. The occurrence of cutaneous irAEs was associated with a lower risk of all-cause mortality (Hazard ratio (HR), 0.58 [95% CI 0.36-0.93]). Patients who developed gastrointestinal irAEs (HR, 1.86 [95% CI 0.74-4.66]), pulmonary irAEs (HR, 1.83 [95% CI 0.72-4.64]), or endocrine irAEs (HR, 1.65 [95% CI 0.48-5.62]) appeared to have a higher risk of mortality than those who did not develop these irAEs, though the differences were not statistically significant.
Conclusions: The occurrence of cutaneous irAEs is associated with a higher 1-year OS in patients with breast cancer receiving pembrolizumab.

P1-08-15: Real-world analysis of breast cancer patients qualifying for adjuvant CDK4/6 inhibitors

Yada Kanjanapan, Angela Rezo, Mirka Smith, Wayne Anderson, Jenny Green, Elizabeth Chalker, Paul Craft

Background: Abemaciclib and ribociclib each improved disease-free survival (DFS) when added to adjuvant endocrine therapy for hormone receptor (HR)-positive HER2-negative early breast cancer (EBC), in the monarchE (NCT03155997) and NATALEE (NCT03701334) phase 3 trials respectively. However, the two studies used different inclusion criteria. Additionally, post mastectomy radiotherapy (PMRT) is recommended for node-positive patients who fulfill the eligibility criteria of these studies to reduce risk of recurrence and improve survival. We aim to assess the proportion of HR-positive EBC patients who satisfy the two different adjuvant CDK4/6 inhibitor criteria, and their outcome, in a real-world population.

Methods: Consecutive female patients with HR-positive HER2-negative EBC diagnosed between 1997-2017 from the Australian Capital Territory and South-East New South Wales Breast Cancer Treatment Group registry were analysed. Eligibility for adjuvant abemaciclib was defined per monarchE trial as >=4 axillary nodes involved or 1-3 nodes plus primary >5cm or grade 3. Ribociclib eligibility was defined per NATALEE trial as node-positive and node-negative with >5cm or >2cm grade 3 primary tumours. Disease-free and overall survival (OS) were examined using the Kaplan-Meier method and compared between groups using log rank tests. Cox proportional hazards model was conducted incorporating potential variables including PMRT-use on recurrence and survival outcomes.

Results: Of 3840 patients, 671 (17.5%) were abemaciclib-eligible and 1587 (41.3%) ribociclib-eligible. Lymph-node negative patients comprised 14% of the ribociclib-eligible cohort. Of all lymph-node negative patients, 9% were ribociclib-eligible. Abemaciclib-eligible registry patients were older (median 55 vs 51 years), with lower nodal burden (>4 nodes involved in 44% vs 60%) than moncharE trial participants. The proportion of stage III cancers was almost three-times greater in NATALEE trial patients (60%) than ribociclib-eligible registry patients (24%). Among registry patients, 46% underwent mastectomy, with PMRT utilised in 34.5%.

The 5-year DFS was 77% and 94% in abemaciclib-eligible and non-eligible registry patients respectively (HR 2.63, 95%CI 2.26–3.05, p<0.001). The 5-year DFS was 86% and 95% in ribociclib-eligible and non-eligible registry patients respectively (HR 1.92, 95%CI 1.67–2.19, p<0.001). Similarly, 5-year OS was inferior in adjuvant CDK4/6-eligible compared with non-eligible patients; in the abemaciclib (HR 2.64, 95%CI 2.28 – 3.07, p<0.001) and ribociclib (HR 1.92, 95% CI 1.67 – 2.20, p<0.001) analyses. Using Cox regression modelling, adjuvant ribociclib-eligibility and age were significantly associated with shorter DFS, while PMRT-use was significantly associated with longer DFS. However, while abemaciclib-eligibility and age remained significantly associated with inferior DFS, there was no significant impact of

PMRT-use on DFS in a separate Cox model.

Conclusions: Many women with EBC will qualify for adjuvant CDK4/6 inhibitors, with 18.7% and 41.3% of patients meeting criteria for adjuvant abemaciclib and ribociclib respectively in our real-world cohort. This has resource and workforce implications for treatment and associated monitoring. As expected, both criteria identify patients at higher relapse risk, with inferior DFS of abemaciclib-eligible patients compared with ribociclib-eligible patients. The difference in outcome between adjuvant ribociclib-eligible versus non-eligible groups remained significant after adjustment for PMRT-use. In the real-world setting, a greater proportion of adjuvant CDK4/6-eligible patients have lower stage disease, therefore the absolute benefit from treatment may be smaller than estimated by the trials.

P1-08-16: Resolution of Active Pyoderma Gangrenosum during Adjuvant Breast Cancer Therapy: A Case Report

Abigail Lauder, Anita Nwiloh, Matthew Eximond, Richard Barth, Mary Chamberlin, Shauna McVorran

Abstract: Pyoderma gangrenosum (PG) is a painful neutrophilic dermatosis that commonly occurs at sites of trauma. Treatment usually involves a combination of corticosteroids and immunosuppression, but management can be challenging and healing times can be prolonged. PG occurring after breast cancer surgery is rare. Furthermore, the effect of radiation on these lesions is not well documented, which can be concerning in cases necessitating adjuvant radiation. Therefore, we present a unique case of a patient with invasive ductal carcinoma who developed postoperative pyoderma gangrenosum and showed rapid resolution of her lesions with adjuvant radiation.
Case Presentation: Our patient is a 66-year-old female with a past medical history significant for bilateral metachronous ductal carcinoma in situ (DCIS) treated with lumpectomy and adjuvant radiation on the right 16 years prior and lumpectomy alone on the left 14 years prior. She also had a history of familial polyposis syndrome status post a right hemicolectomy which was complicated by an unspecified necrotizing infection. Annual surveillance mammograms were benign until 2022 when suspicious calcifications were noted in the posterior left breast. After appropriate work up and management with lumpectomy and sentinel lymph node biopsy, she was diagnosed with a left breast invasive ductal carcinoma, grade III, pT2(m)N0(sn)M), Stage IIB, ER 1-10%/PR negative/HER2 negative with an Oncotype of 58.
Six days after surgery, she presented with gangrenous changes of the skin and erythema surrounding the breast incision. A 5cm area was debrided with pathology revealing a dense neutrophilic abscess involving the dermis and subcutis with overlying ulceration. Despite initiation of broad-spectrum antibiotics and appropriate wound care, her breast and axillary skin became more necrotic, prompting additional debridement. Pathology again showed a dense neutrophilic abscess involving the dermis and subcutis with scattered foreign-body-type giant cell granulomas. Four days after the initial debridement, when the

cultures did not demonstrate bacterial growth, a diagnosis of pyoderma gangrenosum was made. We did not do any additional sharp debridement, and the patient was started on cyclosporine and methylprednisolone. Her disease stabilized but she was left with a 12cm wound of the left lateral breast with a smaller, 2.5cm, deficit in the left axilla.
Given her Oncotype Dx score of 58, the patient was planned for adjuvant chemotherapy to commence one month after her last debridement. Cyclosporine was discontinued and she received four cycles of cyclophosphamide and doxorubicin (AC) followed by four cycles of paclitaxel (T). She had a moderate febrile reaction after each infusion but cultures remained negative and the wound slowly began to form granulation tissue. A slow steroid taper was started during chemotherapy.
To allow for maximal healing prior to the initiation of adjuvant radiation, she was scheduled for CT-simulation 10 weeks after her last cycle of chemotherapy. She was planned for a total of 42.56Gy delivered over 16 daily fractions to the whole breast, using 3D conformal radiotherapy with opposing tangent beams. A boost was not employed as the tumor bed could not be localized. During her radiation therapy, her lesion showed significant healing. At her one-month post treatment visit, her lesions had completely resolved and she was started on adjuvant hormonal therapy.
Conclusion: The literature on the use of radiation therapy in pyoderma gangrenosum is limited but at minimum, our case provides evidence for the safety of radiation therapy in oncologic cases complicated by pyoderma gangrenosum. PG is not a contraindication to radiation treatment and radiation may potentially assist with wound healing through its effects on the microvasculature and modulation of the inflammatory and immune response.

P1-08-17: Successful Treatment of Early Triple-Negative Breast Cancer with Chemotherapy and Immune Checkpoint Inhibitor in the Setting of Sickle Cell Disease: a Case Report

Stevany Saxon-Filipe, Luise Froessl, Samira Syed

Triple-negative breast cancer (TNBC) accounts for 10-15% of all breast cancers and is known for its aggressive clinical behavior and limited treatment options compared to other breast cancer subtypes1. In recent years, immunotherapy, particularly PD-1/PD-L1 checkpoint inhibitors, has shown promise in treating TNBC when combined with chemotherapy2.
The keynote 522 trial3 demonstrated a significant improvement in pathological complete response with the addition of pembrolizumab to multiagent chemotherapy. Although improved responses have been observed, administering this regimen may pose challenges in patients with significant comorbidities. In rare cases, such as in patients with sickle cell disease, the benefit of standard-of-care treatment must be carefully weighed with the increased risk for severe side effects and complications resulting from cancer therapy.
We report a case of TNBC diagnosed in a patient with sickle cell disease. This case underscores the feasibility of the Keynote 522 regimen in such individuals and emphasizes the importance of coordinated care between breast oncology and benign hematology

teams. Our patient of interest is a 46-year-old African-American woman with a longstanding history of sickle cell disease (SCD) on hydroxyurea, diagnosed with a self-palpated T2N0M0 breast cancer that was ER 0%, PR 0%, Ki-67 40%, and HER2-Neu negative (TNBC). The patient's other comorbidities include hypertension, diabetes mellitus, and deep vein thrombosis treated with long-term anticoagulation.
Given the benefits of chemotherapy and pembrolizumab (the keynote 522 regimen) in TNBC, this protocol was offered to this patient with curative intent. A literature review highlighted the paucity of data on the treatment of breast cancer with immunotherapy and chemotherapy in the setting of sickle cell anemia. Our patient was started on neoadjuvant chemotherapy with paclitaxel and carboplatin for the first cycle, with pembrolizumab added to the regimen from cycle 2 onwards. The patient ceased use of hydroxyurea and was switched to chronic simple blood transfusions of 2 units PRBCs every 4 weeks, with a goal Hgb S of <45% and total Hgb of 7.0 g/dL. The care team also elected to forego the use of G-CSF and limited use of dexamethasone during treatment due to the potential increased risk for sickle cell crisis with these agents. Additionally, an extra 500 mL normal saline was administered with each chemotherapy infusion.
With these measures, our patient has successfully completed 3 cycles of therapy without significant adverse events. She is exhibiting an excellent clinical response to therapy with near resolution of the palpable area of disease on physical exam. Following the completion of 4 cycles of carboplatin, paclitaxel, and pembrolizumab therapy, we plan to obtain a mid-treatment breast MRI to further assess treatment response and proceed to anthracycline-based therapy with pembrolizumab.
This patient's reasonable tolerance to therapy coupled with the robust clinical response provides an optimistic view regarding treatment options for breast cancer in patients with sickle cell disease. While close observation and meticulous care coordination are necessary in patients with hemoglobinopathies undergoing cancer treatment, this case demonstrates a significant benefit from treatment with only expected treatment toxicities observed at this time.

P1-08-19: Surgical oncoplastic treatment of a rare case of expansive dermatofibrosarcoma protuberans on the breast

Giovanna Azevedo Gabriele Carlos, Ridania Frederice, Patricia Figueiredo, Karla Prigenzi,

Background: Dermatofibrosarcoma protuberans (DFSP) is a rare soft tissue sarcoma, with low-grade and slow-growing pattern, initiating in the dermis and then invading the

subcutaneous tissue, representing less than 0,1% of all malignancies. Its biological behavior is characterized by aggressive local infiltration with high recurrence rate but rarely metastasizes.DFSP normally occurs in middle-aged adults and exhibits a slight male predominance. It corresponds to 6% of all tissue sarcomas and in the breast is extremelly rare. It resembles a keloid or an atrophic lesion like sclero-derma. These features make the early diagnosis difficult. The main treatment is the surgical excision with safe margins up to 3cm extent. Because of this, a wide resection is necessary, usually followed by a oncoplastic technique to minimize aesthect defect.
Method: We describe a case of a female patient with an expansive dermatofibrosarcoma protuberans on the left breast, diagnosed after 5 years of progression, with a challenging surgical treatment.
Results: A 35-year-old female patient was complaining of a reddish lesion in the left breast with gradually progressive growth for 5 years. There was no history of preceding trauma, surgery, ulceration, papillary discharge, fever or weight loss.The physical examination revealed a light-reddish, delineated nodular cutaneous plaque 7 x 6 cm in the junction of inner quadrant of the left breast. No other finding from the breasts or lymphatic chain was noted. She had an unremarkable personal and family history.She had performed a skin biopsy 1 year before in another service with the following report: “spindle cell injury without atypia in the dermis. The lesion compromises the deep edge of the fragment.”Lesion complete resection with evaluation of intraoperative surgical margins and oncoplastic technique surgery was then indicated for diagnostic elucidation.The intraoperative biopsy report showed a dermis infiltrative spindle cell lesion with atypia and was necessary a wide excision followed by a superior pedicle mastopexy without volume reduction as the patient had requested.The final pathology report confirmed the dermatofibrosarcoma protuberans due to a spindle mesenchymal neoplasm located in the superficial and deep dermis of the breast skin, showing focal extension to the hypodermis, composed of elongated cells with eosinophilic cytoplasm and monomorphic nuclei arranged in a storiform pattern, within a collagenized stroma (figures 1 and 2). Immunohistochemical study was positive for CD34 and negative for Factor XIIIA (figures 3 and 4).
Conclusion: In this rare case, the skin location is one of the most challenging sites for reconstruction after de large excision to maintain symmetry.

P1-08-20: Synchronic invasive lobular breast carcinoma, invasive mammary carcinoma NST, and large cell neuroendocrine carcinoma of the lung.

Leonardo Gil-Santana, Daniela de Almeida Carvalho, Vladmir Cláudio Cordeiro de Lima

Introduction: Synchronous bilateral breast cancer represents 10% of all breast cancers. The occurrence of bilaterality is more common with invasive lobular carcinomas (ILCs). The prognosis appears to be worse when compared unilateral tumors. We describe a rare and challenging clinical case of a patient with three synchronous tumors: bilateral breast carcinomas and a large cell neuroendocrine carcinoma of the lung.

Case Report: A sixty-eight-year-old smoker (18 packs-year), post-menopausal, white female was submitted to a screening breast ultrasound that disclosed a single 23 x 18 mm nodule in the upper quadrant of the right breast without involvement of the axillary lymph nodes. A mammotomy confirmed invasive mammary carcinoma no special type (NST), grade I, estrogen receptor (ER) 98%, progesterone receptor (PR) 40%, HER2 0, and a Ki67 12%. We performed a breast magnetic resonance imaging (MRI), which showed, in addition to the previously reported lesion in the right breast, an irregular nodule with spiculated borders and a late wash-out phase located in the anterior third of the central region of the left breast, measuring 56 x 54 mm and a satellite nodule 5 mm from the index lesion, located in the anterior third of the infero-medial quadrant, measuring 14 x 11 mm. A biopsy was performed and showed a second primary invasive mammary carcinoma, grade II, ER 98%, PR 0%, HER2 0 and Ki67 25%. A thoracic CAT scan yielded an irregular pulmonary nodule located between the anterior and posterior segments of the right upper lobe, measuring 49 mm. An 18-FDG-PET-CT scan showed 18-FDG uptake in the mass in the upper lobe of the right lung (SUVmax-21.9), in an enlarged right hilar lymph node (SUVmax-10.3), and the left breast lesion (SUVmax-2.8). A CT-guided biopsy of the pulmonary lesion showed a large cell neuroendocrine carcinoma (LCNEC) of the lung. A brain MRI identified no CNS metastases. This case was discussed in a multidisciplinary tumor board, and due to aggressiveness and poor prognosis, it was decided to operate on the lung nodule and start neoadjuvant hormone therapy with exemestane 25mg/day. The patient was submitted to a right upper lobectomy with mediastinal lymphadenectomy. The anatomopathological report showed a pT2bpN1M0. We kept the patient on exemestane while we started adjuvant chemotherapy with carboplatin and etoposide for four cycles. After three months, images showed no lesions in the lungs and a partial response in the breasts. Patient was submitted a bilateral mastectomy with axillary lymphadenectomy. The lesion in the right breast was staged as ypT1cypN0(sn)M0 (RCBII) and the left lesion as ypT3ypN0M0 (RCB I).
The patient was referred to adjuvant radiotherapy, and abemaciclib was added to exemestane.

P1-08-21: Synchronous female breast cancer and follicular lymphoma in a single patient: A case report

Zijun Zhao, Qingyao Shang, Chenxuan Yang, Jiaxiang Liu, Jiabin Wang, Xiyu Kang, Jiaxian Yue, Xin Wang, Xiang Wang

Rationale: Multiple primary malignant neoplasms (MPMNs) is a rare condition in tumor diagnosis. Recently, medical workers have commenced to pay attention to this.
Clinical features and diagnoses: A 72-year-old female was admitted to our hospital for touching a painless lump in her right-upper breast. She also complained of incidental finding of another painless lump in her left groin shortly after her finding in breast tumor. Ultrasound showed a 1.2* 0.5 cm hypo-echoic nodule in the right-upper breast with an irregular form and unclear margin. For the left inguinal lump, it was scanned by ultrasound as an inguinal lymph node with a size of 2.8 * 1.2cm, with cortical thickening and eccentric

lymphatic hilum. An enhanced magnetic resonance imaging showed bilateral multiple enlarged lymph nodes with uniformed enhancement.
Interventions and outcomes: An ultrasound-based fine-needle biopsy of the breast tumor was firstly conducted and the pathological result did not show any malignancy. Then an excision biopsy of the tumor was conducted and the intraoperative frozen section indicated "breast invasive cancer". Subsequently, a breast-conserving surgery with sentinel lymph node biopsy in the right armpit was performed. The intraoperative frozen biopsy suggested a negative results in the margin tissues but cancerous tissue was detected in one of six sentinel lymph nodes(1/6). Then the axillary lymph node dissection was performed and the final paraffin section results indicated "non-specific invasive breast cancer, tumor size: 1.3* 0.6* 0.5cm, Grade II; axillary lymph node metastasis (1/27); stage: pT1cN1a". After the breast operation, she went to outpatient clinics of bone tumor and received an ultrasound fine-needle biopsy of the enlarged left inguinal lymph node where she referred to previously. Both the result of immunohistochemistry and gene rearrangement test supported a diagnosis of follicular lymphoma (FL, Grade 2). Besides subsequent adjuvant chemotherapy and radiotherapy for her primary breast cancer, the patient regularly followed up her condition of FL.
Lessons: MPMNs always tend to be misdiagnosed as a locoregional or distal metastatic tumor, especially for lymph node found in different parts of the body. It is easy to cause a delayed or erroneous treatment. An in-time and comprehensive clinical examination, medical imaging, and proper approach of pathological biopsy are essential for an effective management of MPMNs.

P1-08-23: Targeting Brain Metastasis: The Success of Trastuzumab-Deruxtecan in HER2+ Cancers: A Case Report

Annelies Feyaerts, Yannick Van Herck, Françoise Derouane, Kristian Jochems, Thomas Decramer, Adinda Baten, Patrick Neven, Hans Wildiers

A 49-year-old female was diagnosed with invasive ductal carcinoma of the right breast in May 2021. Molecular profile of the tumor was estrogen receptor 0/8, progesterone receptor 0/8, and HER2 3+ with positive FISH, along with a TP53 mutation but without a PIK3CA mutation. Further staging with PET-CT scan showed the presence of bone lesions and extensive liver metastases, suggesting a risk of imminent liver failure. The initial treatment protocol comprised weekly paclitaxel combined with trastuzumab and pertuzumab administered every three weeks along with denosumab. There was a major response in the tumor. Paclitaxel was stopped after 18 administrations because of increasing polyneuropathy, while the administration of trastuzumab and pertuzumab continued, with prolonged disease control and excellent quality of life.
In January 2024, after 25 months of confirmed response, the patient presented with symptoms of nausea, vomiting and dizziness. Neurological examination revealed a wide-based gait and was otherwise unremarkable. A CT scan of the brain identified multiple metastases with a significant mass effect, especially within the posterior fossa. This mass

effect led to signs of ascending transtentorial herniation, crowding at the foramen magnum, and the secondary development of hydrocephalus. As initial treatment, high-dose corticosteroids were administered.
The case was discussed at our multidisciplinary tumor board. Given the substantial burden of brain metastases, the prognosis was deemed poor. The neurosurgical team was reluctant to resect the largest brain metastasis, highlighting the potential complications and risks involved. In case of progressive hydrocephalus during the treatment course, a ventriculoperitoneal shunt was proposed as a palliative treatment to relieve intracranial pressure. Whole-brain radiation therapy was considered, however involved a substantial risk of brain herniation and significant post-treatment morbidity due to its wide-ranging impact, including potential adverse effects on healthy brain tissue.
Based on the data from the Destiny Breast-01 and TUXEDO-1 trials, treatment with trastuzumab-deruxtecan monotherapy at the dose of 5.4 mg/kg was initiated. Significant clinical improvement was observed following the first treatment cycle, with sustained improvement thereafter. After three cycles, a significant radiological response was observed, with near-complete regression of the brain metastases and without signs of extra-cranial progression. At the last visit in May 2025, the patient was still in deep remission with excellent quality of life.
This case illustrates that advancements in oncology and the refinement of antibody-drug conjugates are opening a new landscape of therapeutic possibilities, even in critical situations. In some cases, this progress allows the avoidance of high-risk neurosurgical procedures and reduces the morbidity associated with whole-brain radiation therapy. Initial medical approach rather than surgical or radiotherapy approach of life-threatening brain metastases should be added to the oncological armamentarium in HER2-positive breast cancer.

P1-08-24: The diagnosis of Anti-Yo antibody mediated paraneoplastic syndrome, a rare neurodegenerative disorder in a patient with invasive breast cancer, a case report

Ashley Montgomery, Ismail Jatoi, Carissia Calvo-Strube

Abstract: Background: Paraneoplastic cerebellar degeneration (PCD), also known as Anti-Yo antibody syndrome, is a rare neurodegenerative manifestation described in patients with malignant tumors, including breast cancer. In these patients, the diagnosis of breast cancer usually follows the onset of neurologic symptoms and can be made months to years after symptom onset, most commonly through PET scan or CT whole body scans.
Case presentation: We present the case of a 51-year-old female undergoing neurologic work up for suspected multiple sclerosis (MS) after experiencing sudden onset severe neurologic deficits to include diplopia, dysarthria, gait instability, and extremity paresthesias. As part of her evaluation, CT chest was obtained which revealed an incidental left breast mass. Diagnostic mammogram and subsequent core needle biopsy lead to the diagnosis of an ER/PR negative, HER2 positive invasive ductal carcinoma (IDC). During this time her

neurologic symptoms were not responding to MS treatment regimens and further imaging was inconsistent with MS. In the setting of a newly confirmed breast malignancy, she underwent work up for a paraneoplastic syndrome to include PCA1/Anti-Yo antibodies. She was found to have significantly elevated levels of PCA1 (anti-Yo antibodies) consistent with PCD. She underwent neoadjuvant chemotherapy with TCHP, followed by partial mastectomy with sentinel lymph node biopsy, with minimal improvement in her neurologic symptoms. Surgical pathology revealed no evidence of residual IDC, negative margins, and no evidence of axillary metastasis – ypT0N0. To date she has completed adjuvant radiation therapy and remains on adjuvant Herceptin and Perjeta. Unfortunately, the patient's symptoms have persisted despite breast cancer treatment. She has additionally undergone four cycles of plasmapheresis and IVIG treatments, with no significant improvement noted to date.
Conclusions: Anti-Yo antibodies detected at significantly elevated levels causing a paraneoplastic syndrome of the brain is a rare manifestation and a very uncommon complication of breast cancer. The elevation of Anti-Yo antibodies has been observed in only 1.6% of breast cancer cases, with few documented instances of associated neurologic symptoms. This patient is one of the few rare cases to manifest this neoplastic syndrome and develop severe neurologic symptoms. While an uncommon complication of breast cancer, providers should consider investigating PCD in patients presenting with new-onset neurologic degenerative symptoms alongside a recent breast cancer diagnosis. Additionally, it has also been reported that over-expression of HER2 is frequently seen in patients with elevated levels of PCA1/Anti-Yo antibodies, as in our case.

P1-08-25: The differential diagnosis of a large breast mass in a young woman

Hetal Mistry, MacKenzie Adams, Li Juan Wang, Charu Taneja, Stephanie Graff, Mary Anne Fenton

A healthy 28-year-old G5P3A2, nonpregnant woman presented to the emergency room for evaluation of a 7 cm right breast mass. She recently immigrated to the United States from eastern Europe and had no established primary care provider. Patient reported a breast mass increasing in size over two months and an unintentional weight loss of 5 kg. She visited an urgent care center one month before presentation and was prescribed amoxicillin-clavulanate, but her symptoms had not resolved. The patient was not on hormonal contraception and her menses occurred on a regular, monthly basis. She had no known family history of cancer. At her visit, the patient was afebrile, heart rate was 92, and blood pressure was 115/67. Examination revealed a 7 x 8 cm right breast mass at 7 o'clock with tenderness to palpation, and right axillary fullness and discomfort to palpation. No skin changes were identified. There was no cervical or supraclavicular adenopathy. Breast ultrasound showed diffuse masslike region in the right breast from 6 – 9 o'clock, predominantly tubular in nature, with associated abnormal segmental ducts. A mammogram revealed a right inferior breast mass with associated periareolar skin

thickening, in the background of heterogeneously dense breasts. Left breast was radiographically unremarkable. Ultrasound-guided breast biopsy was performed, initially yielding mobile debris, 5 cc of purulent fluid, and 5 cc of bloody fluid. After the initial aspiration, a core biopsy of the underlying persistent mass was taken. Baseline laboratory studies with complete blood count and basal metabolic panel were notable only for WBC at 11.5x109 cells/L. CT chest, abdomen, and pelvis with contrast showed no evidence of metastatic disease. Differential diagnosis of a breast mass in a young woman includes benign proliferative changes, malignancy, hematoma, papilloma, cyst, galactocele, mastitis, fat necrosis, or infection.
Pathology from the right breast biopsy revealed benign breast tissue with acute inflammation, granulation tissue, microabscess formation, and histiocyte aggregates. Gram stain, fungal studies (PAS), and AFB for mycobacterial organisms were negative. A bacterial PCR 16s rDNA was sent on paraffin-embedded tissue to a reference lab and not detected. Ultimately, aerobic culture from broth only (which generally indicates a low bacterial burden or possible contamination), yielded Corynebacterium species. Final pathologic diagnosis was cystic neutrophilic granulomatous mastitis (CNGM), a rare breast inflammatory process usually due to Corynebacterium species infection. CNGM occurs in reproductive-aged women with a history of pregnancy and often mimics breast carcinoma. Radiology noted pathologic concordance with imaging. The patient was treated with trimethoprim/sulfamethoxazole for 10 days and referred to a breast surgeon. However, her symptoms did not improve, and a repeat ultrasound 14 days later showed increased size of the abscess measuring 4 x 1.5 x 4.3 cm. Repeat ultrasound-guided aspiration was performed and the patient was prescribed doxycycline for one month. Though she experienced increased pain midway through treatment, she ultimately had improvement in her symptoms at her follow-up visit 74 days from presentation. Follow-up breast ultrasound performed the same day did not demonstrate evidence of fluid collection or abscess, but again noted an unchanged irregular mass associated with small loculated areas of fluid. This case brings to light the medical and surgical differential diagnosis beyond malignancy for a large breast mass in a young, nonpregnant woman presenting to an oncology clinic.
A table with differential diagnosis, images and references will be provided for the poster if accepted.

P1-08-26: Triple negative breast cancer in pregnant women with mutated BRCA

Leonardo Gil-Santana, Daniela de Almeida Carvalho, Monique Celeste Tavares

Introduction: The triple negative breast cancer (TNBC) is an aggressive tumor that associated a high grade of spread and worse prognosis.
The treatment differs with clinical stage and patients with BRCA mutation could be beneficiated of treatment with platinium chemotherapy based and PARP inhibitors. We described a challenging clinical case of a BRCA mutated young pregnant patient with TNBC.

Case Report: In a December 2021, a 28-year-old female patient, mutated BRCA1, felt a nodule in the right breast. The ultrasound showed a single 2.3cm x 1,8 cm nodule without involvement of the axillary lymph node. A core biopsy showed invasive carcinoma No Special Type (NST), grade II, negatives hormonal receptor, HER2 0 with Ki67 60%. We realized complete staging exams, including central nervous system resonance, which did not reveal distant disease. We did neoadjuvant chemotherapy with Carboplatin and Paclitaxel for 12 weeks because de patient was 17 weeks pregnant. She completed 11 weeks of chemotherapy due to oligohydramnios and we stopped for 3 weeks to monitory pregnancy. Chemotherapy with dose-dense anthracycline and doxorubicin (ddAC) was restarted. After first cycle we paused treatment for childbirth and completed more 3 cycles of ddAC. After 1 month of finalized chemotherapy, she was submitted to mastectomy and linfadenectomy. The pathology revealed an ypT1miypN1a tumor although it was not possible to start adjuvant Olaparib due to healthcare provider issues.
This patient lost follow up and returned in April/2023 with Thorax CT showed multiple bilateral nodules in the lung that was biopsied and confirmed as recurrence of triple negative breast cancer.
The case was discussed on the tumor board and systemic treatment with chemotherapy and immunotherapy was proposed. PDL1 for CPS was 14. We started Carboplatin, Gemcitabine and Pembrolizumab each 21 days. After 4 cicle we switched carboplatin for cisplatin due grade 3 adverse reaction to infusion. After six cycle of treatment PET-scan showed complete response. Patient presented persistent grade 2 of nauseas a despite of clinical management with antiemetics. We stopped cisplatin after cycle 7 and continue Gemcitabine 1000mg/m^2 D1,D8 and Pembrolizumab D1 each 21 days. In this moment, after 12 cycles patient maintain complete response with excellent tolerance to treatment.

P1-08-27: Unusual Presentation Of Triple-Negative Breast Cancer (TNBC) In A Young Female Patient With Xeroderma pigmentosum (XP)

Bashaer Alsaati, Nora Trabulsi, Reem Ujami, Atlal Abusanad

Background: Xeroderma pigmentosum (XP) is a rare, autosomal recessive (1 in a million) disorder characterized by sensitivity to ultraviolet (UV) rays, resulting in a predisposition to skin cancers, primarily. This case vignette describes an unusual presentation of triple-negative breast cancer (TNBC) in a young female patient with XP.
Case Presentation: A 34-year-old woman with a known history of (XP) presented with a palpable mass in her right breast. Clinical examination revealed a firm, irregular, and non-tender mass in the upper outer quadrant of the right breast, measuring approximately 6 cm in diameter. There was no axillary lymphadenopathy. Mammography and ultrasound confirmed a suspicious lesion, and a core needle biopsy was performed. No family history of breast cancer or other malignancies and gBRCA1&2 were negative. Histopathological examination of the biopsy specimen revealed grade III invasive ductal carcinoma, negative for estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth

factor receptor 2 (HER2), consistent with TNBC.
Management and Outcome: A neoadjuvant chemotherapy (NACT) with four cycles of doxorubicin and cyclophosphamide (AC) DD was prescribed. The response to NACT was limited. Consequently, the patient underwent surgery with a modified radical mastectomy (MRM) with tumor of 6 cm & sentinel lymph node biopsy was negative for metastasis. Postoperative follow-up included adjuvant CT with paclitaxel plus carboplatin. Immunotherapy was not accessible for her. Adjuvant radiotherapy was not prescribed.
Discussion: 1.Association of XP and BC: The evidence that XP patients may also have an elevated risk of internal malignancies is scarce. Understanding the mechanisms linking XP with breast cancer, such as DNA repair deficiencies and genomic instability, could provide insights into targeted prevention and treatment strategies.
2.Addition of Carboplatin in Adjuvant Chemotherapy: Studies suggest that the inclusion of carboplatin in the NACT for TNBC can improve pathological complete response rates and survival outcomes. Given the limited response to initial chemotherapy in this patient, the addition of adjuvant carboplatin was commenced to enhance treatment efficacy and potentially reduce the risk of recurrence.
3.Consideration of Adjuvant Radiotherapy (XRT) in XP Patients: The use of XRT in XP patients is challenging due to their heightened sensitivity to UV and ionizing radiation. Protective measures and alternative modalities should be explored to minimize potential adverse effects. Our patient was offered MRM in an attempt to avoid XRT.
4. Type of Surgery: MRM vs. Breast-Conserving Surgery (BCS) :
The choice between MRM and BCS in XP patients with TNBC must consider oncologic outcomes and future potential risk of XRT, especially the long -term safety of XRT in such patient is questionable.
Conclusion: This case highlights the complexity of managing TNBC in patients with XP. It underscores the need for personalized treatment plans that address the unique challenges posed by XP. Multidisciplinary collaboration and further research are essential to optimize therapeutic strategies for these high-risk patients.

P1-08-28: Unusual Presentation of Metastatic Breast Cancer Mimicking Myelofibrosis

Emily Sargent, David Ramirez

Patient is a 43-year-old female with GERD, HLD, Endometriosis, and history of gastric sleeve who initially presented to an outside hospital for abdominal pain in 12/2023. Initial workup revealed WBC 7.58, Hgb 10.4, and platelet count of 51. Of note, her CBC was normal in 3/2023. She underwent CT of the abdomen/pelvis, which revealed nonspecific diffuse mesenteric and peritoneal thickening. She was discharged home with supportive care. On 1/9/2024, she experienced unusually heavy menstrual bleeding. Due to worsening symptoms and progressive shortness of breath she went to an outside ED and was found to have a platelet count of 25 and Hgb of 7.3 for which she was transfused one unit of packed red blood cells. Due to worsening bicytopenia, she was referred to and seen by an outside

hematologist who recommended a bone marrow biopsy. On 1/24/24, patient presented to MDA for shortness of breath at rest and exertion. Her vital signs were within normal limits. Physical exam at this time was notable for pale skin. CBC revealed Hgb 7.9 and platelet count of 25. CTPE revealed no signs of PE however it did note diffuse hepatosplenomegaly, upper abdominal lymphadenopathy, and increased heterogenous density of bone structures raising concern for myelofibrosis.
Patient underwent bone marrow biopsy on 1/30/24. Results revealed involvement by a metastatic carcinoma replacing 70-80% of the bone marrow space. The immunophenotypic features were most suggestive of breast primary. The neoplastic cells were negative for E-cadherin favoring lobular carcinoma. Corresponding flow cytometry showed no monoclonal B cell population, aberrant T cell antigen expression, or increase in immunophenotypic myeloblasts. Of note, patient had a routine mammogram in March of 2023 that was negative for malignancy. Further workup included breast ultrasound, Breast MRI, and bilateral breast biopsies. Her ultrasound revealed bilateral vague areas of distortion which could not be measured. She had a probable fibroadenoma in the left breast at the 6 o'clock position and bilateral lymphadenopathy. Bilateral breast biopsies revealed invasive lobular carcinoma, grade 1, ER/PR 91-100%, HER2 - 0, Ki 67 1%.
Patient now has a diagnosis of metastatic invasive lobular carcinoma (metastasis to bone marrow) who was briefly on tamoxifen and LHRH until labs were consistent with menopausal state. She is s/p bilateral salpingo-oophorectomy and doing well on LHRH antagonist, an aromatase inhibitor, and ribociclib. She has been responding to systemic therapy with improvement in thrombocytopenia and anemia.

This report discusses a case where metastatic breast cancer was identified unusually through the presence of bicytopenia. The patient's initial presentation was most concerning for a hematologic malignancy, specifically myelofibrosis given bone abnormalities seen on CT imaging. Her bicytopenia led to further investigation that revealed underlying metastatic breast cancer, highlighting the importance of considering unusual symptoms in diagnosing metastatic cancer.

P1-08-29: Utility of 18F-FES PET/CT over 18F-FDG PET/CT in Initial Diagnosis of over Ninety Metastatic Lesions in a Patient with Metastatic ER+ Breast Cancer: A Case Report

Caroline Breit, Valerie Gorman

Approximately 6% of women with newly diagnosed breast cancer will present with metastatic disease. Proper staging workup and diagnosis of metastatic lesions is crucial prior to surgical treatment. 18F-FDG PET/CT is often included in the staging workup of locally advanced breast cancer. Recently, PET/CT with 18F-Fluoroestradiol (18F-FES PET/CT), a radiolabeled form of estradiol that binds to the estrogen receptor, has been approved as an additional imaging technique for the detection of ER-positive lesions in patients with metastatic breast cancer. While the two have been shown to have comparable

sensitivity for diagnosis of metastatic lesions, there is still much debate regarding when to use 18F-FES PET/CT over 18F-FDG PET/CT imaging. We present the case of a 68-year-old patient diagnosed with ER+/PR+ invasive ductal carcinoma of the left breast. On breast MRI, the patient was found to have a 1.3cm sternal mass as well as subtle enhancement of two right-sided ribs concerning for metastatic lesions. The patient first underwent a 18F-FDG PET/CT which did not reveal any metastatic lesions. Due to persistent concern for metastatic disease, the patient then underwent whole body 18F-FES PET/CT imaging. This demonstrated extensive osseous metastatic disease not visualized on the previous 18F-FDG PET/CT scan. There were over ninety foci of increased uptake, including multiple foci within the sternum (correlating to the lesion seen on MRI), as well as foci within the cervical vertebral bodies, ribs, sacrum and pelvis. The detection of multiple osseous metastatic lesions in our patient on 18F-FES PET/CT imaging demonstrates previous findings of increased specificity of 18F-FES PET/CT for ER+ metastatic lesions compared to 18F-FDG PET/CT imaging. In our patient, the results of her 18F-FES PET/CT resulted in upstaging of her cancer, thus preventing her from undergoing unnecessary surgical intervention. This likely resulted in earlier treatment with systemic chemotherapy as surgical intervention and resulting complications may delay initiation of chemotherapy. This study thus illustrates the potential value of 18F-FES PET/CT imaging in the diagnosis of ER+ metastatic lesions, especially in the setting of equivocal or discordant findings on conventional imaging.

P1-08-30: Vitiligo-like reaction in a patient with metastatic RH+/HER2-negative breast cancer treated with ribociclib: A case report and literature review

Anezka Ferrari, Herbert Amaral, Mariana Pina, Bruna Zucchetti, Ângelo Fêde, Renata Arakelian, Karina Sacardo, Cynthia Lemos, Mariana Gouveia, Manuel Cruz, Manoel Carlos Souza, Tiago Takahashi, Renata dos Anjos, Dalton dos Anjos, Romualdo Barroso

Introduction: Cyclin inhibitors have significantly altered the natural history of metastatic RH+/HER2-negative breast cancer and achieved excellent disease control with progression-free survival of more than two years. Ribociclib, the leading agent in this class, is highly effective with manageable side effects. Here we report the case of a patient who experienced an unusual dermatologic side effect, a vitiligo-like reaction.

Case Report: A 65-year-old female patient, married and mother of two daughters, had a long-standing diagnosis of luminal-type breast cancer. Her first primary tumor was diagnosed in 2000 and treated with conservative surgery, adjuvant chemotherapy, radiotherapy and hormone therapy. This was followed by an ipsilateral local recurrence, which led to a mastectomy on the right side, and a new primary tumor in the contralateral breast, which was also treated with a mastectomy and local recurrence. Since 2018, she has been diagnosed with metastatic disease, which initially affected the bones, lymph nodes and lungs. First-line treatment with letrozole, ribociclib and denosumab was initiated. The patient showed significant radiologic improvement, with PET-CT showing complete radiologic and metabolic response, and remission persisted for approximately two years.

After about two years of treatment, the patient developed hypochromic lesions on the face, chest and limbs that resembled vitiligo. A skin biopsy revealed atrophy and basal melanin hypopigmentation with negative fungal findings, suggesting post-inflammatory hypochromia. This vitiligo-like reaction was attributed to ribociclib, which was discontinued, and treatment was continued with letrozole alone. In addition, the patient received topical corticosteroid treatment.
Approximately eight weeks later, the patient experienced repigmentation of the lesions and complete resolution of the disease. She is currently continuing to take letrozole with no evidence of neoplastic disease on imaging.
Discussion: Ribociclib belongs to the class of CDK4/6 inhibitors and is highly effective and well tolerated. The main side effects reported include neutropenia and hepatobiliary changes. Skin reactions such as rashes, dermatitis and alopecia occur in about 5 to 10 of patients taking ribociclib. However, these are usually mild and easily manageable. Grade 3 skin rashes occur in only about 0.9% of patients.
Only a few cases of vitiligo-like reactions associated with cyclin inhibitors are known in the literature. The largest series is a multicenter, retrospective study involving centers in the US and Europe, with a total of 16 patients reported, underscoring the rarity of this reaction. The exact mechanisms leading to this reaction are not fully understood, but there are hypotheses concerning the immune response to treatment. In addition, some studies suggest that these responses may be associated with better survival.
In this case, several points should be emphasized. The first is the excellent response, with complete radiologic and metabolic response. The second is the long duration to the onset of the reported toxicity, which lasted about two years. The third point is the complete reversibility of the lesions after discontinuation of ribociclib and treatment with a topical corticosteroid.
Conclusion: Vitiligo-like reactions associated with cyclin inhibitors are reactions that require further investigation due to their negative impact on patients' quality of life and their possible association with improved survival outcomes. Future studies are needed to better understand the pathophysiologic mechanisms involved.

P1-09-01: Combination of tumor-infiltrating lymphocytes (TILS) and tumor-stroma ratio (TSR) in breast cancer: utility to guide clinical treatment of breast cancer

Fiorita Mundim, Angela Logullo, Karine Infante, Joaquim Neto, Edson Barbosa, Paulo Maia, Nathalia Sousa, Pedro Mundim, Gil Facina

Introduction: Breast cancer is the most common malignant tumour in women and the leading cause of death among them. The incidence rate of breast cancer among women surpassed that of lung cancer in 2020, making it the most common neoplasm in the world, with the exception of non-melanoma skin cancer. The most common histological type is non-special invasive carcinoma (SOE - formerly known as infiltrating ductal carcinoma). Our study highlights the need for new indicators to guide clinical treatment, as the response

of breast cancer to anti-HER2 target therapy may be affected by the level of TILs in the carcinoma. The research evaluates the Tumor-Stroma Ratio (TSR) and Tumor Infiltrating Lymphocytes (TILs) in order to identify possible prognostic indicators in malignant tumours. Methods: 130 cases of patients with invasive breast carcinoma diagnosed and treated at IBCC - Instituto Brasileiro de Controle do Câncer, São Paulo, SP - Brazil, from 2003 to December 2013 were collected. The patients' clinical and pathological data was collected, including age, tumour block diameter, number of positive lymph nodes and histological grade. The most significant sample (invasive area) was selected from the tumour with the highest stromal proportion, and multiple sections were taken from this site. The assessment of sTILs (Stromal Tumor Infiltrating Lymphocytes) followed the recommendations of the International TILs Working Group (ITWG). SPSS 23.0 software was used for the statistical analysis, and Pearson's $\chi 2$ test and Fisher's exact probability method were performed. Results: Analysis of the results of the clinical pathological characteristics and other study items for the selected samples showed that among the 130 cases of primary breast cancer, from the perspective of the tumor-stroma ratio (TSR), there were 73 cases (56.15%) classified as TSR≥50% (high stroma group) and 57 cases (43.85%) with TSR<50% (low stroma group). As for the study of stromal tumor infiltrating lymphocytes (sTILs), there were 77 cases (59.23%) in the low sTILs group and 53 cases (40.77%) in the high sTILs group. As for patients with metastatic cancer, a total of 38 cases were selected, of which 24 cases (63.15%) had TSR≥50% (high stroma group) and 14 cases (36.85%) with TSR<50% (low stroma group). Kaplan-Meier survival analysis was used to compare the relationship between TSR and TILs in patients with primary breast cancer, with a lower prognostic outlook being found in the low stroma group. The single Cox factor analysis showed that the overall survival rate and disease-free survival rate of patients in the low stroma group were higher than those in the high stroma group. Cox multivariate analysis showed that TSR in tumors can be considered an independent risk factor for patients' overall survival and disease-free survival. Discussion: The study discusses the complex interaction between tumour and non-tumour cells in the stroma, which is mainly composed of cancer-associated fibroblasts (CAFs), vascular endothelial cells, lymphocytes and cells. CAFs, compared to normal fibroblasts, have a more evident proliferation capacity and play an important role in promoting tumor proliferation, invasion and metastasis. The research also discusses the importance of the Tumor-Stroma Ratio (TSR) and Tumor Infiltrating Lymphocytes (TILs) in the prognosis of breast cancer patients. Previous studies have shown that the prognosis of patients in the high stroma group was worse than that of the low stroma group in gastric, colon and triple-negative breast cancers . However, this study showed that the overall survival rate and the disease-free survival rate of patients with primary breast cancer in the low stromal group were significantly higher than those in the high stromal group. Conclusion: Our study shows that the positive correlation of TSR in primary and metastatic lymph node cancer can be used as an independent factor in the prognostic judgement of breast cancer. However, TSR in primary cancer has a much more prognosis-orientated significance. The combined analysis of TSR and TILs becomes very useful as a tool for determining prognosis and guiding the clinical treatment of breast cancer.

P1-09-02: Discordance in breast cancer pathology review and its impact on patient care

Teixeira Pires, Lucas Zanetti de Albuquerque, Paula Domith de Oliveira Vieira, Érica Tex Paulino, José Bines

Background: Routine external biopsy review by institutional pathologists is a practice implemented by many cancer centers. However, obtaining prompt and efficient central pathology review in low- and middle-income countries can be challenging. The delay in the review process can potentially hinder timely initiation of treatment, presenting additional challenges for patients.This study assessed the percentage of disagreement between breast biopsy reports from external laboratories and internal pathological reviews conducted at the Brazilian National Cancer Institute (INCA), estimating the impact of such routine on patient care.
Methods: A retrospective analysis of data collected from 500medical charts randomly selected among all breast patients treated at INCA in 2021. Cases with external biopsy samples available for review were eligible. Cohen´s kappa (k) and intraclass correlation coefficient (ICC) with two-way model were used to assess concordance between reports with categorical and numerical variables, respectively.
Results: 305 patients with available external pathology sample were included with a median age of 57.5, with 98.4% women and 61% black/brown. Clinical stages at presentation: I (8,7%), II (30%), III (40%) and IV(9,4%). Agreement of malignancy on reports was 99.6%. Six out of 28 patients had the diagnosis changed from benign to malignant disease.A total of 110 (36%) cases had external immunohistochemistry (IHC) evaluation. The agreement for ER was 96.4% (k=0.897, p-value <0,001) and 90.9% for PR (k = 0.784, p-value < 0,0002). The discordance rate for ER was 4,2% (negative to positive) and 3,4% (positive to negative). The agreement for Ki-67 [ICC = 0,835, IC95% = 0,766-0,885, p-value<0,001] and grading (75.1%, k=0.501, p-value <0,001). 96.4% of agreement was observed for HER2 (k=0.837, p-value < 0,001.09). Discordance rate for HER2 was 3,6% (3 negatives to positive). Systemic treatment changes occurred in 7.6% and 3.6%, due to ER and HER2 discordance, respectively. Median time for pathology review was 21 days (IQR 9,5 - 38 days) and from first medical consultation to treatment was 67 days (IQR 46 - 106 days).
Conclusion: We showed a high level of agreement in the diagnosis of malignancy and and a low disagreement on IHC review of ER and HER2, with a small impact on clinical decision making. As pathology review carries with it an increased cost, medical personnel working time and delay in treatment initiation, institutions should go through their internalprocedures and re-evaluate its necessity.

P1-09-03: An integrated genomic analysis of DCIS heterogeneity to identify signatures of progression and determine the clinical utility of ctDNA.

Philip Elliott, Louise Jones, Michael Allen, Rachel Nelan, Eleni Maniati

It is not possible to distinguish between Ductal Carcinoma In-Situ (DCIS) lesions that are indolent and those that will progress. Furthermore, 1 in 5 patients with a diagnosis of pure DCIS on biopsy have occult invasive carcinoma on surgical excision. Current strategies of risk stratification fail to take account of intra-lesion heterogeneity, and whether DCIS might evolve focally or globally.

The hypothesis of this study is that significant intra-tumour heterogeneity (ITH) exists in DCIS at the spatial morphological, biological, and molecular level which challenges risk-stratification on biopsy alone, and this may be better captured in a 'liquid biopsy'.

A prospective cohort of whole DCIS lesions was assessed for 12 antibody markers previously associated with risk of progression– ER, PR, HER2, αvβ6-integrin, Galectin 7, SMA, CD31, CD34, CD68, Fibronectin, p53, and Ki67. Immunohistochemical (IHC) analysis was performed on 273 regions across 14 cases and copy number alterations (CNA) were assessed using ichorCNA on 93 regions, 76 of which could be mapped to matched IHC.

All cases showed intra-lesional heterogeneity for most markers. By-region analysis showed clustering of epithelial and myoepithelial αvβ6-integrin, SMA, Fibronectin, epithelial and myoepithelial Galectin 7, p53, Necrosis, Grade, HER2, and Ki67. There was no correlation between markers and occult invasive carcinoma. Common CNAs included amplifications in 1q22 (73/93 78.5 %) and 17q23.3 (53/93 57.0 %) and loss in 16q23.3 (45/93 48.4 %), with ERRB2 amplification correlating with HER2 scoring, and 16q23.3 deletion correlating with low-grade ER+ regions as previously described. All cases showed heterogeneity in CNAs within lesions indicating multiple subclonal changes. One case showed heterogeneous subclonal CNAs within and between DCIS and multifocal invasive carcinoma, suggesting multifocal evolution of DCIS prior to progression.

Cell free DNA (cfDNA) concentrations from matched blood samples (n=28) showed significant differences between benign controls (fibroadenomas, n = 4) and both pure DCIS (n=16, p=0.02), and DCIS with invasion (n=8, p=0.03). There was no significant difference between DCIS and DCIS with invasion (p=0.49). CNAs were detected in 2/24 (8.3%) of DCIS cases, both of which were DCIS with invasion, although these showed low tumour fraction (0.048 and 0.066).

This study confirms the extent of ITH in pure DCIS and DCIS with invasion in cases with traditionally "low-risk" morphomolecular features, precluding accurate risk assessment on single representative block or biopsy-based analysis. Further work is needed to establish

the value of liquid biopsy, specifically with regard to low tumour fraction in early stage disease.

P1-09-04: A Phase II study of the efficacy and safety of Perflubutane for Predicting highly Tumor Infiltrating Lymphocytes in early breast cancer

Yuri Kimura

Background: Tumor-infiltrating lymphocytes (TILs), a major component of the tumor immune microenvironment, reflect the host's antitumor immune response and serve as critical biomarkers for predicting prognosis and therapeutic efficacy in breast cancer. Recently, the International Immuno-Oncology Biomarker Working Group proposed a standardized pathological evaluation method for assessing TILs, which has shown good reproducibility and concordance rates. However, due to the inherent heterogeneity of TILs within tissues and the limited sample size of pre-treatment needle biopsies in neoadjuvant chemotherapy cases, there remain challenges in establishing objectivity for clinical implementation.
B-mode ultrasonography (US) allows morphological evaluation of the underlying pathology. We discovered that lymphocyte-predominant breast cancer (LPBC), characterized by abundant TILs, presents with distinctive US findings (small lobulated shape, marked hypoechoic areas, and posterior acoustic enhancement). Based on these findings, we developed a unique scoring model (TILs-US score) to predict LPBC. A multicenter retrospective study (JABTS BC-11) demonstrated that the TILs-US score significantly predicted LPBC, and the prediction accuracy was further enhanced by including tumor vascularity assessment (Area Under the Curve 0.784 vs. 0.770; sensitivity 0.93 vs. 0.83; specificity 0.57 vs. 0.55; accuracy 0.71 vs. 0.66). These results prompted a prospective evaluation of the utility of contrast-enhanced ultrasonography (CEUS), which visualizes detailed intratumoral blood flow and allows real-time qualitative and quantitative assessment of blood flow changes, to improve the accuracy of LPBC prediction in a single-arm phase II study (AppTIL study, jRCT1061220081).
Methods: We performed CEUS using perflubutane on patients with early-stage breast cancer and used a new scoring model (TILs-CEUS score) incorporating the rate of contrast agent inflow to predict LPBC. The predictive accuracy of this model was compared with pathological LPBC evaluation of surgical specimens. The target sample size is 100 patients, and prospective enrollment is ongoing.
Conclusion: This study aims to demonstrate the utility of CEUS as a simple method for pre-treatment evaluation of LPBC, potentially enabling its application in predicting prognosis and therapeutic efficacy of neoadjuvant chemotherapy. We intend to report the results, which may contribute to the establishment of a new radiomics-based therapeutic strategy combining tumor immune microenvironment assessment and imaging diagnostics.

P1-09-05: Simultaneous 3D Mapping of RNA and Protein to Advance Personalized Medicine in Breast Cancer

Yue Li, Shigeaki Kanatani, Per Uhlén

Background: Personalized medicine in breast cancer requires a detailed understanding of the tumor and its microenvironment at the molecular level. Current diagnostic strategies, primarily based on 2D imaging methods, are limited by the lack of spatial molecular 3D mapping. Our study aims to bridge this gap by developing a 3D imaging methodology for simultaneously profiling RNA and protein within breast cancer tissues, providing a holistic view of tumor biology.

Methods: We developed a novel 3D imaging method to achieve high-resolution 3D mapping of RNA and protein expressions in breast cancer tissue samples. This method integrates 3D in situ hybridization chain reaction, 3D immunostaining, and a non-toxic tissue clearing technique. We applied this method to intact triple-negative breast cancer (TNBC) samples, performing multiplex labeling for ErbB-2 (mRNA), HER2 (protein), and CD34 for co-mapping tumor cells with the vascular network. Machine-learning-based topological analysis was utilized to characterize spatial blood vessel organization across samples. Various visualization techniques, including scatter plots, histograms and cumulative plots, were employed to investigate the interactions between tumor cells and their nearest vessels.

Results: Our approach successfully generated 3D maps of RNA and protein distribution within breast cancer sample blocks. Topological analysis of the vascular network identified metrics such as vessel length density (VLD), vessel volume density (VVD), connection density (CD), mean angle (MA), mean diameter (MD), and straightness. The results indicated that VLD and VVD positively correlated with prognosis, while CD and MA showed a tendency towards negative correlation. Notably, a subset of cells with ErbB2-mediate expression and HER2-negative expression (ErbB2++/HER2-) was prevalent in many TNBC cases. By comparing these findings with simulated random cell distribution experiments, we observed that the attraction distance between ErbB2++/HER2- cells and blood vessels in TNBC with lymph node metastasis was 58.77μm, significantly smaller than the 401.20μm observed in TNBC without lymph node metastasis. This implies a closer association of ErbB2++/HER2- cells with blood vessels in metastatic TNBC. The analysis revealed a statistically significant increase in the proportion of perivascular ErbB2++/HER2- cells in TNBC samples associated with lymph node metastasis compared to those without lymph node involvement ($P<0.05$).

Conclusion: The simultaneous 3D mapping of RNA and protein provides unprecedented insights into the molecular architecture of breast cancer. Our findings underscore the critical importance of spatial context in molecular profiling. This newly developed method offers a powerful tool for identifying spatially therapeutic targets, redefining our understanding of tumor biology, and guiding clinical decisions.

P1-09-06: Evaluation of proliferation biomarker serum thymidine kinase activity and prediction of early relapse in HR positive HER2 negative high risk early breast cancer: Analysis from the PENELOPE-B trial

Amy J. Williams, Harry D. Bear, Carsten Denkert, Frederik Marmé, Erik Knudsen, Masey M. Ross, Seock-Ah Im, Angela DeMichele, José Angel García Sáenz, Agnieszka Witkiewicz, Laura Van't Veer, Sung-Bae Kim, Zhe Zhang, Nicholas Turner, Federico Rojo, Martin Filipits, Lesley-Ann Martin, Olga Valota, Peter A. Fasching, Christian Schem, Nicole Mc Carthy, Toralf Reimer, Bärbel Felder, Karsten Weber, Valentina Nekljudova, Sibylle Loibl

Background: Nearly 30% of HR+ early breast cancer (eBC) patients (pts) treated with neoadjuvant chemotherapy (NACT) and surgery will experience BC recurrence, many with incurable distant metastatic disease. There is currently no blood-based biomarker that can identify pts with residual disease and at high risk of recurrence before and during adjuvant therapy. Thymidine kinase (TK) is an enzyme that plays a key role in DNA replication during cell division. The expression of TK is strongly linked to the cell cycle and measurement of TK activity (TKa) is a validated biomarker for both disease prognosis and therapy efficacy in metastatic breast cancer (mBC). We investigated the prognostic utility of TKa in eBC using patient serum samples from the PENELOPE-B study (NCT01864746).
Methods: The PENELOPE-B phase III trial explored the addition of one year of palbociclib (P) to endocrine therapy (ET), in HR+, HER2- eBC pts at high risk of relapse after NACT. Serum samples were collected at baseline (BL), 6 months after starting therapy (C7), and end of treatment (EOT ~ 13 months after starting therapy). Samples were analyzed retrospectively for TKa with the FDA cleared DiviTum® TKa assay (Biovica) using DuA (DiviTum unit of Activity) as the measuring unit. The cutoff for defining high vs low TKa was 250 DuA. In previous mBC studies, a TKa threshold value above 250 DuA was significantly associated with likelihood of disease progression. This same threshold value was applied to the PENELOPE-B sample set. TKa association with early invasive disease-free survival (iDFS) and distant disease-free survival (dDFS) was analyzed using restricted mean survival time (RMST) at a pre-specified timepoint of 1 year. The same method was also used to analyze the association of the clinical-pathologic stage- estrogen/grade (CPS-EG) score with early iDFS and dDFS using a cut-off score of <3 or >3.
Results: 1251 pts enrolled in PENELOPE-B. BL TKa levels were analyzed in a sample set of 871 pts, 444 P+ET, 427 ET alone. Median follow-up time was 84 months. Among these 871 pts, 311 pts had an iDFS event (P + ET, 156; ET alone, 155) with 45 of these pts recurring in the first year. BL TKa ranged between 22 and 1025 DuA, with a mean value of 102 DuA, and a median of 81 DuA. BL TKa levels >250 DuA were significantly associated with both invasive and distant disease recurrence within the first 12 months of adjuvant therapy (RMST estimates for BL TKa>250 DuA vs BL TKa≤250 DuA: iDFS=9.6 vs 11.6 months, p=0.01, dDFS=9.9 vs 11.7 months, p= 0.02). In early relapse pts who had a serum sample taken at the time of study discontinuation, 18/22 (82%) had an increase in TKa at the time of relapse as compared to BL. The CPS-EG score when dichotomized as <3 or =4-5 was not prognostic for early relapse within a year (RMST estimates for CPS-EG >3 vs CPS-EG≤3, iDFS=11.3 vs 11.6 months, p=0.12, dDFS=11.3 vs 11.7 months, p= 0.08). TKa dynamic

changes were also analyzed in 360 pts who had both C7 and EOT samples available for testing. Updated analysis looking at increases/decreases in TKa levels during therapy and association with recurrence, as well as treatment interaction will be presented.
Conclusions: In a subset of pts from PENELOPE-B, TKa was detectable in all pts at BL and levels were significantly correlated with early disease recurrence where BL TKa values >250 DuA were prognostic for early relapse within the 1st year of adjuvant therapy. CPS-EG scores in contrast were not prognostic. Pts with early disease relapse also had an increase in TKa levels at the time of recurrence.
These findings warrant further investigation of serum TKa as a non-invasive dynamic biomarker that could be used to assess in "real-time" the presence of actively proliferating disease in adjuvant BC pts and to monitor response to treatment via serial serum TKa testing.

P1-09-07: Retrospective study evaluating the characteristics of patients (pts) with early-stage estrogen receptor-positive (ER+) HER2- breast cancer (EBC) who relapsed on or after adjuvant (adj) abemaciclib (abema)

Chiara Corti, Alyssa R. Martin, Patrick T. Kurnia, Jorge Gomez Tejeda Zanudo, Melissa E. Hughes, Tonia Parker, Paolo Tarantino, Giuseppe Curigliano, Tari A. King, Elizabeth A. Mittendorf, Nancy U. Lin, Sara M. Tolaney

Background: Adding 2 yrs of adj abema to endocrine therapy (ET) has recently become standard for pts with ER+HER2–, node-positive EBC at high risk of recurrence. Characteristics of pts relapsing on adj abema have not been well characterized.
Methods: Pts who received adj abema at a single institution and had recurred were identified. ER, progesterone receptor (PR) and HER2 expression pre- and post-abema were determined, and the duration of treatment (DoT) for adj ET, abema and the first treatment (tx) in the metastatic setting recorded. If NGS was performed at recurrence, genomic alterations related to ET and CDK4/6i resistance were described.
Results: As of 04/2024, 163 pts received adj abema, starting between 2018-2024, with 15 (9.2%) experiencing recurrence. Among recurrent pts, median age was 48 yrs (31–86). All recurrences were distant, with the most common sites being liver (n = 6, 40.0%), bone (n = 5, 33.3%), lung (n = 2, 6.7%). 2 pts (13.3%) had germline (g)BRCA2 mutations (mts), 1 pt (6.7%) had a gCHEK2 mt.
At diagnosis, stage distribution was: stage I, 2/15 (13.3%); stage II, 5/15 (33.3%); stage III, 8/15 (53.3%); nodal status was: cN0, 4/15 (26.7%); cN1, 9/15 (60.0%); cN2/N3, 2/15 (13.3%). ER IHC staining was ≥50% in 14 pts (93.3%) and >10% in all pts; PR was ≥50% in 6 pts (40.0%), >10% in 8 (53.3%), 1-9% in 5 (33.3%), and <1% in 2 (13.3%). Pts had HER2-low EBC in 7 cases (46.7%), HER2-0 in 7 (46.7%), HER2- (IHC unknown) in 1 (6.7%).
4 pts (26.7%) had upfront surgery, 11 (73.3%) neo-adj tx (chemotherapy [CT], 8/11 [72.7%]; ET, 3/11, [27.3%]). 9 pts (60.0%) had ductal histology, 1 (6.7%) and 5 pts (33.3%) had lobular and mixed, respectively. Pts had well, moderately, and poorly differentiated EBC in 2 (13.3%), 6 (40.0%), and 7 cases (46.7%), respectively. Among pts who received neo-adj

CT, pathologic response was available in 6 cases: RCB-II, 1/6 (16.7%), RCB-III, 5/6 (83.3%). 11 pts (73.3%) had ≥4 metastatic lymph nodes. OncotypeDX was requested in 8 pts (53.3%), with RS 11-25 in 3 cases (37.5%) and 26-100 in 5 (62.5%). After surgery, 12 pts (80.0%) received adj ET, 3 (20.0%) CT+ET, no one olaparib. ET was as follows: aromatase inhibitor, 11/15 (73.3%), AI+OFS, 3/15 (20.0%), fulvestrant, 1/15 (6.7%).
ER, PR and HER2 could be assessed pre- and post-abema in 12 (80.0%) pts. In this subgroup, 6 pts (50.0%) with strongly positive ER status (ER ≥ 95% in 5/6 cases, ER ≥ 20% in 1/6), had ER ≤ 10% and PR <1% at first recurrence. Of 7 HER2-0 cases, 4 (57.1%) remained HER2-0, and 3 (42.9%) became HER2-low; of 5 HER2-low cases, 3 (60.0%) remained HER2-low, and 2 (40.0%) became HER2-0.
7/15 pts (46.7%) recurred while on abema, 8/15 (53.3%) after stopping/completing abema. Median DoT was 8.0 mos (Q1-3: 3.8-21.2) for abema and 18.5 mos (Q1-3: 7.0-23.0) for ET. Median DoT for the first tx in metastatic setting was 3.0 mos (Q1-3: 1.6-5.0). At data cutoff, 2 pts were still on first-line tx. First-line tx received included clinical trials, 4/15 (26.7%; 3/4, ADC combination trials; 1/4, PARPi+immunotherapy); CT, 5/15 (33.3%); ET+CDK4/6i, 3/15 (20.0%); olaparib, 2/15 (13.3%); ET+capivasertib, 1/15 (6.7%).
Among pts with available NGS (n = 10) at recurrence, nearly all of them had genomic alterations in the P53 pathway (n = 9, 90%): n = 5 TP53 oncogenic mts, n = 1 TP53 homozygous deletions, and n = 3 MDM2 high amplifications (amp) (copy number >20). One ESR1 mt and no RB1 mt was detected. Other alterations include PI3K pathway (n = 3; n = 2 PIK3CA mt, n = 1 PTEN mt), RTK alterations (n = 4; n = 2 FGFR1 amp, n = 1 ERBB2 mt, n = 1 FGFR2 amp), and CCND1 amp (n = 3).
Conclusions: In this series of 15 pts relapsing on adj abema plus ET for high-risk ER+ EBC, loss of ER expression occurred in 50.0% of evaluable cases. Median DoT for the first tx line (metastatic) was 3 mos. Post-abema genomic alterations include P53 in 90% of cases.

P1-09-08: A new modified technique "Modus Spirdonov 1" in fine-needle aspiration biopsy

Slavyana Usheva, Yordan Spirdonov, Georgi Varbanov, Ivan Terziev, Theophil Sedloev

Introduction: The most fundamental problem in the assessment of benign and malignant neoplasms is the exact preoperative diagnosis. Fine-needle aspiration biopsy (FNAB) is one of the most used techniques for obtaining cytological material for further evaluation. Insufficient biopsy material is reported as a major drawback, which often requires repeated interventions (25.3% published in the literature for the standard technique). The authors have developed a modified technique “Modus Spirdonov 1” in order to obtain a larger amount of cytological material and verify the results with quantitative analysis in an experimental model.
Material and methods: For the purpose of the experiment porcine liver and longissimus dorsi muscle were selected as target tissues sampled by standard method with direct grip (n = 60), by using CAMECO Syringe Pistol (n = 60) and by applying the technique “Modus Spirdonov 1” (n = 60). The measurements were performed by an authorized specialist in

the only specialized and certified laboratory for standards of the Bulgarian Institute of Metrology. For comparison with the standard methods, in FNAB "Modus Spirdonov 1" after achieving a vacuum, rotational movements are performed along the longitudinal axis in two opposite directions without displacing the needle from the target center. This maneuver provides more efficient tissue cutting with the edge of the needle. A comparative analysis of the weight of the sample obtained by the three methods was performed.
Results: The analysis shows that there is a statistically significant difference when comparing the results from the different techniques. The modified method “Modus Spirdonov 1” significantly exceeds the other two techniques ($p<0,001$) according to the quantity of the obtained material. According to the results of our study in experienced hands we achieved a sensitivity of the method of 98.5%, a false negative rate of 1% and a false positive rate of 0.5% in 1100 biopsies performed in clinical practice with 0% repeated biopsies. In addition, the gathered material is visually significantly richer, including ductal epithelial complexes, abundance of stromal cells, calcifications, detritis and a giant cell, macrophages filling the entire field of view microscopically.
Conclusion: The authors believe that the described modified technique is a viable alternative to the currently used FNAB and could increase the diagnostic value of the preoperative biopsy in a number of diseases.

P1-09-09: Disparities in Second Breast Cancer Events and Survival Persist Despite Optimal Treatment in Hormone-Receptor Positive Breast Cancer: Analysis of the Real-World ASCO CancerLinQ Dataset

Olga Kantor, Alyssa Jones, Erica L. Mayer, Mariana Chavez-MacGregor, Tari A. King, Elizabeth A. Mittendorf

Background: Reports of racial and ethnic disparities in locoregional breast cancer (BC) events are mixed, with disparities often seen amongst hormone-receptor positive, HER2-negative (HR+HER2-) breast cancer. We examined rates of locoregional second breast cancer events (SBCE) and overall survival (OS) by race and ethnicity in the ASCO CancerLinQ real-world dataset amongst patients (pts) receiving optimal treatment.

Methods: ASCO CancerLINQ was used to identify pts that underwent surgery for invasive HR+HER2- stage I-III BC from 2005-2022. We defined SBCE as a second event in the ipsilateral or contralateral breast or axilla after prior treatment for BC. Optimal treatment was defined to include adjuvant endocrine therapy, radiation after lumpectomy in age <70, and regional nodal irradiation for N2-N3 disease. Patient characteristics and rates of SBCE were examined by self-reported race and ethnicity. Kaplan-Meier analysis was used to estimate SBCE-free survival and OS in optimally and not-optimally treated pts.

Results: Among 40,917 HR+HER2- BC pts, 27,803 (68.0%) were Non-Hispanic White (NHW), 4,193 (10.3%) Non-Hispanic Black (NHB), 1,767 (4.3%) Hispanic, 1,112 (2.7%) Asian or Pacific Islander (API), and 6,042 (14.8%) other or unknown race and ethnicity.

NHW pts were more likely to present with clinical stage I disease (60.8% vs 50.5%, 50.1%, and 55.4% for NHB, Hispanic, and API pts respectively, p<0.01), and be older at diagnosis (16.6% of NHW vs 21.5%, 33.0%, and 31.9% of NHB, Hispanic, and API pts were age <50, p<0.01).

Overall, 66.7% of NHW, 70.3% of NHB, 73.3% of Hispanic, and 76.0% of API pts received optimal treatment for all eligible definitions (p<0.01). 5-yr estimated SBCE-free survival in optimally treated pts was 98.4%, 98.3%, 98.8%, and 98.0% for NHW, NHB, Hispanic, and API patients (p<0.01). In pts without optimal treatment, this decreased by 0.5%, 0.1%, 0.9%, and 1.0%, respectively. 5-year OS in optimally treated pts was 94.5%, 93.4%, 97.2%, and 97.2% in NHW, NHB, Hispanic, and API patients (p<0.01). In pts without optimal treatment, this decreased by 3.1%, 4.1%, 2.1%, and 0.1%, respectively.

Conclusions: Differences in SBCE and OS were seen by race and ethnicity in HR+HER2- BC, including in pts receiving optimal treatment. This adds granular real-word evidence to support racial and ethnic disparities are pronounced in HR+HER2- BC despite similar treatment.

P1-09-11: Machine Learning based analysis in chemotherapy resistant triple negative breast cancer

Dongling Wu, Sean Hacking, Yihong Wang

Background: Chemotherapy resistances were believed to be caused by tumor cell DNA alterations; However, recent years' tumor micro-environment (TME) study has increasingly revealed the complementary interactions between tumor cells and peri, intratumoral stromal cells and inflammatory cells. The role of TME in acquired chemoresistance has yet been fully understood.With the development of bioinformatics, the analysis of TME has expanded to a more "micro" molecular level: through ssGSEA analysis, the gene expression differences between normal tissue and peri, intratumoral tissue were able to be calculated. MDAcc group has developed a scoring algorithm to analyze the gene signature of tumor, stromal and immune cell component. High score indicates a high volume of stromal and immune cells intermixing with tumor tissue. Goal: In this study, we aim to use machine learning image analysis and bioinformatics method to analyze stromal and immune components in chemotherapy resistant TNBC.Method: A cohort of TNBC that received chemotherapy is selected from TCGA. QuPath is used for analysis of tumor, mature stroma, immature stroma, and immune cells, a percentage for each component is given by machine. Mature stroma is defined as dense fibrosis, vascular tissue and adipose tissue. Immature stroma is defined as loose "fresh" collagen bundles and myxoid "tissue culture" like desmoplastic stroma. MDAcc scoring R package is used to analyze stroma and immune gene, a score is given to each component. A t-test is used to compare the medium value of each component and score. A K-M analysis is used to compare the survival rate. A Pearson correlation (r) analysis is done to compare imaging analysis results and molecular results.

Result: A total of 137 patients were selected for imaging analysis. High tumor stromal ratio (TSR= tumor percentage/stromal percentage), high tumor percentage are associated with low pT stage (TSR: p=0.008; tumor%: p=0.02). Higher mature stroma percentage is associated with low pT stage (p=0.026), high rate of complete response (p= 0.02) and high disease-free survival (p=0.006). Higher immature stroma percentage is associated with higher tumor stage (p=0.006), low rate of pCR (p= 0.03) and low disease-free survival (p=0.005). Higher immune cell stromal percentage is associated with pT1 disease (p=0.009), high rate of pCR (p= 0.008) and high disease-free survival (p=0.005). Similarly, gene sequencing analysis also shows a high immune score is associate with pT1 disease (p=0.007). For stromal score, high stromal score is associated with high rate of pCR (p=0.04) and although not statistically significant, it also shows a trend of positive association with low stage (pT1) and longer disease-free survival. Correlation analysis shows a high correlation (r=0.8) between immune stromal percentage and immune score results, and a moderate correlation (r= 0.6) between mature stromal percentage results and stromal score.Discussion: Our study explored the complexity of drug resistance mechanism beyond tumor cells and the potential effects of mature and immature stromal and immune cells on chemotherapy outcomes. Our study also showed the potential use of AI in predicating tumor response to therapy.

P1-09-12: Comparative Analysis of the Oncotype DX Breast Recurrence Score® assay for Neoadjuvant Letrozole/Abemaciclib versus Chemotherapy in Stage II-III, Ki67≥20%, HR+/HER2- Breast Cancer: Insights from the GEICAM/CARABELA Trial

Angel Guerrero-Zotano, Emilio Alba, Maria Eva Pérez-López, Manuel Ruiz-Borrego, Noelia Martinez-Jañez, Jose Ignacio Chacón, Miguel Gil-Gil, Raquel Andrés, Pedro Sánchez-Rovira, Eduardo Martínez de Dueñas, Carmen Hinojo, Marta González Cordero, Elisa García-Garre, Blanca Hernando, Juan de la Haba-Rodríguez, Isabel Álvarez, Santiago González-Santiago, José Angel García Sáenz, Ana Santaballa Bertrán, Jesús Herranz, Marta Portela, Rosalia Caballero, Federico Rojo, Miguel Martín

Background: The CARABELA trial (NCT04293393) compared 12 months of neoadjuvant letrozole/abemaciclib (let/abema) versus 6 months of neoadjuvant chemotherapy (CT) in stage II-III, Ki67≥20%, HR+/HER2- breast cancer. Although let/abema did not achieve comparable RCB 0-I rates as CT (13% vs. 18%), an analysis of the Oncotype DX Breast Recurrence Score® (RS) assay revealed higher residual cancer burden (RCB) 0-I rates with CT compared to let/abema in patients with RS result >25 (26% vs. 18%). Conversely, patients with RS≤25 showed similar rates with each treatment (6% vs. 8%). The present study investigates the interaction between treatment, RS result and cell cycle suppression, along with post-treatment (surgery) RS, estrogen and progesterone receptors (ER/PgR) mRNA expression.
Methods: We examined the association of baseline (BL) RS results with rates of complete cell cycle arrest (CCCA, Ki67<2.7%) at 2 weeks (2w) and at surgery. Ki67 was centrally

determined using a standardized assay (Ki67 IHC MIB-1 pharmDx, Dako Omnis, Agilent Technologies). Additionally, ER and PgR mRNA levels were obtained from the surgery Oncotype DX® report (Exact Sciences). Median time from last study dose to surgery was 8 days for let/abema.
Results: Out of 200 patients included in the CARABELA trial, 192 (96%) patients were included in this biomarker study; 184 (92%) had BL RS results and 142 (71%) had at-surgery-RS results. Four (4%) out of 95 patients in the let/abema arm and ten (10%) out of 97 in the CT arm, achieved RCB=0, and these cases were assigned RS=0 and Ki67<2.7%. Rates of 2w-CCCA were higher with let/abema compared to CT (68% vs. 6%, p<0.0001), but not at surgery (53% vs. 45%, p=0.16). In the let/abema arm, the rates of CCCA were numerically higher at 2w and surgery for RS≤25 compared to RS>25 (83% vs. 71%, p=0.34 at 2w and 75% vs. 55%, p=0.11 at surgery). In the CT arm, the rates of CCCA were comparable for RS≤25 and RS>25 both at 2w, where only 7 patients achieved CCCA (6% with RS≤25 and 14% with RS>25, p=0.37), and at surgery (57% vs. 50%, p=0.70). In the let/abema arm, 55% of patients with RS≤25 achieved CCCA at 2w and maintained it at surgery, compared to 33% of patients with RS>25 (p=0.14). This rebound in proliferation did not correlate with the time from the last dose of abemaciclib to surgery (r=0.01, p=0.95).
Surgery-RS result was higher in the let/abema arm than in the CT arm (median RS result of 22 vs. 19, p=0.02) and was inversely correlated with surgery ER levels (r = -0.39, p <0.0001) and surgery PgR levels (r = -0.6, p <0.0001). Let/abema treatment was more effective in suppressing ER and PgR mRNA levels from BL to surgery than CT (ER median change: let/abema -1.0 score units vs CT -0.3, p=0.0002; PgR median change with let/abema: -2.1 vs -0.3 with CT, p<0.0001). For patients with surgery non-CCCA (excluding those achieving RCB:0), Ki67 expression was higher in the let/abema arm, with a median of 26%, compared to 16% in the CT arm, and only 7% had positive surgery-PgR mRNA expression (according to score units) in the let/abema arm, compared to 62.5% in the CT arm.
Conclusions: Neoadjuvant let/abema and CT varied in efficacy by Recurrence Score®. Let/abema achieved higher CCCA rates in RS≤25 patients, accompanied by significant ER and PgR mRNA suppression, highlighting its efficacy in less biologically aggressive subtypes and suggesting it might replace the need for CT. Surgery-RS result was higher in the let/abema arm than in CT and correlated inversely with surgery ER and PgR levels, indicating deeper ER signaling suppression. Additionally, residual disease in the let/abema arm exhibited higher levels of proliferation than in the CT arm, along with greater suppression of ER signaling, suggesting distinct residual disease biology.

P1-09-13: An Adjusted Breast Cancer Index Model to Identify Women with Hormone Receptor–Positive (HR+) Breast Cancer at Minimal Risk of 10-year Distant Recurrence (DR)

Marie-France Jilderda, Yi Zhang, Valerie Rebattu, Ranelle Salunga, Vincent Smit, Jenna Wong, Linda de Munck, Amanda Anderson, Esther Bastiaannet, Kai Treuner, Gerrit Jan Liefers

Background: Five years of adjuvant endocrine therapy (ET) is the standard of care for treating early-stage hormone receptor–positive (HR+) breast cancer (BC) to reduce the risk of disease recurrence. However, many patients discontinue ET early due to poor tolerability and toxicity. Validated biomarkers are critically important to optimize the selection of patients for adjuvant and extended (post–5 year) ET.
The Breast Cancer Index (BCI) is a gene expression–based signature recommended in clinical practice guidelines to aid patient selection for ET. The BCI prognostic score reports an individualized risk of overall (0–10 years) and late (post–5 years) distant recurrence (DR). BCI was previously shown to identify patients with favorable BC-specific survival in the Stockholm trial. In the current study, untreated patients from this trial were used to identify an adjusted BCI cut-point for defining a group with minimal risk of DR, which was subsequently validated in a large cohort of patients from the Netherlands Cancer Registry (NCR), who did not receive any adjuvant endocrine therapy.

Methods: 283 patients from the untreated arm of the Stockholm trial were used for BCI cut-point selection to define a minimal risk group with a 10-year risk of DR of ≤5%. Performance of the adjusted BCI model was initially assessed in the tamoxifen-treated arm of the Stockholm trial (n=317) and then evaluated in a cohort from NCR (n=1247). Women with HR+ N0 breast cancer who were ≥70 years old and did not receive any adjuvant ET were identified from the NCR database and used for BCI validation. FFPE blocks of primary tumor specimens were collected from participating hospitals across the Netherlands and sent to the Leiden University Medical Center for central processing. Sections were shipped to Biotheranostics CLIA-certified and CAP-accredited laboratory for testing blinded to the clinical data. Kaplan-Meier analysis and Cox proportional hazards regression were used to analyze the Stockholm cohorts with DR as the study endpoint. Cumulative incidence analysis and Fine-Gray model with death as a competing risk event, were used to analyze the NCR patients.

Results: The adjusted BCI model stratified patients into four different risk groups: minimal, low, intermediate and high risk. In the Stockholm cohort, the minimal risk group (20%) showed a 10-year risk of DR of 2.3% and 4.3% in the untreated (n=283) and treated arm (n=317), respectively, whereas the 10-year risk of DR was 15.5% and 5% for the low risk (40%), 19.8% and 11.7% for the intermediate risk (23%), and 35.9% and 21.1% for the high risk (17%) groups, respectively. The minimal risk and low risk groups in the tamoxifen-treated arm demonstrated very similar risk profiles. When assessed in the NCR cohort (n = 1247, 55% T1, 42% T2, 22% grade 1, 61% grade2, 94% HER2-, 99.8% no chemotherapy) who did not receive any adjuvant endocrine therapy, the adjusted BCI model was significantly prognostic (p = 0.003) with subdistribution hazard ratios (sHR) for low, intermediate, and high-risk vs. minimal risk of 1.67 (95% CI: 0.81-3.45), 2.39 (95% CI: 1.14-5.01) and 3.23 (95% CI: 1.55-6.74), respectively. The minimal (16%), low (41%), intermediate (24%) and high-risk (19%) groups showed a 10-year risk of DR of 4.5%, 7.5%, 10.3%, 13.5%, respectively, with death as a competing risk event.

Conclusions: The current study demonstrates that an adjusted BCI minimal risk cut-point may identify postmenopausal women with HR+ N0 breast cancer, who are at sufficiently low risk of DR and thus unlikely to derive clinically meaningful benefit from adjuvant ET. These results support BCI as a biomarker to help guide the selection of HR+ breast cancer patients who could be spared from or consider shorter duration of adjuvant ET to avoid potentially serious side effects from these therapies.

P1-09-14: Palbociclib and endocrine therapy diminishes adaptive anti-tumor immunity

Michail Ignatiadis, Andreas Papagiannis, Samira Majjaj, François Duhoux, Elisa Agostinetto, Laurence Buisseret, Denis Larsimont, Isabelle Veys, Marianne Paesmans, Tatiana Besse Hammer, Ahmad Awada, Lieveke Ameye, Francoise Rothe, Francesc Madriles, Tim Cash, Roberto Salgado, Karen Willard-Gallo, Christos Sotiriou, Peter Vuylsteke, Patrick Neven

Background: We examined the effect of palbociclib and endocrine therapy (ET) on transcriptional programs and chromatin accessibility of immune, stromal and tumor cells from breast cancer patients.
Methods: We employed single-nuclei RNA & ATAC sequencing using the 10x multi-omic platform on pre- (baseline) and post- (surgery) treatment frozen tumor samples (minimum 25% tumor cellularity) from patients enrolled in the NeoRHEA trial (N=37; NCT03065621). This was a phase II, single arm study evaluating 4 months of neoadjuvant palbociclib and ET in women with ER+/HER2- early breast cancer. We defined immune cells as CD45+ or CD20+, stromal cells as FAP+ or PECAM+ and tumor cells as ESR1+ and copy number (computed via infercnv) aberrant. We defined T, B and myeloid cells as CD3+, CD20+ and CD68+, respectively. T cells were further divided into CD4+ and CD8+ with the latter examined also as CD8+CD103+ (tissue-resident memory T-cells) and CD8+/CD103- subpopulations. The percent (%) change in subpopulations post-treatment were considered significant at ≥20% change. Differential gene expression and peak accessibility analyses were generated between baseline and surgery, followed by Gene Set Enrichment Analyses (GSEA) using hallmark gene sets. Q values were calculated by adjusting the p-values for the 50 gene sets.
The single-nuclei data was validated using multiplex immunohistochemistry (mIHC) to stain for CK (tumor cells), CD45 (immune cells), Ki67 (proliferating cells) and DAPI (nuclei) on formalin-fixed paraffin embedded tumor tissue followed by imaging on a Vectra Polaris™. Differences in the % of Ki67 positive tumor and immune cells between baseline and surgery samples were evaluated using a two-sided Wilcoxon test.
Responding patients were defined as those with either Ki67≤2.7% by chromogenic immunohistochemistry at surgery (complete cell cycle arrest, CCCA) or a complete/partial response on the post-treatment ultrasound.
Results: Among the 37 patients, 18 had an ultrasound response and 23 patients had CCCA. High quality single nuclei were analyzed at baseline (66201) and surgery (159896).
A 31% decrease in tissue-resident memory cells (CD8+CD103+ among CD8+) was observed

post-treatment. This was detected only in patients with either CCCA or ultrasound response (63% and 66% decrease, respectively). CD8+CD103+ cells were shown to be critical players in anti-tumor immune responses (doi.org/10.1016/j.ccell.2023.01.004).
Analysis of all 37 patients revealed a decrease in E2F target and G2M checkpoint (proliferation related) gene sets post-treatment in immune (Normalized Enrichment Score, NES -1.59, p≤0.01, q≤0.01 and -1.34, p=0.02, q≤0.02, respectively) and tumor (NES -1.77, p≤0.01, q≤0.01 and -1.32, p=0.03, q≤0.13, respectively) but not stromal cells (NES -1.06, p=0.28, q=0.31 and -0.90, p=0.73, q=0.54, respectively). This decrease in E2F target and proliferation related genes in immune cells was principally driven by T cells (NES -1.8, p≤0.01, q≤0.01 and -1.51, p≤0.01, q=0.02, respectively), suggesting that palbociclib and ET decreases T-cell proliferation. GSEA based on genes residing in the differentially accessible peaks revealed similar results suggesting that the observed gene expression changes are associated with altered chromatin accessibility. Decreases in E2F target and G2M checkpoint gene set expression in tumor, immune and T-cells post-treatment were observed only in responding patients with either CCCA or ultrasound responses.
mIHC detected a significant decrease in Ki67+ tumor (median, range from 7%, 1-53% to 1, 0-31, p<0.01) and Ki67+ immune cells (from 4, 0-19 to 2, 0-25, p<0.01) post-treatment, validating these findings.
Conclusion: Treatment with palbociclib and endocrine therapy diminishes adaptive anti-tumor immunity by decreasing T-cell proliferation and the presence of tissue-resident memory T-cells.

P1-09-16: A Phase I Study of ASTX727 plus Talazoparib in Patients with Triple Negative or Hormone Resistant/HER2-negative Metastatic Breast Cancer and non-mutated BRCA

Kathy Miller, Alexandra Thomas, Sandra Althouse, Yong Zang, Erin Condor, Ryan Burgos, Bryan Schneider, Tarah Ballinger, Emily Douglas, Katherine Ansley, H Josh Jang, Jean-Pierra Issa, Kenneth P Nephew, Feyruz V Rassool

Background: Poly (ADP-ribose) inhibitors (PARPi) are effective in patients (pts) with germline BRCA 1/2 and PALB2 mutations but have been largely ineffective as monotherpy in others. PARP interacts with, and is recruited to, DNA damage sites along with epigenetic factors, such as DNA methyltransferase 1 (DNMT 1). In addition to increasing PARP-trapping, inhibitors of DNMT modulate ROS-cAMO-PKA signaling and induce a pathogen mimicry, inflammasome signaling response and a 'BRCAness phenotype' that further sensitizes cells to PARPi. In preclinical in vitro and in vivo studies. combined DNMTi + PARPi therapy was effective in both triple negative (TNBC) and hormone resistant (HRBC) models with intact BRCA.
Methods: We conducted a phase I study combining the oral DNMT1 ASTX727 with the PARPi talazoparib in pts with previously treated TNBC or HRBC; pts with dleterious mutations of BRCA or PALB2 were excluded. Pts. with TNBC had received at least one prior chemotherapy and pts with HRBC had received proir endocrine therapy with a cyclin-

dependent kinase inhibitor for metastatic disease. An ECOG PS 0-1 and adequate organ function was required. A classical 3+3 design guided dose escalation/de-escalation with dose limiting toxicity (DLT) defined as Grade 4 neutropenia or thrombocytopenia lasting > 7 days, or clinically significant grade > 3 non-hematologic toxicity in cycle 1; 28 days constituted each cycle. Serial peripheral blood mononuclear cells (PBMCs) were analyzed for changes in methylation using the Infinium MethylationEPIC BeadChip and LINE1 sequencing.
Results: 34 evaluable pts were enrolled and treated in 8 dose cohorts (Table). Median age was 59 years, 12% identified as Black. Myelosuppresson was common with grade > 3 neutropenia in 42% and grade 3 anemia and thrombocytopenia each in 13%. DLT was limited to neutropenia.
Efficacy was assessed in 29 pts. There were no objective responses, 6 pts had stable disease persisting for > 4 months in 3 pts. LINE1 demethylation ranged from 2-12% and immune-specific CpGs (methylation in immune cells) changed by 1-5% by differential methylation locus analysis at Day 15.Methylation changes were not dose dependent.
Conclusions: ASTX727 plus talazoparib produces significant myelosuppression but is otherwise well tolerated. Attenuated dosing identified dose level 1LDseq or 1LDcon for phase II trials. Methylation changes in PBMCs were detected and some heavilty pre-treated pts had prolonged stable disease.

P1-09-17: Management of Neutropenia and Effectiveness of Sacituzumab Govitecan (SG) in Patients (pts) With Metastatic Triple-Negative Breast Cancer (mTNBC) Treated in Real-World Settings in the United States

Rita Nanda, Clinton Yam, Laura Spring, Manali Ajay Bhave, Ioanna Ntalla, Theresa Valdez, Brian Stwalley, Chenxue Liang, Nikoleta Sjekloca, Catherine Lai, Kevin Kalinsky

Background: SG is a Trop-2-directed antibody-drug conjugate approved for pts with previously treated mTNBC and HR+/HER2— metastatic breast cancer. In previously treated mTNBC, SG demonstrated a statistically significant and clinically meaningful benefit in PFS and OS vs single-agent chemotherapy and a manageable safety profile (phase 3 ASCENT study, NCT02574455). The most commonly reported toxicities, neutropenia and diarrhea, were managed with established guidance. This study describes the incidence and management of neutropenia as well as the real-world effectiveness of SG in pts with mTNBC.
Methods: The US-based, de-identified Flatiron Health electronic medical record–derived database was used. Pts with mTNBC (as defined by ASCO/CAP guidelines) treated with SG in the second line (2L) and later from Apr 2020 to Jun 2023 were included. Data cutoff was Dec 31, 2023. Pt characteristics, SG treatment (tx) duration, incidence of neutropenia, and concomitant granulocyte colony-stimulating factor (G-CSF) use during SG tx were described. Neutropenic events occurring during SG tx were described using ICD10/9 diagnosis codes (D70, 288) and/or laboratory data (absolute neutrophil count <1500mm3). Primary prophylaxis was defined as any G-CSF administration on or after SG tx start (index) date and

before the first neutropenic event. Secondary prophylaxis was defined as G-CSF administration after neutropenia resolution. For therapeutic use, G-CSF was administered upon or after onset of neutropenia and before resolution or end of tx. Real-world OS (rwOS) and time to next tx or death (TTNTD; used as a proxy for PFS) were assessed using the Kaplan-Meier method.
Results: For the 381 pts (99% female) with mTNBC included in the analysis, median (interquartile range [IQR]) age was 61 (52-69) yrs; 18% (n = 70) were Black; 17% (n = 66) had an ECOG performance status ≥ 2; 25% (n = 97) had de novo metastatic disease; 78% (n = 298) were treated in community centers only. Pts received a median (IQR) of 2 (1-3) prior lines of tx in the metastatic setting. Overall, 31% (n = 118) received SG in 2L and 69% (n = 263) in 3L and later. Pts received a median (IQR) of 12 (5-21) SG doses; the maximum number of doses administered during the study period was 74. Median (IQR) SG tx duration was 4.0 (1.9-7.6) mos. Neutropenia (grade ≥2) was reported in 57% (n = 219) pts; grade ≥3 in 27% (n = 101). During SG tx, 59% (n = 225) pts received G-CSF; 31% (n = 117) received it as prophylaxis only (primary prophylaxis: 20% [n = 77]; secondary prophylaxis: 9% [n = 36]; both: 1% [n = 4]). Grade ≥3 neutropenia occurred in 10% (12/117) of pts after any G-CSF prophylaxis and in 4% (3/77) of pts receiving primary prophylaxis only. Median (IQR) time from start of SG tx to first onset of grade ≥3 neutropenia subsequent to G-CSF use was 48 (36-322) days among those who received primary prophylaxis only. Therapeutic-only G-CSF use was observed in 6% (n = 24) of pts with a median (IQR) time to grade ≥3 neutropenia onset of 9 (8-21) days; 21% (n=79) of pts received both prophylactic and therapeutic G-CSF during SG tx. Among 41% (n = 156) of pts who did not receive G-CSF during SG tx, 13% (n = 21) experienced grade ≥3 neutropenia with a median (IQR) time to grade ≥3 neutropenia onset of 8 (8-22) days.
At a median (IQR) follow-up of 8.7 (4.5-14.6) mos, median (95% CI) rwOS and TTNTD were 11.3 (9.9-13.0) mos and 5.6 (5.0-6.4) mos, respectively.
Conclusions: In this real-world analysis of pts with previously treated mTNBC, SG demonstrated effectiveness and a manageable safety profile, consistent with findings from the ASCENT study and other real-world studies. A low incidence of neutropenia was observed among pts receiving G-CSF prophylaxis, suggesting that SG-related neutropenia can be effectively prevented with G-CSF prophylaxis.

P1-09-18: Activation of HERV-R is a biomarker of poor prognosis among rural Nigerian women with triple-negative breast cancer.

Faruk Mohammed, Mohammed Daniyan, Ines Hosni, Halimatu Sadiya Musa, Sani Kamarudeen Owolabi, Adoke Kasimu Umar, Yawale Iliyasu, Rebecca Garnham, Jane Carr-Wilkinson, Sani Ibrahim, Kevin Petrie

Human endogenous retroviruses (HERVs) comprise genetic material from germ cells that were infected with ancient retroviruses during Pan troglodytes' evolutionary divergence. These "non-coding" repetitive elements now make up approximately 8% of the human genome. Once inserted in the genome, HERVs increase copy number via retrotransposition

(a 'copy-and-paste' mechanism) and are involved key functions including transcriptional control and cellular fusion during placenta formation. Aberrant re-expression of HERV-associated genes initially silenced by host epigenetic mechanisms, including DNA methylation, has been linked to many diseases including cancer. Furthermore, in addition to regulating gene expression, including of neighboring genes, reversal of silencing of HERVs may also impact diverse biological functions through the LTRs, and gag, pol, and env proteins. Although previous studies, specifically in white populations, have documented the expression of HERV-K in breast cancer, there is a paucity of data on the expression and role of HERV-R in triple-negative breast cancer (TNBC) among rural West African women from Nigeria. Breast cancer remains the most frequently diagnosed cancer among women globally, with the highest mortality rates across sub-Saharan African nations compared with other countries. Advanced-stage disease at presentation, as well as limited access to treatment options, typically contribute to the poor overall survival rate of breast cancer in African countries including Nigeria. However, the incidence and mortality rates of TNBC in women with West African ancestry are alarmingly high, with an overall survival rate of three years in Zaria, Nigeria. To better understand the molecular basis underlying these high incidence and mortality rates, as well as identify prognostic biomarkers we assessed expression patterns of HERV-R and TNBC-associated genes from Formalin-Fixed Paraffin-Embedded (FFPE) samples of breast cancer, focusing on TNBC in Nigerian women from rural West Africa. To examine gene expression in this study, we used immunohistochemistry, immunoblot, and immunofluorescence, with results showing strong expression of the HERV-R env protein in all but one TNBC patient, as well as in other basal breast cancer subtypes. Our results also strongly suggest that HERV-R expression is associated with overexpression of oncogenes, including TMPRSS2, BRAF, CCND1, BAZ1B, KTM2D, and FOXA1. We found that patients with HERV-R expression have a poor prognosis with low survival. These findings imply that activation of HERV-R may play a role in regulating the expression of genes implicated in TNBC and may serve as a prognostic biomarker in breast cancer.

P1-09-19: IRENE study: Phase 2 study of oncolytic virus pelareorep and PD-1 inhibitor retifanlimab in metastatic triple negative breast cancer

Mridula A. George, Nicole O. Williams, Coral Omene, Danielle Tang, Shou-En Lu, Matt Coffey, Thomas Charles Heineman, Shridar Ganesan, Deborah Toppmeyer

Background: Treatment with checkpoint inhibitors has clinical benefit in PD-L1 positive metastatic triple negative breast cancer (mTNBC). However only 40-50% of mTNBC tumors have PD-L1 expression. Pelareorep, a proprietary isolate of the unmodified replication competent reovirus type 3 Dearing (T3D) strain, a non-enveloped reovirus has been shown to upregulate PD-L1 expression in tumor and inflammatory cells and promote a favorable CD8:regulatory T-cell ratio indicating a less immunosuppressive tumor microenvironment. We hypothesized that the treatment with pelareorep will improve the response rates in patients with metastatic triple negative breast cancer by priming the tumor

microenvironment for enhanced tumor response to PD-1 inhibitor retifanlimab.
Methods: This was a phase II multi-site, single-arm clinical trial to study the combination of the oncolytic virus pelareorep and PD-1 inhibitor retifanlimab in patients with mTNBC. Patients with PD-L1 positive and PD-L1 negative tumors were eligible for the study. Eligible patients received 1-2 prior lines of therapy in the metastatic setting. Patients who received prior immunotherapy were also eligible for the study. Eligible patients received pelareorep 4.5x1010 TCID50 / day intravenous (IV), on Days 1, 2, 15 and 16 and retifanlimab 500 mg IV on day 3 of every 28-day cycle. (ClinicalTrials.gov Identifier: NCT04445844)
Primary endpoint was objective response rate (ORR) and safety, as determined by the number, frequency, duration, and severity of AEs using CTCAE v5.0. The study was designed using Simon's optimal 2-stage design. In the first stage, 14 patients would be accrued. If there were 1 or fewer responses in these 14 patients, the study would be terminated. Otherwise, 11 additional patients would be accrued for a total of 25 patients. The null hypothesis would be rejected if 4 or more responses are observed in 25 patients.
Results: Fifteen patients were enrolled in the study (100% women). Median age was 58.6yrs. (66% White, 20% African American, 13% Asian). One patient withdrew from study due to grade 3 fatigue after C1D15. This patient was not included in the efficacy assessment.
Of the fourteen evaluable patients in stage 1 of the study, one patient had partial response (ORR of 7.1%). Duration of response in this patient was 7 months. The average number of cycles for all patients was 2.18 cycles. Five patients received prior treatment with check-point inhibitors - pembrolizumab or atezolizumab. According to the protocol-specified analysis at the end of the stage 1, the efficacy objective (of atleast 2 objective response) was not met. Hence, the study was terminated at the end of stage 1.
The combination was well tolerated. One patient had Grade 3 depressed level of consciousness, which was not related to pelareorep or retifanlimab. One patient with Grade 5 event, which was attributed to disease progression.
Conclusion: The combination of pelareorep and retifanlimab in patients with mTNBC did not show significant anti-tumor activity. One patient had a partial response. Tumor tissue, stool and blood samples collected during treatment will be assessed to understand the role of PD-L1 expression and gut microbiome, especially in the patient with response.

P1-09-20: Enhancer of zeste homologue 2 (EZH2) inhibition in Triple Negative Breast Cancer (TNBC) attenuates tumor growth in vitro and in vivo altering the tumor immune microenvironment.

Eswar Shankar, Rajni Kant Shukla, Gautam Sarathy, Kate Ormiston, Xilal Rima, Chunyu Hu, Divya S Patel, Radha vaddavalli, Deborah Ramsey, Gwen Fewell, Bhuvaneswari Ramaswamy, Eduardo Reátegui

Background: EZH2 component of the polycomb repressive complex 2 (PRC2) is a histone methyltransferase whose function is to methylate lysine 27 of histone 3. EZH2 is overexpressed in 49% of breast cancers and is associated with worse outcomes especially

in TNBC. EZH2 is overrepresented in African American and Hispanic women, suggesting that clinical targeting of this protein may particularly help improve the disproportionately poor outcomes in these populations. In addition to its role in metastasis, EZH2 regulates tumor immune microenvironment (TIME) by inhibiting T cell activation via suppression of MHC-1 antigen presentation pathway, upregulating PD-L1 expression causing suppression of an antitumor immune response. Current EZH2 inhibitors only targets the catalytic activity of EZH2, leaving its function as a gene activator unaffected. Despite the advancement in the discovery of inhibitors for EZH2 that attenuate its catalytic activity, resistance to these small molecules limits their use in solid tumors. The neurotransmitter dopamine via its D1 receptor activation in TNBC cell lines induces apoptosis and autophagy, as well as inhibits the invasion and regress in mammary tumors in vivo. In addition, dopamine D1 receptor signaling has been reported to attenuate the immunosuppressive effects of myeloid-derived suppressor cells (MDSCs) on T cell proliferation and IFN-g production. We hypothesize that combined treatment of dopamine D1 receptor agonist (A77636) and EZH2 inhibitors (GSK126) inhibits tumor growth and metastasis of TNBC cells both in vitro and in vivo.

Methods: To test the efficacy of the combination inhibiting metastasis we employed an in vivo model system to confirm the results we had obtained from our invitro 3D culture system and 3D organ-on-chip-based microphysiological (MPS) platform (SynTumor). 4-6 weeks old female NSG mice were injected with MDA-MB-231 cells on the breast fat pads. When the tumors became palpable, they were randomized into four groups, Vehicle, GSK126 (2mg/kg BW), A77637 (50mg/kg BW) and the combination. The drugs individually or in combination were administered intraperitoneally five days for 4 weeks. Tumor measurements were also done during the time and at the end of 4 weeks the animals were euthanized. The tissues, tumor, bone, blood, and spleen were harvested and processed for flow cytometer analysis. Tumor weight and volume were also calculated.

Results: The combination of GSK126 and A77636 demonstrated a synergistic effect inhibiting the tumor weight and tumor volume when compared to the individual treatments or the vehicle treated animals. These results matched with our in-vitro data, where the combination synergistically inhibited the growth of spheroids. in the microfluidic SynTumor model, the combination reduced circulating tumor cell numbers by half. The combination significantly decreased the monocyte population in the blood and tumor. Also, the EZH2 expression in the monocytes and neutrophils were significantly decreased by the combination.

Conclusion: Our data indicate that the combinatorial effect of DRD1 agonist and EZH2 inhibitor efficiently attenuates the EZH2-mediated tumor growth and innate immune environment in TNBC (This work is supported by DOD: W81XWH2010065, for Eswar Shankar). Dedicated in memory of Dr. Bhuvaneswari Ramaswamy.

P1-09-21: Metabolic Reprogramming in Breast Cancer Brain Metastasis Mouse Model: Insights from Transcriptomic Analysis

Julie Marin, Nadège Kindt, Sébastien Boutry, Lionel Larbanoix, Matteo Serra, Christos Sotiriou, Florence Lefranc, Fabrice Journé, Ghanem E Ghanem, Ahmad Awada

Breast cancer (BC) is the second leading cause of central nervous system (CNS) metastases, which include leptomeningeal metastasis (5%) and parenchymal brain metastasis (95%). Among BC subtypes, triple-negative breast cancer (TNBC) accounts for around 15-20% of all cases. This subtype is one of the most aggressive, with a higher risk of developing breast cancer brain metastases (BCBM). Brain metastases (BM) occur in approximately 10-30% of patients with advanced metastatic BC and are associated with poor prognosis. Recent studies suggest that cancer cells undergo metabolic reprogramming upon establishing in the brain, but the specific metabolic shifts remain unclear. This study aims to elucidate the metabolic signatures of BCBM xenograft cell lines by examining the expression of key genes involved in various metabolic pathways, with the ultimate goal of identifying novel therapeutic targets to hinder the progression of brain metastases.
To achieve this, we developed a mouse model of brain metastasis by injecting human breast cancer cells (MDA-MB-231) intracranially into immunodeficient mice. These injections were repeated three successive times, allowing us to harvest xenografted BCBM cells that progressively adapted to the brain environment with each injection. Cancer cell lines represent an effective way of modelling the disease. The BCBM xenograft cells, named BR1/BR2/BR3 to refer to the number of passages in the brain, were molecularly characterized using FACS and Short Tandem Repeat (STR) analysis to ensure the purity of the cell lines. We conducted transcriptomic analysis based on RNA purification and quantification to explore the modifications between our various brain xenograft cell lines. Our in vivo models demonstrated increased tumour aggressiveness, as indicated by a significant decrease in mouse survival rates correlated with the number of cycles of intracranial injections (Log-rank test, $p < 0.001$). These findings suggest genotypic modifications in our BCBM xenograft cell lines. Based on Bulk RNA-sequencing database, the Principal Component Analysis (PCA) plot revealed similarities between the BR2 and BR3 cell lines, which differ markedly from the Parental and BR1 cell lines. Moreover, the heatmap of Euclidean distances between the samples, based on normalised DESeq2 gene expression, supports this observation by showing similar gene expression profiles between the BR2 and BR3 lines. By selecting the human Reactome gene sets (C2 collection - GSEA database) to generate a more detailed heatmap, we identified the metabolic pathways differentiating the Parental and BR1 cell lines from the BR2 and BR3 cell lines. These key pathways include the integration of energy metabolism, lipid metabolism, and nucleotide metabolism. The comparison of the overall gene expression in the Parental cells with the BR1, BR2 or BR3 cell lines by volcano plot confirms several up- and down-regulated genes, including those involved in lipid metabolism (significant results for an adjusted P-value < 0.05 and for a Log2(Fold Change) threshold of 1). Finally, RT-qPCR revealed significant upregulation of gene sets involved in the beta-oxidation pathway (Two-way ANOVA with Tukey's Post Hoc test, $p < 0.05$), indicating a shift towards fatty acid metabolism during

tumour progression in the brain.
These findings suggest that metabolic adaptation is a critical feature of BCBM progression. To validate our results from the transcriptomic analysis, further proteomic and metabolomic analyses are required. These additional studies could pave the way for novel therapeutic strategies targeting specific metabolic pathways, potentially improving treatment outcomes for patients with BCBM.

P1-09-22: Mechanistic Insight into DAXX-Modulated Sensitivity to Chemotherapy in Triple Negative Breast Cancer

Debra Wyatt, Michelle Fernandez, Ava Gureghian, Kathy S. Albain, Clodia Osipo

Background: Mechanisms of response and/or resistance to chemotherapy, immunotherapy, or PARP inhibitors in triple negative breast cancer (TNBC) are not well understood. Death Domain-Associated Protein 6 (DAXX) is a multifunctional protein that promotes cell death, represses gene transcription, and maintains a heterochromatin state. We showed previously that DAXX is a potent inhibitor of breast cancer stem cells and resistance to endocrine therapy in estrogen receptor positive (ER+) breast cancer (Peiffer et al., Cancer Res. 2018). In this study, we explored the role of DAXX in TNBC and sensitivity to chemotherapy and olaparib in vitro and in vivo. We also investigated mechanisms by which DAXX modulated growth and response to chemotherapy in TNBC cell lines using RNA sequencing.
Methods: Proliferation and cell cycle analysis were performed for three TNBC cell lines (MDA-MB-231, BT549, and MDA-MB-468) that expressed DAXX or were depleted for DAXX using siRNA. Sensitivity to carboplatin, paclitaxel, and doxorubicin was determined by measuring proliferation. PARP-1 activity was assessed by detecting global protein PARylation levels using Western blotting. Olaparib was used to assess the role of PARP-1 activation in DAXX-depleted TNBC cell lines. Xenografts studies in vivo measured tumor growth of MDA-MB-231 DAXX-expressing or DAXX-depleted tumord treated with vehicle, paclitaxel, olaparib, or the combination. Overall survival of mice was assessed using Kaplan-Meier and a Mantel-Cox Log Rank test. RNA-sequencing was performed on RNA from two TNBC cell lines (MDA-MB-231 and MDa-MB-468) expressing DAXX or depleted for DAXX. The KMplotter tool interrogated recurrence free survival of patients with high DAXX versus low DAXX RNA expressing TNBC.
Results: Depletion of DAXX increased cell proliferation of three TNBC cell lines by promoting cell cycle progression through the S-phase compared to DAXX-expressing cell lines. DAXX-depleted TNBC cell lines were 2-5 fold more sensitive to carboplatin and paclitaxel, but not to doxorubicin as measured by IC50 calculations. Depletion of DAXX increased PARP-1 activity and modestly increased sensitivity to olaparib. In vivo, DAXX-depleted TNBC tumors grew at a faster rate than DAXX-expressing tumors. Although DAXX expression did not change the anti-tumor efficacy of paclitaxel or olaparib in vivo, overall survival of mice was 100% up to 40 days when TNBC tumors had low DAXX compared to only 25% of mice surviving with TNBC expressing high DAXX and treated with paclitaxel.

Mechanistically, RNA-sequencing followed by Gene Ontology pathway analysis showed that DAXX-depleted TNBC cells have higher expression of genes that regulate cell cycle progression and lower expression of genes that regulate the unfolded protein response. The KMPlotter tool revealed that patients (N=370) with TNBC have better recurrence free survival (hazard ratio = 1.79, P=0.0032) if their tumors have lower DAXX RNA levels. Conclusions: These results suggest that DAXX is a critical growth regulator and potential predictor of response to carboplatin or paclitaxel in TNBC. The mechanism by which DAXX modulates sensitivity to chemotherapy and drug resistance could be through regulation of cell cycle genes. Future studies will focus on elucidating the mechanism by which DAXX regulates these enriched genes and pathways and if DAXX is a potential predictive biomarker for recurrence free survival.

P1-09-23: Breast cancer-derived miR-4732-3p promotes breast cancer brain metastasis and brain-metastatic tumor microenvironment

Munazza S. Khan, Grace L. Wong, Mariana K. Najjar, Chuling Zhuang, Hui-Wen Lo

Breast cancer is the most frequently diagnosed cancer among women, constituting 15.2% of all new cancers diagnosed in the United States. Distant breast cancer metastasis accounts for the majority of breast cancer-related deaths; with brain metastases being the third most common site for metastatic breast cancer and the deadliest condition. Mechanisms that drive breast cancer brain metastasis (BCBM) are still not well understood. There has been evidence emphasizing the role of dysregulated microRNAs (miRNAs) in cancer progression and metastasis. Here, we aimed to identify miRNAs that may play important roles in BCBM. To this end, we conducted miRNA-sequencing analysis of extracellular vesicles isolated from the serum samples of 6 BCBM patients and 8 Stage I/II/III breast cancer patients, and identified 49 circulating miRNAs that were upregulated in BCBM patients compared to Stage I/II/III breast cancer. Upon further analysis using publicly available Gene Expression Omnibus (GEO) breast cancer patient datasets, we narrowed the list down to 12 miRNAs that were significantly enriched in brain metastases compared to matched primary breast tumors (GSE37407) and significantly increased in the serum of BCBM patients compared to breast cancer patients without metastases (GSE134108). Of the 12 identified miRNAs, the gene activation signature of four miRNAs (miR-374b-5p, miR-4732-3p, miR-181a-5p and let-7e-pre) significantly correlates with a Breast to Brain Gene signature. Furthermore, three of these miRNAs (miR-4732-3p, miR-374b-5p and miR-181a-5p) were correlated with shortened metastasis-free survival (MFS) and brain MFS of breast cancer patients. To further determine the involvement of miR-4732-3p, miR-374b-5p and miR-181a-5p in BCBM, we analyzed a breast cancer cell line panel for their expression levels. The results showed that only miR-4732-3p is upregulated in the human brain-tropic TNBC cell lines (MDA-MB-231-BRM and CN34-BRM) along with mouse brain-tropic TNBC line (EO771-BRM), compared to their parental lines. Importantly, miR-4732-3p overexpression increased net migration and proliferation in MDA-MB-231 and CN34 cells. Conversely, inhibition of miR-4732-3p led to decreased net migration and proliferation of MDA-MB-

231-BRM and CN34-BRM cells. Furthermore, overexpression of miR-4732-3p in CN34 cells led to a significant increase in mesenchymal biomarkers: fibronectin and vimentin, along with a decrease in epithelial biomarker E-cadherin. To gain an insight into the impact of tumor-derived extracellular vesicle miR-4732-3p on brain-metastatic tumor microenvironment, we determined whether it activates astrocytes, the most abundant brain cells that can promote BCBM when activated. Our results showed that miR-4732-3p mimic strongly activated astrocytes, as shown by immunofluorescence staining for glial fibrillary acid protein (GFAP; a biomarker for activated astrocytes). Furthermore, we isolated extracellular vesicles secreted from CN34 and MDA-MB-231 cells overexpressing miR-4732-3p to stimulate the astrocytes and observed a significant increase in GFAP expression. These results collectively demonstrate that breast cancer-derived miR-4732-3p plays a novel important role in BCBM by promoting migration, proliferation, and maintenance of a mesenchymal state of BCBM cells, along with activating astrocytes in the brain-metastatic tumor microenvironment.

P1-09-24: Cancer cell-derived exosomal miR-20a-5p inhibits CD8+ T-cell function and confers anti-programmed cell death 1 therapy resistance in triple-negative breast cancer

Xiangdong BaiI, Guohui Han, Weina Li, Feng Li, Yating Hao, Li Huang, Peng Bu

Abstract Background: Triple-negative breast cancer (TNBC) remains a formidable challenge in oncology due to its aggressive nature and limited therapeutic options. Our previous investigations have elucidated the role of miR-20a-5p in promoting TNBC cell proliferation, invasion, and migration while inhibiting apoptosis through the RUNX3/Bim/p21 pathway. We have also demonstrated a positive correlation between tissue-expressed miR-20a-5p and circulating miR-20a-5p (cirmiR-20a-5p) in TNBC patients, with elevated cirmiR-20a-5p levels associated with poorer prognosis, suggesting its potential as a prognostic biomarker. While immune checkpoint inhibitors show promise for TNBC treatment, resistance mechanisms remain poorly understood. This study builds upon these findings to investigate the role of cancer cell-derived exosomal microRNA-20a-5p (miR-20a-5p) in modulating CD8+ T-cell function and conferring resistance to anti-programmed cell death 1 (PD-1) therapy in TNBC.Methods: We employed a comprehensive approach combining in vitro cellular assays, in vivo mouse models, and clinical sample analyses. Circulating miR-20a-5p levels were quantified using qRT-PCR in plasma samples from TNBC patients, patients with relapsed TNBC, and healthy donors. Exosomes were isolated from TNBC cell lines and characterized using nanoparticle tracking analysis and transmission electron microscopy. The functional impact of exosomal miR-20a-5p on CD8+ T cells was assessed through cytokine production assays and cytotoxicity tests. Mechanistic studies utilized luciferase reporter assays and Western blotting to confirm direct targeting of NPAT and RUNX3 by miR-20a-5p. A humanized mouse model was employed to evaluate the impact of miR-20a-5p overexpression on anti-PD-1 therapy resistance. Immunohistochemistry was performed

on TNBC tissue samples to assess the correlation between cirmiR-20a-5p levels and CD8+ T-cell infiltration.

Results: Circulating miR-20a-5p levels were significantly elevated in TNBC patients compared to healthy donors (3.2-fold increase, $p<0.001$) and further increased in patients with relapsed TNBC (1.8-fold higher than primary TNBC, $p<0.01$). High cirmiR-20a-5p levels correlated with poor prognosis (HR=2.3, 95% CI: 1.8-2.9, $p<0.001$). TNBC cell-derived exosomes contained high levels of miR-20a-5p, suppressing CD8+ T-cell function by reducing cytokine production (IFNγ, TNF-α, granzyme B, and perforin) and tumor cell killing capacity. Mechanistically, miR-20a-5p directly targeted the 3'-UTR of nuclear protein ataxia-telangiectasia (NPAT) and RUNX3, decreasing their expression in CD8+ T cells and TNBC cells, respectively. In the humanized mouse model, tumors overexpressing miR-20a-5p exhibited resistance to anti-PD-1 therapy, with reduced CD8+ T-cell infiltration and MHC class I expression. Plasma exosomal miR-20a-5p levels were 2.5-fold higher in TNBC patients resistant to anti-PD-1 therapy compared to responders ($p<0.001$). Immunohistochemistry revealed a significant negative correlation between cirmiR-20a-5p levels and CD8+ T-cell infiltration in TNBC tissues ($r = -0.68$, $p<0.001$).

Conclusions: This study identifies exosomal miR-20a-5p as a novel mediator of CD8+ T-cell dysfunction and anti-PD-1 therapy resistance in TNBC. The miR-20a-5p/NPAT and miR-20a-5p/RUNX3 axes represent previously unrecognized mechanisms by which TNBC cells suppress anti-tumor immunity and promote tumor progression. Our findings suggest that circulating miR-20a-5p may serve as a potential biomarker for predicting immunotherapy response and prognosis in TNBC patients. Furthermore, targeting these miR-20a-5p-mediated pathways could be a promising strategy to enhance immunotherapy efficacy in TNBC, potentially improving outcomes for this aggressive breast cancer subtype. These results provide a strong rationale for further investigation of miR-20a-5p as a therapeutic target and prognostic marker in TNBC, opening new avenues for personalized medicine approaches in this challenging malignancy.

P1-09-26: Genomic analysis of circulating tumor DNA (ctDNA) from patients with triple-negative, HER2-mutant metastatic breast cancer treated with neratinib as monotherapy or in combination with trastuzumab in the SUMMIT trial

Komal Jhaveri, James Waisman, Sara A. Hurvitz, Adam Brufsky, Cynthia Ma, Maria de Miguel, Ella Evron, Nisha Unni, Olivier Tredan, Devalingam Malingham, Pavitra Rao, Karthigayini Sivaprakasam, Ronak Shah, Eric Buehler, Karmelina Charalambous, Georg F. Bischof, Daniel DiPrimeo, Lisa D. Eli, David Solit

Background: In HER2-mutant metastatic triple-negative breast cancer (mTNBC) cohorts of the SUMMIT basket trial (NCT01953926), patients treated with neratinib monotherapy (N; original cohort, n=10) appeared to achieve similar response rates but shorter time to

progression than those treated with N + trastuzumab (N+T; subsequent cohort, n=17). N: overall response rate (ORR) 40.0%; median duration of response (DOR) 3.8 months; clinical benefit rate (CBR; CR/mCR, PR/mPR or SD/mSD ≥ 24 weeks) 40.0%; median progression-free survival (PFS) 2.9 months. N+T: confirmed ORR 35.3%; median DOR 6.1 months; CBR 47.1%; median PFS 6.2 months [Jhaveri et al. J Clin Oncol 2024]. These findings were consistent with those reported for SUMMIT hormone receptor-positive (HR+) HER2-mutant mBC cohorts, in which patients treated with N or N + fulvestrant (N+F) experienced promising clinical responses but shorter DOR. In those cohorts, progression in a subset of patients coincided with emergence of additional HER2 mutations and/or amplification of the mutant allele [Smyth et al. Cancer Discov 2020] and addition of T to the combination of N+F prolonged response but did not preclude eventual progression nor emergence of additional HER2 or other alterations [Jhaveri et al. Ann Oncol 2023]. Here we describe serial circulating tumor (ct) DNA sequencing for patients with HER2-mutant mTNBC in SUMMIT who were treated with N or N+T and assessed potential mechanisms of acquired resistance.
Methods: Patients with HER2-mutant mTNBC received N (oral N 240 mg/d) or N+T (oral N 240 mg/d, IV T 8 mg/kg initially then 6 mg/kg q3w). Loperamide prophylaxis was mandatory during the first 2 cycles. Efficacy endpoints: confirmed ORR and CBR (RECIST v1.1 or modified PERCIST); DOR; PFS. ctDNA was collected at baseline, during treatment, and at the end of treatment and analyzed by next-generation sequencing. Samples were analyzed by the Memorial Sloan Kettering-Analysis of Circulating cDNA to Evaluate Somatic Status (MSK-ACCESS™) assay, which interrogates 129 cancer-associated genes.
Results: Longitudinal ctDNA sequencing data for 12 patients with HER2 mutation detected at least at baseline and end of treatment were available for 3 patients treated with N and 9 with N+T. One patient experienced investigator-assessed metabolic complete response (mCR), 6 experienced RECIST-evaluated partial response (PR), 3 had stable disease (SD) or metabolic stable disease (mSD), and 2 had progressive disease (PD) as best response. HER2 mutation variant allele frequencies (VAFs) decreased upon treatment in patients with response or SD and then increased upon progression, consistent with tumor response over time. Emergent mutations coincident with progression were detected in 1 patient treated with N and 5 with N+T who experienced initial response or SD and included on-pathway mutations HER2 T798I (N), ERBB3 E928G (N+T), MTOR A1832_A1842del (N+T), KRAS Q61H (N+T), TP53 R196Q (N+T), and TP53 E294* (N+T). Those with PD did not experience HER2 VAF decrease or acquisition of additional mutations.
Conclusions: Although limited by small numbers, addition of T to N in patients with HER2-mutant mTNBC, despite deepening and prolonging response, did not appear to preclude eventual emergence of either on-pathway (ERBB3) or off-pathway (KRAS, TP53) mutations. In contrast to observations in N+F+T-treated patients with HR+, HER2-mutant disease, no additional HER2 alterations were detected upon progression in N+T-treated patients with mTNBC in this small dataset. Future investigations may evaluate clinical utility of sequencing therapies targeted to mutations acquired in response to N-based therapy in patients with HER2-mutant mTNBC.

P1-09-27: MELK as a mediator of stemness and metastasis in aggressive subtypes of breast cancer

Breanna McBean, Reine Abou Zeidane, Samuel Lichtman-Mikol, Ben Hauk, Johnathan Speers, Savannah Tidmore, Citlally Lopez Flores, Priyanka Rana, Meilan Liu, Alyssa Santola, Alberto Montero, Alan P. Boyle, Corey W. Speers

Background: Triple-negative breast cancer (TNBC) constitutes 15-20% of all breast cancers and is characterized by the absence of estrogen (ER) and progesterone receptors and the lack of HER2 amplification. TNBC is notably aggressive, with limited treatment options, rapid metastasis, and high intratumoral heterogeneity, which may include a higher proportion of breast cancer stem cells. Maternal Embryonic Leucine Zipper Kinase (MELK) is a kinase normally expressed during embryonic development but reexpressed in breast cancers, especially in TNBC. High MELK expression in breast tumors correlates with a shorter time to metastasis in patients (HR 1.91, p = 4.4e-16). We hypothesized that MELK contributes to the aggressive phenotype of TNBC through its role in metastasis.
Materials and Methods: We utilized four breast cancer cell lines: two high-MELK expressing TNBC lines (MDA-MB-231, BT-549) and two low-MELK expressing ER-positive lines (MCF7, T47D). Genetic knockdown of MELK was achieved using doxycycline-inducible shRNAs or stable siRNA expression, while pharmacologic knockdown was conducted using the MELK inhibitor OTSSP-167. We also generated cell lines stably overexpressing MELK for overexpression studies. To assess the impact of MELK on self-renewal capacity, we performed mammosphere formation assays. Tumor invasion and scratch-wound assays were employed to evaluate invasion and migration, respectively. The chorioallantoic membrane (CAM) assay served as an in vivo model to study metastasis to the liver and lungs in chick embryos.
Results: Pharmacologic inhibition of MELK by OTSSP-167 in MDA-MB-231 cells led to a more than fourfold reduction in mammosphere formation efficiency compared to untreated controls (n=3, p=0.0059). Genetic knockdown via shRNA resulted in an approximately twofold reduction in mammosphere formation relative to non-targeting controls (n=2, p=0.054), supporting MELK's role in maintaining a stem-like phenotype. Additionally, siRNA knockdown of MELK in BT-549 and MDA-MB-231 cells significantly reduced invasion (n=4, p=0.0004; n=4, p=0.0023, respectively) and migration (n=6, p<0.0001 for both cell lines). Conversely, overexpression of MELK in MCF7 and T47D cells resulted in a twofold or near twofold increase in metastasis to the liver and lungs in the CAM assay (n=10, p<0.0001 for all conditions).
Conclusions: Our findings suggest that MELK plays a crucial role in the aggressive behavior of TNBC by promoting stemness, invasion, and metastasis. MELK inhibition reduces mammosphere formation, invasion, and migration, while its overexpression enhances metastasis in in vivo models. Confirmatory studies re underway in other subtypes of breast cancer. These results highlight the potential of targeting MELK as a therapeutic strategy to mitigate breast cancer metastasis and improve patient outcomes.

P1-09-28: Sociodemographic Experiences in Treatment (Tx) Patterns and Survival Outcomes in Women With Metastatic Triple-Negative Breast Cancer (mTNBC) in the United States (US): role of disparities

Sara M. Tolaney, Laura Spring, Yara George Abdou, Ioanna Ntalla, Emily Freeman, Adina Estrin, Nikoleta Sjekloca, Catherine Lai, Kevin Kalinsky

Background: TNBC is an aggressive, heterogenous disease that disproportionately affects women of color, specifically non-Hispanic Black women, younger women, and BRCA1/2 tumor mutation carriers. This study assessed the impact of sociodemographic factors on real-world tx patterns, biomarker testing, and survival outcomes in women with mTNBC in the US.
Methods: This retrospective observational cohort study used the US-based, longitudinal, electronic health record–derived, de-identified Flatiron Health database. Women aged ≥ 18 years with mTNBC who received first-line (1L) tx for metastatic disease between Jan 1, 2018 and Jul 31, 2022 (index period), were included. Data cutoff was Jan 2023. Demographics and metastatic tx patterns were described in relation to race (White, Black, Other), socioeconomic status (SES) index (1st quintile [Q1; lowest SES] to 5th quintile [Q5; highest SES]), region (Northeast, Midwest, South, West, or Other) and tx setting (academic or community practice). Cox proportional hazards regression was used to compare unadjusted and adjusted differences in survival outcomes by sociodemographic group.
Results: Of 10,967 women with metastatic breast cancer (mBC), 1555 (14%) had mTNBC. Among women with mBC, 13% of White women and 23% of Black women had mTNBC. For women with mBC in the Q1 and Q5 SES index, 18% and 11% had mTNBC, respectively. The proportion of women with mTNBC in the South US was 16% and ~12% in other regions. About 15% of women in both academic and community practices had the mTNBC subtype. For the women with mTNBC, 501 (32%) had no documented 1L tx during the index period. This includes women who may have received tx with no documentation. Overall, the characteristics of women without documentation of receiving 1L tx were similar to those who received tx. The proportion of women starting 1L tx, the median time to tx initiation (~1 month), and the type of 1L tx were similar across sociodemographic groups. Overall, 28% of women received 1L anti-programmed death-(ligand)-1–based tx, with similar proportions across sociodemographic groups.
Of 930 women who received 1L tx, 55% had evidence of BRCA1/2 testing. The highest testing proportions were found in the West US (63%) and in academic practices (59%). The proportion of women tested was similar across race and SES quintiles. Of 43 women with documented BRCA1/2 mutations, 56% were treated with poly-ADP ribose polymerase inhibitors (PARPis) in any line during the study period, with the lowest proportions observed in Black women (33%, n=2), in Other (non-White) race (30%, n=3), in the lowest SES quintile (36%, n=4) and in the West region (33%, n=2), and the highest proportions were observed in White women (68%, n=15) and in the Midwest (71%, n=5), though sample size was small.
For women receiving 1L tx, there were no statistically significant differences in real-world overall survival (rwOS) within sociodemographic groups before and after adjusting for

confounding factors (P > 0.05). Median rwOS among White and Black women was 12.3 and 11.3 months, respectively. Numerically, among the SES quintiles, the longest rwOS was 14.1 months for women in Q4; the shortest in Q2 (10.7 months). Median rwOS by region ranged from 11.3 months in the Northeast to 13.4 months in the West. Women treated in academic and community practices had a median rwOS of 14.5 and 11.3 months, respectively. Conclusions: Women with mTNBC who were White and treated in the West/high SES index/academic setting had numerically longer rwOS vs non-White/other regions/low SES index/community settings, but this was not statistically significant. The types of tx received were similar across groups, with some differences in use of PARPis. Survival was poor across all groups, highlighting an unmet need for all women with mTNBC.

P1-09-29: Safety, efficacy and emerging biomarker data from the Phase Ib part of a Phase Ib/II clinical study of nadunolimab in combination with gemcitabine and carboplatin in patients with advanced triple negative breast cancer (TRIFOUR study)

Marta Santisteban Eslava, Agostina Stradella, Silvia Antolín Novoa, Pablo Tolosa, Javier García Corbacho, Angel Guerrero-Zotano, Manuel Ruíz Borrego, Irati Garmendia, Paloma Petit de Prado, Juan José Soto-Castillo, Cristina Reboredo, Manuel Alva, Elin Jaensson Gyllenbäck, Petter Skoog, Nedjad Losic, Ignacio Garcia-Ribas, Maribel Casas, Isabel Romero-Camarero, Rosalía Caballero, Sara López-Tarruella Cobo, Susana Bezares, María Muñoz Caffarel

Background: Nadunolimab is a first-in-class, antibody-dependent cell-mediated cytotoxicity enhanced, monoclonal antibody targeting IL1 Receptor Accessory Protein (IL1RAP) on cancer cells, cancer stromal cells, and tumor infiltrating immune cells. Nadunolimab blocks both IL1α and IL1β signaling which is linked to tumor progression, therapy resistance, and immune suppression signals. The TRIFOUR trial (NCT05181462) is a Phase (Ph) Ib/II study evaluating nadunolimab in combination with chemotherapy as a 1L or 2L therapy in advanced triple negative breast cancer (aTNBC) patients. In the TRIFOUR PhIb part, nadunolimab was administered at either 1 mg/kg (n=3) or 2.5 mg/kg (n=12) in combination with gemcitabine (1000 mg/m^2) and carboplatin (AUC 2 mg/mL/min) on days 1 and 8 of each 3-week cycle. Here we present updated safety and efficacy data along with emerging translational research results from the 15 PhIb patients and a characterization of aTNBC.
Methods: PhIb, serum and blood samples were collected pre-treatment and during the study and analyzed for soluble biomarkers and blood immune cell populations by ELISA, the Olink Immuno-oncology 92plex protein panel and hematology. In a different set of aTNBC patients with ≤ 1 previous line of therapy for locally advanced or metastatic BC, biopsies (n=22) were characterized for expression of IL1RAP and IL1α by immunohistochemistry and blood cells were characterized for IL1RAP expression by flow cytometry (n=31).
Results: The PhIb safety profile was comparable to historic control data for gemcitabine plus carboplatin alone. Grade ≥3 treatment-emergent adverse events were reported in 12

(80%) patients, leading to treatment discontinuation in 1 (7%) patient. Five (33%) patients experienced serious AEs, febrile neutropenia being the most frequent (2 [13%] patients). Updated overall response rate was 60% (95% CI: 32-84), median progression-free survival was 6.2 months (95% CI: 3.7-8.3) and median overall survival was 12.8 months (95% CI: 8.5-NE). No PhIb patients remain on treatment. Emerging translational analyses comparing C1D1 and C2D1 time points identified a decreased absolute neutrophil count (ANC) (Hodges-Lehmann estimate and confidence interval for difference (HLE), -1.33, 95% CI: -2.2 to -0.73, P=.003) and neutrophil to lymphocyte ratio (HLE, -1.0, 95% CI: -2 to -0.4, P=.005) as well as decreased C reactive protein (HLE, -6.0, 95% CI: -19.2 to -0.4, P=.001). IL8 was also decreased on treatment, with a trend of correlation to a better outcome.
Characterization in the separate set of patients showed widespread IL1RAP expression on tumor and stromal cells in all biopsies while IL1RAP-positive immune cells were found in 20 out of the 22 (91%) biopsies. IL1α expressing tumor cells were present in all biopsies, as were IL1α positive immune cells. All blood samples characterized by flow cytometry contained IL1RAP-positive immune cells with IL1RAP expression being notably high on monocytic myeloid-derived suppressor cells.
Conclusions: Data from the PhIb TRIFOUR study indicate that nadunolimab at 2.5mg/kg, combined with gemcitabine plus carboplatin, has acceptable safety and tolerability and shows promising antitumor activity. Analyses of immune cell subsets and biomarkers showed potentially beneficial effects on cells and markers related to inflammation and immune response, such as decreased ANC and IL8. Characterization of aTNBC affirmed IL1RAP expression on tumor cells, cancer fibroblasts as well as tumor-associated and blood immune cells. In the biopsies, IL1α was expressed both in cancer and immune cells. The randomized PhII part of the trial is currently enrolling patients at 2.5mg/kg and more translational analyses are underway.

P1-09-30: Characteristics associated with sacituzumab govitecan response in the real-world setting

Megan Wong, Alexis LeVee, Nora Ruel, Heather McArthur, Joanne E. Mortimer

Introduction: Sacituzumab govitecan (SG) is a TROP2-directed antibody-drug conjugate that is approved as a 2nd-line therapy for metastatic triple-negative breast cancer (TNBC) and 3rd-line therapy for metastatic, endocrine-resistant, hormone receptor-positive HER2-negative (HR+ HER2-) breast cancer. TROP2 is expressed in most breast cancers; however, it is unknown whether the degree of estrogen receptor (ER)-positivity and other characteristics impact outcomes of SG. We sought to explore associations between patient/tumor characteristics and SG response in metastatic TNBC and HR+ HER2- breast cancer.
Methods: We performed a single-center, retrospective chart review of patients with breast cancer who received SG in the metastatic setting. Data collected and analyzed included age, gender, race and ethnicity, BMI, UGT1A1 status, SG dosage, number of prior lines of therapy, ER percentage, PR percentage, HER2 score, and reasons for discontinuing SG. Clinical and

baseline characteristics were summarized using descriptive statistics, and univariate and multivariate cox regression was used to identify predictors associated with progression-free survival (PFS).
Results: Between April 2020 and November 2023, 126 females and 2 males received SG as a median 4th line of therapy (range 1-13). Median age was 56 years, median body mass index (BMI) was 24.7, and 74.2% of patients had TNBC. Most patients experienced disease progression or discontinued SG due to death (85.2%), while 11 (8.6%) patients discontinued due to toxicity, 1 (0.8%) patient entered hospice, and 7 (5.5%) patients are still on SG to date.
In univariate analyses, ER percentage predicted for PFS (p= 0.045): ER positivity (>50%) was associated with poorer PFS compared to ER ≤10% (HR 2.02, 95% CI 1.10-3.72, p=0.024). Higher number of prior therapy lines (p=0.0006) was also associated with inferior PFS, while BMI>=30 (p=0.026) and the occurrence of dose reductions (p=0.018) demonstrated improved PFS. Multivariate analysis supported improved PFS observed in patients with a BMI ≥30 (HR 0.57, 95% CI 0.34-0.93, p=0.012) and in patients who were dose-reduced (HR 0.67, 95% CI 0.46-0.99, p=0.044). Not surprisingly, the final predictor in the multivariate model was an indication of 6+ lines of prior therapy which led to poorer PFS than for those whom SG was a 1st or 2nd line (HR 2.54, 95% CI 1.51-4.26, p=0.0004).
Conclusion: Obesity and dose reductions predicted improved PFS while having 6+ previous lines of therapy predicted poorer PFS. Our data suggests that patients with a higher BMI and dose reduction have improved outcomes with SG, which may be attributed to underlying pharmacokinetic mechanisms and optimal dosing strategies that must be further explored.

P1-10-01: Overall survival and treatment patterns of incident triple negative breast cancer diagnosed in 2015-2020: single centre study in Poland.

Roman Dubianski, Magdalena Rosińska, Aleksandra Konieczna, Roman Dubiański, Jan Poleszczuk, Hubert Pawlik, Ewa Szombara, Renata Sienkiewicz, Izabela Lemańska, Elżbieta Brewczyńska, Anna Górniak, Katarzyna Pogoda, Zbigniew Nowecki, Eryk Kamiński

Background: Triple Negative Breast Cancer (TNBC) is one of the subtypes of breast cancer, lacking the expression of the estrogen (ER), progesterone (PgR) and HER2 receptors. TNBC accounts for 10-15% of all breast cancer (BC) cases, but is responsible for approximately 40% of BC deaths. Significant advances in therapeutic approaches have been noted over the past 10 years, including the widespread use of neoadjuvant therapy, post-neoadjuvant treatments, and more recently, the addition of immune checkpoint inhibitors. We report real-world data on overall survival in long term follow-up of TNBC of patients diagnosed before the introduction of pembrolizumab into routine care, as a benchmark for the future evaluation of the impact of newer regimen. We base on experience of the Maria Sklodowska-Curie National Research Institute of Oncology in Warsaw (MSCI).
Methods: Data were extracted from MSCI hospital information system on cases admitted ≥2x with C50 ICD-10 code, undergoing surgery, systemic treatment +/- radiotherapy in

2015-2020. Vital status data for the selected cohort were obtained from the national census registry as of 2023.10.30. Overall survival was estimated from the first visit in MSCI until the date of death or vital status check with standard statistical techniques.
Results: The annual number of BC patients treated at NIO-PIB ranged from 6,359 to 7,548. During the study period, 8,103 patients were admitted for the first time, of which 856 (10.6%) were TNBC cases. In 2020, as a result of the COVID-19 pandemic, there was a significant 22% decline in new admissions. We analysed 604 patients, median age 58, range 26-93, not treated before admission to MSCI. Approximately 33% of them were overweight with BMI > 25, 12% had BMI ≥ 30 kg/m2. Roughly 20% of patients had a positive BRCA1/BRCA2 mutation status, while half had an unknown BRCA status. Most cases were diagnosed at stages IIA (36.1%) and IIB (23.3%); 68.5% received neoadjuvant chemotherapy (NAC), with a significant increasing trend (44.1% in 2015 to 88.7% in 2020). Among those receiving neoadjuvant chemotherapy (NAC), 26.3% received post-NAC treatments, with a notable upward trend. Excluding metastatic cases breast conserving surgery (BCS) was performed in 245 (43.6% of all patients and 47.6% of patients operated in MSCI). Among surgical cases the share of BCS in the NAC and non-NAC groups was: 66.7% and 79.5% in cT1 (p=0.195), 61.0% and 36.4% in cT2 (p<0.0001), 12.2% and 6.7% in ≥cT3 (p=0.53). Among cN0 patients, 74.4% had sentinel node biopsy (SLNB) without axillary lymphadenectomy (ALND).
The median follow-up was 54.3 months, ranging from 1.4 to 105.6 months, overall 168 patient died (27.8%), including 33 of 35 patients with initially metastatic cancer (94.3%). The 5-years overall survival was 72.6% (69%-76.4%), 76.8% (73.3%-80.5%) and 4.3% (0.7%-24.9%) among all patients, non-metastatic and metastatic cases, respectively. The 5-years survival improved by diagnosis year from 60.5% for patients diagnosed in 2015 to 77.1% among those diagnosed in 2020. In multivariable Cox proportional hazard model on non-metastatic subgroup, adjusting for age, stage and ECOG, the use of neoadjuvant was associated with improved survival (HR 0.5, 95% CI 0.3-0.8, p=0.0017) and the year of diagnosis was insignificant.
Conclusions: We confirmed improving prognosis for the TNBC patients in a large real-life cohort in Poland. The use of neoadjuvant therapy was increasingly becoming the gold standard in patients with TNBC during the study period, leading to an increased number of breast-conserving surgeries coupled with improved overall survival. Notably, a large proportion of patients in our cohort had BRCA1/BRCA2 pathogenic mutations suggesting that they could further benefit from newer therapies like PARP inhibitors.

P1-10-03: Real World Effectiveness and Economic Outcomes of First Line CDK4/6 Inhibitors in Combination with AI for HR+/HER2- Metastatic Breast Cancer in a US Medicare Eligible Population

David Veenstra, Adam Brufsky, Timothy Pluard, Lucille Sun, Rickard Sandin, Stella Stergiopoulos, Xianchen Liu, Troy Williams, Sean Sullivan

Background: Cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i) in combination with an aromatase inhibitor (AI) are the preferred first-line (1L) treatment for hormone receptor positive, human epidermal growth factor receptor 2 negative (HR+/HER2-) metastatic breast cancer (mBC). There is increasing interest in the use of real-world evidence to inform policy decisions in the United States. In an observational study of adults with mBC, mean total costs ranged from $172,700 to $249,200 annually in the first four years after diagnosis. While prior cost-effectiveness studies have assessed CDK4/6is palbociclib, ribociclib, and abemaciclib using outcomes from placebo-controlled clinical trials, no such comparisons have been made using real-world evidence, nor in a US Medicare-eligible population. The objective of this study was to estimate the clinical outcomes and healthcare costs of 1L CDK4/6i treatment using real-world data.
Methods: We projected patient time spent in progression-free, progressed disease, and death health states using a partitioned survival model derived from progression-free survival (PFS) and overall survival (OS) curves. Survival outcomes for palbociclib + AI were informed by an analysis of patients aged ≥65 with HR+/HER2- mBC from the Flatiron Health Analytic Database, which included 808 patients treated in 1L with palbociclib + AI. Based on a targeted literature review, ribociclib + AI outcomes were modeled using relative hazard rates from OPAL (NCT03417115), a prospective longitudinal multicenter cohort study that used inverse probability of treatment weighting by propensity score analysis to make an adjusted comparison between ribociclib (n=235) and palbociclib (n=388) for both PFS (hazard ratio [HR]: 1.01 [95% confidence interval [CI]: 0.80 – 1.26]) and OS (HR: 0.99 [95% CI: 0.72 – 1.29]) (Thill, SABCS 2023, PO1-04-12). All-cause medical costs in inpatient, outpatient, and emergency department settings and drug costs for CDK4/6i + AI regimens were based on an analysis of patients in Optum's Clinformatics DataMart who were aged ≥65, enrolled in Medicare Advantage and treated with CDK4/6is for HR+/HER2- mBC (n=2,220). Drug costs reflect real-world utilization accounting for dose adjustments and wastage over the course of treatment. The primary analysis was conducted from the Medicare perspective using a lifetime timeframe in a hypothetical cohort of patients with a mean age of 73 years. Sensitivity analyses were performed to assess the robustness of the results to plausible variation in input values.
Results: Life years (LY) with palbociclib + AI and ribociclib + AI were similar, with base-case projections of 5.29 and 5.33 LYs, a difference of 15 days. Total lifetime healthcare costs were also similar in the base-case ($818,200 and $815,300, respectively, a difference of $2,900 over 5 years), with over half comprised of medical costs. Sensitivity analyses indicated no difference in LYs or total healthcare costs between palbociclib + AI and ribociclib + AI. Using the reported 95% CI for the OS HR, LY gained difference between palbociclib + AI and ribociclib + AI ranged from -0.91 to +1.34 LYs. Similarly, difference in total healthcare costs ranged from -$79,500 to +$101,600 over the projected lifetime of patients. Analysis using abemaciclib real-world comparative effectiveness data is ongoing and will be presented at the conference.
Conclusion: Based on real-world data, our analysis suggests that palbociclib + AI and ribociclib + AI demonstrate similar life expectancy and healthcare costs in elderly women with HR+/HER2- mBC. Additional large comparative effectiveness studies of CDK4/6is, that

appropriately adjusts for patient differences and assesses both PFS and OS are needed to verify the findings.

P1-10-04: First results of the WAVES study: Significant increase of patient satisfaction with longer initial consultation duration for breast cancer diagnosis

Nina Ditsch, Melitta B. Koepke, Renate Haidinger, Brigitte Welter, Ute-Susann Albert, Christoph Aulmann, Traudl Baumgartner, Stefanie Corradini, Christian Dannecker, Johannes Ettl, Nadia Harbeck, Anne Herrmann-Johns, Christian Hinske, Marion Kiechle, Alkomiet Hasan, Klaus E. Jopp, Monika Klinkhammer-Schalke, Oliver Koelbl, Inaki Soto-Rey, Christoph Jung, Olaf Ortmann, Anna Rubeck, Gernot Müller, Verena Schmid, Frank Kramer, Franziska Feiler, Eva Schildmann, Stephan Seitz, Miriam Reicherts, Nadja Will, Achim Woeckel, Eva Schumacher-Wulff, Carl-Mathis Wild, Verina Wild, Carolin C. Hack, Rachel Wuerstlein, Susanne Kinnebrock, Miriam Kunz, Peter A. Fasching, Stefan Schiele, Matthias W. Beckmann

Background: The "WAVES" (Widening Aims and giving patients a Voice for Expanded Structures in breast cancer care jointly developed by patients and physicians) study primarily aims to assess current care structures for breast cancer with a special focus on physician-patient-communication. In the long term, an improved Patient-Centered Communication-Care Concept (PCCCC) for breast cancer will be developed. WAVES is conducted within and funded by the BZKF (Bayerisches Zentrum für Krebsforschung, Bavarian Cancer Research Center) Network.
Methods: The study is structured as a two-part questionnaire for breast cancer patients and a corresponding questionnaire for physicians. Here, we present the first results of the first-part questionnaire for patients regarding the duration of the first diagnosis consultation and satisfaction with this conversation based on the evaluation of 1000 participants.
Results:Participants were between 23 and 89 years old (mean: 59.18 years), and mostly female (98%). More than every second patient felt shocked by the first diagnosis of breast cancer (54.8%). There was a significant association between longer initial consultation duration and higher patient satisfaction ($p < 0.001$). If the conversation lasted more than 30 minutes, 90.1% of the patients rated the duration as "just right", whereas only 12.7% rated “just right” in case of 10 minutes duration. With a first consultation lasting 30 minutes or longer, patients stated more frequently that they felt better informed ($p<0.001$), had fully or substantially understood the content ($p < 0.001$) and felt well prepared for further treatment decisions ($p < 0.001$). Conclusions:These results show a significantly higher satisfaction and better preparation of patients with initial breast cancer diagnosis if the initial consultation with a physician lasted 30 minutes or more. The need for improved communication structures, offering breast cancer patients appropriate time frames, has thus been clearly demonstrated by the cross-sectional survey of the WAVES study. Yet, this need for longer conversations not reflected in the current reimbursement structure. However, study results such as these show a clear need to integrate this in the future in order to ensure optimal care for breast cancer patients.

P1-10-05: Real-World Molecular Profiling After CDK4/6 Inhibition in Advanced Breast Cancer: Analysis of the SOLTI-1903 HOPE Study

Elia Segui, Rubén Olivera-Salguero, Juan Miguel Cejalvo, Mafalda OliveiraPablo Tolosa, Pablo Tolosa, Maria Vidal, Marcos Malumbres, Joaquín Gavilá, Cristina Saura, Sonia Pernas, Rafael López, Mireia Margelí, Judith Balmaña, Montserrat Muñoz, Isabel Blancas, Valentina Boni, Eva Ciruelos, Elena Galve, Antonia Perelló, Raquel Gómez-Bravo, Isabel García-Fructuoso, Susana de la Cruz, Miguel de la Hoya, Teresa Manchón, Juan Manuel Ferrero-Cafiero, Helena Masanas, Rosa Olmos, Gema Rodríguez, Amparo Medina, Maria José Prieto, Aleix Prat, Ana Casas, Tomás Pascual

Background: The optimal treatment strategy for patients (pts) with HR+/HER2- advanced breast cancer (ABC) progressing on first-line endocrine therapy (ET) and CDK4/6 inhibitors (CDK4/6i) is influenced by the molecular alterations driving resistance to this combination. However, financial and logistical challenges hinder the routine implementation of next-generation sequencing technologies, leading to disparities in patient care. To address these issues, the SOLTI-1903 HOPE study (NCT04497285) aims to assess the feasibility of a molecular screening program that actively involves pts with ABC, providing insights into the genomic landscape and improving access to matched-targeted therapies in Spain.
Methods: The SOLTI-1903 HOPE study is a Spain-wide patient-centered study in which pts with ABC actively manage their enrollment, participation, and follow-up through a digital tool. Pts provide clinical data and tumor tissue samples for FoundationOne CDx (F1CDx) analysis. At disease progression (PD), pts undergo a liquid biopsy (LBx) at a local laboratory to be analyzed using the Guardant360 (G360) panel. Clinical and molecular outcomes are evaluated by a multidisciplinary Advisory Board, which interprets the observed alterations and recommends potential routine or clinical trial-based targeted therapies. The primary endpoint of this sub-analysis is to evaluate the genomic profile of pts with ABC who progressed on previous CDK4/6i.
Results: Of the 163 pts enrolled in HOPE who received first-line ET + CDK4/6i, 119 experienced documented PD. Of the 98 pts with a LBx result after ET + CDK4/6i, 22 (22.4%) had the blood extraction immediately after progressing to this treatment; median time from PD on ET + CDK4/6i to LBx was 9.2 months (mo) (range 0.07-64.1). ctDNA was detected in 97 pts (98.9%) with a median of 3 genomic alterations per patient (IQR 2-5, range 1-22) and a median variant allele frequency of 0.7% per alteration (IQR 0.2-3.2%, range 0.02-86.6%). ESCAT level I-II alterations were identified in 71pts (73.2%). Most frequent mutations were PIK3CA (44.3%) and ESR1 (34%). BRCA1/2 mutations occurred in 11.3% of pts, ERBB2 in 6.2%, and PTEN in 7.2%. Notably, co-occurring mutations involving >2 targetable alterations were found in 24 pts (24.7%), predominantly involving alterations in ESR1 and PIK3CA/PTEN/AKT1 pathway (58.3%).
Only 24 pts had F1CDx performed on a tissue sample obtained after first-line ET+CDK4/6i. Median time to tissue obtention was 12.1mo (range 0.23-47.8). Most frequent biopsy sites were liver (37.5%), breast (25%), and skin (16.7%). Median TMB was 3 (IQR 1-4, range 0-18), and the median number of genomic alterations per patient was 8.5 (IQR 5-10, range 2-16). ESCAT level I-II alterations were found in 16 pts (66.7%) and co-occurring targetable

alterations in 4 (16.7%), with no significant differences vs. LBx (p=0.5 and p=0.4, respectively). Most frequent mutations were TP53 (50%), ESR1 (37.5%), and PIK3CA (29.2%).
In 20 pts with both LBx and tissue samples obtained after ET+CDK4/6i, ESCAT I-II alterations were found in 60% and 70% with G360 and F1CDx, respectively (p=0.5), with a concordance rate of 73.3%.
Among 114 pts with follow-up clinical data, 17/55 pts (30.9%) with PIK3CA mut received targeted therapy after inclusion in HOPE; 7/55 (12.7%) had received it previously. None of the patients with BRCA1/2, ERBB2, ESR1, AKT1, or PTEN mutations has received targeted therapy after enrollment.
Conclusions: Over two-thirds of pts progressing on CDK4/6i present with ESCAT I-II level alterations detected via tumor or liquid biopsy. Notably, 15-25% of these pts exhibit co-occurring targetable alterations. In our study, the most frequently targeted alteration was PIK3CA mut, due to lack of approval for targeted therapies for other ESCAT I-II alterations in Spain during the study period. Addressing current barriers to targeted therapies is crucial for expanding options for pts with ABC.

P1-10-06: DETERMINANTS OF SURVIVAL IN MALIGNANT PHYLLODES TUMOR OF THE BREAST: ANALYSIS OF A POOLED DATABASE

Philip Haddad, Millicent Amankwah, Ankita Gupta

Background: Phyllodes tumors are rare fibroepithelial neoplasms of the breast, classified into benign, borderline, and malignant types based on histological features. These tumors account for less than 1% of all breast tumors, and malignant types are rare but can metastasize to organs such as the lung, bone, and brain. While their management often involves surgical resection with clear margins to prevent recurrence, their prognostic factors are not well characterized. We conducted this pooled database analysis to identify key factors that affect the clinical outcomes of malignant phyllodes tumor of the breast (MPB).
Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, prognostic factors, and clinical outcomes, we compiled a pooled database of cases that fit the diagnostic criteria for malignant phyllodes tumor of the breast. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on survival outcomes.
Results: Ninety-seven patients with confirmed MPB were identified, the majority being females (97%). The median age was 48. Fifty-four percent involved the right breast. The median duration of symptoms before diagnosis was 7 months. Axillary lymph nodes were involved in 14% of cases at presentation. The median OS, DFS, and RFS of the whole cohort were 36, 36, 22 months, respectively. Patients younger than 48 had better median OS (60 vs. 28 months, p=0.026). Left MPBs had worse OS (17 vs. 60 months, p=0.004) as well as DFS and RFS. Size>10cm and involvement of axillary LN had numerically worse OS, DFS, and

RFS but did not reach statistical significance. Time to recurrence <12 months was associated with worse OS (13 vs. 60 months, p=0.001). Adjuvant chemotherapy and adjuvant radiation numerically improved DFS but did not reach significance. However, the latter significantly improved RFS (p=0.046). The type of breast surgery, axillary dissection, and margin status did not impact OS. Palliative interventions using mutlimodalities seem to have numerically better OS especially when palliative surgery is involved, though it did not reach statistical significance. Lastly, when compared to borderline phyllodes tumors of the breast cohort, MPB demonstrated a worse median OS (36 months vs NR, p=0.04).
Conclusion: This study presents updated clinicopathologic data from a large, pooled cohort of patients with MPB. It identifies age, laterality, and time to recurrence <12 months as critical determinants of OS in the entire cohort. It confirms the more aggressive course and worse outcomes when compared to borderline phyllodes tumors of the breast.

P1-10-07: PROgress Tracker Breast Cancer Registry: Feasibility of a Longitudinal Peer-Led, National Patient-Reported Outcomes (PRO) Registry

Omar F. Khan, Doris Howell, Shaniah Leduc, Kimberly Carson, Michelle Dean, Amanda JW Gibson

Objective: PROgress Tracker Breast Cancer Registry is a national longitudinal, non-interventional patient-reported outcome measure (PROMs) registry, using a novel, peer-to-peer engagement and retention model directed by patient advocacy group Breast Cancer Canada and database managed by the POET Program. Here, we report initial PROMs results, demonstrating feasibility to amplify the patient voice and inform evidence-based care across Canada.
Methods: PROgress Tracker, launched in October 2023 has a 10-year enrollment goal of Canadians with Stage 0-IV breast cancer. Participants self-refer for registry inclusion and complete a series of validated PROMs via a digital platform every three months for up to 10 years.
Participants self-report demographic, socioeconomic and clinical data (age, social structure, employment, stage, molecular tumor markers, treatments, treatment-related impacts (adverse events, health-related quality of life) and global measures of wellbeing (mental health, social support, financial wellbeing, sexuality, physical functioning) through a series of questionnaires and PROMs. PROMs are dynamic, tailored to the participant's current status at each data collection timepoint.
Results: To date, 485 individuals have enrolled in PROgress Tracker, representing all Canadian geographical regions, including 17% in rural/remote locations. Three-month follow up survey response was 65%.
Socioeconomic data was reported by 399 participants: 94% identify as Caucasian, 28% report an active caregiving role to children or others, 61% are currently employed; 52% reported financial stress. 251 participants provided diagnostic, global functioning and treatment-specific PROMs data.

Diagnoses spanned 1997-2024 (median 2021). 76% reported early/localized stage (Stage 0 - II) disease at diagnosis. 45% reported receiving BRCA mutation testing, of which 15% were positive; 7% report a recurrence, and 4% have metastatic disease. 91% received oncological resection, 71% radiation therapy to the breast (RT); 76% systemic anti-cancer therapy (SACT) (hormonal, cytotoxic, immune checkpoint inhibitors or targeted therapies). Participants reported impairment in overall health-related quality of life (median FACT-B Total score 82.6 out of 148). 16% of participants reported moderate-severe anxiety, while 22% reported moderate-severe insomnia. 36 participants currently on SACT reported at least one adverse event, with 22 (61%) reporting adverse events 'frequently' or 'always' [PRO-CTCAE Systemic Therapy Subset]. Participants ever having radiotherapy (RT) reported moderate function (median 52) and low symptom (median 28) scores [EORTC-QLQ-BR23]; 78% of participants currently receiving RT reported mild adverse events, while 44% reported serious adverse events.
Conclusion: Capturing the lived experience throughout a breast cancer journey and integrating the use of validated PROMs into precision medicine is integral to driving patient-centered change in healthcare systems. Initial directional data from PROgress Tracker has demonstrated ability to capture a wide range of real-world evidence, suggesting that longitudinal digital capture, peer-to-peer involvement and real-time PROMs acquisition is feasible and can yield data of appropriate caliber to inform best practice, health care policy, and identify additional supports to improve outcomes. Efforts in recruitment and retention strategies are a current focus.

P1-10-08: Characterization of breast cancer subtypes in advanced real-world setting: the GEICAM/2014-03 (RegistEM) study

Isabel Alvarez, Angel Guerrero-Zotano, Silvia Antolín, Josefina Cruz, Cesar A Rodriguez, Ariadna Tibau, Purificación Martínez, Catalina Falo, María Hernández, Mireia Margeli, Ana Miguel, Raquel Andrés, Jose I. Chacón, Encarna Adrover, Miguel Corbellas, Iria González, Álvaro Rodríguez-Lescure, Antonio Antón, Maria Marin, César Gomez Raposo, Ana Isabel Ballesteros, Silvia Varela, M. Jose Echarri, Diana Moreno, Sonia Servitja, Jose Luis Alonso-Romero, M. Jose Escudero, Susana Bezares Montes, Federico Rojo, Sara López-Tarruella

Background: Breast cancer (BC) is a heterogeneous disease characterized by distinct subtypes, each with different prognoses and divergent treatment responses. Understanding the real-world distribution of BC subtypes in the advanced setting, and their clinical implications is the primary objective of the RegistEM study.
Methods: Female and male patients (pts) with advanced BC (ABC), either recurrent (rEBC) or de novo metastatic (dnMBC), diagnosed since Jan-16, were enrolled in this ambispective, non-interventional cohort study. Biological samples (primary tumor, metastatic lesions, blood) were also collected. In the current analysis, 1951 pts from 38 GEICAM sites were included (database ongoing, cut-off date 22-Apr-2024). BC subtype was assessed by immunohistochemistry with or without in situ hybridization, in the most recent tumor sample before 1st-line (metastatic lesions, and if not available, primary BC). The definition

of clinical subtypes was according to standard criteria, and information whether there were changes (unstable) or not (stable) in BC subtype between primary and metastatic tumor lesions is reported.
Results: 63%, 34% and 3% pts had rEBC, dnMBC and unresectable locally ABC (ULABC), respectively, with development of distant metastases in 97% pts; 1/3 – 1/2 were dnMBC, but 1/4 in HR−/HER2− pts, and median time to rEBC reduced as HR expression decreased. Median age was 60 years, 98% were white and 99% female (70% postmenopausal at ABC diagnosis). BC clinical subtypes distribution was HR+/HER2− 68% (HER2-low 45%), HR+/HER2+ 12%, HR−/HER2+ 6%, HR−/HER2− 10% (HER2-low 34%), unknown (UK) 4%; 57% cases were assessed in metastatic lesions, 40% in primary tumors and 3% UK. At ABC diagnosis, bone (63%) was the most frequent metastatic location. Visceral involvement was different between subtypes ($p<0.001$, chi-square test) in comparison with no visceral disease. Liver and lung were the most common visceral locations, with the latter higher (40%) in HR− BC subtypes. Within soft tissue metastases, lymph nodes were the most common location in all BC subtypes (>40%). Brain metastases were present in 10% HR− BC subtypes. ≤2 and 3 metastatic locations were reported in 56% and 26% pts, respectively. Family BC and ovarian cancer history was reported in 30% pts, a hereditary-risk genetic test was performed in 31% (n=583/1862) pts, and 19% (n=38/205) had BRCA1/2 mutations (HR+/HER2− [n=25/138, 18%], HR+/HER2+ [n=2/11, 18%], HR−/HER2+ [n=2/9, 22%], HR−/HER2− [n=9/36, 25%]). Paired tumor samples from primary BC and metastatic lesions were available in 32% HR+/HER2−, 33% HR+/HER2+, 33% HR−/HER2+, and 44% HR−/HER2−. Distant metastases were biopsied in 55% rEBC pts and 22% dnMBC pts. Unstable BC subtype (n/pts with paired samples) and the main change were: 9% HR+/HER2− (HR+/HER2+), 33% HR+/HER2+ (HR+/HER2−), 52% HR−/HER2+ (HR+/HER2+), and 42% HR−/HER2− (HR+/HER2−). After a median follow-up of 40 months, no statistically significant differences in survival from ABC diagnosis were observed between pts with stable and unstable BC subtype for any cohort, regardless of subtype.
Conclusions: These data confirm our results from previous analyses, showing that HR+/HER2− is the most predominant subtype in ABC pts. dnMBC was present in one-third of pts at ABC diagnosis, TNBC shows the lowest proportion. Visceral involvement was the main metastatic location in all subtypes, being more frequent in HR−/HER2+. Additionally, the unstable subtype is most common in HR− disease. However, no differences in survival from ABC diagnosis were observed between the unstable and stable subtypes across any BC subtype. Further long-term follow-up studies should be conducted to observe the progression and treatment outcomes of different subtypes, particularly focusing on the transition stable to unstable disease states.
ClinicalTrials.gov Identifier: NCT02819882.
Sponsor: GEICAM Spanish Breast Cancer Group.
Funding: This study has support from Roche Farma, S.A.; Novartis Farmacéutica, S.A.; Celgene, S.L. (a BMS company); Pfizer, S.L.U.; AstraZeneca Farmacéutica Spain, S.A. in alliance with Daiichi Sankyo Spain, S.A.U.; Lilly, S.A.U.; Seagen, S.L.U.; Gilead Sciences, S.L.;

P1-10-09: Underestimation in core-needle biopsies of papillary breast lesions: a retrospective cohort from a university center

Renata Puccini, Vanessa Sanvido, Angela Waitzberg, Gil Facina, Afonso Nazario

Background: Papillary breast lesions (PBL) include a wide spectrum of lesions and can be benign, with atypia or malignant. They correspond to up to 5% of breast biopsies, but their incidence has increased in recent years, mainly due to technical improvements in percutaneous biopsies and the greater use of breast ultrasound. Many studies have been published about the management of PBL identified in biopsies and underdiagnosis rates may vary in the literature. In the presence of atypia, a high rate of underdiagnosis is observed, therefore, complete excision of the lesion is recommended. On the other hand, papillary lesions without atypia identified on core needle biopsy (CNB) remain without consensus regarding management.
Objective: To verify the underestimation (atypia and carcinoma) in ultrasound-guided CNB of papillary breast lesions, after undergoing surgical excision. Furthermore, to verify the clinical and radiological characteristics associated with upgrade.
Method: Retrospective study, through analysis of medical records of 56 patients with papillary breast lesions identified on ultrasound-guided CNB and subsequently undergoing surgical excision of the lesion, between 2007 and 2020, in the Mastology service at Escola Paulista de Medicina - Unifesp (Sao Paulo - Brazil).
Results: Among the 59 lesions considered for the study, of which 40.7% were cases of papillary lesions with atypia, 39% were papillary lesions without atypia and 20.3% were intraductal papillomas, we identified 52.5% (95%CI: 39.1% to 65.7%) of underdiagnosis without distinct percentages by biopsy classification (p=0.295), by characteristics (p>0.05), as well as differences in mean age (p=0.186) and size of the lesion (p=0.196). Univariate and multivariate logistic regression models were applied, but none of the characteristics proved to be significant, even after excluding the variables one by one in order of significance (backward method). Considering only the underdiagnosis of ductal carcinoma in situ (DCIS) or invasive carcinoma, a rate of 32.2% (95%CI: 20.6% to 45.6%) was observed, being 54.2% (95%CI: 32.8% to 74.4%) among papillary lesions with atypia, 26.2% (95%CI: 10.2% to 48.4%) among papillary lesions without atypia and no cases among pure intraductal papillomas. Univariate and multivariate logistic regression models were applied and remained in the final model, the variables age (p=0.022) and normal physical examination (p=0.049). Thus, a 1-year increase in age leads to an increase in 6% chance of underdiagnosis for cancer, adjusted by physical examination. In addition, patients with normal physical examination have an 83% lower chance of underdiagnosis for cancer than patients with changes in physical examination.
Conclusions: This study showed a high rate of underdiagnosis among papillary lesions obtained on CNB and did not identify associated clinical or radiological characteristics.

Considering only the underdiagnosis of DCIS or invasive carcinoma, it was identified that the patient's increasing age and the presence of changes in physical examination as predictive factors for underdiagnosis. Therefore, it is concluded that excision of papillary lesions identified in CNB should be considered, given the risk of underdiagnosis not only of carcinoma, but also of atypia.

P1-10-10: Outcomes of Abemaciclib Dose Escalation Strategy in High-Risk Early Breast Cancer

Noor Lad, Priyanka Sharma, Qamar Khan, Lauren Nye, Anne O'Dea

Background: Abemaciclib is recommended as adjuvant therapy in node-positive, HR+, HER2-, high-risk early breast cancer, based on improved invasive disease-free survival (iDFS) in the monarchE trial. However, there are challenges with tolerability of standard dose abemaciclib. In monarchE, 16.6% discontinued abemaciclib due to adverse events (AEs), 56.9% experienced dose interruptions, and 41.2% had dose reductions.
At our institution, we have implemented a dose escalation (DE) strategy where patients initiate abemaciclib at 100 mg BID (50 mg BID in select patients) and increase to the full dose over 1-2 months, based on tolerance and provider discretion. This study compares the tolerability of abemaciclib using a DE versus standard dosing (SD) strategy.
Methods: This real-world analysis includes 164 HR+, HER2-, node-positive, high-risk EBC patients receiving adjuvant abemaciclib and endocrine therapy (ET) from October 12, 2021, to June 9, 2024. Patients were prescribed either a DE (n=83) or SD (n=81) per provider discretion. Primary outcomes included discontinuation, dose reduction, and treatment interruption rates, which were compared between the DE and SD groups using chi-square.
Results: Median ages were 55 years (DE) and 54 years (SD); 70% (DE) and 62% (SD) were postmenopausal. After a median follow-up time of 7.3 months in the DE group, 48.2% were titrated to full dose. Median time to full dose was 46 days (range 21-165 days).
Abemaciclib discontinuation rates were 18% (DE) vs. 27% (SD) (P=0.139); median times to discontinuation were 66 days (DE) vs. 58 days (SD). Interruptions occurred in 25.3% (DE) vs. 65.4% (SD) (P=0.001); dose reductions in 14.4% (DE) vs. 43.2% (SD) (P<0.005).
The most common reasons for discontinuation were diarrhea (SD 14.6%, DE 6.1%) and fatigue (SD 7.3%, DE 6.1%). Leading AE-related dose modifications were diarrhea (SD 37.8%, DE 9.8%, P=0.001), nausea (SD 12.2%, DE 1.2%, P=0.005), and fatigue (SD 12.2%, DE 4.9%, P=0.094).
Conclusion: This real-world study demonstrates that compared to the monarchE trial, the SD of abemaciclib is associated with a higher discontinuation rate (27% vs 16.6%), underscoring the importance of strategies to improve tolerability. Early discontinuations suggest that enhanced initial tolerability may improve adherence.
An abemaciclib DE strategy may improve tolerability, minimizing interruptions, dose reductions, and AEs vs SD. However, formal protocols are needed to ensure full dose escalation. Future studies should assess long-term outcomes (iDFS) with DE vs. SD abemaciclib schedules.

P1-10-11: Preliminary Analysis of Sociodemographic and Clinical Characteristics of Patients with Early Breast Cancer in the Patient-Centered, Real-World EVOLVE Registry

Haley S. Friedler, Michael C. S. Bissell, Kellie Ryan, Michele Baber, Xiaoqing Xu, Zulikhat Segunmaru, Chintal H. Shah, Qixin Li, Thomas Quinn, Amy Longenecker, Amy Bryer, Colleen Goldberg, Gillian Hanson, Maryam Lustberg, Maryam Lustberg, N Lynn Henry, Rachel A Greenup, Mariana Chavez-MacGregor, Joseph M. Unger, Alice Ho, Deborah Collyar, Miranda Gonzales, Tiffany Haynes, Josefa Briceno

Background: Despite improvement in survival rates over time, recurrence and treatment-related adverse events remain concerning risks for patients with early (stage I-III) breast cancer (eBC). The EVOLVE Registry, a patient-centered United States (US)-based registry was created to address the limitations of existing eBC databases and better understand real-world sociodemographics, clinical characteristics, diagnostic and treatment pathways, clinical outcomes, and patient experience in eBC. This is the first analysis of the ongoing EVOLVE Registry.

Methods: The EVOLVE Registry, created through a collaboration between PicnicHealth and AstraZeneca, consists of the de-identified medical record data, along with patient-reported social determinants of health (SDoH) and patient-reported outcomes (PROs) data. Inclusion criteria were defined as eBC (invasive, non-metastatic) diagnosed ≤3 years prior to enrollment and ≥18 years old at consent. Patient enrollment began May 2023. Using PicnicHealth's platform, all available retrospective medical records prior to enrollment, including pre-diagnosis, were retrieved. Following enrollment, medical records and survey/PRO were prospectively collected. eBC-specific data elements were abstracted from structured and narrative text. Rural/urban categorization was derived from Rural-Urban Commuting Area (RUCA) codes. While enrollment (target: 3,000 patients) and data collection is ongoing, data from medical records collected and completed surveys for patients enrolled in the EVOLVE Registry up to June 2024 were analyzed. Patient demographics, receptor status, and self-reported SDoH data are described.

Results: A total of 1,428 patients with eBC enrolled as of June 2024 with a median of 7 years of visits pre-diagnosis and 2 years of visits post-diagnosis. Mean (range) age at diagnosis was 55 (24 - >89) years, with 76% diagnosed between 40-69 years and 35% diagnosed ≤1 year of enrollment. Almost all patients (n=1,427) were female; 77% were White, 12% Black/African American, 2% Asian, 4% mixed race, and 5% other race; 13% were Hispanic/Latino; 93% resided in a metropolitan/micropolitan area and 7% small town/rural. Most patients had hormone receptor (HR)+/human epidermal growth factor receptor 2 (HER2)- eBC (70%), followed by 15% HR-/HER2-, 11% HR+/HER2+, 4% HR-/HER2+, and 1% unknown. About half (55%) were diagnosed at stage I, 32% at stage II, and 13% at stage III. Of the 58% of patients who responded to the SDoH survey, 98% had some form of medical insurance; 20% had a high school education or less; 31% had full time employment, 10% part-time employment, and 27% were retired; 62% reported a

household annual income of <$75k; 57% owned their own housing; 25% were concerned about losing their housing; 16% reported lack of transportation access kept them from medical appointments. 47% reported current or former use of nicotine-based products, 89% of whom reported cigarette use and 25% reported e-cigarette/vape use.

Conclusions: The EVOLVE Registry to date has enrolled a population broadly representative of patients with eBC in the US with regards to race, ethnicity, and eBC characteristics. The patient-reported SDoH indicated a highly insured population, however, this may not reflect financial burden and unmet needs, including for transportation and housing security, as those were still apparent in this population. With ongoing enrollment, this registry will help further the understanding of the evolving real-world treatment of eBC, existing disparities, and patient needs across diagnostic and treatment pathways that affect breast cancer outcomes.

P1-10-12: Evaluating the Impact of Prosigna® Testing on Adjuvant Chemotherapy Decisions in Early-Stage ER-Positive, HER2-Negative Breast Cancer: A UK Study

Thiraviyam Elumalai, Kelly Lambert, May Teoh, Angela Rajiv, Ishtiaque Hussain, Faatimah Esmail, Aliaa Shamardal, Judith Dua, Nyan Lin Myint, Susan John, Elizabeth Bull, Saif Ahmad

Multi-gene assays are recommended for guiding adjuvant chemotherapy decisions in early-stage ER-positive, HER2-negative breast cancer. This study aimed to evaluate the impact of Prosigna® testing on clinical decisions and to identify factors that predict the Prosigna® risk stratification outcomes. Women with ER-positive, HER2-negative breast cancer, eligible for chemotherapy based on intermediate risk of distant recurrence (using tools such as Predict or the Nottingham Prognostic Index), were retrospectively identified from three UK hospitals. Patient and tumor characteristics, Prosigna® test results, and final treatment decisions were collected. Outcome parameters included disease progression and overall survival. Multinomial logistic regression identified key predictors of low, intermediate, and high-risk categories of Prosigna® test results.
Among 363 patients with a median age of 61, 71% were post-menopausal, and 48% had grade 3 tumors. Based on Prosigna® results, 60% (n=216) avoided chemotherapy despite clinical indications, while 14% (n=52) without initial indications were escalated to receive chemotherapy. Anthracycline and Taxane-based regimens were most common (76%), followed by Docetaxel and Cyclophosphamide (24%). At a median follow-up of 2 years, 2.4% (n=9) had disease progression, all of whom received chemotherapy. High-risk and intermediate-risk (Luminal B subtype) patients were primarily offered chemotherapy. Tumor grade emerged as the most significant predictor across all Prosigna® risk categories, with a positive coefficient for high risk and negative coefficients for intermediate and low risk. NPI and Predict score also influenced risk stratification, positively impacting high and intermediate risk categories and negatively impacting low risk. Age, tumor size, and LVSI had smaller, less consistent influences. The model achieved an overall accuracy of 41%,

with the highest precision and recall in predicting the high-risk category.
This study presents the first real-world data on the implementation of Prosigna® in the UK, potentially optimizing future national guidelines. These findings highlight the importance of tumor grade and prognostic indices in risk stratification, offering valuable insights for personalized breast cancer management.

P1-10-13: Real-world outcomes of physician's choice treatment (PCT) for hormone receptor-positive (HR+)/HER2-0 and HER2-low advanced breast cancer (ABC) patients (pts) after endocrine therapy (ET) and CDK4/6 inhibitors (CDK4/6i)

Aleksandra Lacko, Katarzyna Pogoda, Katarzyna Soter, Aleksandra Grela-Wojewoda, Jolanta Smok-Kalwat, Karolina Winsko-Szczęsnowicz, Iwona Danielewicz, Joanna Streb, Agnieszka Kowalewska-Felczak, Bartosz Szymanowski, Tomasz Lewandowski, Joanna Kiszka, Ewa Kalinka, Anna Bałata, Magdalena Łoboza, Ewa Kustra, Anna Koriat-Błońska, Justyna Żubrowska, Aleksandra Łacko, Marek Ziobro, Bogumila Czartoryska-Arlukowicz, Michał Jurczyk, Grzegorz Kade, Rodryg Ramlau, Jacek Jassem, Michał Bieńkowski, Renata Duchnowska

Background: Treatment for HR+/HER2-0 or HER2-low (Immunohistochemistry (IHC) 1+ or 2+/in situ hybridization, ISH-negative) ABC pts after ET and CDK4/6i depends on disease dynamics, prior chemotherapy (CT), performance status and the presence of actionable genomic alterations. Currently, trastuzumab deruxtecan is approved for HER2-low ABC after ≥1 line of CT, but is not reimbursed in Poland.
Methods: We retrospectively analyzed treatment outcomes of HR+/HER2-0 or HER2-low ABC pts after progression on ET and CDK4/6: palbociclib (PAL), ribociclib (RIB) or abemaciclib (ABM). We analyzed second progression-free survival (PFS2), overall survival (OS) and duration of the subsequent line treatment after ET/CDK4/6i (DoT).
Results: A total of 472 pts (PAL=127; RIB=222; ABM=78) from 12 Polish cancer centers treated between Sep 2017 and Dec 2023 were analyzed. Median follow-up was 33.3 (95%CI 31.2 to 36.3) months (m). Mean age was 59.8 ± 12.4 years. 200 patients (42%) had visceral and 358 (76%) bone metastases. 296 (63%) and 176 (37%) received CDK4/6i with aromatase inhibitor (AI) and fulvestrant (FUL), respectively. HER2 IHC: 0, 1+, 2+/ISH-negative subsets were:228 (48%), 153 (32%), 78 (17%), 13 (2.8%), respectively. PCT included fulvestrant 103 (22%), capecitabine 88 (19%), taxane 51 (11%), anthracycline 47 (10%), vinorelbine 43 (9.1%), anthracycline and cyclophosphamide 33 (7%), aromatase inhibitor 29 (6.1%), platinum compounds 24 (5.1%), alpelisib and fulvestrant 18 (3.8%), and other 36 (7.7%). Median DoT for HER2 0 and HER2 low was 4.2 (3.7-5.6) and 4.9 (4.1-6.0) m, respectively, HR= 0.79 (95%CI: 0.64-0.97), p=0.026; PFS2: 18 (15-20) and 20 m (18-23), HR=0.81 (0.65-0.99), p=0.042; OS: 26 (23-31) and 35 (30-39), HR=0.71 (0.55-0.91), p=0.007.
Conclusions: HR+/HER2-negative ABC constitutes a heterogeneous population that vary in

prognosis and sensitivity to systemic treatments. Compared to HER2-0, HER2-low subgroup has better outcomes following ET/CDK4/6i therapy. The outcomes of PTC and prognostic significance of the HER2-ultralow subtype warrants evaluation.

P1-10-14: Bridging the gap between real-world studies (RWSs) and randomized controlled trials (RCTs) of 1st-line palbociclib+aromatase inhibitors (P+AI) in hormone receptor-positive(HR+)/HER2-negative(-) metastatic breast cancer (mBC)

Daniele Generali, Sabrina Nucera, Francesco Schettini, Fabiola Giudici, Carla Strina, Manuela Milani, Richard Tancredi, Benedetta Conte, Carmen Criscitiello, Mario Giuliano, Matteo Lambertini, Rodrigo Sánchez-Bayona, Tomás Pascual, Paolo Vigneri, Grazia Arpino, Lucia Del Mastro, Massimo Cristofanilli, Hope Rugo, Alessandra Gennari, Giuseppe Curigliano

Background: RCTs remain the gold standard to assess the efficacy of a treatment seeking regulatory approval. However, RWSs provide insights into patients (pts)' outcomes in routine clinical practice. We assessed the real-world (RW) efficacy of 1st-line P+AI and compared it to RCTs' results.
Methods: A systematic review was performed to identify RWSs published from 2019 to 2023 including pts with HR+/HER2- mBC treated with 1st-line P+AI, with available median progression-free survival (mPFS) and/or overall survival (mOS). A meta-analysis was performed to estimate the pooled mPFS/OS using the median of the medians (MM) and weighted median of medians (WM). The RW estimates were deemed comparable to PALOMA1/2 RCTs' mPFS/OS, if MMPFS/OS or WMPFS/OS were in RCTs' mPFS/OS 95% confidence intervals (CI). Similar criteria applied to pooled hazard ratios (HR) of PFS/OS for P+AI vs. AI in visceral/non-visceral subgroups.
Results: Among 8 included RWSs (n=4624 pts) a MMPFS of 22.5 months (95%CI: 19.5-31.8) and WMPFS of 20.0 (95%CI: 19.3-31.8) were observed with 1st-line P+AI. The MMPFS was comparable to those of PALOMA1 (20.2, 95%CI: 13.8-27.5) and PALOMA2 (27.6 months, 95%CI: 22.4-30.3). The WMPFS was inferior to that of PALOMA2. A RW MMOS of 51.2 months (95%CI: 49.1-53.3) and WMOS of 49.1 (95%CI: 49.1-53.3) were observed, outperforming the PALOMA1 mOS of 37.5 months (95%CI: 37.5-47.8) and being comparable to PALOMA2 mOS of 53.8 (95%CI: 49.8-59.2). P+AI vs. AI in RW in visceral disease had superior PFS (HR: 0.56, 95%CI: 0.46-0.68) and OS (HR: 0.61, 95%CI: 0.49-0.77), similarly to the PALOMA2 PFS (HR: 0.62, 95%CI: 0.47-0.81) and better than PALOMA1 (HR: 1.13, 95%CI: 0.68-1.88) and PALOMA2 (HR: 0.86, 95%CI: 0.65-1.13) OS. In RW non-visceral disease, P+AI vs. AI had lower PFS benefit (HR: 0.76, 95%CI: 0.65-0.88) than PALOMA2 (HR: 0.50, 95%CI: 0.37-0.62). RW OS (HR: 0.82, 95%CI: 0.69-0.99) was similar than that of PALOMA2 (HR: 0.86, 95%CI: 0.65-1.13).
Conclusions: Our findings add to the understanding of the generalisability of RCTs results to RW and confirm the role of 1st-line P+AI in clinical practice.

P1-10-15: Treatment patterns and clinical outcomes according to PD-L1 status in more than 2000 patients with early-stage or metastatic triple-negative breast cancer (eTNBC/mTNBC) treated in the real-world setting: VANESSA study results

Lazar Popovic, Romualdo Barroso-Sousa, Nagi El Saghir, Rebecca Dent, Sitki Tuzlali, Saad Akhtar, Elona Juozaityté, Janis Eglitis, Dinesh C. Doval, Carlos A. Castaneda, Alisan Zirtiloglu, Götz Hartleben, Regula Deurloo, Iman Estaytieh, Ehsan Masoudi, João Mouta, Corrado D'Arrigo

Background: Clinical trials in unselected populations of patients with TNBC suggest that positive PD-L1 status is associated with more favorable outcomes in both the early-stage and metastatic settings and predicts benefit from immune checkpoint inhibition in mTNBC; however, additional studies are needed to confirm these findings, and little is known about PD-L1+ prevalence and outcomes in the real-world setting.
Patients and methods: The multicenter retrospective observational VANESSA study evaluated the prevalence and impact of PD-L1 status in consecutively and uniformly enrolled patients diagnosed with eTNBC/mTNBC between Jan 1, 2014, and Dec 31, 2017, and treated with systemic therapy. PD-L1 expression was assessed locally and centrally on archival samples using the Ventana PD-L1 (SP142) immunohistochemistry assay. Data for medical/treatment history and clinical outcomes were extracted from patients' medical records. Primary and secondary objectives focused on diagnostic parameters (reported elsewhere). Exploratory objectives included description of demographic and clinicopathologic characteristics, treatment patterns, and clinical outcomes according to PD-L1 status (PD-L1+ defined as PD-L1 expression on tumor-infiltrating immune cells covering ≥1% of the tumor area).
Results: Overall, 2233 patients from 19 countries were screened, of whom 2054 were eligible and 1967 had centrally assessed PD-L1 status. Chart review showed that among 1902 eligible patients with eTNBC, 681 (36%) received neoadjuvant chemotherapy (CT; predominantly anthracycline- and taxane-based) and 1261 (66%) received adjuvant CT. The prevalence of PD-L1 positivity by central testing was 1007/1822 (55%) in eTNBC and 38/145 (26%) in mTNBC. In the eTNBC cohort, demographic and tumor characteristics were generally similar in the PD-L1+ and PD-L1– subgroups (respectively, median age: 52 vs 52 years; stage I/II at diagnosis: 56% vs 49%; stage III at diagnosis: 26% vs 33%; Asian race: 22% vs 22%; Black/African American race: 5% vs 5%; BRCA mutation: 68/147 [46%] vs 34/84 [40%]). Pathologic complete response (defined as eradication of invasive disease in the breast and lymph nodes after neoadjuvant CT in evaluable patients) was observed in 27/168 patients (16%, 95% CI 11–23%) with PD-L1+ tumors and 31/182 (17%, 95% CI 12–23%) with PD-L1– tumors. Among patients evaluable for invasive disease-free survival (iDFS), annual rates were more favorable in patients with PD-L1+ eTNBC (n=681) than PD-L1– eTNBC (n=549) (1-year iDFS: 80% vs 71%, respectively; 3-year iDFS: 62% vs 47%; 5-year iDFS: 56% vs 40%). Overall survival (OS) rates in the PD-L1+ vs PD-L1– cohorts were 98% vs 97% at 1 year; 87% vs 82% at 3 years, and 82% vs 73% at 5 years. In the mTNBC

cohort, 120 patients had de novo mTNBC (30/38 [79%] with PD-L1+ TNBC, 90/107 [84%] with PD-L1– TNBC). Median age was 61 vs 56 years in patients with PD-L1+ vs PD-L1– mTNBC. There were no Black/African American patients in the group with PD-L1+ mTNBC and only 2 (5%) Asian patients. In patients evaluable for progression-free survival, the median was 7.6 (95% CI 4.1–15.0) months in 30 patients with PD-L1+ mTNBC and 4.9 (95% CI 3.6–6.1) months in 83 patients with PD-L1– mTNBC; 1-year OS rates were 81% vs 62%, respectively.
Conclusion: In eTNBC and mTNBC, PD-L1+ status was associated with more favorable long-term outcomes, possibly due to tumor-intrinsic characteristics and/or the host immune response. The vast majority of patients in the mTNBC cohort were diagnosed with de novo mTNBC; the temporal lack of PD-L1 expression and/or the lack of prior CT may contribute to diagnostic differences compared with clinical trial datasets.

P1-10-16: HER 2 + metastatic breast cancer with central nervous involvement, response to Trastuzumab-Deruxtecan in a heavily treated patient: A case report

Christopher Cerda-Contreras, Marianela Madrazo-Morales, Ricardo Mendoza-Coronado, Manuel A. Marmolejo-Castañeda, Oscar Vidal-Gutierrez

Introduction: Breast cancer (BC) is the leading cause of cancer deaths in women worldwide. Human Epidermal Growth Factor receptor 2 (HER 2) is a tyrosine kinase that shows overexpression in 15-20% of breast cancers. This represents a poor prognostic factor and hassles in disease management. Antibody drug conjugates (ADC's) are emerging new cancer drugs that are gaining accelerated approval as newer cancer treatment lines due to their outstanding results in clinical trials on later lines, improving patient survival and acceptable toxicity.
Case Description: A 39-year-old woman with negative family or personal relevant medical history, presented with stage IIIA grade 3 infiltrative ductal breast adenocarcinoma. IHQ: estrogen receptors 0%, progesterone receptors 0%, HER 2 3+.Informed consent for publication was obtained by the patient.
Neoadjuvant chemotherapy with Doxorubicin/ Cyclophosphamide x 4 cycles was administered, followed by Paclitaxel x 12 cycles plus Trastuzumab (TZB) presenting minor toxicity. Following neoadjuvant chemotherapy, modified radical mastectomy was performed with histopathologic results: ypT1c, ypN2a. Adjuvant TZB was continued to complete 1 year of treatment, and received 50 Gy/25 fx adjuvant radiotherapy (RT) was delivered.
On April 2019, the patient presented disease recurrence in the central nervous system (CNS) documented by Magnetic Resonance (MRI). Two intra axial lesions in right parietal and left cerebellum regions with vasogenic edema, left midline shift and right subfalcine herniation were observed. Oral steroids and palliative holocranial RT with 30 Gy/10 Fx were started with good clinical response.
First line treatment with Trastuzumab Emtansine was indicated due to disease recurrence

while receiving TZB, with partial response measured by RECIST 1.0. Nausea and hypertransaminasemia G1 were reported and treatment continued without modifications. After 45 cycles disease progression on CNS was reported by MRI and treated with CyberKnife, 10Gy/5Fx was administered. Second line treatment with Capecitabine was started, after 4 cycles local progression on breast and axilla was documented. New biopsy was obtained with the same immunochemistry results as previous.
Third line treatment with TZB /Pertuzumab/Docetaxel was given with progression after cycle 9. Then, 4th line treatment with Lapatinib was started and after 5 cycles, disease progression with CNS involvement was documented by MRI. Finally, approval for Ttrastuzumab- Deruxtecan was obtained in Mexico and was started as the 5th line treatment in this patient. At present, she has received 9 cycles with transaminasemia G1 as the only toxicity, with good quality of life preserved. Complete response in axilla and breast and partial response on CNS lesions has been reached.
Discussion: Despite poor prognosis associated with HER2+ breast cancer, seeking for treatment alternatives as health caregivers is essential to improve survival, guarding adverse events drug related and preserving quality of life remains imperative.
Conclusion: This case highlights the advances in clinical oncologic research and its beneficial influence improving survival outcomes in management of metastatic HER2 + breast cancer in a patient with CNS involvement in a heavily treated scenario. As well, it underlines the benefits of sequencing treatments and the efficacy of an ADC, highlighting the acceptable toxicity and guarding patient's quality life.

P1-10-17: HER2+ breast cancer diagnosed in the 2nd trimester of pregnancy

Shiliang Zhang, Samer Alkassis, Aditya Bardia, Nimmi Kapoor, Marla Lipsyc-Sharf

Introduction: Breast cancer diagnosed during pregnancy is rare. However, given the increasing incidence of breast cancer in young women, and the delayed age of first pregnancy in the US, knowledge of treating breast cancers during different stages of pregnancy is critical.
Case: A 34-year-old woman at 19 weeks' gestation felt a left breast lump. At 22 weeks, she was evaluated by her obstetrician who identified a 2.6 cm mass. Ultrasound guided biopsy revealed an ER low positive (1%), PR negative (<1%), HER2 positive (IHC2+, FISH+), poorly differentiated invasive ductal carcinoma with Ki67 of 90%. Given her pregnancy, cancer staging was performed using whole body diffusion weighted MRI (WB DWI), without contrast, at 24 weeks which revealed a 4.8cm left sided biopsy proven malignancy, nonspecific mildly enlarged left axillary lymph nodes and no distant metastasis. Patient had a normal echocardiogram, and a Port-a-Cath was placed. Her case was thoroughly discussed at multidisciplinary conference during which neoadjuvant chemotherapy was recommended including 4 cycles of dose dense doxorubicin/cyclophosphamide (AC) during pregnancy followed by delivery at term (37 weeks) and then Taxol/Herceptin/Perjeta (THP) after delivery, followed by breast surgery. The patient continued to note growth of

her breast mass and associated pain, and she received C1D1 of AC at 25 weeks' gestation with significant clinical improvement of her tumor size to 3 cm after one cycle. She also had resolution of her breast pain. The patient was referred to a maternal fetal medicine (MFM) specialist at 23 weeks with plan for serial growth scans and high-risk obstetric care.
Discussion: Breast cancer diagnosed during pregnancy merits multidisciplinary management given the significant complexities of optimizing treatment and outcomes for both mother and baby. The priorities of breast cancer treatment during pregnancy are to maximize maternal health and survival outcomes as well as to minimize risk of harm to the fetus. This careful calculation of risk versus benefit begins at diagnosis when the clinician must consider the most appropriate screening modality. In general, PET/CT is avoided in pregnancy. MRI scans (without gadolinium) are preferable over CT scans, however if CT scans are necessary, diagnostic imaging which exposes the fetus to less than 50mGy are acceptable. In our patient's case, we were able to obtain MRI WB DWI scan.
Specifically, for HER2+ breast cancers, standard neoadjuvant chemotherapy includes taxanes, anthracyclines, cyclophosphamide, and anti-HER2 agents. Timing of chemotherapy in pregnancy is crucial as it is contraindicated in the first trimester. Breast cancer diagnosed in pregnancy, and particularly in the first trimester, requires careful consideration of the risks and benefits of continuation of pregnancy. In the second and third trimesters, agents such as doxorubicin and cyclophosphamide are generally considered safe. Dosing weight should be based on actual body weight rather than pre-pregnancy or ideal body weight. Taxanes have been associated with oligohydramnios, and notably, serum taxane levels can be significantly decreased during pregnancy, in particular for paclitaxel, which make administration difficult. Trastuzumab is contraindicated during pregnancy as it has been associated with oligohydramnios and anhydramnios. In this patient's case, the chosen regimen is AC in the second and third trimester, followed by THP post-partum, followed by surgery. In deliberation with the patient's MFM specialist, there is a plan to stop chemotherapy 3-4 weeks prior to delivery to avoid risks of myelosuppression. In the post-partum management, the placenta should be evaluated by pathology as there have been cases of metastasis to the placenta and breast feeding would be contraindicated in the setting of the patient's receipt of chemotherapy or anti-HER2 therapy.
Conclusion: Ultimately, this case underscores the importance of personalized, multidisciplinary care in optimizing outcomes for both mother and fetus when managing HER2+ breast cancer diagnosed during pregnancy.

P1-10-19: Hypophysitis and Haziness in HER2: A Case of Breast Cancer with Leptomeningeal Carcinomatosis

Caitlin Sullivan, Nali Gillespie, Brian Boulmay, Rajasree Chowdry, Jonathan Somma, Agustin Garcia, Michelle Loch

Background: HER2 is overexpressed in up to 30% of breast cancers. These patients have increased risk for development of CNS metastases, including leptomeningeal carcinomatosis despite use of HER2 targeted therapy. Historically the development of leptomeningeal

disease has carried a poor prognosis, with studies showing overall survival of 3 to 4 months.
Case Presentation: 41-year-old female with Lynch syndrome originally presented to an outside facility with ER+/HER2+ de novo breast cancer metastatic to liver and brain treated with trastuzumab, pertuzumab, and weekly paclitaxel for one year. There was no evidence of disease on follow-up imaging. Following TAH/BSO, she started daily anastrozole and continued this for 2 years. She presented 2 years later with multiple metastatic brain lesions. She underwent definitive stereotactic radiosurgery (SRS) and was enrolled in a clinical trial using pembrolizumab for 3 cycles following SRS treatment. She presented to our institution 3 months after SRS with fatigue, nausea/vomiting, left eye blurred vision and mydriasis. MRI imaging of the brain showed changes consistent with leptomeningeal carcinomatosis and thickening of the infundibulum, consistent with hypophysitis. CSF cytology revealed abnormal appearing cells, suspicious for mammary carcinoma. Abdominal imaging showed rapid development of numerous hepatic metastases not observed on abdominal imaging two weeks prior. Liver biopsy revealed HER2+ (3+) metastatic breast cancer. She began systemic and intrathecal (IT) trastuzumab, in addition to capecitabine and tucatinib per HER2 CLIMB. IT trastuzumab was given 80mg twice weekly for 4 weeks, followed by once weekly for 4 weeks, followed by 80mg every 2 weeks thereafter. Hypophysitis was treated with steroids. Follow-up after 4 cycles of systemic and IT treatment revealed clinical improvement with return of vision in left eye; imaging showed improvement in leptomeningeal and hepatic disease burden. Most recent imaging seven months after initiation of current treatment course showed stable leptomeningial disease, no abnormal cells in the CSF and improved systemic disease. Nine months following initiation of therapy she remains with stable symptoms.
Conclusion: As demonstrated in this case, treatment of HER2+ breast cancer with leptomeningeal metastases with intrathecal trastuzumab can extend survival above historically reported data, with limited toxicity.

P1-10-20: Idiopathic granulomatous mastitis with superimposed tuberculosis mastitis

Melissa Rangel, Julie Wecsler, Julia Alexevia

Idiopathic granulomatous mastitis (IGM) is a rare condition and exact prevalence is unknown. It may mimic infectious and malignant breast disease and is a diagnosis of exclusion with unknown etiology. Though not life threatening, the pain and disfigurement can be debilitating. In the United States association of IGM with childbearing, lactation, Corynebacterium and Hispanic ethnicity have been reported. Among small retrospective and prospective reviews Hispanic ethnicity accounts for 80-97% of patients. There is no agreed upon treatment and different modalities include a combination of antibiotics, steroids and surgical debridement. We present here a case of a 42-year old woman with a history of pituitary macroadenoma, hyperprolactinemia s/p cabergoline treatment and chronic galactorrhea who presented to breast clinic with chronic breast pain, abscesses and

repeated biopsies over 6 years before eventual conformation of IGM diagnosis and TB mastitis.
The patient initially presented to an outside hospital with complaints or a right breast abscess that was treated over 2 years with multiple aspirations, I&Ds and oral antibiotics. She had no personal or family history of cancer. Mammogram obtained on presentation to our clinic was BIRADS 2 and multiple biopsies showed chronic and acute inflammation consistent with abscess cavity. The IGM, AFB, fungal and TB testing were all negative and remained negative despite relapsing and remitting symptoms of the right breast. After several months of failed management with antibiotics and aspiration she was started on a prednisone empirically. Multiple biopsies obtained and repeat aspirations remained negative for IGM or infectious etiology. Over 4 months symptoms improved, and steroids were weaned. Symptoms recurred again however after stopping steroids and this time biopsy and culture showed corynebacterium. She was started on doxycyline and kenalog injections into the breast with eventual improvement though not full resolution of her symptoms. Over this entire clinical course lasting 3 years repeat screening mammograms remained normal.
She eventually returned with severe bilateral breast pain accompanied by large left breast abscesses. After in office incision and drainage did not provide adequate relief intraoperative drainage of the left breast was planned. A periareolar incision was made and on deeper dissection multiple loculated areas were broken up releasing purulent drainage. The cavity was packed with iodoform gauze. Pathology showed breast tissue with chronic inflammation, granulation tissue and fat necrosis. PAS-F, Gram, and AFB special stains are negative for fungal elements, bacterial organisms, and acid-fast bacilli. The patient slowly improved until 3 months post op when she returns with recurrent left breast symptoms as well as subcutaneous skin nodules on her legs and arms. Pathology at this time was positive for IGM showing granulomatous mastitis and lymphocytic lobulitis. There was some mild improvement with continued kenalog and doxycyline. During a particularly bad recurrent flare a repeat TB quantiferon became positive. Patient was sent to infectious disease to initiate anti-TB treatment and had marked improvement of symptoms.
IGM remains poorly understood and though relatively rare can be incapacitating. Some cases, as the one described here, may have superimposed infections exacerbating patient symptoms. Though there has been an association with the Hispanic community there has been little meaningful research investigating etiology or predisposing factors. Understanding these factors may ultimately lead to improved treatments and outcomes.

P1-10-21: Intrathecal therapy in invasive lobular carcinoma with non-bulky leptomeningeal disease: case report

Daniel Sobral Filho, Aniceto Lopes da Silva Neto, Giulia Mazaro de Oliveira, Rafaela Lopes da Silva Naves, Raelson Rodrigues Miranda, Laura Testa

Introduction: Leptomeningeal disease (LMD) is a challenging complication of breast cancer (BC) with limited treatment options and a prognosis of three to four months in most

cohorts. This case report describes the treatment of a patient with LMD at her initial diagnosis, evaluating its indication and clinical evolution.
Case report: Female, 68y at BC diagnosis, post-menopausal. Previous history: hysterectomy at 43y; hormone implants replacement therapy until diagnosis; pleuropulmonary fibrolastosis. Family history: a sister died of ovarian cancer at 40y, NGS for 25 germline mutations negative. In 2018, the patient experienced bloating. Upper digestive endoscopy: normal. In April 2018, she was hospitalized due to ascites, with positive oncotic cytology. A biopsy confirmed peritoneal carcinomatosis (GATA3 and estrogen/progesterone receptors [ER/PR] positive; CDX-2 and HER2 negative). At initial staging, diffuse gastric thickening compatible with carcinomatosis. In the right breast, nodule measuring 1.6x1.0x0.8cm, biopsy confirmed invasive lobular carcinoma (ER 95%, PR 95%, HER2 negative, Ki67 15%). In May 2018, she received 5 cycles of Carboplatin + Paclitaxel with reduction in ascites and partial response at restaging. She then came to our institution and was started on Tamoxifen (as her estradiol levels were high due to hormone implants that were not able to be removed) and Palbociclib in August 2018. However, at this time, diplopia was present, and she reported it had started before chemotherapy. Cerebrospinal fluid (CSF) cytology was positive for neoplastic cells, and there were suspicious findings on cranial MRI: heterogeneous contrast uptake in the right cingulate gyrus with no parenchymal brain metastases (BM). She received 9 cycles of intrathecal (IT) methotrexate (12mg) from August 2018 until January 2019, with improvement of diplopia. CSF after 8 weeks of IT therapy was still positive, but it was negative in February 2019, with no suspicious findings on new cranial MRI. She remained on Tamoxifen and Palbociclib with stable disease (SD) in the breast, with no other measurable site. In January 2021, she developed epigastric pain. An endoscopy showed an area of infiltration in the duodenum, biopsy confirmed lobular BC. She underwent radiotherapy with resolution of her symptoms. Palbociclib was maintained and Tamoxifen was switched to Letrozole as her estradiol levels were indetectable. In October 2021, she presented a new progression of duodenal disease, and liposomal doxorubicin was administered for 6 cycles until April 2022 with partial response. Afterwards, she continued hormonal treatment with Fulvestrant and Alpelisib (PIK3Ca mutation on NGS). Due to pneumonitis, Alpelisib was suspended in June 2022. In November, Fulvestrant was also suspended due to continued worsening of pneumonitis. She was maintained on treatment holiday due to previous toxicities. In April 2023, she had SD, measurable only in the breast, being maintained with no oncological treatment. However, she continued to worsen her previous pulmonary condition (pleuropulmonary fibrolastosis) and died in August 2023.
Discussion: The patient above presented non-bulky LMD, with no hydrocephalus, and with no parenchymal BM, deriving clinical benefit with improvement in diplopia and survival of 59 months after the diagnosis of LMD. No relapse was observed in the central nervous system after IT therapy. The patient died from non-oncological causes with no disease activity while on drug holiday.
Conclusion: This patient with invasive lobular carcinoma and non-bulky LMD, no hydrocephalus and no parenchymal BM had a longer survival than most patients with LMD.

She received both IT and systemic therapy. This case reinforces the importance of seeking appropriate criteria for selecting patients with potential benefit from treatment.

P1-10-23: Management of Malignant Adenomyoepithelioma of the Breast

Jacqueline Slobin,Theresa Shao, Malini Harigopal, Lakshmi Kowtha, Genevieve Abbey, Manjeet Chadha, Stephanie Bernik, Elisa Port, Jennifer Marti, Daniel W. Kim

Introduction: Adenomyoepithelioma (AME) of the breast is a biphasic tumor comprised of epithelial and myoepithelial components. AME is typically benign, but rarely can be malignant, with malignant cells arising from either the epithelial or myoepithelial components of the tumor. Malignant AME typically presents in post-menopausal women as a single palpable mass or is detected on screening mammography. Because malignant AME is very uncommon and there are few published case reports, there is limited data available to inform treatment guidelines. While surgical excision with negative margins is currently the accepted management for malignant AME, the role of adjuvant chemotherapy and radiation therapy remains unclear.

Case Description We present a case of a 57-year-old woman with screen detected malignant AME of the left breast. Screening mammography revealed a high density 2 cm left breast mass with obscured margins. On ultrasound, the mass was hypoechoic with microlobulated margins and posterior acoustic enhancement, BI-RADS 4, measuring 2.0 x 1.3 x 1.9 cm. Ultrasound-guided core needle biopsy revealed a myoepithelial tumor with atypia. The patient underwent a left breast excisional biopsy, which revealed malignant AME with necrosis, ER 7%, PR-, Her2-, and Ki-67 of 45%. The plan was for re-excision and sentinel node biopsy, after multidisciplinary discussion. Post-operative MRI revealed no residual disease. Re-excision and sentinel lymph node biopsy revealed clear margins and two benign lymph nodes. The patient is currently receiving adjuvant dose dense doxorubicin/cyclophosphamide, followed by paclitaxel for 12 weeks. She will undergo adjuvant radiation therapy. Endocrine therapy was excluded given the weak hormone receptor positivity.

Discussion We present a case of a woman with malignant AME. This tumor is rare – to the best of our knowledge, there are fewer than 100 cases reported in the literature. A three-tier classification of AME has been proposed – benign, atypical, and malignant AME (with malignant encompassing in situ and invasive tumors) – to help guide further management. PIK3CA and HRAS hot spot mutations are found in both benign and malignant AME and vary according to ER status, with HRAS found only in ER negative AMEs. Malignant AME tumors have the potential to metastasize to the lung, brain and liver. Since this tumor was essentially triple negative with a high Ki-67, adjuvant chemotherapy and radiation were recommended. Since the treatment recommendations for malignant AMEs are not standard, we propose starting an international case registry to help further characterize this rare tumor, and to identify the ideal treatment recommendations to maximize benefit and minimize harm.

P1-10-24: Managing Heterogeneous Metastatic Breast Cancer: A Clinical Case Vignette

Sharonlin Bhardwaj, Fang Fan, Joanne Mortimer

The behavior of metastatic breast cancer (MBC) is diverse and frequently unpredictable, posing considerable therapeutic challenges. This clinical vignette describes the path of a 42-year-old woman diagnosed with de novo metastatic breast cancer, whose single tumor population likely evolved into a heterogeneous disease over four years.

In October 2020, the patient was diagnosed with de novo invasive ductal carcinoma (IDC) of the left breast. Imaging revealed symptomatic bone metastases in the cervical (C7) and thoracic (T1, T2, T5, T6) spine, necessitating surgery (anterior cervical corpectomy and fusion C5-T1) followed by adjuvant radiation to the spine. A left breast 2:00 biopsy at diagnosis indicated estrogen receptor-positive (ER+ 95%), progesterone receptor-negative (PR- 5-10%), HER2/neu score 0, and a 50% proliferative index (Ki-67) via immunohistochemistry. HER2/neu FISH showed no amplification, with an average of 1.6 ERBB2 signals per cell and an ERBB2 to D17Z1 ratio of 0.7.

In November 2020, the patient was initiated on palbociclib, letrozole, and pembrolizumab as part of a clinical trial for first-line treatment of her metastatic breast cancer, which she tolerated well with manageable side effects. Additional left breast biopsies taken in December 2020 for research purposes, as part of the clinical trial, confirmed IDC with ER+ 100%, PR- 0%, HER2/neu score 2+, and >20% Ki-67. These samples also tested negative for HER2/neu amplification (ERBB2 signals 1.5, ratio 1.1).

By August 2021, imaging showed the left breast mass and associated left axillary lymphadenopathy had resolved with treatment. However, a recurrence was detected in September 2023 in the prior tumor bed, marked by a biopsy clip. This mass gradually grew, producing satellite lesions and causing ipsilateral left axillary lymph node re-growth. By May 2024, disease progression was evident with an enlarging left breast mass and left axillary lymphadenopathy, and she was taken off the clinical trial. Despite the local progression, her bony lesions remained sclerotic with stable uptake since at least 2022.

On June 14, 2024, the patient underwent a repeat biopsy of the left breast mass as part of the end-of-study requirements. The ultrasound-guided biopsy of the left breast 2:00 mass revealed two distinct tumor populations. IHC staining for both ER and Her2 showed a clear linear demarcation between the two tumor populations. Population 1 was ER 5%, PR 0%, HER2 3+, FISH positive (ERBB2 copy number 18.2, ratio 9.8), Ki-67 30-40%, while Population 2 was ER >95%, PR 0%, HER2 1+, FISH negative (ERBB2 copy number 1.5, ratio 1.1), Ki-67 30-40%. Left axillary lymph nodes were not biopsied.

Given the dynamic nature of her illness, we reviewed her case in a multidisciplinary tumor board. We reached a consensus for local control through lumpectomy and targeted lymph node dissection. Meanwhile, the patient will receive perioperative trastuzumab infusions and will continue letrozole. She will also be initiated on an alternative CDK4/6 inhibitor, ribociclib.

This case underlines the significance of individualized treatment programs for the management of metastatic breast cancer. The coexistence of different tumor types within a

single lesion presents therapy challenges, necessitating regular disease reassessment and therapy adjustment to maintain effective disease control. Additionally, this case raises the question of whether treatment-related pressure from this patient's unique first-line treatment combination with immunotherapy may have influenced her development of HER2/neu gain. This is otherwise uncommon in the general population of hormone-positive metastatic breast cancer.

P1-10-25: Metachronous triple negative breast cancer in a young patient with aggressive presentation of metastatic HER2 positive breast cancer: treatment considerations and management

Alexandra Noveihed, Milagros Cappa, Tal Kaplan, Nisha Ohri, Colleen Ciccosanti, Mridula George, Shridar Ganesan, Deborah Toppmeyer, Coral Omene

Background: Breast cancer (BC) is a heterogenous disease with 3 major subtypes which can be further classified into different molecular subtypes with differing treatment responses. Patients may present with more than one of these subtypes simultaneously and executing a cohesive treatment plan to address the heterogenous nature of this disease is essential.
Clinical Case: This is a case of a 40 year old female who presented with a large left breast fungating mass. She underwent a biopsy that revealed IDC, grade 3 with necrosis, Ki67 40%, estrogen receptor negative (ER- [<1%]), progesterone receptor negative (PR- [<1%]), HER2+ (immunohistochemistry [IHC] 3+). Imaging noted a 17cm x 8.8 cm left breast mass extending to inferior axilla, subpectoral region and skin surface with edema; left supraclavicular (SCV) nodes up to 2.9cm. Bone scan was negative. She was found to have a DVT in her left upper extremity due to disease burden causing lymphatic obstruction. Prior to start of chemotherapy, she developed dysarthria with right facial droop and right upper extremity drift. She received IV thrombolytic therapy due to CTA showing distal LM2 vs M3 occlusion with improvement of symptoms. MRI brain showed small left MCA territory strokes with an enhancing mass in the left cerebral peduncle consistent with metastasis. She completed gamma knife radiosurgery (GKRS) to a left brainstem lesion in 1/2023.
She started 1st line therapy for HER2+ metastatic breast cancer (MBC) using Docetaxel, Trastuzumab and Pertuzumab in 1/2023. Repeat brain MRI in 5/2023 noted 5mm x 2mm left cerebral peduncle lesion, decreased from prior, with no new lesions. Chest CT reported progression in the left breast primary tumor. She received palliative RT to the left breast to 40.05Gy in 15 fractions. Her course was complicated by recurrent DVT and anticoagulant failure, now on a low molecular weight heparin.
She was doing well until she presented to the ER in 7/2023 with fever and right axillary pain. Imaging revealed new right large SCV and right axillary lymphadenopathy. The known left breast/chest wall disease was improved. She underwent a right axillary biopsy which revealed IDC, grade 3, ER-(0%), PR- (0%), HER2- (IHC 1+), Ki-67 70%. Restaging scans remained free of distant disease. However, brain MRI showed development of numerous superficial enhancing lesions in addition to a lesion within the right basal ganglia and persistence of the lesion in the left cerebral peduncle. She was neurologically intact and

subsequently underwent GKRS to 9 lesions.
Given the diagnosis of right sided triple negative breast cancer (TNBC), treatment involved determination of therapeutic options that would simultaneously treat her TNBC and her HER2+ BC. Tumor genomic profile testing was performed which yielded no actionable targets.
Treatment was switched to Trastuzumab Deruxtecan (T-DXd) in 9/2023. She has remained on this regimen to date with resolution of right SCV and right axillary disease, resolution of left breast fungating mass with significantly improved residual left axillary wound defect and continued disease control in the brain.
Discussion: The decision to initiate T-DXd was made due to benefit of T-DXd in the treatment of both HER2+ and HER2 low MBC. In the DESTINY 02 clinical trial in HER2 + MBC, T-DXd showed a longer median overall survival (OS) of 39.2 months compared to 26.5 months with physician's choice therapy. In DESTINY 04 clinical trial in HER2 low MBC, T-DXd led to OS of 23.4 months compared to 16.8 months with physician's choice therapy. In addition, the TUXEDO-I trial demonstrated that T-DXd showed efficacy in patients with active brain metastases, yielding intracranial responses in 73.3% of the population with median progression-free survival of 14 months. In conclusion, this unique case highlights the temporal heterogeneity of breast cancer and supports the use of T-DXd in the treatment of this patient with metachronous TNBC (HER2 low) and HER2+ MBC to the brain.

P1-10-26: NSTI of the breast ; a rare and potentially fatal surgical emergency

Melissa Rangel, Elizabeth Marcus, Micheal Stover

Necrotizing soft tissue infections (NSTI) are true surgical emergencies. When diagnosed quickly and correctly lifesaving surgery is the standard of care. NSTI of the breast is a rare presentation of the disease, increasing the risk for a delay in diagnosis. We present a case of a 63 year-old female presenting with septic shock in the setting of a necrotizing soft tissue infection with actinomyces of the left breast requiring emergent surgical debridement.
Patient was a 63 year old female with insulin dependent diabetes (A1C of 11) who presented with several weeks of increasing pain and overlying skin changes. On admission to the ER she hypotensive and tachycardic, which improved with some volume resuscitation. WBC was 22, sodium 125, blood glucose was 366. She was stated on vancomycin, clindamycin and zosyn in the emergency department. CT scan was obtained showing extensive subcutaneous emphysema of the left breast as well as soft tissue thickening.
The patient was taken to the OR for debridement and essentially central mastectomy of the breast. Thick eschar was encountered over the nipple areolar complex with underlying necrosis. On exam in the OR, it was clear that a standard I&D was not possible due to extent of the necrosis and involvement of the nipple areolar complex. Instead, the cavity was incorporated in the excision without entering it, which involved taking the entire nipple areolar complex. Flaps were raised with some superior breast tissue preserved, essentially

making a thick flap. All inferior tissue was necrotic and was excised down to the inframammary crease. The breast was reflected off the underlying pectoralis major muscle, which appeared pink and reasonably healthy. The wound was packed. Subsequently, the patient returned to the OR for skin edge debridement and eventual wound vac placement and closure with plastic surgery. Once the wound bed appeared healthy and her hyperglycemia had been corrected, the patient underwent closure with drain placement. Final pathology showed necrotic skin and soft tissue. Wound cultures grew out actinomyces and the patient was started on Augmentin for a 4 month course, per recommendations of infectious disease. She followed closely post operatively with her PCP for close hyperglycemic control.

Management of NSTI of the breast requires a high index of suspicion, quick diagnosis and aggressive surgical management. Other authors have described a similar approach with mastectomy and delayed closure with multidisciplinary collaboration in patient care.

P1-10-27: NTHL-1 Syndrome in a Breast Cancer Survivor: Malignant Pleural Effusion Unveils Metastatic Colon Adenocarcinoma

Marian Varda, Lauren K Lewis, Charity A Huang

NTHL1-associated tumor syndrome is an autosomal recessive disorder stemming from mutations in the NTHL1 gene, initially linked with colorectal cancer but now recognized to elevate risks for various malignancies like breast, bladder, and endometrial cancers. This syndrome, characterized by NTHL1-associated polyposis and multiple adenoma development in adults, affects an estimated 0.014% of the population. NTHL1 encodes a DNA glycosidase crucial in repairing oxidatively damaged DNA via the base excision repair pathway.

We present a case which highlights the complex and diverse nature of NTHL1-associated tumor syndrome in a 40 year old premenopausal woman who developed ER+PR+HER2- invasive ductal carcinoma of the left breast in 2021. Subsequently, she underwent a left mastectomy and sentinel lymph node biopsy in May 2021, with one out of three sentinel lymph nodes positive for metastatic carcinoma. Post-operatively, she completed four cycles of docetaxel and cyclophosphamide chemotherapy followed by radiation therapy and tamoxifen. Post-surgical staging was determined as (m)pT2pN1a(sn)Mx. Two years after her breast cancer diagnosis, she developed new-onset dyspnea. Further investigation revealed a pleural effusion with pathology consistent with colon adenocarcinoma, despite no primary lesions being identified during subsequent EGD and colonoscopy. Genetic testing uncovered a heterozygous NTHL1 recessive mutation. The patient was initiated on first-line therapy for metastatic colon cancer and eventually passed within 6 months of therapy.

Heterozygous carriers of NTHL1 mutations face cancer risks, with emerging evidence suggesting increased breast cancer susceptibility, though precise risk estimates and management changes remain unclear. Recognition of NTHL1 syndrome's clinical heterogeneity and overlaps with other hereditary cancer syndromes underscores the

importance of early genetic testing for accurate diagnosis and management. Despite its rarity, increasing awareness and research are vital to comprehending and managing this complex syndrome.
Recent studies highlight that heterozygous NTHL1 carriers may confront notable cancer risks, such as colorectal and breast cancers. However, current literature lacks surveillance guidelines for these individuals. Understanding the prevalence and clinical implications of both heterozygous and homozygous NTHL1 mutations is critical for effective risk assessment, genetic counseling, and clinical management. Further research into molecular mechanisms and gene-environment interactions is essential to delineate how these mutations influence disease progression.

P1-10-28: Pembrolizumab Monotherapy for a Patient with Lynch Syndrome (LS) and Stage 2 Triple-negative Breast Cancer (TNBC): A Clinical Vignette

Sonia Gowda, Fei Song, Seyedeh Aleali, Shannon Young, Erika Simshauser, Jacob Elkon, Judy Garber, Ilana Schlam,

Introduction: LS is an inherited cancer syndrome associated with germline variants in genes responsible for repair of specific errors in the DNA [mismatch repair (MMR)]. LS confers an increased risk of several types of cancer, including colorectal (CRC), endometrial, and other GI malignancies; breast cancer has been controversial. Defects in mismatch repair lead to microsatellite instability (MSI), a condition of genetic hypermutability. Tumors with high MSI (MSI-H) tend to exhibit extensive mutations, which can lead to the production of neoantigens that, in turn, respond to immunotherapy. Thus, patients with LS and MSI-H CRC often have excellent responses to immune checkpoint inhibitor (ICI) monotherapy. Breast cancer is less common in patients with Lynch syndrome. Data on the response of LS-associated or MSI-H TNBC are limited. Biomarkers predictive of response to ICI represent an unmet need in TNBC care.
Case presentation: 69-year-old woman with a prior history of an unspecified gynecologic malignancy in the early 2000s (treated in China, records unavailable) and locally invasive rectal adenocarcinoma in 2022. Germline genetic testing revealed pathogenic variants of MSH6 and MSH3, confirming the diagnosis of LS. In August 2023, the patient was diagnosed with a left breast TNBC, measuring 4.5 x 5.0 cm on ultrasound (US). Concurrently, she was found to have recurrent metastatic rectal cancer with presacral disease and peritoneal implants, chronic sacral osteomyelitis, and a pre-sacral abscess, ultimately requiring long-term antibiotics. Immunohistochemistry performed on peritoneal implant tissue revealed loss of nuclear expression of MSH2 and MSH6.
Given her advanced CRC and increased risk for infections with chemotherapy, she began treatment with pembrolizumab monotherapy. After one cycle, the breast mass measured 3.0 x 2.5 cm; after two cycles, the mass was no longer palpable. Repeat PET/CT and breast US in January 2024 showed complete radiographic resolution of the breast mass, decreased avidity and size of the presacral tumor, and no avid adenopathy in the pelvis or abdomen,

indicating excellent treatment response. In July of 2024, she continues to have no evidence of disease in the breast, and the CRC remains stable. Molecular studies of the TNBC from Foundation®CDx (Foundation Medicine, Inc) demonstrated an extremely high tumor mutational burden (TMB) of 794 Muts/Mb, with 66 distinct genetic mutations, including BRCA2 R2336H/E1455/E292, PIK3CA R108H, and POLE L424P.
Conclusion: This is a unique case of a patient who carries two pathogenic variants in genes associated with LS (MSH6 and MSH3), who developed metastatic recurrent rectal adenocarcinoma, as well as synchronously diagnosed stage 2 TNBC, with a complete clinical response in breast cancer to pembrolizumab.
This case highlights the significant relationship between TMB and its utility as a predictive indicator of response to immunotherapy. It confirms prior studies suggesting that it is a promising biomarker, with the limitation that high TMB is rare in TNBC. It is notable that a complete response with pembrolizumab monotherapy was attained, thereby circumventing the toxicities associated with chemotherapy. This prompts us to consider if there may be value in testing breast cancers for MSI-H status, as this can suggest an increased likelihood of response to ICI. Furthermore, a question is raised about the possibility of avoiding chemotherapy for patients with MSI-H tumors, as has been demonstrated for patients with CRC.
Of note, the patient was found to have somatic pathogenic variants in BRCA2, which were likely a result of MMR deficiency in the setting of LS. However, the presence of these targetable mutations suggests that the tumor may respond to PARP inhibitors, which we will consider as a subsequent line of therapy.

P1-10-29: Periprosthetic breast implant seroma: a case report and discussion on BIA-ALCL

Dominic Collins, Diane M. Krutzler-Berry

Background: Late sequelae of breast implants, such as anaplastic large cell lymphoma, seroma and double capsules are rare. Breast implant associated anaplastic large cell lymphoma (BIA-ALCL) is an especially rare adverse outcome of breast implants that present late and can lead to poorer prognosis. This report outlines a case of late periprosthetic breast implant seroma while focusing on the diagnosis and management of BIA-ALCL.
Case Presentation: A 49-year-old Caucasian female presented to the clinic with significant pain and bluish discoloration of her left breast. Past medical history is significant for diagnosis of stage IIA T2N0M0 ER+/PR-/HER2- left breast cancer and stage IA T1N0M0 ER+/PR+/HER2- right breast cancer without axillary lymph node metastasis in 2019. The patient underwent bilateral mastectomy with placement of textured implants followed by adjuvant endocrine therapy with letrozole. Subsequent revision of the left breast implant was performed in 2020 due to grade 3 capsular contracture. Given her prior history and continued capsular contracture with the left breast implant, concern was present for breast cancer recurrence. Patient underwent MRI evaluation of the left breast which noted a hyperintense peri-implant signal on T1 images circumferentially. A thickening of 2.5cm was

noted inferiorly and posteriorly – BIRADs 4 designation was assigned to the breast following these findings. Due to the distinct clinical presentation of the patient, there was suspicion for BIA-ALCL. CT guided 17-gauge needle biopsy was performed allowing for multiple core samples of the lesion. Analysis of the core needle biopsy revealed degenerated acellular material that was consistent with fibrin. The patient then underwent subsequent removal of the left breast implant with a complete left breast capsulectomy. Pathology report following the complete breast capsulectomy indicated a paucicellular specimen with necrotic cells revealing bilateral fibroadipose tissue with chronic lymphoplasmacytic inflammation and fat necrosis without malignancy. Flow cytometric analysis with CD45 and side scatter properties of the lymphocytes of the left chest wall capsule and fluid revealed no significant findings, thus indicating no presence of BIA-ALCL. B-lymphocyte markers such as CD19, CD20, CD23 were negative in the sample. An elevated CD5 ratio was present in the sample most likely indicating a reactive T-lymphocyte mediated inflammatory process.
Conclusion: Although the patient presented in this case was negative for malignancy, it is important to outline the significance of her presentation regarding suspicion of breast implant associated anaplastic large cell lymphoma and the subsequent work up which led to her diagnosis of chronic lymphoplasmacytic inflammation and fat necrosis. While BIA-ALCL is a rare complication of breast implants with only 134 reported cases, it is essential to distribute information pertaining to cases like this to help better refine the clinical presentation for the disease. Given the multidisciplinary nature of breast care, reported cases such as this one will help aid physicians across various fields in gaining a better understanding of what signs and symptoms to be aware of in their patient populations; potentially leading to a diagnosis of an exceptionally rare, but life threatening, condition.

P1-10-30: Pulmonary vein thrombi in metastatic breast cancer: a management dilemma

Kriti Ahuja, Riya Patel, Jayasree Krishnan, Shipra Gandhi

Background: Pulmonary Vein thrombosis (PVT) is an infrequently reported complication in oncology, particularly so in breast cancer, with potentially devastating complications particularly due to the risk for intracardiac extension, systemic embolization and potential stroke. We present what we believe to be the second reported case in literature. PVT may be asymptomatic or present with cough, hemoptysis, dyspnea, weight loss, pleuritic chest pain or rarely with transient ischemic attack/stroke, end organ infarction or sudden cardiac death. It is diagnosed by imaging including CT Chest, echocardiogram, or occasionally cardiac MRI. There is no clear consensus on management strategy and it usually entails a multidisciplinary approach with surgical resection, systemic or radiation therapy to reduce tumor burden, as well as anticoagulation.
Case Presentation: Here, we share our experience with extensive PVT with cardiac extension in a patient with metastatic triple negative breast cancer and a systematic review of similar cases reported to date. Our patient was a 63 year old female with ER/PR negative

HER2 low (1+ by IHC) breast cancer initially diagnosed as pT3 N0 Mx, managed surgically, who subsequently developed recurrence with metastatic disease to left upper lobe of the lung). She progressed on multiple systemic treatments, including atezolizumab with nab paclitaxel, eribulin, capecitabine, sacituzumab govitecan, and a clinical trial. She was also initiated on therapeutic anticoagulation with apixaban for a PICC line thrombus. While on trastuzumab deruxtecan, a restaging scan demonstrated development of tumor thrombus in the left superior pulmonary vein which progressed to involve the left atrium. At the time, anticoagulation was continued and surgical management deferred. Given the development of tumor thrombus, in order to control further invasion into the heart, the thrombus was irradiated and systemic therapy was switched to carboplatin and gemcitabine, with resultant partial response. To prevent further growth and invasion of the tumor thrombus, a complete sternotomy, left atrial thrombectomy, left upper lobectomy and ligation of superior pulmonary vein was performed. Pathology of the left atrial mass was consistent with metastatic breast cancer. She recovered well from the surgery with a well healed surgical site. Later, due to infection at the surgical site, she developed sepsis which excluded her from active treatment.
Discussion: We performed an extensive literature search which revealed that most cases occurred in lung cancer, or in metastasis from choriocarcinoma, leiomyosarcoma, hepatocellular cancer, or renal cancer among others. Only one such case in breast cancer seems to reported thus far. We evaluated management strategies in 21 cases which included resection occasionally followed by chemotherapy/radiation (11) with 1 mortality from perioperative stroke, chemoradiation (2), chemotherapy (4), gamma knife radiation therapy (1). Two patients died without any cancer-directed treatment. The patient with breast cancer underwent embolectomy, thereafter, opting for domiciliary care. Some patients received anticoagulation[RP1] in combination with cancer directed care. Overall, surgical resection appears to be the most common approach, followed by chemotherapy, chemoradiation and radiation, respectively with similar success rates in the cases we reviewed. Anticoagulation is usually utilized as a temporizing measure when employed.
Conclusion: PVT in metastatic breast cancer is an extremely rare but lethal complication. Early diagnosis and multimodal approach, focusing on treatment of underlying malignancy to reduce the disease burden with careful consideration of risks and benefits of surgery is essential in treating these patients.

P1-11-01: Immune Infiltration Correlates with Transcriptomic Subtypes in Primary ER+ Invasive Lobular Breast Cancer

Fangyuan Chen, Sayali Onkar, Jian Zou, Yujia Li, Haley Arbore, Sai Maley, George Tseng, Peter Lucas, Tullia Bruno, Dario Vignali, Julia Foldi,

Background: Understanding the interplay between breast cancer and its microenvironment is crucial for improving treatment strategies. While immunotherapy has shown promise in triple-negative breast cancer, its role in estrogen receptor-positive, HER2-negative (ER+/HER2-) breast cancer, particularly invasive lobular carcinoma (ILC), remains

understudied. The immune landscape in ILC and its prognostic implications need further exploration.

Methods: We conducted a comprehensive analysis of RNA sequencing (RNA-seq) and multiplex immunohistochemistry (mIHC) data from 21 primary ER+/HER2- ILC tumors. RNA-seq was performed on all samples, and mIHC was conducted on 13 tumors from the same formalin-fixed, paraffin-embedded (FFPE) blocks. Transcriptomic subtypes were identified using unsupervised clustering and TCGA classifiers, while immune infiltration patterns were derived using non-negative matrix factorization (NMF) clustering.

Results: Our analysis revealed two distinct transcriptomic subtypes: proliferative and non-proliferative. The proliferative subtype, characterized by higher expression of cell-cycle pathways, showed increased immune infiltration compared to the non-proliferative subtype, which exhibited higher stromal scores. Five unique immune infiltration patterns were identified, with the proliferative subtype predominantly associated with immunosuppressive regulatory T-cells and macrophages.

We further defined a tumor-associated macrophage (TAM)-Low signature, comprising genes negatively correlated with macrophage infiltration. This signature was enriched in extracellular matrix pathways and showed an inverse correlation with proliferative, pro-inflammatory TAMs (Prolif-TAMs). In public datasets, the TAM-Low signature predicted improved relapse-free and overall survival in ER+ breast cancer. Analysis of the POETIC trial data indicated that the lower Prolif-TAM signature expression was associated with better response to neoadjuvant aromatase inhibitor therapy.

Conclusion: This study provides a comprehensive characterization of transcriptomic subtypes and immune infiltration patterns in ER+/HER2- ILC. The proliferative subtype is associated with a more immunosuppressive microenvironment, while the TAM-Low signature emerges as a promising biomarker for predicting reduced infiltration of pro-inflammatory macrophages and improved patient outcomes. These findings highlight the need for further research to validate the TAM-Low signature and to explore its potential in guiding immunotherapy and endocrine treatment strategies in ER+ breast cancer.

P1-11-02: Risk of Recurrence by Nodal Status and High-Risk Features in Patients with HR+, HER2-, Early Breast Cancer: An Analysis of Real-world Data

Sara M. Tolaney, Sarah Sammons, Javier Cortes, Astra M Liepa, Tomoko Sugihara, Zhanglin Lin Cui, Wambui Gathirua-Mwangi, Brenda Grimes, Ashwin Shahir, Mauricio Monaco, Patrick Neven, Stephen Johnston

Background: Tumor involvement of axillary lymph nodes (ALN) is the most significant prognostic marker for recurrence for HR+, HER2- early breast cancer (EBC). For node-

positive EBC, most patients (76%) present with 1-3 ALN (N1) disease; however, outcomes for N1 disease are variable. The monarchE trial selected patients at high risk of recurrence based on nodal status and included patients with 4-9 ALN (N2) or ≥10 ALN (N3); however, patients with N1 disease were required to have additional clinicopathological risk features including tumor size ≥5 cm and/or grade 3 disease. To further evaluate the risk of recurrence in patients with N1 disease, real-world data were used to describe outcomes for patients with N1 disease with and without high-risk clinicopathological features. Outcomes for patients with node-negative (N0) disease and N2 and N3 disease were also described for additional context. Methods: This study used the US nationwide Flatiron Health electronic health record (EHR)-derived de-identified database, predominantly with patients from community oncology settings. The database included >15,000 patients diagnosed with EBC from Jan 2011. Data cut-off was September 2020. Eligible patients had: (1) pathological stage I-III, HR+, HER2- disease, (2) undergone definitive surgery for primary breast tumor, and (3) initiated adjuvant ET by March 2020. Patients with N1 disease and high-risk clinicopathological features (i.e., tumor size ≥5 cm and/or grade 3) were assigned to the high-risk group (N1-HRG) and patients with N1 disease who did not meet monarchE criteria were assigned to the non-high-risk group (N1-NHRG). IDFS was defined as time from adjuvant ET initiation to recurrence or death; patients without events were censored at last structured EHR activity date prior to data cut-off. IDFS was estimated using the Kaplan-Meier (KM) method. Cox proportional hazards regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CI) for N1-HRG vs N1-NHRG (and vs N0), adjusting for patient and disease characteristics. Additional models evaluated N2, N3, and N1-HRG+N2+N3 each vs patients who did not meet monarchE criteria (NHRG). Patient and disease characteristics were summarized descriptively for all (sub)groups.
Results: 4658 patients met eligibility criteria, with N1-HRG (n=286), N2 (n=161), N3 (n=99), and NHRG (n=3999; N1-NHRG [n=548], N0 [n=3293]). Median follow-up was 43.5 months for N1-HRG+N2+N3 and 42.2 months for NHRG. For N1-HRG, 67% of patients had stage II, 82% had grade 3, and 25% had tumor size ≥5 cm. Five-year IDFS rates were 74% for N1-HRG, 89% for N1-NHRG, and 93% for N0. Recurrence risk for N1-HRG was >2-fold as high as N1-NHRG and N0 with adjusted HR (95% CI) of 2.18 (1.45, 3.29; nominal p-value = 0.0002) and 2.97 (2.19, 4.02; nominal p-value <0.0001), respectively. Five-year IDFS rates were 66% for N2, 65% for N3, and 71% for N1-HRG+N2+N3. Relative to NHRG, HR (95% CI) was 3.68 (2.63, 5.15) for N2, 4.03 (2.75, 5.91) for N3, and 3.25 (2.62, 4.03) for N1-HRG+N2+N3. Additional characteristics and KM curves for (sub)groups will be presented.
Conclusion: These real-world data demonstrate that patients with N1 EBC and high-risk clinicopathological features had a recurrence risk of 26% at 5 years which is nearly as high as recurrence risk in patients with N2/N3 disease. In contrast, patients with N1 EBC without high-risk features had a recurrence risk of 11% at 5 years which is similar to N0 disease. Patients that met monarchE criteria (N1-HRG, N2, N3 EBC) had a 5-year risk of recurrence of 29%, supporting the use of adjuvant abemaciclib plus ET in these patients with high-risk EBC.

P1-11-03: The Benefits and Burdens of Adjuvant Endocrine Therapy for Older Individuals with Hormone Receptor Positive Breast Cancer

Ezra Hahn, Rinku Sutradhar, Katarzyna Jerzak, Danielle Rodin, Lena Nguyen, Cindy Fong, Sabina Trebinjac, Lawrence Paszat, Eileen Rakovitch

Purpose: Adjuvant endocrine therapy (ET) is associated with significant morbidity amongst older women with breast cancer, but evidence on health service utilization is limited. The purpose of this study is to: 1) determine the difference in health care utilization between women who were adherent to ET, non-adherent to ET, and those who never initiated ET, and 2) estimate the risk of recurrence and death.
Methods: We identified a population-based cohort of individuals age >65 years, diagnosed with stage T1N0 HR+, HER negative EBC, treated with breast-conserving surgery (BCS) +/- radiotherapy (RT) between 2012 and 2021. Individuals with prior malignancy or who received chemotherapy were excluded. Exposure to ET was ascertained and proportion of time adherent to ET was calculated for a 24 month exposure period beginning 3 months after diagnosis date. For each case >65% adherent to ET, we matched 1 case <65% adherent and 1 control who did not receive ET on age at diagnosis, stage, type of nodal surgery, receipt of RT, history of diabetes and socioeconomic status. We used hospital records, billing claims and the cancer registry to identify the development of ipsilateral local recurrence (LR), contralateral breast cancer (CBC), breast cancer mortality (BCM) and all-cause mortality. We calculated the cumulative incidence of LR, CBC and BCM adjusting for competing risk of death from other causes and stratified by receipt of RT. We identified primary care and specialist visits, imaging tests, and visits with diagnostic codes for venothromboembolism (VTE), fracture, cardiovascular disease and diabetes to examine health care utilization from 5 years to 1 year prior to diagnosis date, and 3 years following the exposure period. We computed rates per 100 person-years to conduct a difference-in-differences analysis and used negative binomial regression to test change in rates of health services usage between cases and controls.
Results: The study cohort includes 3486 individuals (median age 72; 690 received RT); 1162 were >65% adherent, 1162 were <65% adherent and 1162 did not receive ET. Among individuals treated with BCS alone and were adherent (>65%) to ET, ET was associated with a 5% absolute reduction in 7-year LR risk compared to those who did not receive ET (1.7% (95% CI: 0.3, 5.7) vs 6.7% (95%CI: 3.4, 11.5); p=.09), with no difference in BCM (0% vs 3.1% (95% CI: 1.1, 6.8) p=0.08). Individuals treated with BCS+RT who were adherent (>65%) to ET, had a 2.6% absolute reduction in the 7-year cumulative LR risk compared to those who received no ET (0.5% (95%CI: 0.1, 1.5) vs 3.1% (95%CI: 1.9,4.8); p=.01) with no difference in BCM (0.4% (95% CI: 0.1, 1.2) vs 1.4% (95% CI: 0.7, 2.7); p=0.09). There was no significant difference in 7-year cumulative incidence of CBC between those >65% adherent versus those who did not receive ET (2.0% (95%CI: 1.1, 3.5) vs 4.2% (95%CI: 2.9, 5.7); p=0.22).
Individuals who received ET and were >65% adherent had significantly more visits to primary care (RR=1.1 95%CI: 1.04, 1.1; p<.001), specialists (RR=1.25 95%CI: 1.2, 1.3; p<.001) and gynecologists (R=1.2 95%CI: 1.02, 1.5; p=.03), more visits with a diagnosis of

VTE (RR=17 95%CI: 1.4, 2.0; p<.001), received more CT scans (RR=1.16 95%CI: 1.05, 1.29; p<.001), MRI (RR= 1.15 95%CI: 1.02, 1.3; p=.02), bone mineral density exams (RR=2.0 95%CI: 1.8, 2.2; p<.001) and more ambulatory visits (RR= 1.2 95%CI: 1.1, 1.3; p<.001) compared to those who did not receive ET. Individuals who were <65% adherent to ET had smaller absolute benefits but similar increased burdens.
Conclusions: For older individuals with HR+EBC treated with BCS, adjuvant ET is associated with small absolute reductions in recurrence risk, no difference in BCM and significantly more physician visits and imaging tests. This suggests that for some individuals treated with BCS+RT, the burdens of ET may outweigh the benefits.

P1-11-04: Neoadjuvant Z-endoxifen for Premenopausal Estrogen Receptor (ER)+, Human Epidermal Growth Factor Receptor (HER2)- Breast Cancer (BC): Evaluation of the Pharmacokinetic (PK) Run-in for the EVANGELINE Study.

Matthew Goetz, Vera J. Suman, Joel M. Reid, Lida A. Mina, Pooja Advani, Arezoo Mirad, Roberto Leon Ferre, Karthik Giridhar, Felipe Batalini, Sarah Buhrow, Stephanie Safgren, Swaathi Jayaraman, Patricia Cronin, Mara Piltin, Amy C. Degnim, Sarah Premji, James N. Ingle, Tufia Haddad, Amye J. Tevaarwerk, Jason Jones, Daniel Flora, Harjinder Singh, Nusayba Bagegni, Katie N. Hunt, Judy C. Boughey, Matthew Schellenberg, John Hawse, Steven C. Quay

Background: Aromatase inhibition (AI) with ovarian function suppression (OFS) is standard for premenopausal women (PrW) with ER+/HER2- primary breast cancer (BC). However, > 40% are intolerant of OFS leaving tamoxifen (TAM) as their only option. In the neoadjuvant endocrine setting, PrW with endocrine sensitive disease (ESD) (week 4 Ki-67 ≤ 10%) have 5-year disease free survival > 97%; however, only 35% achieve ESD with TAM vs 76% with AI+OFS (Gluz SABCS 2023). Z-endoxifen (ENDX) is a selective estrogen receptor modulator targeting ERα at 3-5 ng/ml and PKCβ1 ≥ 500 ng/ml, the latter resulting in AKT inhibition and apoptosis (Jayaraman NPJ Breast Cancer). EVANGELINE (NCT05607004) is an open label, randomized neoadjuvant phase II study with a PK Run-in to evaluate whether ENDX is non-inferior to exemestane plus goserelin in terms of ESD rate. The PK Run-in was designed to identify an ENDX dose that targets both ERα and PKCβ1, defined as day 28-day ENDX steady state concentration (Css) > 500 ng/ml in ≥ 5/6 patients (pts), and to assess antitumor activity and toxicity. In the PK Run-in, pts received either ENDX 40 mg/day (as monotherapy) or 80 mg/day (+/- goserelin). Pts with ESD remained on ENDX for 6 cycles (24 weeks) followed by surgery. We reported (Goetz AACR 2024) that among 7 pts (age 28-51; median 46) enrolled at the 40 mg/day dose, the median ENDX 28-day Css was 264 ng/mL (range:180-377), and ESD rate was 86% (6/7 pts), with either week 4 Ki-67 remaining ≤ 10% (n=3) or decreasing to ≤ 10% (n=3) with 1 pt remaining >10%. Grade 2 or higher AEs included grade 2 amenorrhea (n=2), grade 2 hot flashes (n=1) and grade 2 hypertension (n=1). The 6 pts with ESD completed 24 weeks of ENDX followed by surgery. Here we present the surgical findings of these 6 pts including Cell Cycle Arrest (CCA),

Residual Cancer Burden (RCB), as well as the preliminary 4 week ESD rate for the 80 mg/day +/- goserelin cohorts.
Methods: All pts who started protocol treatment are included in the summarized results. Results: The 6 pts treated with 24 weeks of ENDX 40 mg/day underwent surgery with no complications. cT stage was T2 in 5 pts and T3 in 1 pt. Central review of pre- and week 24 breast MRIs using RECIST criteria found tumor diameter reductions of 15 to 100% resulting in 1 CR, 1 PR and 4 SD. Median pre-Ki67 was 11 (range: 4-33%). Surgical CCA (Ki67 ≤ 2.7%) rate was 67% (4/6). The remaining 2 pts had Ki-67 of 3% (n=1) or in the patient with a near pCR, too few cells to quantitate (n=1). RCB was 1 (n=1), II (n=3), and III (n=2). PEPI scores will be reported at the meeting. At the 80 mg/day dose, ten pts were randomized to either ENDX alone (n=5, age 44-53; median 46) or ENDX + goserelin (n=5, age 37-52; median 44) with similar ER expression (all > 80%), cT, cN category and tumor grade in each arm. Ki-67 testing was completed pre- and week 4 for 9 pts where pre Ki-67 was ≤ 10% in 3 pts, > 10% in 4 pts, and not available in 2 pts (inadequate tumor cellularity). Following drug treatment, week 4 Ki-67 was maintained or fell to ≤ 10% in 6 pts, remained > 10% (1 pt), was indeterminate in 2 pts (inadequate tumor cellularity). PK data (80 mg/day) was available from the first 9 pts, and demonstrated a median 28 day ENDX Css of 344 ng/ml (range 161-959) with 3/9 pts > 500 ng/ml. At the 80 mg/day dose, there were no grade 3-4 toxicities. Grade 2 toxicities included hot flashes (2 pts), dyspepsia (1 pt), amenorrhea (1 pt), oligomenorrhea (1 pt), and nausea (1 pt). No VTE events were reported. Conclusions: Neoadjuvant ENDX, when administered to PrW, demonstrated substantial antitumor activity when administered as monotherapy (40 or 80 mg/day) or with OFS (80 mg/day). Increasing the ENDX dose from 40 to 80 mg improved the likelihood of achieving an Endx Css > 500 ng/ml without significantly increasing toxicity. We will present the final results from the 80 mg/day cohort at the meeting.

P1-11-05: Molecular and tumor microenvironment (TME) dynamics and correlations with response of estrogen receptor (ER)-positive breast cancer treated with endocrine therapy (ET), avelumab with or without palbociclib

Phaedon Zavras, Hanfei Qi, Ruizhe Chen, Mary Kate Jones, Ann Folmer, Hayden Chae, Jeffrey Reynolds, Ashley Cimino-Mathews, Rebecca Wingfield, Won Jin Ho, Luciane Kagohara, Allen Khodab, Lisa Kay Jacobs, Lisa Ann Mullen, Christie Hilton, Ahmed Elkhanany, Katia Khoury, Massimo Cristofanilli, Elizabeth Jaffee, Vered Stearns, Cesar A. Santa-Maria,

Background: Cyclin-D kinase 4/6 inhibitors (CDK4/6i) have been shown to improve antigen presentation and recruit activated T cells into the TME, with pre-clinical and clinical data suggesting synergy when combined with immune-checkpoint inhibitors (ICIs). We previously reported the clinical responses of patients (pts) with stage II/III ER+ breast cancer treated with neoadjuvant ET with a programmed cell death ligand 1 (PD-L1) inhibitor (avelumab) with or without a CDK4/6i (palbociclib, palbo) on the ImmunoADAPT trial (NCT03573648). We hereby present our correlative work to identify pts most likely to

respond.
Methods: This is a phase 2 pilot study including pts with stage II/III ER-positive/HER2-negative breast cancer who were randomized 2:1 to receive ET (aromatase inhibitors for post-menopausal pts; tamoxifen+/-ovarian function suppression for pre-menopausal pts) with avelumab, with or without palbo (palbo vs. control arms). We investigated molecular and pathologic characteristics, including baseline stromal tumor infiltrating lymphocytes (sTILs), HER2 scoring, histologic type and grade, ER and progesterone receptor (PR) % expression as well as genetic score (Oncotype Dx [ODx] or Mammaprint [MMP]) testing in association with response to treatment by RECIST 1.1 on MRI (overall response rate). A breast pathologist evaluated histology, grade, and sTILs (0-100%). Standard immunohistochemistry was used for ER, PR, and HER2 scoring; and in situ hybridization (ISH) as indicated by ASCO/CAP for HER2. Genetic scores are reported as either high-risk (ODx ≥26 or MMP high) or low-risk (ODx <26 or MMP low). Descriptive statistics and results from univariate logistic regression are reported. Additional translational correlatives, including imaging mass cytometry (IMC) and spatial transcriptomic (ST) analysis, will be reported at the meeting.
Results: From 2018-2023, 30 pts were enrolled and eligible for the primary analysis, including 20 pts on the palbo arm (1 pt with bilateral breast cancer, response to each breast cancer evaluated separately) and 10 on the control arm. Ten pts achieved an objective response (9/21, 42.9% from the palbo arm and 1/9, 11.1% from the control arm; 1 pt did not receive the final MRI). We observed a numerical trend towards improved responses with lobular/mixed vs. ductal histology, OR 2.0, p=0.402, 95% CI 0.4 – 10.42, and also in lower grade tumors; grade 3 vs 1/2, OR 0.44, p=0.497, 95% CI, 0.02-3.61. Baseline sTILs were calculated in 16 of the samples; 50% of the samples had sTILs <1%. There was a trend towards better responses with low baseline sTILs; sTILs ≥1% vs <1%, OR 0.24, p=0.199, 95% CI 0.02 – 1.93. Genetic testing was performed in 27/30 pts. None of the pts with a high-risk ODx/MMP (n=5) achieved an objective response. All pts with high-risk vs. only 36% of those with low-risk genetic testing had baseline sTILs ≥1%. There were no statistically significant associations between level of ER/PR/HER2 expression and response to treatment.
Conclusions: Responses in the ImmunoADAPT study were largely restricted to the ET+avelumab+palbo arm; lobular histology, lower tumor grade and sTILs <1% demonstrated a trend towards improved responses. None of the pts with high ODx/MMP responded. These observations require further investigation to understand the individual contributions of treatment and biological changes to the TME; serial IMC and ST data will be presented at the meeting.

P1-11-06: Impact of OncotypeDx Risk Categorization & Receipt of Chemotherapy on Survival Outcomes Among Patients with Small (T1mi/a/b) Node-Negative (N0/N0(i+)/N1mi) Hormone Receptor Positive (HR+) Breast Cancer

Kai Johnson, Julie A Stephens, Brittany Sandoval, Andrea House, Blair Hoeting, Sachin R Jhawar, Dionisia Quiroga, Gilbert Bader, Ashley P Davenport, Nicole Williams, Mathew A Cherian, Sagar Sardesai, Daniel G Stover, Margaret Gatti-Mays, Samilia Obeng-Gyasi, Bridget A Oppong, Doreen Agnese, Robert Wesolowski

Background: Application of genomic assays in clinically low-risk hormone receptor positive breast cancer (HR+BC) is understudied as patients with small (T1mi/a/b) node-negative (N0/N1mi) disease were often excluded from prospective trials. However, use of these tests in real world clinical practice, including OncotypeDx, occurs not infrequently, leading clinicians to question the reliability of the results produced whenever they are performed.
Methods: We aimed to help address this question by conducting a large, retrospective analysis of available survival data within the National Cancer Database (NCDB) for patients with small, node-negative disease. Where OncotypeDx recurrence score (RS) results were available, we categorized patients into low (RS <11), intermediate (RS 11-25), & high risk (RS 26-100) groupings. Additionally, we categorized patients based receipt of adjuvant chemotherapy. The primary outcome of Overall survival (OS) was explored for patients with high-risk disease via univariate analysis (cox proportional hazard models & Kaplan Meier survival estimates). Secondary outcomes included univariate analysis of OS based on OncotypeDx testing (regardless of chemotherapy receipt or risk group) & OS between low, intermediate, & high-risk patients, independent of chemotherapy use.
Results: In total, of the 308513 patients with T1mi/a/b N0/N0(i+)/N1mi HR+BC identified within the NCDB between the years 2010-2020, 18372 (6.0%) had received chemotherapy. Among those chemotherapy recipients who underwent OncotypeDx testing (n=8700), 363 were low risk (4.2%), 3475 were intermediate risk (39.9%), & 4862 were high risk (55.9%). Conversely, 81223 patients with T1mi/a/b N0 HR+BC underwent OncotypeDx testing without receipt of chemotherapy during this period. Of those, 29954 were low risk (36.9%), 48569 were intermediate risk (59.8%), & 2700 were high risk (3.3%). When comparing OS among high-risk patients where chemotherapy was omitted versus administered, a significant reduction in OS was noted with omission (HR 1.73, 95% CI 1.44-2.10, p<0.001), with 5-year OS being 94.9% vs 96.8%, respectively. When comparing OS for patients who underwent OncotypeDx testing versus those who did not, regardless of chemotherapy receipt, there was a significant improvement in OS for those tested (HR 0.45, 95% CI 0.43-0.47, p<0.001), with 5-year OS being 97.2% versus 93.7%, respectively. Furthermore, when comparing OS among low, intermediate, & high-risk patients, regardless of chemotherapy receipt, a significant difference between groups was noted (p<0.001), with high-risk being least favorable.
Conclusions: The findings above suggest that risk stratification may be advantageous, even among otherwise clinically low-risk individuals with HR+BC. Multivariable analysis is

further planned to better examine the association between OncotypeDx risk categories & pathologic features such as tumor size, nodal findings, tumor grade, estrogen receptor expression levels, progesterone receptor expression levels, & the presence of lymphovascular invasion. Clinical factors, such as age, race, ethnicity, & receipt of endocrine therapy will also be examined.

P1-11-07: Associations between Breast Cancer Index Classifications and MSK-IMPACT Genomic Profiles in HR+/HER2- Breast Cancer

Hong Zhang, Li Ma, Anton Safonov, Natalia Siuliukina, Julia Ah-Reum An, Subhiksha Nandakumar, Enrico Moiso, Edaise da Silva, Mehnaj Ahmed, Lisa Loudon, Konner Nelson, Kevin Murphy, Jade Oghoanina, Mark Robson, Sarat Chandarlapaty, George Plitas, Yi Zhang, Kai Treuner, Pedram Razavi

Background: The Breast Cancer Index (BCI) is a gene expression-based signature that stratifies patients based on the risk of overall (0-10 years) and late (post-5 years) distant recurrence (DR). BCI also predicts the likelihood of benefit from extended endocrine therapy in early-stage, HR+ breast cancer (BC). This study aims to explore the correlation between BCI and disease-free interval and possible associations between gene-expression-based classification by BCI and the genomic features of primary breast cancers in patients with HR+/HER2- breast cancer who developed metastatic relapse.
Methods: Primary tumor samples from HR+/HER2- metastatic/recurrent BC patients underwent both BCI and MSK-IMPACT targeted sequencing. MSK-IMPACT identifies somatic mutations, rearrangements, and copy-number alterations in up to 505 cancer genes. Time to DR (TTDR) defined as the time between date of surgery and distant recurrence. Kaplan-Meier survival analysis and Cox proportional hazards regression were used to evaluate BCI's prognostic performance. Pearson's correlation (R) was used for correlation between BCI score and TTDR. Fisher's exact tests were used to identify genomic alterations with significant differences comparing BCI prognostic groups. Due to small sample size, comparisons were not adjusted for multiple testing.
Results: The study includes 107 HR+/HER2- metastatic patients with primary tumors tested with both MSK-IMPACT and BCI: 44% post-menopausal, 60% T2/3, 64% grade 3, 56% lymph node positive (LN+).
Consistent with the nature of this cohort (all experienced DR), BCI classified the majority of the patients (n=94, 88%) as high-risk for DR. The BCI score was negatively correlated with TTDR (R=-0.24, p=0.011). Patients classified as high-risk by BCI tended to have DR earlier than low-risk patients (median TTDR: 2.8y vs. 3.4y; HR=1.95 with 95% CI: 1.05-3.62; p=0.031).
Overall, the genomic profile of the cohort was consistent with high-risk luminal primary tumors, with higher than expected rate of TP53 mutations (35%). Analysis of somatic genomic alterations by MSK-IMPACT revealed a trend that there are more mutations in PIK3CA and TBX3 in the BCI low-risk group compared to the high-risk group (77% vs 46%, p=0.038) and (38 vs 3%, p=0.020), respectively.

Conclusion: In this cohort of high-risk BC patients who all had a DR event, BCI remained prognostic with lower BCI scores associated with longer TTDR. Initial findings from the genomic correlative analysis suggested an association of BCI with certain genomic features. Further analyses with additional samples are ongoing to substantiate these findings.

P1-11-08: Practice patterns and uptake of adjuvant abemaciclib in high risk localized hormone receptor positive, HER2-negative breast cancer

Sarah K. Premji, Tanmayi S. Pai, Savannah S. Liddell, Nathaniel E. Wiest, Dhauna Karam Prasad, Whitney R. Harris, Lisa L. Ellsworth, Jenna E. Hoppenworth, Shikha Patel, Farah Raheem, Melissa Noyes, Lida A. Mina, Pooja Advani, Amye J. Tevaarwerk, Brenda J. Ernst, Matthew P. Goetz, Karthik V. Giridhar

Introduction: In MonarchE, two years of adjuvant abemaciclib combined with endocrine therapy (ET) improved invasive disease-free survival and distant relapse free survival, with recent data confirming continued benefit beyond the two-year treatment period. The FDA approved abemaciclib in October 2021 in patients (pts) with HR+, HER2- early breast cancer (EBC) with node positive and Ki-67 ≥20%, based on an unplanned MonarchE analysis. The approval was amended in March 2023 to revert back to the intention to treat (ITT) protocol, including ≥4 axillary lymph nodes (ALN) or 1-3 ALN with size >50 mm or grade 3. There is a paucity of real-world data surrounding abemaciclib adoption in the eligible patient (pt) population. In this study we aimed to define practice patterns at Mayo Clinic, a large academic enterprise, to understand adjuvant abemaciclib Electronic Medical Record (EMR) documentation, physician recommendations and pt preferences in abemaciclib utilization.
Methods: As part of an IRB exempt quality improvement project, we retrospectively analyzed a registry database of pts meeting MonarchE eligibility criteria at Mayo Clinic. We analyzed if pts met criteria for adjuvant abemaciclib based on the October 2021 approval and the amended March 2023 approval along with diagnostic and staging information. EMR notes were reviewed for documented abemaciclib discussion, discussion outcome with pts, oncologist prescriptions and timing of drug start. Time dependent analysis related to FDA label indication were based on abemaciclib start within 6 months of adjuvant ET initiation.
Results: 400 pts met MonarchE criteria and initial analysis included 123 consecutive pts in Rochester, MN who started ET between April 2021 and October 2023. The median age at diagnosis was 56 years. Race/ethnicity included 104 (85%) White, 11 (9%) Asian, 7 (6%) Black, and 2 (1.6%) Hispanic. A total of 65 (53%) pts received neoadjuvant systemic therapy including 14 (11%) with neoadjuvant ET. 85/123 (69%) pts had EMR indicated abemaciclib discussion. Of these, 53 met both early and late FDA criteria, 25 pts were eligible only for the original FDA-label criteria and 45 were eligible only based on the March 2023 indication. The proportion of pts meeting each specific criteria included N2/N3 disease (60/123) or N1 with ≥5 cm (32/123), G3 (28/123) or elevated Ki-67 (58/123). Adjusting for time dependence of the FDA approval, 64/87 (73%) pts had a documented

adjuvant abemaciclib discussion in the EMR. Of the 36 pts that met the IIT population but prior to the recent FDA approval, 21 (58%) had a documented abemaciclib discussion. Of the 85 documented discussions, 73 pts were recommended adjuvant abemaciclib. Of the 12 pts that were not recommended abemaciclib, main reasons included adjuvant olaparib in gBRCA1/2 carriers (n=3), comorbidity concerns (n=2), and ET tolerance difficulties (n=2). Of the 73 pts recommended to take abemaciclib, 13 (18%) pts declined. The most common EMR documented reasons for declining included concerns for side effects (n=4), perceived benefit (n=1), cost (n=1) or unknown/other (n=7). 4 pts (3.3%) had a breast cancer recurrence, 3 of these pts had EMR abemaciclib documentation. Of these, all 3 pts developed distant recurrence, 1 was prior to abemaciclib start and 2 were 22-24 months after surgery with intermittent abemaciclib use due to side effects.
Conclusions: In this retrospective study of high-risk HR-positive EBC, an adjuvant abemaciclib discussion was documented in the EMR 69% of the time. Most pts who were recommended abemaciclib did start it, though nearly 20% declined. With the possible approval of a second adjuvant CDK 4/6 inhibitor, prospective real-time capture of practice patterns from the EMR may inform pt management. Data for the full Mayo Clinic Enterprise will be available at the time of the meeting.

P1-11-09: Clinical Outcomes and the 21-Gene Recurrence Score Assay in Early-Stage Breast Cancer Associated with CHEK2, ATM and PALB2 Germline Pathogenic Variants

Fatma Nihan Akkoc Mustafayev, Nihan Akkoc Mustafayev, Angelica M. Gutierrez, Sarah Pasyar, Clinton Yam, Rachel M. Layman, Darya Kizub, Roland Bassett, Banu Arun

Background: The 21-gene recurrence score assay (Oncotype DX Breast Recurrence Score) is widely used to predict the risk of recurrence and guide adjuvant therapy decisions in early-stage hormone receptor-positive, HER2-negative breast cancer (BC). Despite its widespread use, the impact of CHEK2, ATM, and PALB2 germline mutations on clinical outcomes and Oncotype DX recurrence score (RS) remains unclear. This study aims to investigate the relationship between these germline pathogenic variants and Oncotype RS, and to assess their combined impact on clinical outcomes in early-stage BC.Methods:Patients with invasive hormone-positive, HER2-negative BC who underwent the 21-gene RS assay and genetic testing in the Breast Medical Oncology and the Breast Clinical Cancer Genetics Clinic at the University of Texas MD Anderson Cancer Center were identified from the prospectively maintained research database. Clinical and tumor characteristics were analyzed using descriptive statistics. The Chi-square test, Fisher exact test, and Wilcoxon rank-sum test were used to compare the groups where appropriate. Univariate and multivariate Cox regression models were employed to evaluate the relationship between covariates and overall survival (OS) and relapse-free survival (RFS).Results: Between 1996 and June 2023, 5652 patients with Oncotype RS were included in this analysis. Among 796 estrogen receptor-positive, HER2-negative BC patients with Oncotype RS and genetic testing, 22 (2.8%) had an ATM mutation, 18 (2.3%) had a CHEK2 mutation, and 17 (2.1%)

had a PALB2 mutation. The median age at diagnosis was 51 years (22-80), with no statistically significant differences in baseline patient characteristics among the three groups. The overall median Oncotype RS was 17 (0-67). Tumors that were progesterone receptor-negative or with higher nuclear grade had higher Oncotype RS (p <.0001). The distribution of Oncotype RS differed among the three groups, with significantly higher Oncotype RS higher in PALB2 group compared to without pathogenic variants (p =.0047). The PALB2 group also demonstrated a trend towards higher median Oncotype RS in patients aged over 50 (p=.009). In the univariate analysis, older age (>50 years) (HR 0.68, 95% CI, 0.45-1.02; p=.0492), adjuvant endocrine therapy (ET) (HR 0.24, 95% CI, 0.14-0.41; p<.0001), and adjuvant radiotherapy (XRT) (HR 0.49, 95% CI, 0.33-0.74; p<.0001) were associated with better RFS. In contrast, poorer RFS was associated with presence of a CHEK2 mutation (HR 3.02, 95% CI, 1.14-8.01; p=.0263), high Oncotype RS (HR 1.53, 95% CI, 1.01-2.31; p=.0432), lymphatic invasion (HR 2.16, 95% CI, 1.35-3.46; p=.0011) , vascular invasion (HR 2.22, 95% CI, 1.39-3.55; p<.0001), and high Ki67 levels (HR 2.05, 95% CI, 1.37-3.08; p<.0001).Only adjuvant ET significantly improved OS (HR 0.30, 95% CI, 0.13-0.71; p=.006). In multivariate analysis, high Ki67 levels (HR 2.52, 95% CI, 1.45-4.58; p=.0018) were associated with poor RFS, whereas adjuvant ET (HR 0.17, 95% CI, 0.07-3.35; p<.0001) and adjuvant XRT (HR 0.53, 95% CI, 0.30-0.90; p=.0259) were associated with better RFS. The presence of the mutation did not show a statistically significant effect on OS (p=0.6).Conclusion: Our data demonstrate that higher Oncotype RS, CHEK2 mutations, lymphatic and vascular invasion, and higher Ki67 levels were identified as predictors of poorer RFS. Conversely, older age (>50 years), adjuvant ET, and adjuvant XRT were associated with improved RFS. Importantly, the presence of ATM, CHEK2, or PALB2 mutations did not significantly impact OS. These findings highlight the importance of individualized treatment strategies that integrate genetic profiling and clinical factors to optimize outcomes in BC management.

P1-11-10: Current Endocrine/Systemic Treatment Landscape of ER+ HER2 negative early-stage Breast Cancer: First Data from the RESCUE trial

Johannes Ettl, Evelyn Klein, Christine Heinz, Ji Young Kim, Jens-Uwe Blohmer, Carsten Denkert, Stefan Paepke, Christine Mau, Katja Gnausch, Jasmin Yamamoto, Sven-Thomas Graßhoff, Tilmann Lantzsch, Cornelia Meisel, Kay Friedrichs, Andreas Schnelzer, Stephan Seitz, Axel Gatzweiler, Sirrka Kluge, Markus Borner, Pamela Lammert, Anke Kleine-Tebbe, Anja Pelzl, Dorothea Fischer, Amelie Bletscher, Christian Schindlbeck, Carmen Schade-Brittinger, Michael Wittenberg, Marion Kiechle

Background: RESCUE is a prospective, international, multicenter health care study on risk assessment by the clinicomolecular test EndoPredict® and long-term patient outcome in early luminal breast cancer. For patients (pt) with early luminal breast cancer, precise national and international guidelines on (neo)adjuvant systemic therapy exist. Nevertheless, especially regarding endocrine therapies, treatment landscape has been shown to be heterogeneous in real world.

Objective: By analyzing baseline and follow up data from RESCUE, we describe the current (neo)adjuvant treatment landscape for pt with ER+ HER2neg early-stage breast cancer including: type of endocrine agents used, addition of GnRH analogs (GnRHAa)/ovarian function suppression (OFS) to ET in premenopausal pt, use of chemotherapy and use of bone modifying agents (Bisphoshonates or Denosumab) in the adjuvant setting.
Methods: Data from pt, who entered the RESCUE trial between July 2018 and September 2022 at 45 (42 German/3 Swiss) breast centers were collected via electronic case report forms. Pt were eligible, if they had been diagnosed with HR+/HER2- primary invasive breast cancer stage I/II, T1 to T3 with 0 to 3 positive lymph nodes and if they had an EndoPredict®-test within six months before inclusion.
Results: 1143 pt were analyzed. Median age was 57,0 years (range26,0-82,0). 614 pt(53,7%) were classified as pN0. Tumor-Grading was reported as follows: G1 (137pt, 12,0%), G2 (893pt, 78,1%), G3 (111pt, 9,7%). Distribution of Ki-67 was recorded as follows: £10% (228pt, 20,0%), 11-24% (162pt, 14,2%), ^{3}25% (753pt,65,9%). Of the 1134 female pt, 394 were premenopausal and 734 postmenopausal. Systemic treatment recommendations given by the centers´ documented tumor board decisions were as follows: 62,9% (n=248) of premenopausal pt and 61,0% (n=448) of postmenopausal pt were recommended to undergo (neo)adjuvant Chemotherapy (CTX). In the premenopausal cohort, the choice of ET recommendation included an GnRHa/OFS in 14,5% of cases (57pt). In these 57 pt, GnRHa/OFS was recommended to be combined with an aromatase inhibitor as initial ET in 15 cases (3,8% of premenopausal pt) and with tamoxifen in 41 cases (10,4% of premenopausal pt). 47 pt (82,5%) of the 57 pt with GnRHa/OFS-recommendation and 183 pt (54,3%) of the 337 pt without GnRHa/OFS-recommendation were recommended to undergo (neo)adjuvant CTX. Bone modifying agents (Bisphosphonates or Denosumab) were recommended in 10,2% of premenopausal and 32,7% postmenopausal pt. Follow up data on actually received ET (including +/- GnRH) and CTX (including +/- anthracyclines) will be presented in detail.
Conclusion: These real world data show that in spite of existing guideline recommendations for the use of GnRHa/OFS in premenopausal women with early luminal breast cancer at higher risk for relapse, this is not routinely implemented. Therefore, regarding the ET recommendation, this patient cohort might be undertreated. Follow up data on actually received ET (including +/- GnRH) and CTX (including +/- anthracyclines) will be presented in detail.

Sponsor: The study is sponsored by the North-Eastern-German Society of Gynecological Oncology (NOGGO) e.V.

P1-11-11: Pathological Complete Response and Survival Outcomes of Single Hormone Receptor-Positive/HER2-Negative Breast Cancer after Neoadjuvant Treatment and Further analysis of its Intrinsic Biological Features and Immune Landscape

Lei Ji, Xi Chen, Ge Song, Min Xiao, Qing Li, Jiayu Wang, Ying Fan, Yang Luo, Qiao Li, Shanshan Chen, Fei Ma, Binghe Xu, Pin Zhang

Background: Prior research has predominantly concentrated on the overarching hormone receptor-positive (HR+)/HER2-negative (HER2-) classification, frequently amalgamating double HR-positive (dHR+) and single HR-positive (sHR+) tumors, consequently neglecting the distinctiveness of the sHR+ subgroup, particularly in the neoadjuvant context. The objective of this study was to evaluate the rates of pathological complete response (pCR) and survival in sHR+/HER2- breast cancer following neoadjuvant therapy, as well as to delve into its inherent biological characteristics and immune profile.
Methods: This study incorporated six cohorts. The first and fourth cohorts were from the Cancer Hospital, Chinese Academy of Medical Sciences (CHCAMS, n=1049), and the Surveillance, Epidemiology, and End Results (SEER, n=21092) database for analyzing neoadjuvant chemosensitivity and survival outcomes. Clinicopathological and subtype data from CHCAMS, SEER, the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC, n=1052), and Fudan University Shanghai Cancer Center (FUSCC, n=570) were utilized to explore intrinsic biological features correlating with the pCR rate and prognosis of sHR+/HER2- breast cancer. Genomic and transcriptomic profiles from METABRIC, The Cancer Genome Atlas (TCGA, n=741), and MSK-IMPCAT (n=1535) were also examined to explore potential associations with endocrine and immunotherapy responsiveness.
Results: Compared with double HR-positive (dHR+, ER+ and PR+)/HER2- breast cancer, sHR+ (ER+/PR- or ER-/PR+)/HER2- disease exhibited a higher pCR rate (20.2% vs. 3.2%, P <0.001) but significantly worse survival (hazard ratio, 2.97; 95% confidence interval, 1.62–5.43, P <0.001) in the CHCAMS neoadjuvant cohort. Clinically, sHR+/HER2- tumors showed higher histological grade and proliferation rate than did dHR+/HER2- tumors, along with a higher HR-low positivity rate (50.9% vs. 3.0%, P <0.001) in primary tumor and showing a preference towards changing to triple-negative tumors in residual disease (42.7% vs. 1.8%, P <0.001). Additionally, patients with sHR+/HER2- breast cancer manifested lower endocrine sensitivity scores, with nearly 20% of them belonging to the PAM50-defined basal-like subgroup. Immunologically, sHR+/HER2- tumors showed higher tumor mutation burden (TMB), expression of immune checkpoint-related genes (PD-1, PD-L1, CTLA4 etc.), and infiltration of tumor-infiltrating lymphocytes (TILs), especially CD8+ T cells, than did dHR+/HER2- tumors.
Conclusion: Patients with sHR+/HER2- breast cancer were characterized by relative sensitivity to neoadjuvant chemotherapy but worse prognosis, resembling triple-negative breast cancer in biological behavior. Immune relatively hot phenotypes of sHR+/HER2- breast cancer revealed a potential to benefit from immunotherapy.

P1-11-12: Early-stage HR+/HER2- breast cancer patients under 50 years old with a low-risk identified by the 70-gene signature (MammaPrintTM) could benefit from ovarian function suppression: A real-world study in China.

Weijuan Jia, Yongwen Jiang, Anqin Zhang, Fengxia Gan, Qian Ouyang

Background: The introduction of multigene assays has significantly altered the indications for adjuvant chemotherapy in hormone receptor positive/human epidermal growth factor receptor 2 negative (HR+/HER2-) early breast cancer. The 70-gene signature (MammaPrintTM) test has demonstrated its ability to identify prognostic capability. Patients with high clinical risk classified as low risk by MammaPrintTM (MP) can be safely spared adjuvant chemotherapy. However, it is worth noting that the majority of clinical studies conducted on MP have predominantly involved Caucasian populations. Breast cancer is known to exhibit biological and clinical differences across different ethnicities and races. In China, the onset of breast cancer occurs a decade earlier than in Western populations, with an average age of diagnosis at 48.7 years and a peak incidence between 45 to 49 years. The prevalence of breast cancer among patients under 50 is significantly higher than in Western countries. Consequently, it is crucial to validate the performance of MP across diverse populations to ensure its generalizability and reliability. This study aimed to explore the real-world utilization of MP among Chinese patients.
Method: From March 2018 to June 2022, genomic analysis utilizing the 70-gene platform, MammaPrintTM, was conducted on a consecutive series of 637 patients. An evaluation was performed to assess the distribution of clinicopathological characteristics across various risk groups as determined by the MP assay. This assessment was further compared with the findings from the pivotal MINDACT trial to indentify any notable differences. A robust analysis was conducted using the Kaplan-Meier method for survival curves and the Cox proportional hazards model to estimate hazard ratios.
Results: Among the 637 patients enrolled in the study, 261 (41.0%) were identified as high risk, with a substantial majority, 214 (82.0%), undergoing chemotherapy. In contrast, 376 (59.0%) were categorized as low risk, with a significantly smaller proportion, 46 (12.2%), receiving chemotherapy. A stark contrast was observed in the distribution of risk categories between the two groups, with a statistical significance ($p < 0.001$). Patients characterized by tumor grade 1, Ki67<30%, and PR ≥ 20% were predominantly classified as low risk. Compared to the MINDACT study population, the patients in this cohort were notably younger, with 33.3% versus 56.2% being under 50 years of age, and had larger tumors with higher tumor grades ($p < 0.001$). Notably, younger patients, those with Ki67≥ 30%, and lymph node-positive patients were more inclined to receive chemotherapy, even when classified as low risk. Conversely, older patients in the high-risk group were less likely to be treated with chemotherapy.
During a median follow-up period of 33 months (8 -66 months), 17 events were recorded. No significant difference in breast cancer free interval (BCFI) was observed between genetically high and low-risk groups for all patients (96.5% vs 97.3%, P=0.28), including

those under 50 years of age (95.5% vs 97.5%, P=0.863). However, among patients aged 50 or older, those classified as genetically low risk exhibited a superior BCFI compared to their high-risk counterparts (98.9% vs. 97.1%, P=0.047).
It was interesting to observe that the BCFI significantly improved following ovarian function suppression in patients under 50 years of age identified as low risk, compared to those without such suppression (P=0.035). Nonetheless, no significant difference was noted between the two groups for high-risk patients (P=0.115).
Conclusion: The real-world data clearly illustrate the benefits of the MP assay in decreasing the necessity for adjuvant chemotherapy in Chinese patients with low genomic risk in HR+/HER2- early breast cancer. The recurrence rates were similar in the high and low risk groups, which might be due to the favorable prognosis of the study population, the effectiveness of tailored treatments in managing breast cancer across different risk profiles and the short follow-up period. The poorer prognosis observed in high-risk patients aged 50 or older might be attributed to the fact that a significant number older patients did not receive chemotherapy.
Our data showed that low-risk patients under the age of 50 could benefit from ovarian function suppression. This finding warrants further investigation.

P1-11-13: Development and Validation of a Deep Learning Model for HR+/HER2- Early-stage Breast Cancer Recurrence Prediction (HERPAI) using Conventional Clinical and Pathological Data: A Real-world Study in Chinese Population

Ruixin Pan, Haoting Shi, Yiqing Shen, Xiaosong Chen, Kunwei Shen

Background: Escalation of adjuvant endocrine therapy for selected hormone receptor-positive (HR+) human epidermal growth factor receptor 2-negative (HER2-) early-stage breast cancer patients has been a standard-of-care treatment. Effective prognostic model is crucial for identifying patients who have unmet treatment needs and supporting personalized decision-making to improve the patients' outcomes. However, existing prognostic models fallen short when applied to these patients with low recurrence risk, especially among Chinese population. Thus, we sought to develop and validate a deep learning model for HR+ early-stage recurrence prediction (HERPAI) based on conventional clinical and pathological data.
Method: HR+/HER2- early-stage (T1-2N0-1) invasive breast cancer patients who received definitive surgery and followed by endocrine therapy from four independent medical centers were included in this retrospective study. Patients from center 1 were used as derivation cohort (90% in the development and 10% in the internal test cohort), while those from other centers were combined as an external test cohort. A deep learning prognostic model, HERPAI, was developed based on Transformer to predict risk of invasive disease-free survival (iDFS) utilizing clinical and pathological predictors (age, menopausal status, body mass index, family history, breast and lymph node surgery modality, T stage, N stage, histology, grade, expression levels of ER, PR, HER2, and Ki67). Hyper-parameter

random searching was performed using five-fold cross-validation strategy in the development cohort. The model performance was evaluated using Concordance index (C-index) for all of the cohorts, as well as the subgroups defined by menopausal status, N stage, Ki67 expression, adjuvant chemotherapy, and radiation therapy status. Cut-off value for selecting patients with 5-year recurrence risk > 10% was determined in the validation cohort for risk stratification. Hazard ratio (HR) was estimated between risk groups for iDFS. The association between HERPAI score and selected gene were explored using linear regression in the patients with genetic data in the derivation cohort to provide insights into the biological foundation of HERPAI.
Results: A total of 5,424 patients were included in the derivation cohort, of who 4,882 were used as development and 542 were used as internal test cohort, while 942 patients were included in the external cohort. HERPAI yielded a C-index of 0.73 (95% CI, 0.65 to 0.81) 0.73 (95% CI, 0.62 to 0.85), and 0.68 (95% CI, 0.60 to 0.77), in the validation, internal, and external test cohort, respectively. Consistent performances were observed for all pre-specified subgroups in three cohorts. High-risk patients (approximately 25% of the overall population) were associated with an increased risk of iDFS for validation (HR 2.56 [95% CI 1.25 to 5.22], P = 0.01), internal (HR 2.52 [95% CI 0.97 to 6.57], P = 0.06) and external test (HR 1.94 [95% CI, 1.00 to 3.74], P = 0.049) cohort, respectively. Moreover, HERPAI could predict distant recurrence and overall survival with a C-index of 0.68 (95% CI, 0.49 to 0.86) and 0.71 (95% CI, 0.47 to 0.94) in the external test cohort, respectively. In addition, HERPAI outperformed other prognostic factors in predicting iDFS, including T stage, N stage and Ki67 (C index ranged 0.54 to 0.59 in external test cohort). The HERPAI score was significantly associated with GRB7, GSTM1, Ki67, and RPLPO gene expression, after adjusted for age and family history (all P < 0.05).
Conclusions: HERPAI is a promising tool for selecting vulnerable HR+/HER2- early-stage BC patients who are at high-risk of recurrence and may benefit from escalating adjuvant endocrine therapy.

P1-11-14: Hormone receptor positive (ER+) HER2+ Lobular Breast Carcinoma: Molecular Response to Perioperative Endocrine Therapy and Clinical Outcomes in the POETIC Trial

Milana Bergamino Sirvén, Xixuan Zhu, Elena López-Knowles, Holly Tovey, Lucy Kilburn, Anthony Skene, Chris Holcombe, Alistair Ring, Ian Smith, John Robertson, Judith Bliss, Eugene F. Schuster, Mitch Dowsett, Maggie Chon U Cheang

Background: Invasive Lobular Carcinoma (ILC) represents about 15% of all invasive breast cancers (BC). ILC seldom exhibits overexpression of human epidermal growth factor 2 (HER2+), and majority of research focuses on ER+ HER2-negative phenotypes. There is limited data on response of ER+HER2+ ILC to endocrine therapy (ET) and the therapeutic efficacy of combined chemotherapy and anti-HER2 treatments (C+T). This study aims to report the biological responsiveness of ER+HER2+ ILC to perioperative aromatase inhibitors (POAI) and their clinical outcome within POETIC trial, one of the most

comprehensive studies of the ER+HER2+ BC.
Methods: POETIC trial was a phase III study of post-menopausal patients with ER+ BC, randomized 2:1 to 2-weeks of POAI or control, followed by standard-of-care. This study focused on ER+HER2+ BC (n = 342), 27 of whom had ILC at baseline (B) (17 POAI and 10 control). Ki67 levels were assessed at B and on-treatment (2wk) (low ≤10%; high >10%). Biological response to AI were categorized to LowB -Low2wK (LL); HighB –Low2wk (HL) or HighB–High2wk (HH). Baseline and on-treatment samples were gene expression profiled (NanoString BC360TM) for BC intrinsic subtypes (IS) (Luminal A: LumA, Luminal B: LumB, HER2-enriched: HER2E, Basal) and 46 gene signatures. T-tests were used to compare gene expression profiles (GEP) between ILC and invasive ductal carcinoma (IDC). P-values were adjusted using false discovery rate (FDR). Time to recurrence (TTR) was estimated using Kaplan-Meier method.
Results: Among the 27 ILC cases, the clinicopathological characteristics were similar to IDC. At the molecular level, the frequencies of IS in ILC were 22% (n = 6) LumA, 37% (n = 10) LumB and 41% (n =11) HER2E, compared to IDC being 17% (51/301) LumA, 37% (112/301) LumB, 44% (133/301) HER2E, and 2% (5/301) Basal.
In terms of early response to POAI in ILC, 33% (5/15) were HH, 53% (8/15) were HL and 14% (2/15) were LL. In comparison in IDC, 53% (100/188) were HH, 36% (68/188) were HL and 9% (17/188) were LL.
The 5 HH ILCs were mainly HER2E (1 LumB, 4 HER2E), while most HL were Luminals (1 LumA, 5 LumB, 2 HER2E), and all LL were Luminals, showing the poor anti-proliferative effect conferred by HER2E.
There were no distinct GEP associated with ILC compared to IDC in the hierarchical clustering of gene signature scores. IS and immune signatures drove the distinct expression patterns across the population of ILC and IDC. ILC had lower expression of cell adhesion than IDC (T-test FDR < 0.001). The impact of POAI to molecular changes were comparable based on histological tumor types and were driven by their intrinsics subtypes.
The 5-year TTR survival probabilities of ILC and IDC were 88% and 89.5% respectively. Fifty-two percent (14/27) of ILC received C+T and all remained recurrence free. Out of the 48% (13/27) ILC that did not receive adjuvant C+T and were only treated with ET, three (23%) had recurrence at 0.7, 2.1 and 4.1 years. Sixty-one percent (183/301) of IDC received C+T, of which 8% (14/183) had a recurrence event. Forty-nine percent (118/301) of IDC did not receive adjuvant C+T, from which 17% (20/118) recurred.
Conclusions: This study reported comprehensive study on the molecular features and their clinical behavior of the understudied ER+HER2+ ILC. Our findings suggested there were no distinct molecular profiles between ILC and IDC phenotypes of ER+HER2+ at baseline; their response and molecular changes after POAI were driven by IS as expected. While there was an enrichment of early sensitive tumors to POAI, the combined C+T treatment and ET might represent a good option to preventing recurrence in clinical high risk ILC. However, the small sample size precludes definitive conclusions.

P1-11-15: Enhancing Risk Stratification in HR+ Early Breast Cancer: A Real-World Evaluation of Oncotype Dx and Prosigna

Nicola Fusco, Giulia Cursano, Konstantinos Venetis, Elisabetta Munzone, Eltjona Mane, Mariia Ivanova, Chiara Frascarelli, Elisa De Camilli, Oriana Pala, Giovanni Mazzarol, Silvia Dellapasqua, Antonio Marra, Carmen Criscitiello, Giuseppe Viale, Giuseppe Curigliano, Elena Guerini-Rocco

Introduction: Oncotype Dx (ODX) is the most widely used genomic test for adjuvant treatment decision-making in patients with hormone receptor (HR)+ early breast cancer (EBC). Risk stratification in this clinical setting is crucial and often challenging, thus additional molecular information could significantly enhance patients' management. We hypothesized that Prosigna, a prognostic assay estimating distant relapse-free survival in postmenopausal women with HR+ EBC, could serve as a complementary test to ODX for risk stratification. This study aims to evaluate the concordance between ODX and Prosigna in a real-world scenario.
Methods: A total of 30 postmenopausal HR+ EBC patients, who were previously tested with ODX and classified as low (n=12), intermediate (n=5), and high (n=13) genomic risk, were included. The three risk categories were assigned considering the recurrence score (RS) and lymph node status: low (RS 0-10), intermediate (RS 11-25), and high risk (RS 26-100) for node-negative (pN0), as reported in TAILORx trial; low (RS ≤ 25) and high risk (RS>25) for 1-3 node-positive (N1-3), as reported in RxPONDER trial. For each case, RNA was extracted from the same formalin-fixed paraffin-embedded (FFPE) tumor block that was used for ODX, and subjected to Prosigna testing on a NanoString nCounter® DX Analysis. The Prosigna risk of recurrence (ROR) score also considers lymph node status: for pN0, 0-40 indicates low, 41-60 intermediate, and 61-100 high risk; for N1-3, 0-15 indicates low, 16-40 intermediate, and 41-100 high risk. Descriptive analyses of clinicopathological features were performed. Cohen's Kappa and Spearman (rs) correlation analyses were calculated between RS, ROR, and clinicopathological factors.
Results: The overall agreement between the two platforms was the same as in the TransATAC study (κ=0.32; p<0.001). Considering ODX as the gold standard, a low-high disagreement was found in n=6 (20.0%) cases, while a low-intermediate or intermediate-high disagreement was observed in n=7 (23.3%) cases. The lowest concordance was seen in the ODX low (1/12) and intermediate (3/5) risk groups, with Prosigna tending to assign a higher risk. This tendency was confirmed by the 100% concordance (13/13) in the high-risk group. Prosigna assigned luminal A, luminal B, and HER2-enriched molecular subtypes to n=7, 23.3%; n=22, 73.3%; and n=1, 3.3% cases, respectively. Most luminal B (n=20; 90.9%) cases had high ROR scores, whereas n=12 (54.5%) cases were classified as high RS. A significant proportion of luminal A (6/7; 85.7%) cases were classified as intermediate ROR, while ODX classified n=1 (14.3%) of them as intermediate and n=6 (85.7%) as low RS. Tumor samples with high ROR were more likely G3 (p=0.002), pT2 (p=0.021), and Ki67>20% (p=0.01) in comparison with the intermediate risk ones. ROR showed a strong correlation with Ki67 expression (rs=0.72, p<0.001), whereas RS demonstrated a moderate correlation (rs=0.57, p<0.001). According to available follow-up (F/U) data (median 6

months; range 1-36), recurrence was detected in only one case (G2; Ki67=40%; F/U=14 months), which both assays classified as intermediate risk.
Conclusions: Our study confirms that ODX and Prosigna provide different types of clinical information for postmenopausal HR+ EBC patients, as they analyze distinct genes and pathways. In our real-world cohort, Prosigna generally assigned a higher risk category compared to ODX. Therefore, integrating multiple molecular assays could potentially refine risk assessment and enhance personalized treatment strategies in this patient population. However, it remains to be defined which specific subpopulation might benefit from this integrated approach for molecular testing. Further investigations with larger cohorts and long-term F/U data are needed to validate these preliminary findings.

P1-11-16: Impact of ribociclib dose reduction on efficacy in patients with hormone receptor– "positive/human epidermal growth factor receptor 2–negative (HR+/HER2–) early breast cancer (EBC) in NATALEE”

Erika Hamilton, Thomas Decker, Hope S. Rugo, Maria Fernandez Abad, Kevin Kalinsky, Qiang Liu, Mariya Rozenblit, Barbara Radecka, Seock-Ah Im, Frances Visco, Alejandro Perez, Yogesh Chattar, Murat Akdere, Vaidyanathan Ganapathy, Sorcha Waters, Joyce O'Shaughnessy

Background: The phase III NATALEE trial demonstrated statistically significant and clinically meaningful invasive disease–free survival (iDFS) benefit with ribociclib + a nonsteroidal aromatase inhibitor (NSAI) vs NSAI alone in patients with stage II/III HR+/HER2− EBC that deepened even after all patients stopped ribociclib (HR, 0.715; 95% CI, 0.609-0.840; 4-year absolute benefit, 4.9%; median follow-up, 44.2 months). Here, we present an exploratory analysis of efficacy in patients with and without dose reduction in the NATALEE trial.

Methods: Men and pre- and postmenopausal women with HR+/HER2− EBC were randomized 1:1 to receive ribociclib (400 mg/day; 3 weeks on/1 week off for 36 months) + NSAI or NSAI alone (men and premenopausal women also received goserelin). Key inclusion criteria were stage II or III disease (per AJCC 8th edition); patients with node-negative stage IIA disease (T2N0) were required to have additional high-risk criteria (grade 2 with Ki-67≥20% or high genomic risk; or grade 3). Only one dose reduction of ribociclib (400 mg/day to 200 mg/day) was allowed for the management of adverse events (AEs). Relative dose intensity (RDI; defined as the actual cumulative dose per duration of exposure [adjusted for the 3-weeks-on/1-week-off schedule] divided by the planned dose intensity of 400 mg/day) was analyzed by grouping patients into low, medium, or high RDI tertiles and summarized using Kaplan-Meier methods. A stratified Cox proportional hazards model was used to compare iDFS rates with ribociclib across these tertiles. The data cutoff date was April 29, 2024 (median follow-up, 44.2 months). Additional analyses on efficacy in patients who discontinued ribociclib earlier than the planned 3 years of treatment and additional analysis considering the immortal time bias will be included in the presentation.

Results: Among 2526 patients who received treatment in the ribociclib + NSAI arm, 687 (27.2%) had a ribociclib dose reduction, and 1839 (72.8%) did not. Median time to the dose reduction was 3.3 months. The most common reason for dose reduction was an AE (23.0% [582/2526]), and the most common AEs leading to dose reduction included neutropenia (14.0% [353/2526]), alanine aminotransferase increased (1.9% [48/2526]), and fatigue (1.0% [26/2526]). Baseline characteristics were balanced between those with and without dose reduction. Duration of ribociclib exposure was similar among patients with and without a dose reduction (median, 35.7 months in both groups). RDI did not impact iDFS rates. Patients with low (0 to <82.27%), medium (82.27% to <97.44%), and high (≥97.44%) RDI had similar iDFS rates (low vs high HR, 0.931; 95% CI, 0.690-1.254; medium vs high HR, 0.985; 95% CI, 0.736-1.319).

Conclusions: This post hoc exploratory analysis of NATALEE demonstrated that iDFS benefit was maintained among patients who had a dose reduction of ribociclib and was not impacted by ribociclib RDI. These data suggest that it may be possible to implement a dose reduction of ribociclib to 200 mg/day when necessary to manage AEs without compromising treatment efficacy for patients with HR+/HER2− EBC.

P1-11-17: High Tumor-Infiltrating Lymphocyte Levels Correlate with High MammaPrint® Recurrence Risk in Early-Stage Breast Carcinomas

Zoran Gatalica, Inga Rose, Faruk Skenderi, Nataliya Kuzmova, Semir Beslija, Timur Ceric, Inga Marijanovic, Ilir Kurtishi, Semir Vranic

Introduction: Tumor-infiltrating lymphocytes (TIL) are linked to responses to chemotherapy and immunotherapy and clinical outcomes, especially in high-risk breast carcinomas. MammaPrint® (MP) and BluePrint® (BP) are genomic tests designed to provide risk stratification and molecular classification for early-stage hormone receptor (HR)-positive breast carcinomas, which could include tumors with HER2-low expression. We investigated correlations between TIL measurements, HER2 status, and MP/BP assays in early-stage HR-positive breast carcinomas.
Materials and Methods: 167 early-stage HR-positive breast carcinomas with known MP/BP risk categorization were evaluated for TIL using whole slide scanned images according to the International TILs Working Group 2014 guidelines. HER2-low breast cancers were identified by IHC scores of 1+ and 2+ without HER2 amplification. A subset of high-TIL, high-risk cases underwent TSO500 (Illumina) next-generation sequencing (NGS).
Results: The patients had a mean age of 51 years, ranging from 26 to 75 years. Among the profiled cases, 97% were either luminal A (96/167) or luminal B (66/167) breast carcinomas, with only five cases classified as HER2-enriched (n = 2) or basal-like (n = 3) carcinomas. Tumor grade was strongly associated with recurrence risk ($p<0.001$). The prevalence of the HER2-low phenotype was 65%, including 46/69 (67%) high-risk cases. TIL levels ranged from 0 to 70% and were low (≤10%) in the majority (75%) of cases in the cohort. However, high TIL levels were more frequently observed in cases with high recurrence risk (56% vs. 39%, $p = 0.03$). Additionally, TIL-enriched high-recurrence risk

carcinomas contained targetable genomic alterations, including PIK3CA, BRCA1, BRCA2, and HER2 mutations.
Conclusions: TIL levels are higher in early-stage HR-positive breast carcinomas with a high recurrence risk. These tumors also harbor targetable genomic alterations, suggesting that TIL measurement and genomic profiling could enhance risk stratification and identify patients who might benefit from targeted therapies. Her-2 low expression in high-risk patients provides a consideration for including novel ADC therapies in this subset of patients.

P1-11-18: Detrimental effect on survival of neoadjuvant (NACT) versus adjuvant (ACT) chemotherapy in stage II-III hormone receptor-positive & HER2-neg (HR+/HER2-) breast cancer: A propensity score-matched (PSM) analysis of a retrospective patient series.

Armando Orlandi, Giorgia Arcuri, Lucia Sacco, Letizia Pontolillo, Antonella Palazzo, Giovanna Garufi, Luca Mastrantoni, Elena Di Monte, Noemi Maliziola, Angela Chiara Rotondi, Valentina Frescura, Ida Paris, Luisa Carbognin, Paola Fuso, Sergio Pannunzio, Alba Di Leone, Martin Sanchez, Lorenzo Scardina, Sabatino D'Archi, Gianluca Franceschini, Alessandra Fabi, Diana Giannarelli, Giampaolo Tortora, Emilio Bria

Background: The use of NACT in stage II-III HR+/HER2- breast cancer are controversial for low rate of pathological complete response (pCR) and is an ongoing debate whether NACT or ACT provides better survival outcomes for these patients.
Patients and Method: Seven hundred sixty-one patients (pts) with HR+/HER2- local advanced breast cancer at stage II-III undergoing NACT (503 pts) or ACT (258 pts) chemotherapy between 2005 and 2021 were identified from our center Fondazione Policlinico Universitario A. Gemelli IRCCS of Rome.
A PSM was employed to create cohorts with balanced characteristics at the baseline, across different categories (age, menopausal status, grading, stage, Ki67, ER, PgR, HER2). The efficacy of NACT and ACT in terms of overall survival (OS) and real-word invasive disease free-survival (rwiDFS) was evaluated using Kaplan-Meier analysis and the Cox proportional hazards model.
Results: Using PSM, a total of 492 pts was ultimately included in the study (246 vs 246). The OS was significantly longer for ACT versus NACT (80.6% vs 98.3% survival rate at 5 years, HR 0.10, 95%CI 0.04-0.23, p <0.0001). The rwiDFS was longer for ACT versus NACT (NR vs 127 months, HR 0.67, 95%IC 0.45-1.0,1 p 0.054).
Pts underwent ACT had significantly better OS in comparison to those achieved pCR (HR 0.24, 95%IC 0.09-0.61) or not-pCR (HR 0.09, 95%IC 0.05-0.15) after NACT.
Conclusion: For patients with stage II-III and HR+/HER2- OS and rwiDFS were found to be worse with NACT compared ACT. NACT in HR+/HER2- should be used only in selected local advanced case and when other strategy is not possible. We need new treatments in neoadjuvant setting for local advanced HR+\HER2-.

P1-11-19: Evaluation and Management of Incomplete Ovarian Function Suppression in Premenopausal Breast Cancer Patients Receiving Anti-Hormone Therapy

Elizabeth Weil, Yee Chung Cheng, Lubna Chaudhary, Sara Bugamelli, Ruchi Patel, Sailaja Kamaraju, Emma Carroll, John Burfeind, Janet Retseck, Deepika Sriram, Colin Mooney, Jutta Deininger, Angela Halbach, Maressa Sweeney, Kylie Steinke, Erinn Stockhausen

Background: Breast cancer is the most common malignancy among females. The Tamoxifen and Exemestane Trial (TEXT) and the Suppression of Ovarian Function Trial (SOFT) were two landmark studies, which showed adjuvant therapy with the aromatase inhibitor (AI), exemestane, or tamoxifen combined with ovarian function suppression improved disease-free survival among premenopausal women. However, data has since emerged regarding incomplete OFS with Gonadotropin-releasing hormone (GnRH) agonists in some premenopausal patients. The SOFT Estrogen Substudy (SOFT-EST) was a prospective substudy of SOFT, which evaluated estradiol (E2) levels to determine if patients on exemestane and triptorelin experienced suboptimal ovarian function suppression (OFS). In this study, 17% of patients had an E2 level greater than 2.72 pg/mL at each time point, which was determined to be incomplete OFS. This study called into question whether E2 levels should routinely be monitored in women on GnRH agonists. The National Comprehensive Cancer Network (NCCN) and the American Society of Clinical Oncology (ASCO) provide recommendations to monitor E2 levels in premenopausal patients on an aromatase inhibitor (AI) due to the concern of incomplete OFS for patients receiving GnRH agonist therapy. The purpose of this study is to develop and implement a protocol for monitoring E2 levels at Froedtert & MCW based on the NCCN and ASCO recommendations.

Methods: This study implemented an OFS monitoring guideline in combination with a collaborative practice agreement at Froedtert & MCW. Pharmacists were responsible for ordering and monitoring E2 levels on eligible patients based on a specified protocol. An E2 level ≤ 2.72 pg/mL while receiving an AI or ≤ --------21 pg/mL while receiving tamoxifen in addition to a GnRH agonist injection was defined as complete OFS. E2 levels were retrospectively analyzed to evaluate if patients had incomplete OFS. The primary outcome was proportion of patients identified per the E2 monitoring protocol that fail to achieve OFS for two consecutive levels over an 18-month period.

Results: A total of 85 patients were reviewed at the time of analysis. Fifty-three patients (62.4%) achieved complete OFS (three consecutive E2 levels within goal), compared to 17 patients (20%) demonstrating incomplete OFS. Seven patients (8.2%) have labs that are still pending. Patients with labs pending include those who have not had enough consecutive levels demonstrating complete or incomplete OFS. Eight patients (9.4%) declined lab monitoring. Of the 17 patients with incomplete OFS, six patients (35.3%) achieved OFS after switching their GnRH agonist agent and one patient (5.8%) achieved OFS with continued monitoring without switching agents. Five patients continue to have incomplete OFS despite switching GnRH agonists (29.4%). More patients were

chemotherapy naïve in the continued incomplete OFS group compared to those who had complete OFS after intervention (p = 0.010).

Conclusion: Our study has shown a trend toward the need for checking E2 levels to assess for incomplete OFS and that changing GnRH agonist agents may improve rates of complete OFS for some patients. Additionally, our study has shown that chemotherapy naïve patients experience more incomplete OFS; however, further data is needed to validate these results.

P1-11-20: Chemotherapy use in patients with early-stage high-risk ER+/HER2- breast cancer in the United States (US) community setting: A retrospective observational cohort study

Peter Fasching, Jagadeswara Rao Earla, Yezhou Sun, Kim M Hirshfield, Yu-Han Kao, Giovanna I Cruz, Amin Haiderali

Background: Novel options for perioperative systemic anticancer immunotherapy are currently being evaluated for early-stage high-risk ER+/HER2– breast cancer, for example, neoadjuvant pembrolizumab plus chemotherapy (chemo) followed by adjuvant pembrolizumab plus endocrine therapy in the phase 3 KEYNOTE-756 trial (NCT03725059). This retrospective cohort study aimed to describe patient characteristics and chemo treatment patterns in this patient population overall and based on chemo receipt status.
Methods: This study used the Syapse Learning Health Network, a database capturing the continuum of care for patients treated at US community practices, to select adults (≥18 years) with initial diagnosis (1/1/2016 – 1/30/2023) of high-risk (grade 3 AND T1c–T2/cN1–cN2 or T3–T4/cN0–cN2) ER+/HER2– breast cancer who had first surgery at the primary site, as in KEYNOTE-756, with latest data up to 05/31/2024. Patients enrolled in a clinical trial or with lobular carcinoma in situ, lymphoma, or other primary cancer were excluded. Using descriptive statistical tests, we compared baseline characteristics between patients who received chemo in the neoadjuvant and/or adjuvant setting and those who did not receive chemo. Real-world time on treatment (rwToT) with neoadjuvant and adjuvant chemo was estimated using Kaplan-Meier curves.
Results: Of 16,998 adults with HR+/HER2– nonmetastatic breast cancer at diagnosis, 441 patients (2.6%) with high-risk ER+/HER2– breast cancer (clinical stage I/II/III: 4%/55%/41%) underwent surgery and were eligible for the analyses. Median age was 55 years (range 23–89); 99% were women (60% postmenopausal); 68% were White; 95% (n=160) with known performance status had ECOG 0/1. Ductal carcinoma was most common (91%). Overall, 7% had ER-low positivity; 89% had positive clinical nodal status (cN1/N2: 81%/8%); and 69% were PR+. Of the 16% (n=71) with available Oncotype DX score, 42% scored high (>25), 31% intermediate (18–25), and 27% low (<18). Of the 44% (n=192) with available data, 7% were documented to have a germline BRCA mutation. Of 441 patients, 400 (91%) received systemic therapy in the neoadjuvant and/or adjuvant setting. About 78% of the cohort (346/441) received chemo, including 71% (n=244) in neoadjuvant, 23% (n=78) in adjuvant, and 7% (n=24) in both settings. Chemo recipients,

compared with chemo non-recipients (22%; n=95), were relatively younger (median [range]: 53 years [23–84] vs. 68 years [30–89]; p<0.001) and less often postmenopausal women (55% vs. 78%; p<0.001) with Medicare insurance (19% vs. 53%). Several baseline clinical characteristics differed significantly between chemo recipients and chemo non-recipients, including clinical stage III (44% vs. 29%; p=0.03), node-positive status (92% vs. 79%; p<0.001), ductal carcinoma tumor histology (93% vs. 84%; p=0.02), and Oncotype Dx high RS (61% vs. 10%; p<0.005). Median follow-up time was 26.2 months (range: 1.1–87.9). Among patients who received neoadjuvant only (n=69) or adjuvant only chemo (n=19), rwToT was 4.1 months (95% CI, 3.7–4.4) and 2.5 months (2.1–4.5), respectively. Conclusions: In this real-world study among patients with early-stage high-risk ER+/HER2– breast cancer, approximately 3 out of every 4 patients received chemo in the neoadjuvant and/or adjuvant setting. Younger patients with more advanced tumor stage and node-positive status were more likely to receive chemo than older patients with less advanced tumor stage and node-negative status. Our future work will describe more details of chemotherapy use and its impact on clinical outcomes, characterizing the unmet need in this high-risk patient population.

P1-11-21: Dose Reduction Impacts Persistence on Abemaciclib: A Retrospective Analysis of Real-World Data From the IntegraConnect PrecisionQ De-Identified Database

Vikram Gorantla, Rushir Choski, Stephan Rosenfeld, Debra Patt, Anupama Vasudevan, Teena Sura, Aryamaan Shrivastava, Mike Gart, Harshal Davé, Prateesh Varughese, Brandon Wang, Simon Blanc

Background: In the phase III monarchE study, patients treated with the CDK4/6 inhibitor abemaciclib in the adjuvant setting had significantly improved invasive disease-free survival and distant relapse-free survival which were not compromised by dose reductions.1 This study explored the impact of dose reduction on time to treatment discontinuation (TTD) in the real-world setting. Methods: This was a retrospective, observational analysis of data from patients in the IntegraConnect PrecisionQ real-world de-identified database. The study included patients with breast cancer who initiated adjuvant treatment with abemaciclib after October 1, 2021, with follow-up through May 15, 2024. The primary outcome was TTD among patients with and without a dose reduction (with a starting dose as per the label); also included were patient demographics, clinical characteristics, starting dose, and rates of dose reduction. Data are presented using descriptive statistics. Results: Of the 1,326 included patients, most were female (98.9%) and white (53.6%), and the average (standard deviation) age at diagnosis was 58.8 (13.3) years. The median (interquartile range) follow-up from diagnosis was 19.8 (12.9-27.2) months. Most patients (79%) started at the 300 mg (150 mg BID) dose, followed by 200 (100 mg BID) mg (15%) and 100 mg (50 mg BID) (6%). The median (95% confidence interval [CI]) TTD for the 100 mg, 200 mg, and 300 mg starting dose groups were 24.49 (22.20-not reached [NR]) months, 25.67 (22.92-28.98) months, and 23.18 (22.26-26.10)

months, respectively. Across all patients, median (95% CI) TTD was 28.98 (22.20-NR) in those with dose increases (n=53), was 27.34 (25.93-NR) in those with dose reductions (n=490), and was 19.34 (18.49-22.30) in those with no dose changes (n=783). Among patients who started at the 300 mg dose as per the label (n=1047), 436 (42%) had a dose reduction. The median (95% CI) TTD was 27.34 (25.93-not reached) months and 19.08 (18.10-21.64) months for patients with and without dose reductions, respectively. The treatment probability (95% CI) at 6 months was 97.6% (95.6, 98.7) and 84.7% (81.3, 87.6) in patients with and without dose reductions, respectively; at 18 months, these values were 78.6% (73.3, 83.1) and 55.9% (50.4, 61.0), and at 24 months, they were 62.4% (54.5, 69.4) and 36.4% (29.6, 43.3). Demographics were similar between patients with and without dose reductions. Conclusion: In the real-world setting, 21% of patients treated with abemaciclib in the adjuvant setting had a starting dose below the dose recommended by the label, and 42% of those who started at the 300 mg dose underwent dose reduction. Patients who had dose reductions spent a longer time on treatment than those who did not. Further analysis would need to be performed to understand why patients are treated for more than two years with abemaciclib. Reference 1 Goetz MP et al. NPJ Breast Cancer. 2024;10(1):34.

P1-11-22: Adjuvant Endocrine Therapy in HR+ Breast Cancer: HCPs Report on Real-World Barriers to Treatment Adherence

Jane Lowe Meisel, Brandi Hobbs, Ilona Dewald, Samuel Dooyema, Jeffrey Carter, Cherilyn Heggen, Kelly McKinnon

Background: Endocrine therapy remains the treatment backbone for patients with hormone receptor-positive (HR+) breast cancer. However, many patients with early-stage HR+ breast cancer struggle with treatment adherence due to treatment-related adverse events (TRAEs) and menopausal symptoms that affect quality of life. Research shows that nonadherence is especially prevalent among Black patients and patients younger than 40. In premenopausal patients, ovarian function suppression (OFS) is recommended in addition to standard endocrine therapy. OFS can increase the incidence and severity of TRAEs, but also significantly reduces the risk of recurrence of breast cancer. Use of a GnRH agonist during chemotherapy can also reduce the incidence of ovarian failure. Therefore, it is critical that providers understand the importance of selecting the appropriate adjuvant therapy, managing TRAEs, and promoting treatment adherence so that patients can stay on their treatment plan reliably and achieve the best disease-related outcomes. This study aimed to identify real-world provider barriers and knowledge gaps in managing AEs and enhancing patient adherence to adjuvant endocrine therapy.
Methods: In January-February 2024, 118 healthcare providers (HCPs) completed surveys on practice gaps and challenges related to care delivery, treatment selection, AE management, and shared decision-making in HR+ Breast Cancer.
Results: Over 70% of HCPs reported high or very high confidence in differentiating available endocrine therapy regimens for premenopausal versus postmenopausal HR+ breast cancer patients. However, significant challenges remain, as providers estimated that less than 50%

of their early HR+ breast cancer patients adhere to their endocrine therapy for the full 5 years. HCPs reported individualizing treatment plans, engaging patients in shared decision-making, and recognizing and managing treatment-related adverse events as their top 3 challenges. Sixty-three percent of providers cited side effects of endocrine therapy as the top reason for inconsistent adherence to treatment by patients. They reported that patients struggle the most with vaginal dryness (40%), arthralgias and bone pain (39%), and nausea and vomiting (32%). Providers' perceived top barriers to patients' communication about side effects were that patients are not sure which symptoms are important or relevant to share (66%), there is not enough time during their appointment (36%), or they do not wish to complain so they do not mention their symptoms (31%). Around half of HCPs reported utilizing patient navigators to support individuals from diverse backgrounds (54%), regularly assessing and updating cultural competence and implicit bias training (45%), and providing education materials in multiple languages (44%) as strategies to address health care disparities and promote equitable access to shared decision-making to support patient engagement and adherence. However, only 15% reported that they display affirming messaging in waiting rooms and patient rooms, and only 12% reported that their institution or leadership has made a public statement of support in advocating for health equity. When asked about strategies that would most improve adherence to endocrine therapy, HCPs selected improved patient education on the importance of treatment adherence (54%), tools to support adherence monitoring (52%), and improved patient education on expectations for treatment and when/how to reach out to their health care team (47%). Conclusions: Oncologists face multiple challenges that limit sustained adherence to endocrine therapy in their patients with HR+ breast cancer, especially in diverse patients and patients younger than 40 years old. Further research and implementation of strategies to address healthcare disparities and improve sustained adherence to endocrine therapy are needed to improve outcomes for all HR+ breast cancer patients.

P1-11-23: Risk of Disease Recurrence Among Patients with Stage II and III HR-positive, HER2-negative Breast Cancer in Colombia: A Retrospective Cohort Study

Marcela Chalela Jhon Bolaños, Carlos Bello, Carolina Benavides

Background: In HR+/HER2- breast cancer (BC), most patients are diagnosed in early stages (ES) when treatment (tx) is administered with curative intent; however, cancer recurrence remains a significant problem in this population. In Colombia, regardless of this disease being a public health problem, there is no data regarding disease recurrence (DR) and few data on the natural history of the disease. We conducted a study to assess risk of DR and better understand clinical characteristics of stage II-III HR+HER2- BC patients.
Methods: A retrospective analytical cohort study was conducted. Patients were selected from Suramericana database, one of the main health insurance companies in the country. Adults with a diagnosis (dx) of stage II-III HR+/HER2- BC between January 2017 and December 2022 were selected. Primary endpoint was local, regional, or distant recurrence

after primary surgery. We calculated cumulative incidence and incidence rates (IR) of recurrence per 1000 person-years stratified by stage. Kaplan-Meier method was used to estimate cumulative probabilities during follow-up.
Results: A total of 2142 patients were included. Median age at dx was 56 years, 99.3% of the patients were women and 57.7% were postmenopausal. Most pts (68.7%) were stage II, 43.9% had no nodal involvement at dx, and 54.7% had a Ki67 greater than 20%. A total of 1876 patients had surgical resection with median follow-up time of 24.7 months. Cumulative incidence of DR was 11.1% at 5 years, while the IR was 43.0 and 61.1 per 1000 person-years in stages II and III, respectively. Of the patients with DR, 56.6% were still receiving tx with endocrine therapy. Risk of DR was 5.9%, 13.1%, and 24.1% at 1, 3 and 5 years respectively. A significant increase of cumulative incidence of DR was observed in stage III (p=0.012, HR 1.43, 95%CI 1.08 - 1.91) and patients with high nodal involvement (p=0.004, HR 2.86 95%CI 1.56 - 5.24).
Conclusions: Real world data from this cohort show a similar incidence of DR in Colombia to the reported in the international literature. Regardless of adjuvant tx with endocrine therapy, patients persist at risk of DR and more effective therapies are needed to provide better outcomes for patients in this potentially curative scenario.

P1-11-24: Neoadjuvant Chemotherapy for T3 tumors in the Era of Precision Medicine - Biology is Still King

Rakhshanda Rahman, Laura Lee, Alfredo Santillan, Mehran Habibi, Peter Blumencranz, James Pellicane, Peter Beitsch, Pat Whitworth, Harshini Ramaswamy, Nicole Stivers, Andrea Menicucci, William Audeh, Joyce O'Shaughnessy

Background: Clinical T3 (cT3) breast cancer is a vexing problem due to the challenge of cosmetically acceptable breast conservation leading NCCN and ASCO to recommend neoadjuvant chemotherapy (NCT). However, MammaPrint® risk of recurrence and BluePrint® molecular subtyping genomic signatures have demonstrated high accuracy in predicting chemotherapy response. Thus, genomic profiling can potentially enable Choosing Wisely® informed treatment choices and reduced toxicity for patients unlikely to benefit from NCT, despite larger size at presentation. In this study, we examined the utility of MammaPrint and BluePrint for identifying cT3 tumors that respond to NCT.
Methods: A pooled analysis from NBRST (NCT01479101), FLEX (NCT03053193) and MINT (NCT01501487) trials was conducted on all cT3 patients who received NCT, had MammaPrint and BluePrint results, and post-surgical pathological Complete Response (pCR) data. MammaPrint risk was characterized as Low or High Risk. BluePrint subtype classified tumors as Luminal-Type, HER2-Type, or Basal-Type. Luminal-Type tumors were further classified as Luminal A (Low Risk) or Luminal B (High Risk). Tumor pCR rates were analyzed as an outcome measure. The association of genomic subtype and clinical features with likelihood of pCR was evaluated by multivariate logistic regression. Differences in pCR rates between genomic risk categories were evaluated by two-sided proportional z-test and stratified by nodal status.

Results: A total of 404 patients (MINT, n=67; NBRST, n=214; FLEX, n=123) with cT3 breast cancer underwent NCT followed by resection and 87 (21.5%) achieved pCR. The mean (SD) age was 52 (±12) years; 186 (51.7%) were premenopausal; 287 (71%) were node positive. Logistic regression revealed that MammaPrint/BluePrint subtyping showed significantly higher odds ratios for pCR in High Risk Basal-Type (OR= 3.06, 95% CI: 1.15-8.19, p=0.025) and HER2-Type (OR=6.27, 95% CI: 2.19-19.38, p=0.001) compared to the reference category (Luminal-Type), indicating strong positive associations. Only clinical subtype hormone receptor-positive (HR+), human epidermal growth factor-positive (HER2+) exhibited a higher likelihood of pCR (OR = 2.91, 95% CI: 0.97-8.23, p=0.048). Menopausal status, nodal status, and grade were not significantly associated with likelihood of pCR. Of the 209 (51.7%) patients with HR+, HER2- disease, 6.7% (14) achieved pCR. Among patients with HR+HER2-, cT3 MammaPrint/BluePrint Low Risk, Luminal A tumors (n=58), no (0%) pCR was achieved regardless of nodal involvement (n=37 node positive Low Risk). In contrast, MammaPrint High Risk (n=151) had significantly higher rates of pCR compared to Low Risk (p=0.036). By molecular subtype, pCR was achieved for 7 (5.8%) of the 120 Luminal B, and 7 (23.3%) of the 30 Basal Type, cT3 tumors.
Conclusion: These data suggest that patients with MammaPrint Low Risk, cT3 tumors are unlikely to respond to NCT. These data are in alignment with long-term follow-up, level 1A evidence from MINDACT showing that patients with MammaPrint Low Risk HR+HER2- tumors may safely omit chemotherapy, regardless of nodal involvement. Intuitively, testing newer agents or neoadjuvant endocrine therapy for downstaging or proceeding to definitive surgery should be considered for genomically low-risk, cT3 cancers.

P1-11-25: Real-World Data on Adjuvant Abemaciclib in High-Risk Hormone Receptor-Positive Early Breast Cancer: A Retrospective Study

Paola Zagami, Miller Mckenzie lynn, Erin Adelaide Kelly, Claire Critchley, Lisa Anne Crey, Yara Abduoa

Background: The addition of Abemaciclib to adjuvant endocrine therapy (ET) in high-risk hormone receptor positive (HR+) early breast cancer (EBC) was approved based on the monarchE trial results. This retrospective study aims to evaluate real-world clinical outcomes of ET combined with abemaciclib in the curative setting.
Methods: A total of 97 patients with HR+ EBC receiving adjuvant abemaciclib (as per the monarchE study) were identified at a single institution between 2021- 2024. Clinical and pathological data, including demographics, treatment details, adverse events and outcomes were retrospectively reviewed. Descriptive statistics were used to analyze and report patients' characteristics. Continuous and categorical variables were analyzed with Fisher's exact test, Wilcoxon rank sum test and Pearson's Chi-squared test as appropriate. Statistical analyses were performed with R Studio v.4 at a significance level of 0.05.
Results: Patients had a median age of 51 years (interquartile range (IQR) 43-62). The majority of patients were White (71%), and Black women comprised 20%; 51% of the patients were post-menopausal. Initial clinical stages were predominantly stage II (46%),

followed by stage I (36%) and stage III (18%). Approximately 40% had received neoadjuvant chemotherapy and 50% of patients received adjuvant chemotherapy.
The most common indication for adjuvant Abemaciclib was the presence of ≥4 involved lymph nodes, accounting for 42% of patients. Among those with 1-3 involved nodes, the most frequent associated characteristic for adding Abemaciclib was a high Ki67 level (34%), followed by grade 3 tumors (16%) and tumor size ≥5 cm (14%). Aromatase inhibitors were the most common choice of adjuvant ET and 41% of patients were also on ovarian suppression. 12% of the patients received tamoxifen as the choice of ET. One patient harbored a BRCA2 mutation and received adjuvant olaparib for three months (interrupted for toxicity) before starting abemaciclib. The median duration of adjuvant Abemaciclib treatment was 14 months (IQR 9-23), with a median relative dose intensity (RDI) of 80% (IQR 33-100). Grade 3 adverse events (AEs) occurred in 60% of patients, with 53% requiring dose reductions. The most common grade 3 AEs were diarrhea (29%), fatigue (11%), neutropenia (8%), and abdominal pain (6%). 3% of patients experienced interstitial lung disease and one patient had G3 hepatotoxicity.
Patients who required dose reductions due to AEs were older than patients who did not require a dose reduction (median age 55 years, IQR 46-64 vs 47 years, IQR 43- 53; p=0.024). Patients with dose reductions had a longer duration of Abemaciclib treatment compared to patients who received the full dose (18 months, IQR 10-24, vs. 13 months, IQR 8-21; p=0.2).
Of the 14 patients who discontinued Abemaciclib, 8 had a previous dose reduction. No differences by age and race were observed amongst patients who discontinued abemaciclib vs who did not. Only 3% of the patients experienced disease recurrence (2 distant and 1 local recurrence).
Conclusion: In this retrospective study, adjuvant Abemaciclib combined with endocrine therapy demonstrated real-world applicability in treating high-risk hormone receptor-positive early breast cancer. However, our real-world data showed a higher incidence of grade 3 adverse events compared to the monarchE registration trial, indicating a need for careful management of toxicity in clinical practice.

P1-11-26: Impact of pre-operative MammaPrint/BluePrint use for final treatment decisions in patients with Stage II/IIIa HR+/HER2- early-stage breast cancer eligible for neoadjuvant chemotherapy: the DETERMIND study.

Antonio Llombart-Cussac, Serafin Morales, Manuel Ruiz-Borrego, Antonio Anton-Torres, Luis Cruz-Merino, Vega Iranzo, Antonia Perello, Angel Guerrero, Jose Ponce, Pedro Sanchez, Juan Toral, Encarna Adrover, Francisco Ayala, Maria-Dolores Torregrosa, Leonor Fernández-Murga, Andres Pellicer, Paula Llor, Antonio Llombart-Cussac

Background: MammaPrint (MP) and BluePrint (BP) signatures have been validated in the adjuvant setting to identify patients for which adjuvant chemotherapy (CT) could be spare. Neoadjuvant Chemotherapy (NCT) is a common approach for patients (pts) with clinically

high-risk Early Breast Cancer (EBC). Other options include neoadjuvant endocrine therapy (NET) or primary surgery particularly for those patients with low-risk luminal tumors. In the DETERMIND study, we explore whether pre-operative use of MP/BP may help clinicians to reinforce the best treatment strategy for clinically high-risk patients.
Methods: DETERMIND is a prospective, open-label, multicenter study, assessing the utility of MP/BP signature on the decision-making process of optimal therapy for patients with operable clinically high-risk HR+/HER2- EBC, stage II-IIIA (up to N1) and recommendation for NCT. A total of 165 pts have been included in 13 centers. Patient data were collected at inclusion (baseline), at the time of MP/BP results and at 1- and 3-years follow-up.
Results: 165 patients with valid MP/BP results were included in 13 centers in Spain. A total of 13 cases (7%) were excluded due to the impossibility of determining MP/BP in the baseline biopsy. The median age was 57 years; 86% had clinical stage II and 45% were cN1. MP/BP classified 60 patients (37%) as luminal A, 97 (60%) as luminal B, and 4 cases with non-luminal phenotype (3 Basal, 1 HER2). In the initial decision, 70 patients (44%) did not receive NQT, being referred to NET (16%) or initial surgery (28%). Of the patients with luminal A MP/BP, 57 (95%) did not receive NQT. In the one-year follow-up results, 67% of luminal A MP/BP patients de-escalated QT, while the MP/BP test supported QT in 92% of patients with a high-risk result ($p<0.01$). The confidence of both the oncologist and the patients in the final therapeutic decision significantly increased with the MP/BP result.

Conclusion: The DETERMIND study indicates that the MP/BP test is a useful tool for establishing the indication of QT in high clinical risk HR[+]/HER2[-] EBC, as well as its feasibility in the initial tru-cut biopsy. These results are consistent with the data from the MINDACT study, supporting QT de-escalation in patients with low genomic risk and good prognosis.

P1-11-27: Comparative Evaluation of Digistain and Oncotype DX in Predicting Metastasis-Free Survival in Early Stage Hormone-Receptor Positive Breast Cancer: A Randomized Study at Charing Cross Hospital

Arnav Gautam, Manveer Sroya, Zamzam Al-khalili, William Matthieson, Hemmel Amrania, Darius Francescatti, Chris Phillips, Anthony Magliocco, Chang Yoo Young, Louise Jones, Swapnil Rane, Abeer Shabhaan, Nick Wright, Charles Coombes

Background: Oncotype DX is an established genomic test for risk stratification in early-stage hormone-receptor positive, HER2-negative breast cancer. Digistain employs mid-infrared spectroscopy to assess tumor aneuploidy, offering a rapid, cost-effective alternative with potential for higher sensitivity. This study aims to compare the predictive accuracy of Digistain against Oncotype DX for metastasis-free survival.
Methods: In this double-blinded study, 233 randomly selected lymph node-negative patients from Charing Cross Hospital, previously scored by Oncotype DX, were reassessed using Digistain. The primary endpoint was metastasis-free survival, with a median follow-up of 6 years.

Results: The comparative analysis revealed a high degree of consistency in risk classification between Oncotype DX and Digistain. After adjusting for missing data, 50% of patients were classified as low-risk by Oncotype DX (defined as <10% risk of recurrence), while Digistain classified 44% of patients within the same risk category. Importantly all patients deemed low-risk by Oncotype DX were consistently categorized as low-risk by Digistain, confirming a robust concordance in risk stratification by both tests.
A noteworthy observation involved a single patient classified as low-risk by Oncotype DX but assessed as high-risk by Digistain, who subsequently developed metastatic breast cancer within five years. This case underscores a potentially heightened sensitivity of Digistain in identifying risks of metastasis, suggesting that Digistain may offer critical advantages in precise risk assessment in certain clinical scenarios.
Conclusions: These findings underscore Digistain's potential as a valid alternative to Oncotype DX, with a possible edge in sensitivity for identifying metastasis risk. The congruence in high-risk patient identification and the critical observation of an at-risk patient missed by Oncotype DX highlight Digistain's promise for enhancing clinical decision-making in breast cancer management.
Keywords: Breast cancer, Digistain, Oncotype DX, metastasis-free survival, risk stratification, hormone-receptor positive

P1-11-28: Time to Next Treatment of Abemaciclib Plus Endocrine Therapy in Early-Stage High Risk HR+/HER2- Breast Cancer: A Retrospective Analysis of Real-World Data From the IntegraConnect PrecisionQ De-Identified Database

Vikram Gorantla, Rushir Choski, Stephan Rosenfeld, Debra Patt, Anupama Vasudevan, Aryamaan Shrivastava, Teena Sura, Mike Gart, Lindsay Aton, Harshal Davé, Prateesh Varughese, Brandon Wang, Simon Blanc

Background: In the phase III monarchE study, patients treated with the CDK4/6 inhibitor abemaciclib in the adjuvant setting had significantly improved invasive disease-free survival compared to those receiving endocrine therapy alone.1 This real-world study explored whether patients are receiving the new standard of care of abemaciclib plus endocrine therapy and assessed the time to next treatment (TTNT), as a surrogate for progression free survival, of abemaciclib plus endocrine therapy (A+E) versus endocrine therapy alone (E-mono). Methods: This was a retrospective, observational analysis of data from patients in the IntegraConnect PrecisionQ real-world de-identified database. The study included patients with breast cancer who were initiated on adjuvant treatment after January 1, 2022, with follow-up through January 31, 2024. Patients must not have been metastatic at time of treatment initiation, must have been HR positive, HER2 negative, and had met one of the following conditions: N2 or greater, N1 and T3 or greater, or N1 and Grade 3. Data are presented using descriptive statistics. Results: Of the 1,363 patients included, 515 (37.8%) received A+E and 848 (62.2%) received E-mono. Among the A+E patients, most were female (98.6%) and white (55.5%), and the average (standard

deviation) age at diagnosis was 58.6 (13.2) years. Among the E-mono patients, most were female (96.5%) and white (55.0%), and the average (standard deviation) age at diagnosis was 63.9 (14.1) years. The median (interquartile range) follow-up from treatment initiation in A+E was 12 (7.1, 17.3) months and in E-mono was 12.6 (6.8, 18.7) months. The median (95% CI) TTNT in the A+E cohort was not-reached (22.4-not reached) and in the E-mono cohort was 20.9 (19.10-21.9) months. The percentage of patients who discontinued in the A+E cohort was 17.1% vs. 36.9% in the E-mono cohort. The percentage (95% confidence interval) of patients who did not advance after 18 months in the A+E cohort was 77.3% (71.4-82.1) vs. the E-mono cohort which was 57% (52.6-61.1). Conclusion: In the real-world setting, just 38% of early-stage high risk HR+/HER2- breast cancer patients were treated with abemaciclib plus endocrine therapy in the adjuvant setting. Among patients treated with abemaciclib plus endocrine therapy they had greater likelihood of not advancing to the next line of therapy compared to endocrine therapy alone. This study suggests there is an opportunity to improve adherence to the guidelines in the treatment of patients with early-stage high risk HR+/HER2- breast cancer.

P1-11-29: Clinical Characteristics and Treatment Persistence in US Patients with HR+/HER2-, Node Positive Early Breast Cancer Treated with Abemaciclib: Real-World Study from First Year After Approval

Kathryn Hudson, Wambui Grace Gathirua-Mwangi, Zhanglin Lin Cui, Madeline Richey, Brenda Grimes, Jingru Wang, Astra M Liepa, Erich Brechtelsbauer, Raisa Volodarsky, Katheryn Moreira, Hatem Soliman

Background: Abemaciclib in combination with endocrine therapy (ET) is approved for adjuvant treatment of adult patients with HR+/HER2-, node-positive, early breast cancer (EBC) at high risk of recurrence and this regimen falls under NCCN category 1 (preferred) recommendation. The monarchE trial established the efficacy of abemaciclib plus ET for EBC, with the highest rates of early discontinuations observed in the first few months. The utilization of abemaciclib in the real-world EBC setting after Oct 2021 approval can provide insights on the treatment patterns beyond the controlled clinical trial setting and help inform adverse event management strategies. This retrospective study describes clinical characteristics and treatment persistence in patients with HR+/HER2-, node positive EBC initiating abemaciclib.
Methods: Data were accessed from the US nationwide Flatiron Health electronic health records-derived de-identified database. Adult patients with node positive, stage I-III EBC initiating abemaciclib between Oct 2021 and Nov 2022 at 150mg twice daily (BID) were analyzed. Persistence rate was defined as the proportion of patients remaining on abemaciclib at 3 months allowing for up to 60-day medication gap. All results were summarized descriptively.
Results: A cohort of 354 patients were selected, with a median follow-up time from abemaciclib initiation of 8.8 months (interquartile range [IQR] 5.9–12.1). The median age

was 56 years (IQR 48–64), 25.4% were ≥65 years old, 12.7% were Black, 4.0% were Asian, 12.4% were other non-White race, and most patients (80.8%) received care in a community setting. Over half of the patients were postmenopausal (55.4%) and had an ECOG performance status (PS) 0 (57.9%), while 25.1% had ECOG PS 1 and 2.5% had ECOG PS 2. Approximately one-third of the patients (33.9%) had ≥1 comorbidity and 12.1% had ≥2 comorbidities with diabetes (14.1%) as the most frequent one. Most patients had stage II (41.8%) or III (38.4%) disease, nodal status N1 (45.2%) or N2 (35.3%), and tumor grade 2 (52.3%). Abemaciclib was initiated at a median of 11.1 months (IQR 9.3–13.5) after diagnosis. Prior to abemaciclib initiation, most patients received chemotherapy (83.1%), with 46.3% receiving neoadjuvant chemotherapy and 96.3% underwent radiotherapy. Most patients (74.0%) initiated ET prior to abemaciclib, with the median time from initiation of ET to abemaciclib initiation as 1.6 months (IQR 0.0–5.0). The median time to abemaciclib initiation from breast surgery was 6.7 months (IQR 4.2–9.9). The most frequent regimen was abemaciclib plus aromatase inhibitors (91.0%). At 3 months, 81.6% of patients were persistent; 5.6% resumed abemaciclib after >60-day interruption and 11.3% had discontinued due to adverse events. Additional information on dose modifications will be presented.
Conclusion: In this real-world study of utilization of abemaciclib in the first year after approval for EBC, an older, less fit, and more racially diverse population than participated in the monarchE trial, as well as a higher proportion of patients with lower nodal status was observed. The high rate of persistence at 3 months suggests that abemaciclib for EBC is tolerated in routine clinical practice.

P1-11-30: The Clinical Utility of NGS-based Multigene Assay in Optimizing Chemotherapy Decisions for Hormone Receptor-Positive Early Breast Cancer: A retrospective study

Min Jung Lee, Jinyoung Byeon, Hyelim Kang, Changhoon Lee, Ji-Jung Jung, Eunhye Kang, Hong Kyu Kim, Han-Byoel Lee, Hyeong-Gon Moon, Wonshik Han

Background: Multigene assays play a crucial role in guiding adjuvant chemotherapy decisions for hormone receptor (HR)-positive breast cancer. This study evaluates the clinical utility of the NGS-based multigene assay in determining the need for adjuvant chemotherapy in HR-positive early breast cancer patients in Korea.

Methods: A retrospective analysis was conducted on HR-positive, HER2-negative early breast cancer patients treated at Seoul National University Hospital (SNUH) from October 2019 to March 2024. A total of 1,700 patients with stage I-II (pT1-3, pN0-1), who underwent the NGS-based multigene assay for adjuvant therapy decision-making, were included. Exclusions comprised male patients, assay test failures, and referrals to other hospitals. Multivariate logistic regression analyzed factors influencing the adjuvant chemotherapy decisions. Patients were stratified by menopausal status to evaluate Decision Index (DI) distribution and treatment decisions. Clinical risk score (CRS) categorized

patients based on histologic grade, tumor size, and nodal status, similar to criteria from the MINDACT trial. DFS analysis was conducted according to DI and CRS subcategories.

Results: In total of 1700 patients, 65.2% (1,108/1,700) were categorized as low-risk DI, and 34.8% (592/1700) as high-risk DI risk. Factors significantly associated with high-risk DI included postmenopausal status, larger tumor size, higher histologic grade, nodal metastasis, lymphatic invasion, and high Ki-67 expression (all $p < 0.001$). Multivariate analysis identified high DI, high Ki-67, premenopausal status, histologic grades II and III, and pathologic N1 state as prognostic factors influencing chemotherapy decisions. In total, of the 662 patients in the high clinical risk group, 60.9% (403/622) avoided adjuvant chemotherapy. Among patients with low clinical risk but high DI, 64.6% (181/280) received chemotherapy, while 98.3% (344/350) of those with high clinical risk but low DI avoided chemotherapy. In the high DI risk group, 26.0% (154/592) patients did not receive adjuvant chemotherapy. Of the 154 patients, 38.3% (59 patients) refused to undergo chemotherapy, while 61.7% (95 patients) did not receive adjuvant chemotherapy based on the decision of surgical or medical oncologists. Among patients who did not receive chemotherapy according to surgical or medical oncologists' decision, the mean age was 60.2 years, with 81.1% (77/95) being postmenopausal. All premenopausal women (18.9%, 18/95) had a mean DI of 20.8 (range 20 – 22.2) and the adjuvant therapy included either tamoxifen or an aromatase inhibitor with ovarian function suppression. DFS (including local, regional, and distant metastasis) analysis with a median follow-up of 2.9 years showed a significant difference between the high and low DI risk groups ($p < 0.05$). Moreover, DFS analysis of stratified groups within the DI and clinical risk groups demonstrated significantly worse survival ($p < 0.001$) in the clinical high and high DI risk groups compared to other groups, with no significant differences among the other groups ($p = 0.868, 0.144, 0.506$).

Conclusion: This study demonstrates the potential of the NGS-based multigene assay to significantly reduce avoidable chemotherapy in clinically high-risk HR-positive early breast cancer patients in Korea. Factors affecting the treatment decisions irrespective of high-risk DI, include premenopausal status, high Ki-67, histologic grade, and nodal involvement. Further long-term studies are needed to validate the oncologic safety implications of utilizing the NGS-based multigene assay.

P1-12-01: HER2 categorical changes after neoadjuvant chemotherapy: A real world data of matched breast cancers with the inclusion of HER2-Low category

Marcelo Antonini, Andre Mattar, Leticia Xavier Feliz, Francisco Pimentel Cavalcante, Felipe Zerwes, Eduardo de Camargo Millen, Fabrício Palermo Brenelli, Antônio Luiz Frasson, Denise Joffily Pereira da Costa Pinheiro, Marina Fleury de Figueiredo, Odair Ferraro

Objectives: The aim of this study was to investigate the HER2 expression status in the initial pre-neoadjuvant chemotherapy (NAC) and residual post-NAC tumors, focusing on HER2

categorical changes after NAC treatment, including the HER2-low category.
Methods: This retrospective cohort study included female patients over 18 years of age diagnosed with non-metastatic breast cancer undergoing NAC from 2011 to 2023. Patients who did not achieve complete pathological responses were evaluated for changes in immunohistochemistry (IHC) before and after NAC. HER2 IHC was re-evaluated with consensus according to the current ASCO/CAP guidelines. Tumors were categorized into HER2-negative (IHC0), HER2-low (IHC1+ or IHC2+/ISH-), and HER2-positive (IHC3+ or IHC2+/ISH+) subgroups. Quantitative and qualitative factors related to changes in IHC were assessed. The study received approval from the research ethics committee (CAAE 80127724.1.0000.5463).
Results: We included 369 patients, most of whom (215/58.3%) did not change their IHC profile. Baseline statuses were HER2-negative (24/6.5%), HER2-low (256/69.4%), and HER2-positive (89/24.1%). Tumors with HR+ were observed in 227 patients (61.5%). HER2-positive tumors exhibited more changes in IHC (63/63.0%, $p<0.0001$) compared to HER2-negative (5/20.8%) and HER2-low tumors (92/35.9%). Significant differences were found in the changes: all HER2-negative tumors changed to HER2-low; HER2-positive tumors changed to HER2-low in 30 cases (43.7%) and to HER2-negative in 26 cases (41.2%). Most HER2-low tumors (51/55.4%) remained HER2-low or changed to HER2-negative (26/29.2%). The presence of HR+ was significantly associated with greater changes to HER2-negative (125/55.0%) and HER2-low (83/36.5%).
Conclusions: Our findings indicate that changes in IHC profiles post-NAC are common, particularly among HER2-positive and HER2-low tumors. Significant alterations in HER2 status were observed, with many HER2-positive tumors shifting to HER2-low or HER2-negative post-NAC. Additionally, the presence of hormone receptors (HR+) is associated with a higher likelihood of conversion to HER2-negative. These changes are clinically relevant, as they correlate with increased mortality rates, underscoring the importance of re-evaluating HER2 profiles post-NAC as potential prognostic indicators in breast cancer patients.

P1-12-02: Real-World Use of Gene Expression Tests in Swedish Breast Cancer Patients: A Multi-Institutional Study of 35 hospitals

Emelie Karlsson, Balazs Acs, Irma Fredriksson, Johan Hartman

Background: Gene expression profiling (GEP) tests are used to provide prognostic insights for breast cancer (BC) patients with intermediate risk in the adjuvant setting. GEPs provide guidance for the clinical decision-making on administering chemotherapy by stratifying the risk of relapse, aiming to avoid overtreatment or undertreatment. Since 2019, GEP tests are recommended in Swedish healthcare. The GEPs approved for clinical use in Sweden are the Prosigna/PAM50 and the Oncotype Dx tests. In addition, a non-CE-IVD certified laboratory-developed test called GEX is used at some hospitals. All GEP tests are based on different techniques which analyze different sets of breast cancer-related genes, hence a direct comparison between the test results will be deceptive for treatment guidance.According to

Swedish national guidelines, patients eligible for GEP tests are women with ER+/HER2- BC with up to 3 lymph node metastases with an intermediate risk of relapse. The distribution of BC phenotypes across Sweden is considered to be homogenous. This study aimed to compare and assess real-world use of GEPs, and their risk profiling results among 35 hospitals in Sweden in 2023.
Materials and methods: All Swedish BC cases diagnosed in 2023 were identified in the National Quality Register for Breast Cancer (NKBC). In accordance with Swedish national BC guidelines, all surgically resected specimen from patients with intermediate risk were identified for the study, resulting in 8483 patient cases from 35 investigated hospitals dispersed across six regions in Sweden. GEP tests were performed on 1815 of the 8483 identified patient cases. Data from six hospitals were excluded due to insufficient information reported to the NKBC registry.
Results: During 2023, GEP tests were performed on more than 20% of the eligible BC patients distributed over 29 hospitals in Sweden. The distribution of GEP usage in Sweden showed high variability between the hospitals, where the patients getting access to risk profiling ranged from 15% to 70% depending on what hospital the patient was admitted to and what GEP test was used for the risk assessment. Additionally, the distribution of GEPs risk results showed a high variability between the Swedish hospitals: low risk score ranged from 11.1% to 61.9%, intermediate risk score ranged from 0.0% to 77.8%, and high risk score ranged from 7.1% to 50.0%.
Conclusions: This study demonstrates a high variability in both usage and risk categorization by GEPs for BC patients in Sweden. The clinical utility of independent prognostic tests is valuable for eligible BC patients, but our study indicates a critical lack of standardization for the usage of GEP tests that may lead to discrepancy in treatment outcome. Even though the Swedish national guidelines have clearly defined indications for using GEPs on BC patients, our data imply that some hospitals may run GEP tests on BC tumor samples that do not meet these indications. The variability in risk score distribution among hospitals may also be due to the different GEPs being used. Further standardization of clinical practice guidelines is needed to decrease the large variability in the use of GEP in practice and to limit the associated risk for incorrect patient selection for breast cancer treatment.

P1-12-03: Clinical Efficacy and Outcomes of Astragalus Polysaccharides (PG2) toward Cancer-related Fatigue of Advanced Breast Cancer Patients

Ming-Shen Dai, Chih-Chiang Hung, Liang-Chih Liu, Guo-Shiou Liao, Yuen-Liang Lai, Hsu-Huan Chou, Chan-Keng Yang, Shen-Liang Shih, Kun-Yun Yeh, Yen-Min Huang, Chun-Hui Lee, Wen-Ling Kuo, Shih-Che Shen, Jen-Seng Huang, Chi-Chang Yu, Hui-Yu Ho, Hsiu-Pei Tsai, Chen-Teng Wu, Pei-Hung Chang, Yueh-Shih Chang, Fang-Ming Chen, Shin-Cheh Chen, Kun-Ming Rau

Background: Cancer-related Fatigue (CRF) is the most prevalent and disturbing symptom among breast cancer patients. Astragalus Polysaccharides (PG2, PhytoHealth Corporation,

Taiwan) is a drug approved for CRF treatment and marketed in Taiwan. In the PG2 phase IV clinical trial demonstrated that PG2 improved CRF in over 60% of cancer patients, particularly significant in the breast cancer subgroup. Then PG2 got reimbursement from National Health Insurance of Taiwan. The aim of this study was to assess the real-world treatment efficacy of CRF by PG2 among advanced breast cancer patients.

Methods: This was a retrospective study. Enrolled patients were aged 20 years and above with stage IV breast cancer, experienced moderate to severe fatigue that fulfilled the diagnostic criteria defined in ICD-10, with other interventions proving ineffective, and had an Eastern Cooperative Oncology Group performance score of 0-2. Patients' demographic information, disease characteristics, cancer treatment, and visual analog fatigue scores (Fatigue-VAS) were collected. The efficacy on CRF treatment by PG2 were analyzed in intention-to-treat (ITT) population and subgroups based on accumulated doses, menopausal statuses (pre-menopause and post-menopause), BMI (< 25 kg/m^2 (normal weight) and ≥ 25 kg/m^2 (overweight) and sites of metastases (visceral metastases (VM) and non-visceral metastases (non-VM)).

Results: This study included a total of 204 evaluable breast cancer patients. After completion of pre-planned PG2 treatment, there were significant improvements from baseline in the worst fatigue scores whether assessed over the past 24 hours or during the last cancer treatment ranged from 2.6 to 3.5 across ITT population and all menopausal statuses, BMI, and metastases subgroups (both $p<0.001$). A numerically higher proportion of premenopausal patients experienced relief to mild or no fatigue over past 24 hours and during last cancer treatment compared to postmenopausal patients (92.86% vs. 60.71% and 92.86% vs. 58.57%), and the distribution of fatigue severity levels in the population between various menopausal status groups showed a statistically significant difference ($p=0.023$ and $p=0.014$). The categorization of fatigue severity during last cancer treatment results showed that patients with non-VM treated with PG2 had significantly better fatigue improvement outcomes compared to those with VM ($p=0.041$). Improvements in fatigue were similar between normal weight and overweight groups after PG2 treatment.

Conclusions: The retrospective study demonstrated that PG2 exhibits significant therapeutic efficacy in relieving CRF among advanced breast cancer patients. Premenopausal and non-VM patients might be more beneficial to PG2 treatment.

P1-12-04: Correlation between Immune-Related Adverse Events (irAE) and Survival Outcomes in Metastatic Breast Cancer Patients Treated with Immune Checkpoint Inhibitors (ICI): a multi-institutional study

Madhuri Chengappa, Thejaswi K Poonacha, Nikitha Vobugari, Go Nishikawa, Saya Jacob, Samantha Fisch, Carolyn Face, Alexis LeVee, Nikita V. Baclig, Andrew Soliman, Laura Huppert, Laura Quintal, Michelle Melisko, Melanie Majure, Jo Chien, Joanne Mortimer, Kelly McCann, Hope S. Rugo, Dame Idossa, Anne Blaes

Background: There have been discrepant results between development of irAE, and their effect on overall survival (OS) in several cancer types treated with ICI. Some studies have shown a positive correlation between incidence of irAE and OS. While these effects are being explored in breast cancer, there is a paucity of data regarding patients (pts) with metastatic breast cancer (mBC) treated with ICI.

Methods: This multicenter retrospective study, involving four academic institutions, evaluates the incidence of irAE in pts with mBC who received ICI between 2014 and 2024. The presence and grading of irAE were determined by physician documentation. Pts demographic data and characteristics were summarized using descriptive statistics. OS was calculated from the date of treatment initiation to death from any cause. Pts who were still alive were censored at the last clinic encounter. Survival probabilities were estimated with Kaplan–Meier curves and log-rank tests. All other co-covariables were analyzed using multivariate logistic regression and cox proportional hazards model.

Results: There were a total of 252 evaluable cases, with median age at the start of ICI of 54. The study population consisted of 66% white, 9% black and 25% others. Median body mass index (BMI) was 26.4. Among the pts, 64% were triple negative breast cancer (TNBC), 30% hormone receptor positive (HR+), 5% human epidermal growth factor receptor 2 positive (HER2+) and 1% both HR/HER2+. Combination therapy was received by 78% of the patients, while 22% received ICI alone. Amongst pts who received ICI, 45% pts were enrolled in clinical trials. Pts were on ICI for an average of 138.38 days before their first irAE. irAE were noted in 47% pts, with 35% experiencing at least 1 irAE, 11% had 2 irAE and 1% with 3-4 irAE. Grade 1-2 irAE were noted in 34%, and grade 3-4 in 13.5%.

The median OS was 17 months amongst all pts. Pts with irAE had a longer median OS compared to those without irAE (23 vs 13 months; HR, 0.50; 95% CI 0.36-0.69; $p < 0.00001$). Pts with TNBC had improved overall survival (OS) with ICI in comparison to HR+ and HER2+ pts (OS 17 months; 95% CI 13-28; $p = 0.0074$). In addition, those with higher grade irAE had improved OS compared to those with low grade irAE (HR 0.41, 95% CI 0.15-1.16; $p=0.03$). Higher number of treatment cycles and higher baseline BMI were associated with a significantly lower risk of mortality ($p=0.006$ and $p=0.018$, respectively). Clinical factors such as age, smoking and other comorbidities, while potentially influential, did not reach statistical significance in this multivariable analysis.

Conclusion: Our analysis shows that almost half of the pts in the study (47%) had irAE with median OS of 17 months. Pts with irAE had a longer OS (23 months) compared to those without irAE (13 months). The median OS for TNBC was higher than HR+ and HER2+ breast cancer. The total number of ICI cycles and baseline BMI were shown to have a significant impact on the survival of mBC pts. The combined irAE grades show a trend towards a decreased risk of mortality, but the findings are not statistically significant.
Overall, while there are indications that specific side effects and treatment factors may influence patient outcomes, including increased OS among patients with irAE, further

research with larger datasets is needed to confirm these results. This study provides a foundation for understanding how various factors contribute to the survival of breast cancer patients undergoing ICI therapy.

P1-12-05: Improving Outcomes in Patients With High-risk Breast Cancer: Outcomes and Analysis From an Educational Program on HR+/HER2- Early and Metastatic Breast Cancer

Jerfiz Constanzo, Yara Abdou, Tanya Gupta, Stephanie L. Graff, Jane L. Meisel, Michelle E. Melisko, Krista Marcello, Timothy A Quill, Laura M. Spring

Background: Treatment of breast cancer has advanced rapidly over the past decade. However, patients with hormone receptor-positive (HR+), HER2-negative (HER2-) disease with high-risk features are particularly vulnerable to relapse or progression in both the early stage (EBC) and advanced/metastatic stage (MBC) settings, respectively. Here, we report results from formative educational surveys and post-education assessments on improving outcomes for patients with high-risk HR+/HER2- breast cancers.
Methods: A multidisciplinary curriculum was developed to provide CME/CE-certified education on identifying high-risk features, assessing for endocrine resistance mutations, and selecting the optimal therapy for each patient with high-risk HR+/HER2- breast cancer, as well as provide education on oral therapy adherence and toxicity management. From December 22, 2023, to May 28, 2024, data were collected from online interactivity software live and online healthcare professional (HCP) surveys administered during and after CME/CE education. Expert-endorsed patient resources and clinical guideline–based PowerPoint slidesets were provided for download to all program participants. Program follow-up survey data were also collected on the impact of the education on current clinical practice and other barriers to changing practice.
Results: Over 1000 learners participated in the live or enduring education program. From a total of 898 HCPs (physicians, nurses, pharmacists), 84% cared for patients with breast cancer. At baseline, approximately 19% of participants felt confident in their ability to assess high-risk features in patients with HR+/HER2- breast cancer, which increased to 43% following the education. Compared with 62% at baseline, post-education 92% of learners were able to identify patients with EBC with tumor ≥5 cm and positive axillary lymph nodes as a higher risk population; 61% at baseline vs 95% post-education correctly selected aromatase inhibitor (AI) plus abemaciclib as the optimal guideline-recommended/evidence-based treatment for patients with high-risk EBC; and 66% vs 90%, respectively, selected AI or fulvestrant with a CDK4/6 inhibitor in high-risk MBC. An absolute 50% and 65% value increase was achieved for learners' knowledge/competence in individualizing therapy for high-risk metastatic breast cancer and for recommending strategies to promote oral treatment adherence with CDK4/6 inhibitors, respectively.
The most common barriers cited (n = 364) to implementing the recommended changes to practice included acceptance of recommendations by peers and colleagues (34%) and insurance/formulary restrictions (24%). Of those completing post–CME education follow-

up surveys (n = 417), 48% indicated a shift from awareness to agreement with best practices, 13% increased adoption or application of best practices, and 21% stated the education helped in another way. In total, 860 downloaded PDF resources and 1866 downloaded slides tailored to improving patient–HCP communication and reinforcing takeaways and self-learning after event conclusion.
Conclusions: This large, expert-led, multidisciplinary, CME/CE-certified educational program on HR+/HER2- high-risk breast cancer showed substantial improvements in HCPs' confidence, knowledge, and competence in their ability to identify patients with high-risk features, recommend optimal guideline-based therapies, and promote oral therapy adherence by following best practices and strategies. There remain key but addressable barriers to implementing best practices. These results highlight the importance of ongoing education and the need for a multidisciplinary program to improve HCPs decisions for high-risk HR+/HER2- breast cancer.

P1-12-06: The Effectiveness of Trastuzumab, Pertuzumab and Docetaxel Combination as a First-Line Treatment of HER2-Positive Metastatic Breast Cancer Patients : A Real-World Evidence in Korea

Min Jeong Kim, Hyo Jung Kim, Jin Seok Ahn, Ji-Yeon Kim, Junghoon Shin, Yeon Hee Park

Background: The combination of trastuzumab, pertuzumab, and docetaxel (THP) has been established as a standard first-line treatment for HER2-positive metastatic breast cancer, following the CLEOPATRA study, which demonstrated the added efficacy of pertuzumab compared to placebo with trastuzumab and docetaxel. In the CLEOPATRA study and previous real-world evidence studies, patients who discontinue docetaxel due to adverse events after the induction period continue HER2 blocking treatment with trastuzumab and pertuzumab (HP). In the era of trastuzumab deruxtecan introduction in earlier treatment lines, it is important to evaluate the effectiveness of the THP treatment, especially long-term continuous HP without docetaxel, as a meaningful option for the quality of life of patients, by utilizing real-world evidence (RWE).
Methods: We conducted a retrospective analysis of 320 HER2-positive patients who began receiving THP treatment at Samsung Medical Center between April 2015 and December 2021. This analysis utilized de-identified and anonymous data from the Clinical Data Warehouse based on institutional real-world electronic medical data. Patients included in the study received at least one cycle of THP. The cutoff date for the analysis was 31st May 2024.
The primary outcomes of the study were Progression-Free Survival (PFS) and Overall Survival (OS). The secondary outcome assessed the OS differences between different subgroups.
Result: The median follow up was 46.8 months (range 0.35-109.1). Among 320 patients, 151 patients (47.2%) were hormone receptor (HR) negative, while 133 patients (41%) were HR positive either estrogen receptor or progesterone receptor. The median cycle of the THP was 22 cycles (range 1-158) and the median cycle of docetaxel was 8 cycles (range

1-34). Median PFS was 30.8 months and median OS was not yet reached.
In our study, the median number of cycles of HP after discontinuation of docetaxel was 12 cycles (range 0-144). Sixty-six patients (20.6%) maintained HP for more than 3 years, 37 patients (11.6%) received it for more than 4 years, and even 23 patients (7.2%) continued HP for more than 5 years. The median number of cycles of HP was 3 (range 0-103), 14 (range 0-128), and 17 (range 0-144) in patient groups who received fewer than 6 cycles of docetaxel (50 patients, 15.6%), 6-10 cycles (200 patients, 62.5%), and more than 10 cycles (70 patients, 21.9%), respectively. Patients who received fewer than 6 cycles of docetaxel showed significantly poorer survival outcomes compared to the other groups (6-10 cycles of docetaxel: HR = 0.39, 95% CI 0.24-0.64, p = 0.0001; more than 10 cycles of docetaxel: HR = 0.25, 95% CI 0.13-0.48, p < 0.0001). However, the overall survival between the patient group who received 6-10 cycles of docetaxel and the group who received more than 10 cycles of docetaxel showed no significant differences (HR = 0.62, 95% CI 0.34-1.15, p = 0.13).
Conclusion: Our findings are consistent with the survival benefit of the THP regimen in real-world practice, aligning with the results of the randomized clinical trial, CLEOPATRA. This study highlights that HP after the induction phase with docetaxel is a clinically meaningful treatment option, considering both patients' quality of life and survival benefit.
This study showed a relevantly longer survival outcome compared to CLEOPATRA, addressing diversity and healthcare system-specific variations in treatment outcomes that may not be fully captured by global clinical trials. While acknowledging the limitations in generalizability inherent in this single-center, retrospective analysis, the study provides valuable insights into the effectiveness of this treatment regimen in a Korean population, contributing to the broader understanding of its performance in Asian patients. Our results underscore the importance of RWE in complementing clinical trial findings and optimizing treatment strategies for HER2-positive metastatic breast cancer patients.

P1-12-07: First-line (1L) treatment decision patterns and survival in Peruvian patients (pts) with hormone receptor (HR)-positive HER2-negative advanced breast cancer (ABC)

Guillermo Valencia, Patricia Rioja, Miguel Chirito, Olenka Peralta, Jorge Sánchez, Connie Rabanal, Zaida Morante, Hugo Fuentes, Carlos Castañeda, Tatiana Vidaurre, Silvia Neciosup, Cristian Pacheco, Henry L Gómez

Background: Advanced breast cancer (ABC) is an incurable disease, with a median overall survival (OS) of 3 years, even in high-income countries. Endocrine therapy (ET) + cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is recommended for pts with HR (+) HER2 (-) ABC. Although chemotherapy (CT) is reserved in some cases, it is still used in many countries as first-line (1L) therapy. The aim of our study is to evaluate the 1L available treatment choices in a Peruvian public oncologic institution and the factors that influence on therapy decision. In addition, we explore the OS of sequencing treatments.
Methods: Retrospective analysis of HR (+) /HER2 (-) ABC pts (de novo,

recurrent/progressive) classified in 3 groups according to the treatment received in 1L and second-line (2L): ET-CT, ET (aromatase inhibitor)-ET (fulvestrant) and CT-ET between January 2021 and December 2023. Clinicopathological data was retrieved from clinical files, and factors were evaluated to test the association of the choice of 1L (ET vs. CT) with outcomes. Survival curves were constructed with the Kaplan-Meier method.
Results: A total of 145 female pts were included. The median age was 53.9 years (24-85); 63.4% were post-menopausal, 29.2% were diagnosed as metastatic de novo, 93.1% had ECOG 0-1 and 69.0% were luminal B subtype. 5.7% of patients have visceral crisis at diagnosis and receive CT. Regarding available treatment options, 1L CT was chosen in 43.4% of pts. In univariate analysis, the presence of visceral metastases (most frequent lung metastases) (OR 2.31, 1.07-5.09, p=0.034) and de novo disease (OR 2.15, 1.04-4-52, p=0.039) were associated with a higher use of CT, while lymph node metastases were associated with the choice of 1L ET (OR 0.36, 0.12-0.92, p=0.044). In multivariate analysis, de novo disease was the prognostic factor for select 1L CT (OR 2.26, 1.02-5.07, p=0.046). 44.2% of our pts who received 1L CT met “aggressive disease” criteria from RIGHT Choice trial (which showed a benefit of CDK4/6i + aromatase inhibitor vs. CT in pts with aggresive disease), including: 78% met "rapid disease progression", 52% with "markedly symptomatic non-visceral metastases" and 30.4% “symptomatic visceral metastases” definition. At treatment sequencing, 42.5% pts were CT-ET, 40.8% ET-ET and 16.7% ET-CT. Progression-free survival (PFS) 1L ET (aromatase inhibitor) was 18 months. With a median follow-up of 41 months, the OS rates at 12, 36 and 60 months were 98.5%, 82.0% and 64.5%, respectively. No differences were found in PFS or OS according to sequencing groups.
Conclusions: The presence of de novo disease and visceral metastases were prognostic factor in Peruvian pts with ABC RH (+) /HER2 (-) for choosing 1L CT. Almost half of pts met the “aggressive disease” criteria of RIGHT Choice trial for select 1L CT. Treatment sequencing regimens (including CT) increases PFS and OS in Peruvian patients. There were no statistically differences in PFS or OS with sequential treatments groups.

P1-12-08: Cyclin-Dependent Kinase 4/6 Inhibitors in Metastatic Breast Cancer and Use of Concomitant Proton Pump Inhibitors: Real-World Experience from a Tertiary Care Center

Maria Alameda-Guijarro, Jesus Peña Lopez, Javier Alvarez Criado, Antonio Rueda Lara, Gema Martin Montalvo Perez, Enrique Espinosa Arranz, Pilar Zamora Auñon, Virginia Martinez Marin, Beatriz Castelo Fernandez, Diego Alvaredo Rodrigo, María Martínez Balaguer, Jaime Feliu Batlle, Sergio Martinez Recio

Introduction: Cyclin-dependent kinase 4/6 inhibitors (CDKI) are indicated for the treatment of women with hormone receptor (HR) positive, human epidermal growth factor receptor 2 (HER2) negative locally advanced or metastatic breast cancer in combination with an aromatase inhibitor or fulvestrant as initial endocrine-based therapy. Little is known about the concomitant use of other common drugs, such as proton pump inhibitors (PPI). The

present retrospective series analyzes the outcomes of patients receiving these drugs in a single institution.
Methods: Patients with HR-positive, HER2-negative metastatic breast cancer who received either palbociclib or ribociclib plus endocrine therapy between 2015 and 2021 were included. Clinicopathological variables and data on efficacy, toxicity, and the use of concomitant PPI were collected. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method. A Cox proportional hazards model was used to estimate the hazard ratio.
Results: A total of 154 patients were included: 71.4% of patients received palbociclib and 28.5% received ribociclib. There were more de novo metastatic patients in the ribociclib group (34.1%). Regarding the hormone therapy received, 64% of patients received concomitant treatment with aromatase inhibitors and 34.4% with fulvestrant. Letrozole was the most used in both groups; however, patients in the Palbociclib group received Fulvestrant (42.7%) more frequently than those in the Ribociclib group (13.6%). As for the concomitant use of proton pump inhibitors (PPIs), there were no differences in distribution between the two groups (Palbociclib 42.7% - Ribociclib 38.6%).
A higher rate of toxicity was recorded in patients who received ribociclib (40.9%), with hematological toxicity (65.6%) and asthenia (22.7%) being the most frequent. Severe grade 3 or 4 hematological toxicity, primarily neutropenia, was most common, with no statistically significant differences between palbociclib (61.8%) and ribociclib (63.6%).
After a median follow-up of 47.2 months, 54 deaths were recorded. It was found that patients who received ribociclib had a longer PFS than those who received palbociclib (50 months vs 29.49 months, p=0.025). Hazard Ratio (HR) 0.59, 95% Confidence Interval (CI95%) (0.37-0.96), p = 0.033.
Populations were stratified based on whether they received concomitant PPI treatment. It was evident that in patients who received PPI treatment, differences in PFS in favor of ribociclib persisted (median PFS 50 months vs 11.27 months; p = 0.002); however, in patients who did not receive PPI treatment, no differences in PFS were observed (median PFS 44.74 months vs 34.58 months; p= 0.650).
Regarding overall survival, no statistically significant differences were observed between the two treatment groups (p = 0.353). However, when stratifying the population, in patients who had received PPI treatment, statistically significant differences in overall survival were evident (Ribociclib median OS 71.44 months VS Palbociclib median OS 29.55 months, p= 0.025).
Conclusions: Our study suggests that there may be differences between ribociclib and palbociclib, particularly in terms of PFS. Additionally, the concomitant use of PPI treatment may have a detrimental effect on the outcome of patients treated with palbociclib. Further studies are needed to confirm these findings.

P1-12-09: Real-world prescribing patterns and outcomes of CDK4/6 inhibitors in elderly patients with metastatic HR+/HER2- breast cancer

Xiao-Wei Tan, Ghazal Kango, Sampada Koshatwar, Paula Rosenblatt, Grace Hsu

Background: Older patients are a heterogeneous group often underrepresented in clinical trials. Yet, a significant proportion of our patient population are elderly, with the median age of 68-74 years old at cancer diagnosis. Elderly patients are perceived to be less tolerant of cancer therapy with higher rates of adverse events, dose reductions, and discontinuation. In metastatic HR+/HER2- breast cancer, use of CDK4/6 inhibitor with endocrine therapy is often first line therapy. Our objective is to describe real-world prescribing patterns of CDK4/6 inhibitors in an elderly patient population with metastatic breast cancer, identify adverse events that contribute to dose adjustment and discontinuation, and determine progression free survival of patients based on the initial dose of a CDK4/6 inhibitor.
Methods: This is a retrospective study within the University of Maryland Medical System. All patients prescribed a CDK4/6 inhibitor between 11/8/2015-11/30/2022 were reviewed. Inclusion criteria included patients 75 years or older when initiated on a CDK4/6 inhibitor, metastatic breast cancer, and patients who received CDK4/6 inhibitors for at least one cycle. The analysis cutoff date was 2/8/2024. Analysis was done using the SAS computer program.
Results: Out of 397 patients reviewed, 45 patients met criteria for analysis. Palbociclib was used in 32 (70%) patients, abemaciclib in 8 (17%) patients, and ribociclib in 6 (13%) patients. At initiation, 24 (53%) of patients were started on full dose of CDK4/6 inhibitor. Of the other 21 (47%) of patients, initiation at a reduced dose was due to advanced age for 8 patients, however no reported reason was documented for 13 patients. Baseline characteristics of ECOG score, prior chemotherapy, brain metastases, and bone metastases were not statistically different between patients initiated at full or reduced dose. Of 45 patients, 26 patients had a subsequent dose reduction. Seventeen (65%) patients were reduced to dose level -1, and 9 (35%) patients were reduced to dose level -2. Two patients had a dose escalation. The median duration until first dose reduction was 2.6 months (0.6-35). The most common reasons for dose reduction were due to myelosuppression (50% vs 75%) and fatigue (16.7% vs 25%) whether initiated on a full dose or reduced dose of CDK4/6 inhibitor, respectively. However, 18 of 26 (69%) patients initiated at a full dose needed dose reduction due to adverse events compared to 8 of 26 (31%) patients initiated at a reduced dose (p=0.19). The most common reasons for discontinuation were due to progression of disease (47.1% vs 44.4%) and adverse events (29.4% vs 44.4%) whether initiated on a full dose or reduced dose of CDK4/6 inhibitor, respectively. Two patients who had a severe adverse event required hospitalization. The median total duration of a CDK4/6 inhibitor was 18.1 months (0.86-77). Ten patients did not experience any adverse events, and ten patients continued on a CDK4/6 inhibitor at data cutoff. Median progression-free survival if initiated at a full dose versus reduced dose was 18.6 months (3.5-75.1) and 19.2 months (1.2-77.0), respectively (p=0.51; 24 month PFS HR 1.04, 95% CI 0.85-1.27).
Conclusion: In this study, most older patients either initiated CDK4/6 inhibitors at a reduced dose or needed subsequent dose reductions. Study limitations include retrospective nature, small sample size, and larger proportion of patients on palbociclib as it was the first approved CDK4/6 inhibitor. This study supports initiating CDK4/6 inhibitors at a reduced dose for patients with metastatic HR+/HER2- breast cancer who are 75 years or older due to fewer incidence of adverse events with no difference in survival outcomes.

This aligns with pooled analyses of PALOMA-2, MONALESSA-2, and MONARCH-3 and another real-world study in Asia.

P1-12-10: Prediction and Survival Analysis of Regional Recurrence in Breast Cancer: Impact of Mode of Detection

Eun Sook Ko, Myoung Kyoung Kim

Purpose: To develop a predictive model for regional recurrence in breast cancer and to evaluate the survival outcomes based on the mode of detection.
Methods and Materials: This retrospective cohort study examined medical records of patients who underwent invasive breast cancer surgery at a single institution from January 2011 to December 2019. Surveillance breast ultrasound, covering the axilla, internal mammary, and supraclavicular areas, was conducted semiannually for five years, then annually for those with a personal history of breast cancer (PHBC). Regional recurrences were identified, and associated factors were analyzed. Interval regional recurrences were defined as those diagnosed after a negative screening but before the next scheduled screening. Overall survival (OS) rates were estimated using multiple Cox regression models, and the impact of the mode of detection on survival outcomes was evaluated using the multivariable Fine-Gray subdistribution hazard model.
Results: Among 13,406 women (mean age: 49.8 ± 10 years), 126 (0.9%) developed regional recurrence over a median follow-up of 6.5 years. Of these, 37 cases (0.3%) were interval regional recurrences. Patients with regional recurrence had worse overall survival (OS) compared to those without recurrence (all Ps < .001). Interval regional recurrence exhibited worse OS compared to surveillance-detected or non-regional recurrence, although the difference was not statistically significant (HR: 1.6 [0.6, 4.1]; P = .32; HR: 1.5 [0.8, 2.7]; P = .19). Factors associated with an increased risk for regional recurrence included high T stage (HR: 2.1 [1.5, 3.2]; P < .001), triple-negative breast cancer (TNBC) subtype (HR: 1.8 [1.2, 2.8]; P = .009), receipt of axillary lymph node dissection (ALND) (HR: 2.0 [1.2, 3.3]; P = .007), and lack of adjuvant radiation therapy (HR: 2.8 [2.0, 4.1]; P < .001). In the 126 patients with regional recurrence, factors increasing the hazard of death included shorter time to recurrence (HR: 3.3 [1.7, 5]; P < .001), older age (HR: 1.1 [1.0, 1.1]; P < .001), and the TNBC subtype (HR: 6.5 [2.5, 16.8]; P < .001).
Conclusions: In patients with a personal history of breast cancer, regional recurrence is associated with poorer overall survival. The mode of detection may also impact survival outcomes.
Clinical Relevance/Application: Advancements in adjuvant treatment have made regional recurrence of breast cancer very rare, with rates dropping to less than 2%. While it is well-known that interval breast cancers have worse prognoses, the clinical significance of interval regional recurrence in breast cancer, especially in women with a personal history of breast cancer (PHBC), is not well understood.

P1-12-11: Individualized Breast Cancer Treatment Strategies: Real-World Insights from the ROSE Study

Alessandra Fabi, Luisa Carbognin, Alessandro Rossi, Ferdinando Riccardi, Carmen Mocerino, Raffaella Ruocco, Giulia Valeria Bianchi, Giuseppe Fotia, Giuseppe Capri, Antonella Palazzo, Elena Di Monte, Valentina Frescura, Michelino De Laurentis, Vincenzo Di Lauro, Valérie Perrot, Giorgio Mauri, Manuelita Mazza, Nadia Bianco, Elisabetta Munzone

The ROSE study (NCT05377684) is an ongoing observational trial evaluating the Quality of Life (QoL) as the primary endpoint in premenopausal patients with Hormone Receptor (HR)+, HER2-negative early Breast Cancer (BC). The trial focuses on patients treated with a Luteinizing Hormone–Releasing Hormone (LHRH) analogue (triptorelin) combined with oral endocrine therapy, with or without chemotherapy depending on the risk of relapse, as determined by multidisciplinary meetings. Since April 2022 and up to October 2023 (18 months), the trial reached 50% enrollment of its target population. At this milestone, a predetermined interim analysis focused on the evaluation of baseline demographic characteristics, tumor features, and BC treatments. Other secondary objectives (e.g. hormonal levels) were not evaluated at this timepoint.

Out of the approximately 200 patients initially enrolled, 195 were deemed eligible for the study. All patients had estrogen receptor-positive early BC and, at baseline, were planned to receive adjuvant endocrine therapy with tamoxifen or aromatase inhibitors combined with triptorelin as ovarian function suppression therapy. The median age at BC diagnosis was 45.5 years, ranging from 30 to 56. Tumor characteristics showed that 97.4% of enrolled patients (n=189) had invasive carcinoma, while 2.6% (n=5) had carcinoma in situ. The grading distribution included 10.8% grade 1 lesions, 69.9% grade 2, and 19.4% grade 3. Staging data according to AJCC 2017 criteria were available for 187/195 patients and revealed the following distribution: 44.9% had stage IA BC (stage IB: 5.3%), 27.7% had stage IIA (stage IIB: 16%), and 5.7% had stage IIIA. The Ki-67 proliferation index was available for 193 patients, with a median value of 17% and a mean value of 22.3%.

Regarding therapeutic plans, the monthly triptorelin formulation was prescribed to 92.3% of patients (n=180), while the trimestral was prescribed to 7.7% of patients (n=15). The choice between tamoxifen or aromatase inhibitors depended on the relative risk of recurrence based on the aforementioned prognostic factors, with patients receiving the latter in higher-risk cases. Among the 195 patients, 27.2% (n=53) received adjuvant or neoadjuvant chemotherapy, classifying them as high risk for recurrence. Of these patients, nearly all received aromatase inhibitors and triptorelin (n=48). The remaining 72.8% of patients (n=142) were not considered high-risk enough to warrant chemotherapy, placing them in the intermediate-risk category. These patients were planned to receive triptorelin and either tamoxifen (n=28) or aromatase inhibitors (n=114) in chemotherapy-free treatment plans. The majority of intermediate-risk patients received aromatase inhibitors, indicating a higher risk profile, closer to the high-risk category.

The ROSE study highlights an Italian best practice approach that tailors therapeutic plans to the individual needs of each patient, allowing for treatments based on personalized risk assessments. This approach aligns with current national oncology guidelines by minimizing

chemotherapy use when possible and instead adopting individualized treatment plans based on specific prognostic factors. However, the observational nature of the ROSE trial provides a realistic snapshot of clinical practices, which may differ from the highly-selected populations typical of randomized controlled trials. This observational study of Italian best practices suggests the potential to redefine relapse risk cutoffs based on prognostic factors, providing more accurate and realistic patient-specific therapeutic approaches based on individual risk. The findings of this study, combined with results from ongoing post hoc analyses which aim to identify these new cutoffs, could potentially support the redefinition of relapse risk to better align with clinical practice, thereby fostering patient-specific therapeutic approaches.

P1-12-12: Leptomeningeal Metastases in Breast Cancer: Uni-institutional Experience

Daniel Sobral Filho, Mateus Zapparoli Claro, Aniceto Lopes da Silva Neto, Felippe Lazar Neto, João Vitor Antunes Marques Gregório, Hugo Sterman Neto, Laura Testa

Background: Breast cancer (BC) is the tumor most associated with leptomeningeal metastases (LM), a challenging complication of solid tumors with a poor prognosis and limited treatment options. This study explores the interplay between clinical presentation, treatment and survival outcomes in LM patients.
Methods: this is a retrospective cohort of patients with BC and a cerebrospinal fluid (CSF) positive for neoplastic cells between 2015-2021. Data on CSF cytology, neuroimaging, presenting symptoms, treatments and overall survival (OS) were collected. Symptoms were classified via hierarchical clustering into three neurological syndromes: intracranial hypertension, focal neurological deficit and diffuse encephalopathy. The Kaplan-Meier method was used for survival analyses. Hazard ratio (HR) and 95% confidence interval (95%CI) were calculated using Cox regression.
Results: Of 181 patients diagnosed with LM, 92 (50.8%) had BC as primary site and were included in this analysis. All patients were female with median age of 50.1 years at diagnosis of LM (younger for triple-negative breast cancer (TNBC): 46 years; older for RH+/HER2-: 52.2 years; p=0.09). 48 (52.2%) patients had ECOG-PS 3-4. The most common histology was invasive breast carcinoma of no special type (74 [80.4%]), followed by 9 (4.9%) lobular carcinoma. The most common BC profile was RH+/HER2- (34 [37.0%] patients; 7 [7.6%] luminal A and 27 [29.4%] luminal B), followed by TNBC (32 [34.8%]) and HER2+ (26 [28.2%]). The median time from cancer diagnosis to LM diagnosis was: 35.1 months (m) for HER2+; 20.8m for TNBC; 42.5m for RH+/HER2-; p=0.007. At the time of LM diagnosis, 84 (91.3%) patients had systemic metastatic disease, with 57 (62.0%) presenting brain parenchymal metastasis. The HER2+ profile was more associated with concomitant presence of brain metastasis (25 [96.1%] patients) when compared to RH+/HER2- (16 [47.1%]) and TNBC (16 [50.0%]); p<0.001. Patients were previously treated, on average, with 1-2 lines of chemotherapy in all profiles (p=0.2). RH+/HER2- patients also received 1-2 previous lines of endocrine therapy (ET). Most diagnoses were made during hospitalization

(78 [84.8%]), with 23 (25.0%) deaths before discharge. 82 (89.1%) patients had an MRI ≤ 1 month apart from the CSF. Of those, suggestive report findings of LM were found in 50 (54.3%), which was not prognostic for OS (HR=1.11, p=0.70). The median OS was 1.1m (0.7-4.7) for HER2+; 0.9m (0.6-1.6) for TNBC; 2.8m for RH+/HER2- (1.8-4.8); p=0.17. No differences in OS were found by neurological syndrome (intracranial hypertension, focal neurological deficit or diffuse encephalopathy). Post-LM diagnosis, only 47 (51.1%) patients received additional systemic therapies: 20 (21.7%) received chemotherapy (p=0.75); 10 (10.9%) RH+/HER2- patients received ET, 7 (7.6%) received intrathecal chemotherapy with methotrexate and 24 (26.0%) were submitted to radiotherapy (p=0.63). Patients who received intrathecal therapy had longer overall survival (4.0m [3.8-NA]; HR=0.38 [95%CI 0.15-0.96], p=0.04) when compared to other treatment options (3.1m [1.8-5-5]) or to no treatment (0.6m [0.4-1.12]).
Conclusion: In this cohort, patients who received intrathecal therapy had longer survival. Still, only 7 patients were prescribed this treatment. 25% of patients were not discharged after LM diagnosis and only half of the patients were able to receive any treatment strategy. Therefore, our cohort highlights the need for novel therapeutic approaches to improve outcomes.

P1-12-13: Characteristics and Prognosis of Inflammatory Breast Cancer according to Race: A population base study using SEER database

Chai Won Kim, Soo Youn Bae

Background: Inflammatory breast cancer (IBC) is classified as T4d in the TNM staging system and is notably aggressive and rare. We aim to understand the clinicopathological characteristics of IBC according to race and analyze both the features of IBC influencing prognosis and socioeconomic factors.
Method: Using the National cancer institute's Surveillance, Epidemiology, and End Results (SEER) Research data from 17 registries, we analyzed data from 7,075 women aged 20 and older diagnosed with IBC from 2010 to 2020. Results
Of 7,075 female patients with IBC, there were 48 (0.7%) American Indian/Alaska Native (AI), 468 (6.6%) Asian or Pacific Islander (API), 1238 (17.6%) Black, and 5285 (75.1%) White patients. The incidence rate of IBC was approximately 50% higher among those aged 50-69 and white patients had a higher incidence rate after the age of 70 compared to patients of other races. Stage IIIB was more common among White patients, while Black patients showed a higher proportion in stage IV. Triple-negative breast cancer (TNBC) was more prevalent among Black patients.
There was no significant difference in the rates of surgery and chemotherapy. However, complete response (CR) rate after neoadjuvant chemotherapy was lowest among Black patients. API and White patients had higher rates of being married, whereas 43.4% of Black patients were single. Also, Black patients had lower incomes.
Black patients had the shortest average overall survival (OS) at 29.6 months. The 5-year OS rates were 43.6% for API patients, and 42.2% for White patients. In contrast, the Black

patients was 28.3%. ($p < 0.001$). Economic income and marital status influenced OS rates, but residence was no significant difference in the race group. ($p = 0.107$).
Black patients tended to have an unfavorable prognosis due to higher rates TNBC subtype, advanced stage, lower CR rate. White patients had a lower stage and histological grade.
Conclusion: Black patients with IBC exhibited unfavorable prognoses compared to patients of other races. These results suggest that racial disparities in IBC prognosis are significantly influenced by the clinicopathological characteristics of the tumor, with socioeconomic factors also playing a role.

P1-12-14: Characteristics and outcomes of patients with triple negative breast cancer (TNBC) treated with neoadjuvant chemotherapy (NACT) according to race

Leticia Kimie Murazawa, Vinicius Vitor Oliveira, Victor Rocha Pinheiro, Diana del Cisne Pineda Labanda, Yumi Ricucci Shinkado, Romualdo Barroso-Sousa, Luciana Rodrigues Carvalho Barros, Abna Faustina Sousa Vieira, Laura Testa, Renata Colombo Bonadio

Introduction: Previous literature, originated mainly from the United States, describes differences in outcomes between races in patients (pts) with TNBC, with worse survival results in African-American women compared to the white population. Both inequalities in access to healthcare and different biological tumor behavior have been sought as possible explanations. This study tried to evaluate the differences in characteristics and outcomes of pts with TNBC treated with NACT according to race in a Brazilian cohort.
Methods: We retrospectively reviewed our institutional database to identify pts who underwent NACT for TNBC from 2012 and 2024 and collected data from medical records. Data regarding ethnicity, age, marital status, clinical stage, tumor characteristics and type of treatment were collected. Pts were classified by ethnicity into categories, mostly by heteroidentification registers at hospital admission: “White” (W), “Black” (B), (“Mixed or Browns” were categorized as Black) or “Others or unknown”. The last group represented less than 5%, and was excluded from analysis. Event-free survival (EFS) events were defined as death, disease recurrence or disease progression that precluded surgery. EFS and overall survival (OS) were analyzed from the first cycle of NACT until an event occurred. Survival was estimated with the Kaplan-Meier method and Cox regression model was used to calculate Hazard Ratio (HR). Chi-squared test was used to compare categorical variables.
Results: Of 737 pts, 41.4% were black. There was no significant difference between groups regarding median age (B: 48 years vs W: 49 years), marital status (married - B: 43.0% vs W: 42.6%, $p = 0.19$), as well as clinical stage III (B: 61.3% vs W: 63.7%, $p = 0.57$) and histological type (invasive ductal carcinoma - B: 88.2% vs W: 88.7%, $p = 0.48$). However, there was a difference in histological grade, with a higher proportion of black pts with grade 2 disease (39.0% vs 30.8%, $p =0.03$). A statistically significant difference was found in relation to the time of starting treatment, being greater in the black population (B: 2.3 months vs W: 2.0 months, $p = 0.03$). There were no significant differences in chemotherapy regimen, mostly AC-T (B: 87.5% vs W: 87.7%, $p = 0.35$) and type of surgery performed

(mastectomy - B: 47.9% vs W: 56.0%, p = 0.12), as well as pathological complete response rate (B: 28.5% vs W: 29.4%, p = 0.86). With a median follow-up of 61 months, white population had worse 5-year OS (72.9% vs 63.2%, HR 1.3, 95% Confidence Interval [95CI] 0.99 - 1.76, p =0.05) and 5 year EFS (65.5% vs 56.6%,HR 1.34, 95CI 1.04 - 1.72, p =0.02) than black population. When stratified according to histological grade, no differences were found between races for OS (p=0.20) and EFS (p=0.16) in grade 2 and for OS (p=0.28) and EFS (p=0.12) in grade 3 disease.
Conclusion: Black women had better EFS and OS than white women with early TNBC in our cohort. While reasons for this finding are not clear, it may have been influenced by a higher proportion of grade 2 disease in black pts. Furthermore, results may be influenced by heteroidentification bias, which may not reflect personal racial identification. This study highlights the importance of evaluating populations of different ethnicities to better understand racial disparities in TNBC.

P1-12-15: Real-World Assessment of biosimilar Trastuzumab MYL-1401O vs. reference Trastuzumab in HER2-Positive Breast Cancer: Utilization, Efficacy, and Safety in Asian patients

Ming-Chang Tsai

Background: MYL-1401O, a biosimilar of trastuzumab, has demonstrated efficacy and safety equivalent to reference trastuzumab (RTZ) in clinical trials for treating human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer (MBC). This study presents a real-world analysis comparing MYL-1401O with RTZ, focusing on single and dual anti-HER2 blockade therapies. The analysis encompasses neoadjuvant and first-line palliative treatments for HER2-positive early breast cancer (EBC) and MBC patients within a single hospital in Taiwan.

Methods: A retrospective analysis was conducted using medical records from Kaohsiung Veterans General Hospital. Patients treated with RTZ from January 2010 to December 2022 and MYL-1401O from January 2020 to December 2022 were included. The study focused on HER2-positive EBC patients who received neoadjuvant chemotherapy with RTZ or MYL-1401O ± pertuzumab (n = 140) and untreated stage IV MBC patients who received first-line palliative treatment with RTZ or MYL-1401O ± pertuzumab (n = 150). Primary endpoints included achieving pathological complete response (pCR) in the EBC group and progression-free survival (PFS) in the MBC group. Secondary endpoints were objective response rate (ORR), disease control rate (DCR), and cardiac safety. Subgroup analyses included patients receiving dual anti-HER2 blockade.

Results: Comparable pCR rates were observed between MYL-1401O and RTZ in the neoadjuvant chemotherapy group: 42.2% (19/45) for MYL-1401O and 51.6% (49/95) for RTZ (p = 0.301). Median PFS in MBC patients was similar between groups without statistically significant difference: not reached for MYL-1401O and 14.1 months for RTZ

(95% CI, 9.0-19.1, p = 0.061). ORR, DCR, and cardiac safety profiles did not significantly differ between MYL-1401O and RTZ.

Conclusions: This real-world study demonstrates that MYL-1401O is as effective and safe as RTZ in Asian patients with HER2-positive EBC or MBC, supporting its clinical utility in these populations.

P1-12-16: A Rare Case of Moderate Grade Intraductal Carcinoma in a Young Patient with known Neurofibromatosis 1

Nicholas Gore, Madeline Silva, Carissia Calvo-Strube

Background: Neurofibromatosis type 1 (NF1) is a genetic disorder characterized by the development of tumors along nerves in the skin, brain, and other organs. It arises from mutations in the NF1 gene, which encodes neurofibromin, a tumor suppressor protein involved in regulating cell growth and division. NF1 patients have an increased susceptibility to various cancers, including breast cancer, though the precise mechanisms linking NF1 to breast cancer are still being investigated. Research indicates that the NF1 gene may play a role in modulating pathways involved in breast cancer development, such as the Ras signaling pathway. The risk of developing breast cancer before age 50 is estimated to increase fivefold in NF1 patients, with poor disease specific survival. Current NCCN screening guidelines suggest starting annual mammograms at age 30, with consideration of additional MRI screening. However, screening remains challenging in this patient population due to cutaneous neurofibromas, cafe-au-lait spots, and dense breast tissue. Enhancing our understanding of these connections could facilitate improved screening and management strategies for breast cancer in individuals with NF1.

Case Presentation: We present a case of a 17 year old female with a confirmed pathogenic NF1 mutation diagnosed in childhood, who presented with early-onset invasive ductal carcinoma (IDC). The patient presented with new-onset symptoms of right breast bloody nipple discharge and nipple retraction. Initial work-up with breast ultrasound noted only benign simple cysts. Further diagnostic work-up with MRI breast, however, demonstrated a 2 cm mass at the 4 o'clock axis of the right breast with associated 5 cm of segmental non-mass enhancement. Diagnostic mammogram revealed correlating right breast 5.8 cm segmental pleomorphic calcifications. Stereotactic core needle biopsy of these calcifications confirmed a diagnosis of IDC, grade 2, ER/PR +, HER2+ with extensive intermediate grade ductal carcinoma in-situ (DCIS). She underwent treatment with neoadjuvant TCHP followed by right nipple sparing total mastectomy, right sentinel lymph node biopsy (SLNB), and contralateral risk reducing nipple sparing mastectomy with direct to implant reconstruction. Pathologic examination of the right breast demonstrated extensive DCIS with no residual IDC, negative margins, pathologically negative sentinel lymph nodes (ypTis N0). Multidisciplinary adjuvant treatment included adjuvant Tamoxifen and Phesgo along with recommendations for post mastectomy radiation therapy.

Conclusion: Neurofibromatosis 1 and its heightened risk of early-onset breast cancer are well documented. However, diagnosing breast cancer in NF1 patients remains challenging due to prevalent cutaneous neurofibromas and dense breast tissue in young patients, which may obscure imaging and physical exam findings. While current guidelines recommend annual screening to begin at age 30, earlier initiation of high-risk screening with annual MRIs should be considered, potentially starting as early as age 18. Given the increased risk for breast cancer, it is crucial to implement age-appropriate diagnostic breast imaging in patients with known pathogenic NF1 mutations experiencing breast-specific symptoms.

P1-12-17: A case of sequential alpelisib and capivasertib in a patient with metastatic breast cancer harboring both a PIK3CA and AKT mutations

Sanjna Rajput, Karthik V. Giridhar

Introduction: Somatic mutations in the PIK3CA/AKT/mTOR pathway are associated with resistance to first-line endocrine therapy in hormone-receptor positive (HR+) breast cancer (BC). PIK3CA and AKT1 mutations are reported in 35-40% and 4-7% of HR+ BC respectively, with less published about the rates of co-occurrence (PMID: 32983983). Therapies targeting mutations in this pathway approved in conjunction with endocrine therapy include alpelisib, everolimus and capivasertib. Prior cohort data showed limited benefit of alpelisib after everolimus (PMID:36292649). Recent data notes that AKT emergent mutations may be a resistance mechanism to PIK3CA inhibition (PMID: 37916958).
As Capitello-291, BYLieve, and SOLAR-1 excluded patients with prior PIK3CA/AKT/mTOR inhibitors, minimal data exists on how to optimally select and sequence these therapies. Here we present a case of a patient with co-occurring PIK3CA and AKT1 mutations who gained clinical benefit from alpelisib and subsequently capivasertib.

Case presentation: A 64-year-old female presented with a left-sided parasternal mass. She had a prior estrogen receptor positive (ER+), human epidermal growth factor negative (HER2-) left mixed ductal and lobular carcinoma (pT2pN1a) 17 years ago, treated with lumpectomy, chemotherapy, radiation and 10 years of adjuvant endocrine therapy. 7 years later, PET-CT revealed presence of metastatic disease in the sternum and supraclavicular lymph nodes. Biopsy of the parasternal mass noted invasive ductal carcinoma, grade II, ER low+ (11-20%), progesterone receptor negative (PR-), HER2-. A second site biopsy was ER-, PR-, and HER2-. Tempus tumor sequencing of this sample noted both AKT1 E17K [variant allele fraction (VAF) 21.4%] as well as PIK3CA E545K mutation (VAF 8.1%).
The patient progressed on several lines of therapy due to adverse effects and disease progression. She received nab-paclitaxel/atezolizumab for 4 months, letrozole and abemaciclib for 2 months, letrozole alone for 6 months, and letrozole and ribociclib for 6 weeks. Given presence of PIK3CA mutation, 4th line treatment with fulvestrant and alpelisib was planned. However, the patient developed transaminitis after the first fulvestrant

treatment, prior to initiation of alpelisib, which resolved with steroids. After progressing on capecitabine after 2 months, alpelisib with exemestane was initiated. The patient had a partial metabolic response on PET/CT imaging and eventually progressed on alpelisib and exemestane after 15 months. Due to a low ejection fraction despite work with cardio-oncology, she was not a candidate for trastuzumab deruxtecan. She progressed on oral cyclophosphamide and methotrexate after 2 months and Sacituzumab govitecan after 3 months.
Guardant 360 liquid biopsy testing revealed the same prior AKT1 E17K (VAF 2%) and PIK3CA E454K alteration (VAF 1.7%). She started 9th line therapy with the pan-AKT inhibitor capivasertib with fulvestrant. Guardant Response assessment after 4 weeks noted clearing of the AKT1 and PIK3CA mutations with no cfDNA detectable. 2-month follow-up PET-CT revealed significant favorable response to treatment. At 6-month follow-up, the patient continues on this treatment.
We interrogated publicly available datasets in TCGA, MSK-IMPACT, METABRIC, and AURORA and note that across 7204 samples, mutation prevalence for PIK3CA and AKT1 was 39% and 5%, with significant mutual exclusivity and co-occurrence observed in only 41/7204 samples (0.6%) (PMID: 22588877).

Conclusion: This case report highlights a response of AKT1 targeted therapy with capivasertib in a patient who previously progressed on PIK3CA targeted therapy with alpelisib. Comprehensive biomarker assessment is needed to identify patients who may benefit from sequential therapies. There is a need for trials comparing therapies that target the PI3K pathway at distinct points, potential sequencing of these therapies, and the optimal sequence strategy.

P1-12-18: A case report of paraneoplastic rapidly progressive cerebellar syndrome in a patient with locally recurrent hormone receptor positive (HR+)/HER2- breast cancer

Kelsey Natsuhara, Michael D. Alvarado, Prashanth Ramachandran, Laura A. Huppert, Jessica Knapp, Sarah Donahue, Hope S. Rugo

Introduction: Paraneoplastic syndromes (PNS) are rare neurologic complications of breast cancer that can be life threatening. However, little is known about clinical risk factors for PNS. Furthermore, diagnosis can be challenging requiring a high index of suspicion to appropriately treat patients' PNS and their primary cancer.
Clinical Case: A 40 yr old woman with a history of locally recurrent right breast cancer presented with progressive neurologic symptoms. She was first diagnosed with stage IA (pT1bN0) multifocal grade 3 invasive ductal carcinoma with lymphovascular invasion; ER 90%, PR 10%, HER2-, recurrence score 31. After mastectomy, she received docetaxel + cyclophosphamide x 4 cycles and tamoxifen for 2 yrs, until she presented with a multifocal local recurrence with extension to skin (grade 3, ER>95%, PR-). She underwent surgical resection then received doxorubicin x 4 with ovarian function suppression (OFS). She then

developed a 2nd extensive local recurrence invading skin and muscle and started letrozole. Within 1 wk, she developed headaches, ataxia, dizziness, diplopia, and dysarthria that rapidly became disabling and was admitted to the hospital. MRI brain and spine were benign, except for subtle T2 hyperintensities in the cerebellum. Extensive infectious workup was negative. Cerebrospinal fluid (CSF) showed 72 WBCs with 97% lymphocytes. She was treated with broad spectrum antibiotics and antivirals for possible occult infection, but serial CSF sampling showed persistent lymphocytic pleocytosis. IgG index, oligoclonal bands, autoimmune encephalitis and paraneoplastic testing were negative. In consultation with neurology and oncology, she was diagnosed with probable paraneoplastic rapidly progressive cerebellar syndrome (RPCS). She was treated with 1g IV methylprednisone x 2 doses and intravenous immunoglobulin (IVIG). She was discharged and continued a slow steroid taper and monthly IVIG x 8 mos. Her symptoms began to improve after 1 mo of treatment and were largely resolved by 6 mos. For her breast cancer, she continued OFS + letrozole and, after significant neurologic improvement, underwent resection of the local tumor with 2 residual sub-cm foci followed by radiation and abemaciclib initiation. She remains stable on OFS, letrozole and abemaciclib 3.5 yrs after diagnosis of RPCS without worsening neurologic symptoms or breast cancer recurrence.
Discussion: Breast cancer is one of the most common solid tumors associated with PNS. The presentation of PNS varies widely, as any part of the nervous system can be affected. RPCS is one of the most frequent PNS in breast cancer. Patients typically presents with a severe pancerebellar syndrome that develops in <12 wks, including dizziness, nausea, gait instability, diplopia, ataxia, dysarthria and dysphagia. Symptoms typically stabilize after initial worsening, but if untreated, can leave patients with severe sequelae. Diagnosis requires ruling out alternative causes of cerebellar ataxia (e.g. metabolic causes), MRI brain, and CSF analysis. Though, MRI is not sensitive in the early stage of disease and CSF findings are often non-specific (e.g. elevated proteins and lymphocytes). RPCS is mediated by antibodies against onconeural antigens, with anti-Yo being most common in breast cancer. However, antibodies are identified in <50% of cases, making diagnosis difficult. Treatment typically includes high dose steroids +/- additional immunosuppressive therapies such as IVIG or plasmapheresis in severe cases. In addition, the underlying cancer must be treated for neurologic stabilization, but neurologic improvement is not always seen. Fortunately, our patient had significant neurologic improvement after treatment of her RPCS and breast cancer, with no signs of cancer recurrence after 3+ yrs.

P1-12-19: A case report of successful hair preservation using scalp cooling with doxorubicin and cyclophosphamide during pregnancy

Kelsey Natsuhara, Annalisa Post, Michael D. Alvarado, Sally Fang-Tu, Gretchen Fulgencio, A. Jo Chien

Introduction: The management of breast cancer during pregnancy requires complex decision making to optimize the health of the patient and minimize risks to the baby. Some systemic therapy agents, such as HER2-targeted agents, are contraindicated in pregnancy,

while for other agents there are less data. Doxorubicin + cyclophosphamide (AC) is a regimen that has been shown to be safe during pregnancy. However, hair loss is near universal without scalp cooling. There are no published reports of scalp cooling during pregnancy and the safety and activity of scalp cooling in pregnancy are unknown, though short term exposure to cold is not thought to be harmful.

Clinical Case: A 38 year old woman palpated a mass in her right breast. Breast ultrasound showed 1.5 cm and 1.3 cm masses with benign-appearing axillary lymph nodes. US-guided core biopsy revealed a grade 2 invasive ductal carcinoma (IDC) ER+, PR+, HER2+. At the time of diagnosis, she was found to be 10 weeks pregnant and desired to continue the pregnancy. Since HER2-targeted therapy is contraindicated during pregnancy, the patient started neoadjuvant systemic therapy with AC and used scalp cooling for hair preservation starting cycle 1. She received C1D1 at 14 weeks gestation and completed 4 cycles without complication. She had nearly 100% of her hair after 4 cycles of AC. At 30 weeks gestation, she underwent right partial mastectomy and sentinel lymph node biopsy which showed 2.5 cm of grade 2 IDC with 10% cellularity, ER+/PR+/HER2+. She had 6.5 cm of grade 2-3 DCIS, 1/1 lymph nodes with isolated tumor cells, and negative margins. At 34 weeks gestation, the patient was induced and delivered a healthy baby girl. At 2 weeks postpartum she started weekly paclitaxel, trastuzumab and pertuzumab (THP). She continued to use scalp cooling with minimal hair loss (<5%) after 12 weeks of THP. She has completed adjuvant T-DM1 and experienced no further hair loss.

Discussion: The diagnosis of breast cancer during pregnancy poses unique challenges both for treatment and symptom management. Data are limited in this space and largely from retrospective series, highlighting the need for careful monitoring and reporting of pregnant patients' experiences with breast cancer treatment. Hair loss is one of the most visible and psychologically distressing side effects of chemotherapy. Multiple randomized trials have demonstrated the efficacy of scalp cooling in reducing chemotherapy related hair loss, with more than half of women who use scalp cooling retaining more than 50% of their hair. However, rates of hair preservation are significantly lower with anthracyclines (16% in the SCALP trial). To our knowledge, there are no published reports on scalp cooling during pregnancy. This case is notable given the remarkable success of hair preservation with AC during pregnancy. In addition, scalp cooling was well tolerated for this patient and she went on to deliver safely. We hypothesize her notable hair preservation may be due in part to pregnancy related hair changes. Many women report thicker hair during pregnancy, due to slowing of hair follicle cycling with more follicles staying in growth phase (anagen) and fewer hairs entering resting phase (telogen), which results in less shedding and hair loss. After pregnancy, more hair follicles enter telogen phase resulting in postpartum hair loss (telogen effluvium). During her post-partum taxane treatment, she experienced ~5% hair loss, which may have represented telogen effluvium. This case demonstrates that scalp cooling can be safe and remarkably effective during pregnancy and should be considered in pregnant patients to mitigate the distress associated with alopecia.

P1-12-20: A rare case of metastatic atypical adenomyoepithelioma of the breast: challenges in systemic treatment.

Anezka Ferrari, André Perina, Ana Carolina Muhlberger, Paula Ferreira, Lorine Teixeira, Fabiana Miranda, Renata dos Anjos, Dalton dos Anjos, Isadora Sousa, Mariana Pina, Bruna Zucchetti, Karina Sacardo, Ângelo Fêde, Renata Arakelian, Manuel Cruz, Manoel Carlos Souza, Cynthia Lemos, Katia Pincerato, Mariana Gouveia, Tiago Takahashi, Romualdo Barroso

Introduction: Adenomyoepithelioma is a rare histologic type of primary breast tumor characterized by a biphasic presentation with cells of the epithelial and myoepithelial lineage that rarely become malignant and may metastasize. We present a case of metastatic atypical adenomyoepithelioma and the challenges associated with its systemic treatment.

Case Report: A 61-year-old woman with a history of grade 2 obesity, prediabetes and well-controlled hypertension presented with a lesion in her left breast. She had been under observation for about 7 years and had undergone several biopsies, all of which showed benign results and were treated as chronic granulomatous mastitis.

In 2022, she noticed a significant enlargement of the left breast lesion and sought our treatment. MRI of the breast showed an oval, exophytic lump in the anterior third of the left breast measuring 10.5x8.9x5.2 cm. Ultrasound-guided core biopsy revealed a ductal carcinoma in situ (DCIS) measuring 2.0 mm within a complex sclerosing lesion. A left mastectomy with sentinel lymph node biopsy was then performed. Pathologic analysis revealed an atypical adenomyoepithelioma with a size of 14.5 cm, mild to moderate atypia, clear margins and no involvement of the sentinel lymph nodes.

Staging with PET-CT revealed a hypermetabolic pulmonary nodule in the left lower lobe measuring 1.2 cm, which was confirmed by biopsy to be a metastasis of a primary atypical adenomyoepithelioma of the breast. The case was discussed in a tumor board to decide between SBRT and metastasectomy for the apparently solitary lung lesion. However, a PET-CT scan two months later revealed multiple lung nodules and multiple bone metastases.

First-line chemotherapy with weekly carboplatin and paclitaxel was initiated. After 12 weeks, a new PET-CT scan showed progression of the disease in both the bones and the lungs. The patient received second-line chemotherapy with liposomal doxorubicin as monotherapy, which also proved ineffective after 10 weeks, as the disease progressed in several bone segments and lung function deteriorated.

Genome profiling using NGS revealed mutations in AKT1, HRAS, IKZF1 and MPL, for which there are no targeted therapies in the Brazilian healthcare system. In addition, the TMB was 5 mutations/Mb without microsatellite instability. Other chemotherapy lines, including FOLFIRI and cisplatin with gemcitabine, were administered without satisfactory results. Although the patient had a good performance status (ECOG 1) and remained motivated for

new treatments, a sudden deterioration in consciousness occurred 16 months after diagnosis. She was taken to the nearest emergency room where a large ischemic stroke associated with a CNS tumor lesion was diagnosed, leading to her demise.

Discussion: The pathologic diagnosis of malignant adenomyoepithelioma is challenging because it is difficult to differentiate it from benign conditions such as intraductal papillomas, tubular adenomas, and sclerosing adenoses. In our patient, previous biopsies suggested granulomatous mastitis and the last biopsy revealed a large sclerosing adenomatous area with a small DCIS focus. Only analysis of the entire tumor sample led to the diagnosis of atypical adenomyoepithelioma. Reports from the literature emphasize the difficulty in characterizing morphological features indicative of malignancy.

The largest case series from the late 1980s and early 1990s reported 17 and 31 cases, respectively. More recent series are much smaller, emphasizing the rarity of the disease. Most cases are localized in the breast and can be well controlled by complete excision. However, local recurrences and metastases occur in up to 30% of patients and have a poor prognosis. The most common metastases include the thyroid, lung, CNS, bone and liver, suggesting hematogenous spread.

Treatment of malignant adenomyoepithelioma is not well established beyond complete removal at an early stage. The need for sentinel lymph node biopsy remains uncertain, and the efficacy of adjuvant chemotherapy has not yet been established. Chemotherapy for metastatic disease has generally shown limited efficacy. Therapies with anthracyclines, 5-fluorouracil and even eribulin have been reported, all of which have no proven efficacy.

Genomic profiling often identifies mutations in the AKT pathway, indicating a potential beneficial effect of targeted therapies in future trials. In this case, the patient had only received cytotoxic chemotherapy and had not responded to any of the therapies administered.

Conclusion: We await further studies to evaluate the role of molecular targeted therapies and immunotherapy in such a rare and aggressive malignancy. The case presented emphasises the need to continue research and development of effective treatment strategies for metastatic atypical adenomyoepithelioma.

P1-12-21: Angiosarcoma of the breast

Alexander V. Petrovsky, Danila A. Denchik, Yelena A. Kim, Elizaveta A. Golovina

Angiosarcoma of the breast is a rare malignant tumor of mesenchymal origin, rich in atypical cells of either endothelial or periocytic nature. It is characterized by rapid growth with a recurrent course, early metastasis of a hematogenic nature and a poor prognosis. Angiosarcomas account for less than 1% of all malignant breast tumors and less than 5-8% of soft tissue sarcomas. We report the case of a 28–year-old woman with a tumor in her

right breast that appeared during lactation. After performing a core biopsy of the formation, according to histological and immunohistochemical evaluations, primary angiosarcoma G1 (FNCLCC) was diagnosed with the presence of anti–CD31, anti-Fli-1 and anti-PanCK. From November 2021 to February 2022, 8 courses of neoadjuvant chemotherapy according to the HD AI scheme (doxorubicin + ifosfamide) were performed. Then, in March 2022, an oncoplastic sectoral resection of the right breast was performed. Postoperative histological examination: angiosarcoma G1 (according to the FNCLCC system) therapeutic pathomorphosis IIA according to Huvos. From 04/14/2022 to 07/05/2022, a course of adjuvant radiation therapy was performed only on the right breast without regional zones (3D CRT), photon energy 6/18MeV, single focal dose (SFD) 2 Gy, average focal dose 45.39 Gy. Currently, the patient is alive and has had a relapse-free course of the disease for two years. This clinical case shows the importance of continuity of treatment for angiosarcoma, which is a very aggressive disease.

P1-12-22: Breast Implant Associated Squamous Cell Carcinoma (BIA-SCC): A Mayo Clinic Multidisciplinary Approach to Treatment:

Dhauna Karam Prasad, Kimberly S. Corbin, Tina J Hieken, Samir Mardini, Malvika Solanki, Ciara C. O'Sullivan, Ciara O'Sullivan

Introduction: Breast implant associated squamous cell carcinoma (BIA-SCC) is a rare occurrence with approximately 400 cases reported to the FDA as of March 2023, however, the incidence is rising. Optimal management of this aggressive malignancy is not well defined, and is unfortunately associated with high morbidity and mortality. Herein, we describe the case of a woman who was diagnosed with and treated for BIA-SCC in a multidisciplinary fashion at the Mayo Clinic in Minnesota, USA.
Case Presentation: A 53-year-old post-menopausal woman presented in March 2024 with a 4-week history of pain, erythema and skin nodules concerning for an abscess of the right(R) breast implant. Her oncology history was significant for lobular carcinoma in situ of the left breast, and a right breast fibroadenoma (both diagnosed in 2009). She was treated with bilateral nipple-sparing mastectomies, which confirmed the aforementioned diagnoses. She subsequently underwent a bilateral breast reconstruction with gel implant placement in 2010. In 2014, she developed R breast pain secondary to implant capsular contraction, necessitating replacement of the R breast implant. She proceeded with a right-sided partial capsulectomy and bilateral silicone gel implant placement with fat injections. In March 2024, she presented with erythema, nodules and purulent drainage from the R breast which required hospitalization for IV antibiotics (minimally effective). Imaging (US and MRI of R breast) revealed complex intracapsular and subcutaneous fluid collections, enlarged right axillary and internal mammary chain lymph nodes, and 3 complex foci (the largest 4.3 cm) in the R breast. Core biopsy of a R breast lesion showed invasive carcinoma with squamous differentiation (triple negative, p63, p40-positive, PD-L1-positive [CPS >10]); right axillary lymph node FNA was negative for malignancy. Differential diagnoses were triple negative breast cancer vs. implant-associated squamous cell carcinoma vs. metaplastic breast cancer.

The diagnosis of BIA-SCC was made following multidisciplinary discussion, including a comprehensive review of the clinical presentation, case history, radiology and pathology reports.
She ultimately underwent surgical removal of the R breast implant with chest wall resection, capsulectomy and R axillary LN biopsy. Pathology revealed moderate to poorly differentiated invasive carcinoma with squamous differentiation, forming a 13.5 cm mass; 2 of 8 lymph nodes were positive for metastatic carcinoma. The patient was readmitted shortly after surgery complaining of dyspnea and chest pain. CT chest revealed a R pleural effusion. Diagnostic thoracentesis was negative for infection or malignancy. Despite broad-spectrum IV antibiotics, her symptoms worsened. A PET-CT revealed an FDG-avid infiltrative chest wall lesion (5.4 cm x 13 cm x 14.5 cm) worrisome for residual tumor, with a recurrent R pleural effusion. We commenced concurrent chemoradiation with weekly carboplatin (AUC 2), weekly paclitaxel (50 mg/m2) (1) and proton beam radiation (200cGy over 33 fractions). The patient responded clinically and radiologically to this approach . Next steps are to add pembrolizumab, and continue chemotherapy based on the KEYNOTE-522 regimen, continuing weekly carboplatin (AUC 1.5) and paclitaxel (80mg/m2) for a total of 12 weeks.. She will then complete 4 cycles of q 3 weekly adriamycin. cyclophosphamide and pembrolizumab. She is being monitored closely by medical and radiation oncology teams.

Conclusion: Awareness of BIA-SCC is key to early diagnosis and appropriate management of this rare and aggressive malignancy, as well as to ensure prompt reporting to regulatory authorities. Oncology and primary care providers should be vigilant when conducting long-term follow-up visits with patients who have had breast implants placed. Giventhe rarity of BIA-SCC , information sharing is critical to raise awareness and guide treatment recommendations. In-depth characterization of tumor genetics may aid development of personalized therapeutic strategies moving forward.

P1-12-23: CASE SERIES OF PATIENTS WITH BREAST CANCER WHO USED HORMONAL IMPLANTS

Rafaella Britto Toledo, Antonio Carlos Buzaid, Carolina Cavalcanti Gonçalves Ferreira, Sara Batista Micheletti

Scenario: Symptoms attributed to menopause are the cause of many dissatisfactions and searches for Hormone Replacement Therapy. The numerous advantages associated with this replacement therapy have led to the widespread and unrestricted prescription of

different hormones. However, breast cancer remains the most common malignancy in Western countries in menopausal women and the estrogen receptor positive (ER+) subtype is the most prevalent. In patients with hormone receptor positive tumors, adjuvant endocrine therapy has a great impact on overall survival and the choice of endocrine therapy to be used will be determined by menopausal status. Objective: The primary objective of our study was to review the clinical characteristics and clinical course of patients that had hormonal implants and were diagnosed with breast cancer. Method: Case series of patients with hormone receptor-positive breast cancer who had undergone hormonal implants prior to the diagnosis of breast cancer. We retrospective reviewed the medical records of women with a histopathological diagnosis of invasive breast carcinoma aged over 18 years who reported having subcutaneous hormone replacement implants and were treated at Hospital Beneficência Portuguesa in São Paulo from November 2018 until November 2023. Results: Data were reported from 5 patients with hormone receptor-positive invasive breast carcinoma who had previously undergone SC implants as hormone replacement therapy. Among them, one patient whose last implant was more than 3 years old still had estradiol measured para mass spectometry (E2) of 23. Only after surgical removal of all her implants the E2 levels reduced to menopausal levels. Another had implants of about one year old and her E2 levels was 233. Her implants could not be surgically removed and the only adjuvant endocrine therapy possible was tamoxifen. Conclusion: Hormonal implants are a real problem in patients diagnosed with breast. E2 levels may remain elevated even many years after implant placement and some implants cannot be surgically removed resulting in chronic elevation of E2 levels. In these cases, only tamoxifen can be used as part of the adjuvant endocrine therapy.
Keywords: Hormone Replacement Therapy; Breast cancer; hormonal implant.

P1-12-24: Case Report: Activity of Pembrolizumab in Metastatic Merkel Cell Carcinoma and TNBC

Jessica Liu, Jane Kanowitz, Maryam Lustberg, Kelly Olino

The anti-PD-1 immune checkpoint inhibitor (ICI) pembrolizumab blocks the T-cell-inhibitory PD-1 pathway and has gained tumor agnostic approval for treatment of high mutational burden and PD-L1-expressing tumors [1,2; References Available].
Triple negative metastatic breast cancer (TNBC) is a highly aggressive subtype of breast cancer, accounting for 15-20% of incidence [3]. In combination with chemotherapy, pembrolizumab has improved overall survival in patients with metastatic TNBC [4,5,6]. Similarly, pembrolizumab has demonstrated tumor control against the neuroendocrine Merkel cell carcinoma (MCC), a rare and aggressive skin cancer [7,8,9]. Yet, for both MBC and MCC, study of ICIs' tolerability and efficacy in older patients (> 75 y.o.) is limited, despite higher incidence of cancer and reduced T-cell reserves [15].
Therefore, we present a case of a 98-year-old patient with metastatic MCC and locally advanced TNBC who achieved complete remission of both diseases on anti-PD-1 ICI pembrolizumab alone.

Case Presentation: A 98-year-old woman presented with a skin mass in the lower extremity in May 2022. The patient has a history of hypertension, hypercholesterolemia, aortic stenosis, and bradycardia with syncope, for which she had a cardiac pacemaker just prior to diagnosis. She is clinically frail and ambulates with a walker. Pathology reported the lesion as CD-20 negative, TTF-1 negative, and INSM1 positive, supporting diagnosis of neuroendocrine carcinoma. Given the small tumor size (1cm) and location on the medial aspect of the left ankle, she opted for one dose of 8Gy in August 2022 which led to complete regression of the lesion. In September 2023, biopsy showed in-transit Merkel cell carcinoma. Given good and improving performance status, she underwent PET CT for staging. PET CT imaging revealed a 3cm mass in the right lobe of the liver and a 3cm left breast mass. Laboratory data noted stage II renal insufficiency. Biopsy of the liver mass revealed Merkel cell carcinoma. Breast biopsy identified a poorly differentiated invasive ductal carcinoma mass, stage IIB TNBC with PDL-1 combined positive score (CPS) > 10 by pathology.
CARG (Cancer and Aging Research Group Chemotherapy Toxicity Calculator), a validated geriatric chemotherapy toxicity assessment tool, was utilized. Her CARG score of 15 indicated a 92% risk of grade 3 or higher toxicity, making chemotherapy an unfavorable palliative option.
As such, pembrolizumab (anti-PD-1 ICI) was recommended. Beginning November 2023, the patient received four treatments (200mg every 3 weeks) of pembrolizumab without toxicity. After the first cycle, her breast mass and skin lesions were no longer palpable. PET and clinical examination in March 2024 demonstrated complete radiographic and clinical remission of all sites of disease. Presently, there has been no clinical evidence of recurrence and most recent imaging has been negative.
Discussion: Both advanced MCC and TNBC are rare and aggressive carcinomas that have been found to respond to PD-1/PD-L1 targeted immunotherapy, with comparable ICI efficacy in patients aged younger or older than 85 years [6,12]. While recent multicenter, prospective studies did not find a correlation between age and immune related adverse event (irAE) occurrence, older patients were more likely to discontinue treatment due to irAEs [12,13,14,15]. Thus, assessment of functional status, comorbidities, and psychosocial factors is increasingly important for selecting geriatric patients for immunotherapy.
Our 98-year-old patient was diagnosed with MCC metastatic to the liver and PD-L1 positive TNBC. The complete remission of all sites of disease with pembrolizumab alone presents a remarkable case of PD-1 ICI-induced regression of advanced MCC and TNBC. Thus, this case suggests PD1-inhibitor immunotherapy can be effective, tolerated, and may be considered in older adults who are otherwise fit.

P1-12-25: Circulating Tumor DNA (ctDNA) Detection of Local Recurrence in a Patient with Early-Stage Triple Negative Breast Cancer

Samer Alkassis, Marla Lipsyc-Sharf, Shiliang Zhang, Caterina Gianni, Arielle Medford, Aditya Bardia, Shahryar Ashouri, Nimmi Kapoor

Introduction: Triple negative breast cancer (TNBC) accounts for 15-20% of invasive breast cancer cases. While most patients with early-stage TNBC are treated with curative intent, approximately 50% of patients experience recurrence in the first 5 years. There are no current recommended assays for early signs of recurrent disease, though novel diagnostic tests are currently in development. Circulating tumor DNA (ctDNA) assessment has been investigated as a way to evaluate response to treatment, determine prognosis, and detect minimal residual disease (MRD) after curative-intent treatment. However, while ctDNA detection is known to be strongly associated with poor prognosis, the incorporation of ctDNA evaluation in early breast cancer care has been challenging due to lack of evidence of clinical actionability. No data are currently available regarding the predictive utility of ctDNA detection on local recurrence. Herein, we present a case of a patient with early-stage TNBC who had positive ctDNA testing in the adjuvant setting that identified local recurrence.

Case: A 53-year-old thin woman palpated a mass in the right breast. A mammogram and ultrasound revealed an 8 mm lesion, and biopsy showed a grade 3 TNBC. CT scan of the chest, abdomen, and pelvis (CT CAP) revealed no evidence of metastatic disease. MRI of the right breast showed conglomerate area spanning up to 5.2 cm, with possible nipple involvement. She received 4 cycles of neoadjuvant carboplatin and Taxol, due to patient preference, followed by repeat MRI showing the same size of the mass with decreased enhancement. She then had bilateral skin-sparing mastectomy, including nipple removal, with implant reconstruction. Pathology revealed an 8 mm TNBC and involvement of one lymph node. She then completed 4 cycles of adjuvant cyclophosphamide and doxorubicin. One month after completing adjuvant chemotherapy, she had positive plasma ctDNA testing. A subsequent PET/ CT scan showed no evidence of metastatic disease. She had three additional plasma ctDNA tests at 2, 3, and 6 months after initial testing which were positive with increasing variant allele frequency. After additional PET/CT and CT CAP at 3 and 6 months from initial PET/CT scan respectively, an MRI breast was performed showing multiple masses in the skin flap of the reconstructed right breast. She underwent complete right mastectomy and implant removal which confirmed multifocal TNBC in the skin flap. She subsequently completed a course of radiation to the right breast, with negative plasma ctDNA afterwards.

Discussion: The detection of ctDNA post-treatment in early stage TNBC is a strong predictor of recurrence risk. During neoadjuvant chemotherapy, improvement in ctDNA detection has been associated with improved distant recurrence-free survival, even in patients with extensive residual cancer. The c-TRAK TN prospective trial in adjuvant TNBC found that ctDNA detection was associated with poor prognosis, with median time from ctDNA detection to recurrence of 4.1 months. However, to our knowledge, MRD testing has not yet been systematically utilized for detecting local recurrence. Fortunately, our patient did not have evidence of distant metastatic disease and dedicated breast imaging was obtained to identify local recurrence.

Conclusion: This case highlights the potential of MRD assessment in the adjuvant setting in TNBC to identify local recurrence and, in cases of adjuvant ctDNA detection, guide thorough evaluation with both systemic scans and dedicated primary breast imaging. As

demonstrated here, this may impact treatment and surveillance. Further prospective trials are needed to determine the clinical utility of MRD assessment for prognosis and early detection of local and distant recurrences in this setting.

P1-12-26: Clinical Case Vignette - Molecular PET Imaging to Guide Selection for Endocrine Therapy in Estrogen-Receptor Positive Metastatic Breast Cancer

Wenhui Zhou, Benjamin Franc, Eric Rosen

Introduction: Approximately 80% of all breast cancers are estrogen receptor (ER) positive, and determining ER status is vital for selecting appropriate treatment. 16α-[18F]-fluoro-17β-estradiol (18F-FES) is an FDA-approved radiopharmaceutical that enables non-invasive, in vivo assessment of ER status in patients with recurrent or metastatic breast cancer.
Clinical case: A 60-year-old woman diagnosed with right breast cancer (invasive ductal carcinoma, ER+/PR+/HER2-) underwent bilateral nipple-sparing mastectomy with clear margins and negative sentinel lymph nodes. The patient opted against adjuvant chemotherapy or radiation. About 6 months after surgery, biopsy confirmed metastatic breast cancer of the ER+/PR+/HER2- subtype. Due to the ER positivity of her metastatic breast cancer, she underwent an 18F-FES PET scan which revealed ER+ metastatic lesions in the right chest wall, right axillary and mediastinal lymph nodes, as well as in the axial and appendicular skeleton. This patient was deemed a candidate for and received first-line endocrine therapy (Anastrozole).
A 67-year-old woman diagnosed with left breast cancer (invasive ductal carcinoma, ER+/PR+/HER2-) underwent breast conservation surgery followed by adjuvant radiation. She remained on anastrozole for approximately six years until a re-staging 18F-FDG PET scan revealed hypermetabolic thoracic lymphadenopathy, pulmonary, hepatic, and osseous lesions. Considering the ER positivity of her initial cancer, an 18F-FES PET scan was performed, showing no uptake in any of the metastatic lesions. Liver biopsy confirmed metastatic breast cancer of ER-/PR-/HER2- subtype. The combination of disease progression on endocrine therapy and negative ER expression in both the liver biopsy and 18F-FES PET scan indicated acquired resistance and likely transformation to triple-negative disease. Consequently, endocrine therapy was discontinued, and she was switched to alternative cytotoxic chemotherapy (Abraxane).
Conclusion: These two complementary clinical vignettes illustrate the value of 18F-FES PET in patient selection for endocrine therapy. Together, these examples advocate for wider implementation of the recent NCCN guidelines recommending the use of 18F-FES PET in patients with metastatic or recurrent ER+ breast cancer.

P1-12-27: Clinical Case Vignette: Estrogen Receptor Targeting PET Imaging to Monitor Treatment Response to Endocrine Therapy in Lobular Breast Cancer

Wenhui Zhou, Benjamin Franc, Eric Rosen

Introduction: Estrogen receptor (ER)-targeting therapeutics play a large role in breast cancer treatment, given that 80% of breast cancers are ER positive. Molecular-based imaging strategies targeting ER are evolving to become integral to breast cancer management. 16α-[18F]-fluoro-17β-estradiol (18F-FES) is an FDA-approved PET agent that enables non-invasive imaging of ER status in patients with recurrent or metastatic breast cancer.

Clinical case: A 57-year-old woman with metastatic breast cancer (invasive lobular cancer, ER+/PR+/HER2-) who was initially diagnosed after bilateral salpingectomy for a left adnexal mass that showed metastatic ILC, and subsequent workup showed biopsy-confirmed primary ILC in the right breast. Her initial staging 18F-FDG PET scan showed no evidence of metabolically active malignancy. She underwent lumpectomy and axillary lymph node dissection, revealing 4/4 positive nodes. Due to the ER positivity of her metastatic breast cancer, a re-staging 18F-FES PET scan was performed, revealing 18F-FES uptake in subcentimeter right axillary and subpectoral lymph nodes. She was deemed eligible for and received first-line endocrine therapy (Letrozole) in combination with a CDK4/6 inhibitor (Ribociclib). At the 3-month follow-up 18F-FES PET scan, decreased FES avidity was noted in the right axillary and subpectoral lymph nodes, which completely resolved by the 1-year follow-up 18F-FES PET scan.

Conclusion: This case vignette illustrates the value of 18F-FES PET not only for patient selection for endocrine therapy but also for predicting the likelihood of treatment response. Thus, 18F-FES PET offers a promising opportunity for molecularly targeted PET radiopharmaceuticals to guide and monitor treatment in patients with metastatic or recurrent ER+ breast cancer.

P1-12-28: De Novo Metastatic Breast Cancer to the Orbit: A Case Study

Haley Westervelt Mabry, Katherine Ansley, Christina Cramer

Among new hormone receptor positive and HER2-negative breast cancer cases, less than 4% of patients aged 41-60 are diagnosed with metastatic disease at presentation. Of this small percentage, very few cases of orbital metastasis as the first presenting finding have been identified. We present the case of a 44 year old female who initially presented with redness and discharge of the left eye and was diagnosed with conjunctivitis. Despite treatment with courses of moxifloxacin eye drops, fluoromethalone eye drops, and oral amoxicillin, her symptoms persisted after 2 months prompting an ED visit. A CT scan demonstrated an osseous mass of the left sphenoid bone with a soft tissue mass involving

the left superolateral orbit, anterior and middle cranial fossa with associated proptosis. MRI scan of the orbits revealed an aggressive mass of the left frontal bone and left sphenoid wing with extraosseous soft tissue components. Further full-body imaging showed 2 small masses measuring 1.9 and 1.8 centimeters in the lower outer quadrant of the left breast and an enhancing lesion of the left parietal bone concerning for metastatic lesion but otherwise no convincing evidence of metastasis within the intradural parenchyma of the brain, abdomen, pelvis, or spine. She underwent left orbitofrontal craniotomy for resection and biopsy without complications; pathology revealed metastatic adenocarcinoma of breast primary. Tumor markers were found to be estrogen receptor and progesterone receptor positive and HER2 receptor negative. Subsequent breast biopsy confirmed consistent tumor markers within the breast masses. She received gamma knife radiation to the left periorbital region. At the time of gamma knife, 17 Gy was prescribed to the 59% isodose line to cover the high-risk post-operative peri-orbital dura. MRI 8 weeks later showed no evidence of local recurrence or new intracranial metastases. Radiation was followed by first line medical therapy for metastatic breast cancer with abemaciclib, an aromatase inhibitor and ovarian function suppression with goserelin. In conclusion, we present a rare case of metastatic breast cancer with the presenting feature of orbital mass; this case will contribute to earlier diagnosis and treatment in subsequent cases as well as add to the small body of known cases to further characterize long term prognosis of this specific type of organ involvement of metastatic breast cancer.

P1-12-29: Extreme response to sacituzumab-govitecan in a patient with metastatic triple-negative breast cancer

Allison Poles, Melody Cobleigh, Gene Solmos

Background:In 2020, Sacituzumab-govitecan was granted accelerated approval by the US Food and Drug Administration (FDA) for locally advanced or metastatic triple-negative breast cancer in patients who had received two or more chemotherapy regimens. Since then, very few case reports have demonstrated exceptional response. This presentation describes the remarkable clinical course of a patient with metastatic breast cancer who had an extreme response to sacituzumab-govitecan and has remained disease-free years after stopping treatment.

Findings: A 64-year-old female underwent a screening mammogram in the fall of 2018 which showed faint macrocalcifications in the lower outer quadrant of the right breast, warranting biopsy. One year later, she returned for further work-up after palpating a mass in the lower outer quadrant of the right breast. Diagnostic mammogram at that time demonstrated a 2.8 cm spiculated mass with suspicious microcalcifications in the lower outer quadrant of the right breast, and subsequent biopsy showed grade 3 triple-negative invasive ductal carcinoma, Ki-67 88%. Staging work-up revealed lung nodules, with subsequent excision revealing metastatic adenocarcinoma, consistent with breast primary. The patient started nab-taxel and atezolizumab, but experienced disease

progression[MC1] and was subsequently started on sacituzumab govitecan-hziy. After only a single cycle of sacituzumab govitecan, the breast mass decreased from 9 cm to 5 cm on physical examination and axillary lymphadenopathy resolved. After 3 cycles, the mass had shrunk to 2 cm. She underwent 22 cycles (ultimately stopped due to toxicity) with subsequent lumpectomy and sentinel node biopsy revealing pathologic complete response (pCR) in both breast and lymph nodes. Over the last two years since stopping sacitizumab govitecan, the patient has had serial exams, computerized tomography (CT) scans and mammograms every 3 months (nearly five years after her initial biopsy-confirmed diagnosis and nearly six years after her initial mammogram) and has no clinical or radiographic evidence of disease.

Conclusions: We are documenting an exceptional response to sacitizumab govitecan in a patient who presented with metastatic triple-negative breast cancer (TNBC). Despite notable disease progression on prior regimens, sacitizumab-govitecan showed dramatic and rapid response, with complete pathologic response (pCR) in breast and lymph nodes. Almost five years after this patient's initial diagnostic mammogram, and two years after stopping treatment with sacituzumab-govitecan, she remains without evidence of disease. Such findings are important to share in hopes that more research can focus on extreme responders. Results of next generation sequencing of her tumor will be presented.

P1-12-30: Genetic Predisposition to Cancer Associated with a Germline Pathogenic BRCA2 Variant: A Clinical Case Report

Zaida Morante, Henry Gomez

BACKGROUNDBRCA1 and BRCA2 are tumor suppressor genes involved in DNA repair and maintaining genomic stability. The presence of pathogenic variants (PV) in BRCA2 is associated with an increased risk of cancer in males, mainly for breast, prostate, and pancreatic cancer.Breast cancer in males is a rare disease. In the United States, it accounts for 1% of all breast cancer cases and 1% of all malignant neoplasms in males. In Lima, Peru, the cancer registry reported 31 new male cases during the years 2013-2015, out of a total of 7068 cases in both sexes.A lifetime risk of 1.8% to 7.1% at 70 years of age has been estimated for breast cancer in males carrying PV in BRCA2. They are characterized by presenting more advanced clinical stages (CS) at diagnosis compared to their female counterparts, with a high expression of estrogen receptors (ER), greater proliferative activity, and more aggressive behavior.Regarding prostate cancer, those with PV in BRCA2 have an 8.6-fold increased risk of developing prostate cancer by the age of 65 compared to the general population, with a higher likelihood of lymph node involvement and distant metastases at onset.Although the risk of cancer in women with PV in BRCA1 and BRCA2 has

been extensively investigated, the characteristics of cancer in male carriers of these mutations have not been adequately studied. This case report follows the CARE Guidelines. Case Presentation: 67-year-old male with a family history of prostate, breast, and pancreatic cancer on the paternal side (table 1), carrying a PV in BRCA2, was diagnosed in 2006. A routine screening in March 2022 found a PSA level of 8.58 ng/dL. On digital rectal examination (DRE), a 60 x 50 mm, non-tumorous, soft prostate was observed. Considering the history of carrying a PV in BCRA2, a prostate MRI was included in the screening, which reported findings consistent with a PI-RADS 4 score. Prostate core biopsy guided by ultrasound confirmed the presence of an acinar adenocarcinoma, Gleason score 7 (4+3) in the left lobe, corresponding to a stage IIA prostate cancer (T2bN0M0), ISUP 3, of unfavorable intermediate risk.The patient was treated with high-dose-rate brachytherapy (HDR-BT) to the prostate, followed by external beam radiation therapy (EBRT) using VMAT (volumetric modulated arc therapy) technique. Subsequently, he received androgen deprivation therapy (ADT) for 6 months with triptorelin and bicalutamide. He was placed under observation and follow-up with a PSA value of 0.2 ng/mL.In May 2023, a 1 cm retroareolar nodule was detected in the right breast, with no palpable axillary lymph nodes. Mammography revealed a high-density nodule measuring 10.8 mm, located retroareolar towards the upper-outer quadrant of the right breast. Ultrasound confirmed an irregular solid nodule measuring 10.3 x 9.2 mm with no axillary lymphadenopathy (figure 1.). Fine-needle biopsy confirmed an infiltrating carcinoma, ductal variety, NST/NOS subtype, intermediate grade. Immunohistochemistry (IHC) reported positive estrogen receptors (ER) (+++/100%), positive progesterone receptors (PR) (+++/60%), negative Her2/Neu, and KI67 15%. Tomographic studies showed no evidence of metastatic lesions.Bilateral total mastectomy was performed, with pathology reporting infiltrating breast carcinoma, NST/NOS subtype, intermediate grade, 20% TILS, associated ductal carcinoma in situ of 10%, negative lymphovascular invasion, and positive perineural infiltration. The tumor size was 14 mm, with nipple and terminal duct involvement due to direct extension of in situ and invasive carcinoma. No tumor infiltration of the skin was reported, and surgical margins were clear. Micrometastasis of 0.2 mm was found in 1 of 3 examined lymph nodes. The pathological stage was pT1c pN1mi.The Oncotype DX study had a Recurrence Score (RS) of 22 points, leading to a recommendation for adjuvant chemotherapy with Docetaxel-Cyclophosphamide for 4 cycles, followed by tamoxifen.

Discussion: Identifying the BRCA1 and BRCA2 genes has revolutionized how we use genomic information in individuals at high risk of developing cancer. However, most studies have focused on women, and the information available for men is limited.Contrary to what was reported in the clinical case, the typical presentation in carriers of PV in BRCA2 is of an aggressive disease, with a Gleason score ≥ 8, more advanced local extension (T3/T4), lymph node involvement, and the presence of metastasis at diagnosis.For male carriers of PV in BRCA2, prostate cancer screening is recommended from the age of 40 through PSA testing and DRE. With PSA levels ≤3 ng/mL and a normal DRE, repeating screening tests every 1 to 2 years is suggested. However, if the PSA level is >3 ng/mL or an abnormality is found in the DRE, a multiparametric prostate MRI is recommended.Although conservative management with prostate radiation therapy was chosen in this case, a widely accepted approach for

patients with unfavorable intermediate-risk is radical prostatectomy (RP). A meta-analysis by Luo et al. evaluated the benefit of RP versus observation in patients with localized disease. A 9% reduction in mortality risk and a 43% reduction in disease progression were observed.Regarding breast cancer in men, the age at diagnosis in patients with PV in BRCA2 precedes that of non-carriers by approximately a decade. The ductal histological subtype is the most prevalent, representing approximately 90% of cases. The Luminal A immunophenotype corresponds to 42% of reported cases. It is characterized by larger tumors, a higher frequency of lymph node metastasis, and distant metastases, resulting in a less favorable prognosis and lower survival rates compared to breast cancer in women. Xingyu Chen et al. reported a 10-year estimated survival rate of 53.9% versus 68.5% in men and women, respectively.For carriers of PV in BRCA2, education and training in breast self-examination and clinical breast examination every 12 months, starting at age 35, are recommended. Additionally, annual mammography should be considered from the age of 50 or 10 years before the first known case of breast cancer in men in the family, especially for those with PV in BRCA2 or for whom the lifetime risk of breast cancer is up to 7%.Regarding breast surgery, observational studies describe that breast-conserving surgery in men is associated with similar survival rates compared to total mastectomy. Like in the female population with clinically negative breast cancer and axilla, sentinel lymph node biopsy is the standard approach.The performance of contralateral risk-reducing mastectomy (CRRM) in patients carrying PV in BRCA2 is controversial. There is no high-quality evidence to support CRRM to reduce the risk of contralateral breast cancer in men. Whether the benefits of overall survival (OS) and disease-free survival (DFS) outweigh the associated costs and disadvantages has not been conclusively determined.S. Shak et al., in the analysis of 347 men and 82,434 women using Oncotype DX, obtained a similar distribution for both sexes based on RS, with an average RS of 18.1 (± 11.2) for men and 19.1 (± 10.2) for women. Similarly, Tal Grenader et al. found similar data regarding RS in the Oncotype DX analysis of 65 male patients and 2,455 women. These results support, to some extent, the use of Oncotype DX to guide breast cancer treatment in men.Although initially designed for patients without lymph node involvement, Oncotype DX was included in premenopausal women with 1 to 3 positive axillary lymph nodes in the RxPONDER study. In this study, the benefit of adjuvant chemotherapy in premenopausal women with an RS ≤ 25 was demonstrated.Wang et al., in the analysis of 848 men and 110,898 women with breast cancer evaluated using Oncotype DX, found that the distribution and RS patterns associated with mortality differ between men and women. Intermediate and high-risk RS values, defined by the TAILORx study parameters (11-25 and ≥26), were associated with a higher mortality risk in men and had a lower risk threshold than the female population. Additionally, there was little benefit of chemotherapy in men with intermediate risk.Currently, there are no clinical practice guidelines supporting the use of Oncotype DX to predict the benefit of adjuvant chemotherapy in men with breast cancer. However, the recommendation made in this patient is based on the inference of data from studies conducted in the female population.

Conclusion: Men carrying PV in BRCA2 have a higher relative risk of breast and prostate cancer, both occurring at younger ages than the general population and exhibiting

characteristics that confer greater aggressiveness and a less favorable prognosis. Oncotype DX is a genomic test that provides prognostic and predictive information on early breast cancer in women; however, information regarding its use in men is still limited. Further research is essential to establish precise guidelines for the Recurrence Score (RS) in male patients with breast cancer. Tumor suppressor genes BRCA1 and BRCA2 are involved in DNA repair and are crucial in maintaining genomic stability. Early detection through screening and appropriate medical follow-up improves the prognosis in patients carrying PV in BRCA2. Therefore, risk control monitoring and adequate genetic counseling are necessary.

P2-01-01: Lifestyle Linked Biomarker is Associated with Poor Prognosis in Estrogen Receptor Negative Breast Cancer

Lindsay Peterson, Yu Tao, Jingqin Luo, Graham A. Colditz, Yikyung Park, Jennifer A. Ligibel, David Turner

Background: Advanced glycation end-products (AGEs), reactive metabolites produced as a by-product of sugar metabolism, have been linked to higher breast cancer (BC) risk and increased mortality after BC diagnosis. The total body AGE pool is composed of endogenous AGEs and exogenous AGEs (consumed mainly through processed and fried foods common in Westernized diets). Diets high in AGEs have been linked to BC risk and outcomes. In our prior work, we reported that higher serum AGE (sAGE) levels, a reflection of total body AGE, are associated with reduced overall and BC-specific survival. sAGE was positively associated with BMI ($p<.0001$, $rs = 0.10$) and negatively associated with physical activity ($p< .001$, $rs = -0.06$). Comparing the highest quintile to the lowest quintile, sAGE was negatively associated with all survival outcomes in the entire cohort (overall survival (OS) HR=1.66 p=.014, recurrence free survival (RFS)=1.66 P=.004, BC specific survival (BCSS) HR=1.78 p=.013, distant metastasis free survival (DMFS) HR=1.81 p=.004). Here we explore the relationship between sAGE and BC outcomes by hormone receptor status in the Women's Healthy Eating and Living (WHEL) study.
Methods: The WHEL randomized 3088 BC patients stage I-III who completed their primary therapy to a high-vegetable, low-fat diet or control and followed for a median of 7.3 years. Main outcomes were invasive BC events (recurrence or new primary N=518), death due to BC (N=262) and deaths from any cause (N=315). Fasting blood was collected at study entry. sAGE was measured as the AGE metabolite carboxymethyllysine (ug/ml). sAGE was log transformed and corrected for plate batch effect via linear regression, and analyzed in continuous scale and in quintiles. The relationship between sAGE and survival endpoints was calculated using Kaplan-Meier and Cox regression models. In multivariable Cox models, we evaluated the interaction between sAGE (in quintiles) and ER or ER/PR status, adjusting for potential confounding covariates (age, race, BMI, smoking, alcohol use, physical activity, tumor characteristics).
Results: 2564 participants had sAGE available. After excluding samples for excessive variabilities, 2315 samples were analyzed. Patient characteristics: median age 52, 85%

white, 79% menopausal, 70% received chemotherapy, 43% node positive, 71% stage II or III. 1727 patients were ER+ and 556 were ER-. Raw corrected sAGE ranged from 0.0-48.15 ug/ml (median 7.39); logged and corrected ranged from -5.04-1.67. In the multivariable Cox model, the main effects of sAGE were significant for all the survival endpoints (OS p=0.023, RFS p=0.042, DMFS p=0.012, BCSS p=0.028), as well as the sAGE and ER interaction effects (OS p=0.017, RFS p=0.011, DMFS p=0.015, BCSS p=0.008). The strongest associations between sAGE and BC outcomes were seen within ER- cases: ER- patients of the highest sAGE quintile showed significantly higher risk compared to those with the lowest quintile (OS HR=2.37 p=.02, RFS HR=2.02 p=.02; BCSS HR=2.74 p=.01, DMFS HR=2.62 p=.01). Among the patients with the highest quintile sAGE, ER- cases showed consistently higher risk than ER+ (OS HR=1.83 p=.03, RFS HR=1.78 p=.02; BCSS HR 2.39 p=.004, DMFS HR=1.58 p=.11). Similar but slightly less significant results were seen with combined ER/PR status, likely due to the reduced sample size from missing values.
Conclusions: In a cohort of women with early BC, higher sAGEs were associated with worse survival outcomes in BC, with a stronger association in ER- BC compared to ER+ BC. AGEs may represent a novel, lifestyle-linked, modifiable prognostic biomarker in ER- BC. Interventions aimed at lowering sAGE levels should be tested in this high-risk subgroup for their impact on prognostic and metabolic biomarkers as well as clinical outcomes.

P2-01-02: Patient's Preference for Shared Decision Making-Based Distant Metastasis Surveillance and Its Effect on the Quality of Life: A Prospective Pragmatic Trial

Ji-Jung Jung, Jonghan Yu, Jong-Ho Cheun, Ki-Tae Hwang, Jai-Min Ryu, Se-Kyung Lee, Byung-Joo Chae, Jeong-Eon Lee, Seok-Won Kim, Seok-Jin Nam, Hong-Kyu Kim, Han-Byoel Lee, Wonshik Han, Hyeong-gon Moon

Background: Major guidelines recommend against the routine use of surveillance imaging tests to detect distant metastasis in patients with early-stage breast cancer, as such tests in asymptomatic patients do not significantly impact survival rates and often lead to unnecessary follow-up procedures and increased patient anxiety. Despite these guidelines, a significant number of imaging studies are still performed, highlighting a gap between recommendations and clinical practice. This study aims to assess the patient's preference for the use of surveillance imaging tests for distant metastasis detection and to evaluate degree of quality of life associated with different surveillance strategies in early breast cancer patients.

Methods: A prospective pragmatic clinical trial was conducted from July 2021 to December 2023 at three breast cancer centers in Seoul, South Korea. The study initially aimed to enroll 264 patients, but enrollment was stopped after enrolling 238 patients. Patients with early-stage breast cancer who had completed treatment within the past two years were enrolled and randomized into a shared-decision making (SDM) group or a control care group. Patients in SDM group were educated with videos and leaflets about the lack of clinical

evidence for performing imaging tests to detect asymptomatic distant metastasis. The control care group underwent surveillance imaging studies of institutional practice during the follow-up period, while the SDM group was followed according to their preference for distant metastasis surveillance. Primary endpoints were quality of life (QoL), anxiety, and depression at enrollment, and at 6-month, 1-year, and 2-year visits. The Functional Assessment of Cancer Therapy-Breast (FACT-B) and the Hospital Anxiety and Depression Scale (HADS) were used for assessments.

Results: A total of 787 questionnaires were collected from 238 patients. The FACT-B total score of the control group was significantly higher at enrollment (107.6 ± 21.1 vs. 102.0 ± 20.8, p=0.040), but converged over time with no significant differences at subsequent visits. The overall anxiety score (6.1 ± 3.3 vs. 5.5 ± 3.7, p=0.017) was significantly higher in the SDM group, but the difference was insignificant when compared at each visit. There were no significant differences in depression score at any time point. In the SDM group, 117 patients were asked for their preferences for distant metastasis surveillance and 33 patients (29.1%) preferred not to receive unnecessary imaging. At enrollment, this guideline-based surveillance group had significantly higher FACT-B total scores compared to those who preferred imaging for distant metastasis (113.9 ± 15.6 vs. 97.4 ± 20.5, p<0.001). The difference remained significant at 6-month visit (107.7 ± 15.4 vs. 98.6 ± 20.8, p=0.026), but not at 1-year or 2- year. Similarly, both anxiety and depression scores were significantly lower in those who preferred guideline-based surveillance at enrollment, but not at subsequent time points.

Conclusion: This pragmatic trial demonstrates that with adequate patient education and shared decision making, guideline-based surveillance imaging does not negatively impact patients' quality of life, anxiety, or depression level. These findings support an evidence-based strategy for the surveillance of patients with early-stage breast cancer.

P2-01-03: Is trastuzumab associated with new-onset hypertension in adolescents and young adults with breast cancer?

Renata Abrahão, Kathryn J. Ruddy, Cecile A. Laurent, Jessica Chubak, Eric C. Haupt, Ann Brunson, Erin E. Hahn, Chun Chao, Lisa M. Moy, Ted Wun, Theresa H.M. Keegan, Candice A. M. Sauder

Background: Studies have documented new-onset hypertension (hereafter referred to as "hypertension") and heart failure during and after breast cancer therapy. Trastuzumab, a monoclonal antibody used to improve survival in women with human epidermal growth factor receptor 2 (HER-2) positive breast cancer, carries a risk of cardiovascular complications. While most congestive heart failure events are reversible after trastuzumab is paused or stopped, the reversibility of trastuzumab-induced hypertension is uncertain. To date, no study has investigated hypertension as a potential adverse effect of trastuzumab therapy in adolescent and young adult (AYA) cancer survivors. Methods

Using data from Kaiser Permanente Northern and Southern California, we included all female AYAs ages 15–39 years, diagnosed with a first primary invasive breast cancer between 2006 and 2020, who survived at least 2 years after diagnosis. Patients were categorized into two groups: those who received chemotherapy plus trastuzumab (exposed group) and those who received chemotherapy without trastuzumab (non-exposed group). We looked at their outcomes 2 years post-diagnosis. We compared the cumulative incidence of hypertension between exposed and non-exposed groups and evaluated factors associated with hypertension. Hypertension was defined according to criteria described in the Pathways Heart Study, using the International Classification of Diseases codes and anti-hypertensive medications.

Results: We identified 2,371 AYA women with breast cancer; 33.4% of patients received trastuzumab. During a median follow-up of 5.8 years, the 5-year cumulative incidence of hypertension did not differ between the exposed (6.1%, 95% Confidence Interval (CI) 4.5–8.0%) and non-exposed (6.0%, CI 4.9–7.3%) groups. In the multivariable model, trastuzumab administration was not associated with hypertension (hazard ratio (HR)=1.06, CI 0.78–1.45). Factors associated with higher risk of hypertension included older age at diagnosis (35–39 vs. 15–34, HR=1.56, CI 1.15–2.11), non-Hispanic Black/African American (HR=2.55, CI 1.64–3.95) or non-Hispanic Asian/Pacific Islander (HR=1.99, CI 1.34–2.97 vs. non-Hispanic White) race/ethnicity, overweight/obesity (body mass index >25kg/m2, HR=2.57, CI 1.87–3.53 vs. normal weight), and ever smokers (HR=1.53, CI 1.10–2.12 vs. non-smokers).

Conclusion: Trastuzumab was not associated with an increased risk of hypertension in AYA chemotherapy recipients, but there was a higher risk of hypertension among non-Hispanic Black/African American and non-Hispanic Asian/Pacific Islander women, older age at diagnosis, overweight/obese patients, and smokers. Strategies promoting healthy diet, exercise, and smoking cessation should be employed for AYA patients with breast cancer who are at higher risk of hypertension.

P2-01-04: Impact of Mobile Healthcare Apps on Patient-Reported Quality of Life after Breast Cancer Surgery: A Randomized Controlled Trial

Yung-Huyn Hwang, Young-Jin Lee, Seunghee Baek, Yura Lee, Seung Hee Seo, Jiyun Hwang, Tae-Kyung Robyn Yoo, Sae Byul Lee, Jisun Kim, Il Yong Chung, BeomSeok Ko, Hee Jeong Kim, Byung Ho Son, Chang-Min Choi, Seockhoon Chung, Sung-Cheol Yun, Min-Woo Jo, Jong Won Lee

Background: While numerous mobile healthcare applications (apps) have been developed, there remains a paucity of evidence regarding their efficacy in enhancing the quality of life for cancer patients. To bridge this gap, we conducted a randomized trial involving 320 breast cancer patients to evaluate the impact of utilizing apps postoperatively for six months on their overall well-being.
Methods:Between November 2020 and September 2021, we enrolled stage 0-III breast

cancer patients aged 20-60 who underwent surgery at Asan Medical Center. These participants were randomly assigned in a 1:1:1:1 ratio to three commercial apps (A for general health management, B for walking encouragement, and C for cancer-specific support) or a control group receiving conventional care. Comprehensive assessments were conducted at baseline, 6 months, and 12 months using the five-dimension EuroQol five-level version (EQ-5D-5L) questionnaires. Quality of life was measured using both the index score and visual analog scale (VAS) of EQ-5D-5L. Additionally, we investigated the proportions of patients who reported problems in the five dimensions.
Result: While the overall cohort showed no significant improvement in index score or VAS with the apps, a subgroup analysis revealed notable trends. High-compliance users of app B reported a lower proportion of problems in usual activities compared to the control group (0% vs. 27.4%, P < .001). Additionally, among those undergoing adjuvant chemotherapy—a population typically experiencing decreased quality of life—app C users demonstrated higher index scores than the control group (0.908 vs. 0.761, P = 0.004).
Conclusion: Our study did not demonstrate the effectiveness of mobile apps in improving the quality of life for postoperative breast cancer patients. However, these healthcare apps showed the potential to enhance the quality of life not only among patients with high app adherence but also among those whose quality of life was initially compromised.

P2-01-05: Quality-adjusted Time Without Symptoms of disease progression or Toxicity of treatment (Q-TWiST) Analysis of Sacituzumab Govitecan vs Chemotherapy in Previously Treated Patients with HR+/HER2– Metastatic Breast Cancer

Hope S. Rugo, Aditya Bardia, Peter Schmid, Sara M Tolaney, Anandaroop Dasgupta, Ankita Kaushik, Wendy Verret, Marine Gosset, Adam Brufsky, Javier Cortés, Frederik Marmé

Background: The randomized, open-label phase 3 TROPiCS-02 study demonstrated that sacituzumab govitecan (SG) was associated with significantly improved overall survival (OS) and progression-free survival (PFS) vs chemotherapy for patients with previously treated hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2– [HER2 immunohistochemistry 0, 1+, or 2+/in situ hybridization-negative]) metastatic breast cancer (mBC). SG also had a manageable safety profile consistent with prior clinical studies in mBC. We present the results of a quality-adjusted time without symptoms of disease progression or toxicity of treatment (Q-TWiST) analysis to better assess the benefit and risk of SG treatment vs chemotherapy while accounting for patient quality of life.
Methods: Survival time was partitioned into 3 health states as follows: A) TOX: with toxicity (treatment-emergent adverse event [TEAE] of grade ≥ 3) before disease progression until TEAE resolving, disease progression, death, or end of follow-up, whichever was first; B) TWiST: without toxicity and before disease progression; and C) REL: disease progression until death or end of follow-up, whichever was earlier. Health state utilities were determined using published literature. Q-TWiST was calculated as the utility-weighted sum

of health state durations, and differences in Q-TWiST and relative Q-TWiST gains between the treatment groups were assessed. The established threshold for clinically important relative Q-TWiST gain is ≥10%. The utility weighting for the health states was: u-TWiST- = 0.715, u-TOX- = 0.605, and u-REL-- = 0.443. A threshold analysis was conducted in which u-TOX- and u-REL- were varied between 0 and 1 to assess robustness of treatment benefit in relation to utility values. This was performed with u-TWiST- = 0.715 (base case, stable disease with no toxicity) and u-TWiST- = 1 (best overall health state). Another sensitivity analysis was conducted to show restricted mean Q-TWiST difference at various follow-up times up to approximately 39 months.
Results: SG demonstrated significantly longer Q-TWiST (9.7 months; 95% CI, 8.9-10.5) vs chemotherapy (8.1 months; 95% CI, 7.3-9.0) in patients with HR+/HER2– mBC with a difference of 1.6 months (95% CI, 0.4-2.7; P = .0067) between treatment groups. The relative Q-TWiST gain was 10.8%, passing the threshold for clinical meaningfulness. SG had a longer TWiST by 2.0 months (95% CI, 0.1-3.9) compared with chemotherapy. In the threshold sensitivity analysis, adjusted weighted utilities of --u-TOX- and u-REL- had minimal impact on relative Q-TWiST gain with SG vs chemotherapy. With u-TWiST = 0.715, Q-TWiST gain depended primarily on u-TOX- value, and Q-TWiST gain was ≥ 10% when u-TOX- was > 0.07. Q-TWiST gain ranged from 9.9% to 11.4%. When u-TWiST- was set to 1, Q-TWiST gain also depended mainly on u-TOX- value, but Q-TWiST gain was ≥ 10% for all values of u-TOX- and u-REL-. In this analysis, Q-TWiST gains ranged from 13.9% to 15.3%. In both cases, Q-TWiST gains were statistically significant across the entire range of u-TOX- and u-REL- values. In the sensitivity analysis, Q-TWiST gain increased or was maintained with longer follow-up time.
Conclusions: In patients with HR+/HER2– mBC, SG showed a clinically meaningful and statistically significant improvement in Q-TWiST time compared to chemotherapy, and this improvement was enhanced with longer follow-up. The results from this analysis further strengthen the benefit-risk for SG as a treatment for patients with HR+/HER2– mBC.

P2-01-06: Supportive care concerns of young women living with metastatic breast cancer from an ongoing prospective virtual intervention

Kate E Dibble, Yue Zheng, Shoshana M Rosenberg, Tal Sella, Philip Poorvu, Craig Snow, Sarah Sammons, Nancy U Lin, Jennifer W Mack, Ann H Partridge

Background: Adolescents and young adults (AYAs) living with metastatic breast cancer (MBC) experience physical and psychosocial difficulties often amplified by a disrupted life trajectory. Data regarding age-specific needs and concerns of AYAs within the context of the MBC disease experience are lacking. We describe psychosocial and supportive care concerns among AYAs with MBC to better understand and address their survivorship needs over time.
Methods: AYAs (18-39 years) diagnosed with MBC participating in an ongoing prospective intervention study (Young, Empowered and Strong [YES], NCT04379414) at Dana-Farber Cancer Institute complete an electronic REDCap survey at baseline (BL) and every 6 months

(mos) post-enrollment for 3 years, then annually for 2 years. Through the YES web-based portal, participants respond to electronic patient-reported outcomes and receive information on ways to manage symptoms and concerns they endorse in addition to other resources. Here we describe REDCap survey-reported psychosocial and supportive care concerns at BL, 6-, and 12-mos. Clinical information was abstracted from medical records. Concerns were assessed with items adapted from the AYA Health Outcomes and Patient Experience survey and dichotomized (not at all/a little, somewhat/very concerned). Financial burden was assessed using National Health Interview Survey items such as burden from diagnosis (a little/none, a lot/some). We used generalized estimating equations to model proportional changes in concerns from BL to 6- and 12-mos.
Results: As of 5/1/2024, 100 of 103 (97.1%) women sent the BL survey completed it. Of those eligible (N=91), 53 (58.2%) completed the 6 mo survey; 23 (25.3%) did not respond, 11 (12.1%) died, and 4 (4.3%) had withdrawn. At 12-mo, 40 of the 75 eligible participants responded (53.3%); 24 (32%) did not respond, 9 (12%) died, and 2 (2.7%) had withdrawn. Median age at enrollment was 37 years (range=26-45), 33 years at MBC diagnosis (range=22-39), and time from metastatic diagnosis to enrollment was 15 mos (range=0.2-96.3). Time from primary to metastatic diagnosis varied: 34.0% de novo, 17.0%, 3 mos-2 years and 49.0% ≥2 years. Most participants were white (85%), non-Hispanic (92%), and had a college degree or higher (80%).
Concerns were pervasive at BL, but many concerns lessened over time including the possibility of the cancer worsening (BL: 92.0% v. 6 mo: 86.8% v. 12 mo: 71.8%, p=0.02), potential long-term side effects of treatment (71% v. 56.6% v. 47.4%, p= 0.01), potential long-term effects of cancer on health (70.0% v. 60.4% v. 46.2%, p=0.03), and a family member's risk of getting cancer (39% v. 41.5% v. 20.5%, p=0.01). Though other concerns followed a similar pattern over time, differences were not statistically significant: how to check for signs of cancer worsening (61.6% v. 52.8% v. 41.0%, p=0.06), physical fitness/exercise (54.6% v. 50.9% v. 43.6%, p=0.48), nutrition/healthy diet (51.5% v. 45.3% v. 35.9%, p=0.19), and having financial support for medical care (40.0% v. 45.3% v. 33.3%, p=0.31). BL financial burden difficulties were endorsed least (a lot/some: 41.2%) followed by those at 12- (47.4%) and 6-mo (55.8%) but were not significantly different (p=0.14).
Conclusion: Among AYAs with MBC enrolled in the YES study, selected cancer-related concerns improved over time, still a substantial proportion continue to experience concerns over time. These preliminary results suggest an intervention to support young survivors with MBC may improve AYA concerns while others may need additional attention; alternatively, some concerns may wane as patients adapt to diagnosis and treatment. Addressing concerns such as financial toxicity, physical and mental health, disease progression, and treatment side effects, may optimize disease expectations and wellbeing.

P2-01-07: The Co-Occurrence of Obesity and Cancer-Related Fatigue and Their Combined Impact on Physical Function in a Nationwide RCT of 456 Breast Cancer Survivors (a URCC NCORP Study).

Lindsey Mattick, Po-Ju Lin, Luke J. Peppone, Allison Magnuson, Umang Gada, Viktor Clark, Jeremy McGuire, Timothy D. Moore, Janos Molnar, J. Scott Maul, Karen M. Mustian

Background: Cancer-related fatigue (CRF) is one of the most prevalent and debilitating toxicities - experienced by nearly half of breast cancer survivors, with over 60% reporting their fatigue as moderate to severe. Up to 75% of breast cancer (BC) survivors also report being overweight or obese. Both CRF and obesity are independent risk factors for impaired physical function which ultimately impacts cancer survivors' ability to perform essential daily activities, such as personal hygiene, meal preparation, engaging in physical activity, working, and engaging in meaningful relationships. Despite their high prevalence, the co-occurrence of CRF and obesity is not well characterized and how these conditions may synergistically impact physical function is not fully understood.
Methods: We conducted a secondary analysis of baseline data from 456 BC survivors who participated in a multicenter, nationwide phase III RCT comparing the effects of Yoga for Cancer Survivors (YOCAS©®), CBT-I, and a behavioral placebo on insomnia. The Brief Fatigue Inventory (BFI) was used to assess CRF (0-10 scale; mild = 1-3; moderate = 4-6; severe = 7-10). Anthropometric measures, height and weight, were utilized to calculate body mass index (BMI; kg/m2). Cardiorespiratory function was assessed via 6-minute walk test (6MWT Distance, 6MWTD [in feet]). Muscular strength was assessed via hand grip dynamometry strength test (kg). Age-adjusted marginal mean BFI scores (total, severity, and interference with activities of daily living) were calculated according to BMI category (normal weight = 18.5 - 24.9 kg/m2; overweight = 25 - 29.9 kg/m2; obese >30 kg/m2) via the Least Squares Means method. We also conducted an age-adjusted logistic regression for the odds of moderate-severe CRF according to BMI category. Finally, we cross-classified participants into four groups 1) normal weight with mild CRF (N=53), 2) normal weight with moderate-severe CRF (N=121), 3) overweight/obese with mild CRF (N=54), and 4) overweight/obese with moderate-severe CRF (N=228). We calculated age-adjusted marginal mean physical function measures according to these categories via the Least Squares Means method.
Results: 456 BC survivors (avg. age 56 years, 1.9 years post primary treatment, 86% White, 81% receiving hormonal therapy) were recruited from University of Rochester Cancer Center NCI Community Oncology Research Program (URCC NCORP) Research Base-affiliated community oncology practices across the nation. BC survivors who are obese (mean: 4.9, SE: 0.1) or overweight (4.4 ± 0.2) experienced moderate CRF while BC survivors who are normal weight experience mild CRF (3.8 ± 0.2; both $p<0.05$). We report similar trends in the CRF severity (normal weight = 5.0 ± 0.2, overweight = 5.6 ± 0.2, obese = 6.1 ± 0.1; both $p<0.05$) and CRF interference subscales (normal weight = 3.3 ± 0.2, overweight = 3.7 ± 0.2, obese = 4.3 ± 0.2; both $p<0.05$). Logistic regression revealed the odds of moderate-severe CRF were over 2x higher (OR [95%CI] = 2.24 [1.38-3.66]) among obese survivors when compared to normal weight survivors. Overall, overweight/obese breast cancer

survivors with moderate-severe CRF had significantly worse cardiorespiratory function (6MWTD = 1,432.4' ± 19.4) compared to other groups (overweight/obese and mild CRF = 1549.3' ± 26.5, normal weight and moderate-severe CRF = 1613.5' ± 39.9, or normal weight and mild CRF = 1706.2' ± 40.2; all p<0.001). No significant difference in hand grip strength was observed between any of the groups (p-trend=0.365).
Conclusion: Obese BC survivors are twice as likely to have moderate-severe CRF compared to their normal weight counterparts. Further, BC survivors with co-occurring overweight/obesity and moderate-severe CRF have significantly worse cardiorespiratory function than those with just one or neither of these morbidities.

P2-01-08: Follow-up in Early and Locally Advanced Breast Cancer Patients: An EORTC QLG-BCG- ROG study.

Vesna Bjelic-Radisic, Katarzyna Pogoda, Helen Westenberg, Samantha Serpentini, Hikmat Abdel-Razeq, Joanna Kazmierska, Thomas Kuhnt, Eva Fernandez Lizarbe, Elisabetta Cretella, Icro Meattini, Frederieke van Duijnhoven, Isabel Teresa Rubio, Razvan Popescu, Sue Hartrup, Heidi Roelstraete, Nora Nevries, Corneel Coens, Melanie Beauvois, Luisi Lim, Galina Velikova, David Cameron, Fatima Cardoso

Background: Breast cancer (BC) is the most frequent type of cancer in women worldwide. Evidence-based follow-up strategies regarding risk, patients' needs and quality of life are lacking. The main objectives of this study are to determine the range and prevalence of physical, psychological and social problems following breast cancer treatment, and to identify patterns of physical, psychological and social problems based on demographic and clinical factors.
Methods: The EORTC 1617-QLG-BCG-ROG is an international cross-sectional non-interventional follow-up study in patients who are disease-free at least 1 but no more than 3 years since completion of primary treatment (except hormonal treatment) for early BC (EBC) and locally advanced BC (LABC). Institutional, demographic, tumour and treatment history data were collected. Patients completed a PRO questionnaire set once including the EORTC QLQ-C30, QLQ-BR45, EORTC QLQ-SHQ-22, EORTC QLQ-OUT-PATSAT-7, one question regarding follow up strategy from the patient´s point of view, and the Distress Thermometer, 139 items in total. A total of 830 patients would allow adequate estimation of prevalence rates and 90% power to detect a 10% difference between two cohorts. Patients were stratified by age, NPI risk score and treatment to ensure adequate representation within each stratum.
Results: Between November 2020 and September 2022, a total of 833 patients were enrolled in 25 institutions (of which 17 had a dedicated breast unit) across 10 countries. Of these 833 patients, 686 (82%) had EBC and 144 (17%) LABC. A total of 805 (97%) questionnaires set were completed, either in whole or partially, by eligible patients. More than 60% reported maximal score on the role and social functioning scale, as well as 50% reported no symptoms on nausea/vomiting, diarrhoea, insomnia, appetite loss and

constipation. Regarding stage of the disease, EBC patients showed statistically significant better (at 1% level of significance) scores in the physical functioning, role functioning, and cognitive functioning scales of EORTC C30 compared to the patients with LABC. Regarding age, young patients (< 50y) showed statistically significant worse scores in emotional functioning, cognitive functioning, social functioning, fatigue, and insomnia and reported more financial difficulties compared to the older population. Regarding type of therapy, patients receiving chemotherapy showed statistically significant worse scores in the physical functioning, role functioning, cognitive functioning, social functioning, fatigue, nausea/vomiting, pain, and financial difficulty scales, compared to the patients without chemotherapy even though the therapy had ended 1 to 3 years before.
Further analyses of EORTC QLQ-BR45, EORTC QLQ-SHQ 22, and EORTC QLQ-OUT-PATSAT7 including comparison with normative data, are currently being performed and will be presented at SABCS 2024.
Conclusions: Patients with EBC and LABC showed a distinct increase in physical functioning, role functioning, and cognitive functioning scales during follow-up after completion of primary treatment. Results showed that especially young patients and patients received chemotherapy are vulnerable groups, even after the end of therapy. These problems were associated with cognitive functioning, social functioning, fatigue, and financial difficulty. Information gained from this study will be useful for refining follow-up programs in EBC and LABC.

P2-01-09: Patient-reported outcomes in premenopausal breast cancer patients with or without ovarian suppression therapy – a subgroup analysis from a Brazilian prospective cohort

Natalia Cristina Cardoso Nunes, Giselle de Souza Carvalho, Lilian Lerner, Gustavo Queiroz Di Giusto, Paola Kelly Martins dos Santos, Amanda Soares Gonçalves, Perla de Mello Andrade, Juliana Pompeu Pecoraro, Carolina Galvão Teixeira, Mariana Ribeiro Monteiro

Background: Young women with breast cancer (BC) treated with chemotherapy or endocrine therapy (ET) often experience physical and psychosocial changes during treatment, partly due to non-physiological menopausal symptoms. These symptoms tend to be worse with ovarian function suppression (OFS), and it can significantly affect the quality of life (QoL), leading to nonadherence to treatment. Our study aims to assess patient-reported outcomes (PRO) in premenopausal breast cancer patients receiving or not OFS.
Methods: This report is a sub-analysis of our institutional multicenter, prospective, observational study involving female patients with BC who received treatment in private healthcare facilities in the Brazilian states of Rio de Janeiro and São Paulo. For this analysis, we focused on patients aged 50 years or younger with stage I to III invasive breast cancer who underwent adjuvant ET between 01/01/2013 and 01/31/2023. Patients were divided based on whether they received OFS. PRO was evaluated through EORTC-QLQ-BR23 functional scales at baseline, 3, 6, 9, 12, and 24 months. Patients were included before any systemic treatment, including chemotherapy. We used linear mixed models with

adjustments for the cancer stage to compare the scales between the two groups. Results were reported relative to the baseline category, using 95% confidence intervals and p-values. The R software, version 4.1.2, was used for the analyses.
Results: In total, 363 patients met the inclusion criteria. Of these, 290 received ET alone, and 73 were assigned to receive OFS+ ET. Patients who received OFS were more likely to be younger (64.4% vs. 25% <40 years), had a more advanced cancer stage (31% vs. 13% stage III), and were more likely to receive chemotherapy (90.4% vs. 73.4%). The number of patients who completed the questionnaires was 363, 152, 272, 250, 252, and 171 at baseline, 3, 6, 9, 12, and 24 months, respectively. Regarding the functional scales "sexual functioning" and "sexual enjoyment," despite the absence of statistical significance between groups, the OFS group experienced a more pronounced clinically significant (>10 points) decrease in the first 6 months of treatment and an inability to return to baseline after 24 months. At months 6 and 12, a higher number of sexually active patients reported not having sexual desire or satisfactory sex. Furthermore, after 24 months of treatment, patients in the OFS group were more likely to report hot flashes, headaches, being physically less attractive, less feminine, less sexual interest, and less sexual activity.
Conclusion: Despite OFS contributing to improved disease-free survival and overall survival in adjuvant treatment, its side effects significantly affect the patient's long-term QoL. Discussing these side effects with patients before starting systemic therapy and developing treatment plans is crucial to enhance the QoL of patients dealing with OFS-related concerns. Our study emphasizes the need for a personalized, empathetic approach to patient care and regular sexual health assessments by oncology healthcare professionals.

P2-01-10: A real-world evidence study of an online Mindfulness-Based Stress Reduction intervention: Effects on the symptomatic burden of patients with breast cancer

Misael Salazar-Alejo, Daniela Oscura-Paredes, Mauricio Zegarra-López, Fernanda Mesa-Chavez, Daniela Vázquez-Juárez, Javier Gutiérrez-Ornelas, Cynthia Villarreal-Garza

Introduction: Patients with breast cancer (BC) experience significant psychological distress, fatigue, insomnia, and menopausal symptoms throughout their treatment and survivorship. Mindfulness-Based Stress Reduction (MBSR) has been implemented to alleviate these symptoms. Our group previously demonstrated in a randomized study with BC survivors that an online MBSR program is beneficial. This study now aims to evaluate the effectiveness of online MBSR in reducing the symptomatic burden of patients with BC in a real-world, uncontrolled setting.
Methods: Women aged ≥18 years, diagnosed with BC, were invited to participate. The 8-week online MBSR intervention was provided by a certified instructor. Data were collected at 3 timepoints: baseline, 1 week after program completion, and 1 month thereafter. Intervention effectiveness was assessed using the following outcome measures: GAD-7 (anxiety), PHQ-9 (depression), FACIT-F (fatigue), MAAS (mindfulness state), ISI (insomnia), CWS (worry of cancer recurrence), and MEN-QoL (menopausal symptoms). Data on

satisfaction and attendance barriers were also collected. Linear mixed models including evaluation timepoint, antidepressant use, menopausal status, clinical BC stage, BC treatment modalities, and recurrence as fixed effects, and individual participants as a random effect were used to assess outcome changes.
Results: A total of 37 patients were included. Their median age was 53 years (IQR: 49-62). The majority were married (56%), college-educated (53%), most frequently stay-at-home spouses (39%), and publicly insured (50%). Most were diagnosed with stage II (33%) or III (33%) BC. A considerable percentage of participants were undergoing active treatment, mainly with endocrine therapy (53%), chemotherapy (14%), or anti-HER2 therapy (14%). Notably, antidepressants were used by 22% of participants and 14% were already practicing mindfulness.
Participants were able to attend a median of 6 MBSR sessions (IQR: 5-8). After taking part in the program, most participants were very satisfied (78%) or satisfied (11%), and rated the program as very useful (84%). The most frequently reported barriers for attendance were lack of time/inability to conform to time schedule (19%), personal/family commitments (16%), and forgetfulness (14%). At the first follow-up, a significant mean difference was observed in GAD-7 (-2.79 points, $p<0.01$), PHQ-9 (-3.15 points, $p<0.01$), FACIT-F (-2.54 points, $p=0.03$), MAAS (+0.65 points, $p=0.01$), CWS (-3.54 points, $p<0.01$), but not in ISI (-2.02 points, $p=0.08$) or MEN-QoL (+0.41 points, $p=0.44$). One month after program completion, significant improvements persisted in GAD-7 (-2.82 points, $p<0.01$), PHQ-9 (-3.29 points, $p<0.01$), FACIT-F (-3.61 points, $p<0.01$), MAAS (+0.92 points, $p<0.01$), and CWS (-2.69 points, $p=0.01$). At this timepoint, a significant mean change in the ISI scale was also observed (-3.64 points, $p<0.01$), but no significant changes were found in MENQoL (+0.32 points, $p=0.86$).
Conclusion: An online MBSR program is an effective intervention to reduce the symptomatic burden of patients with BC in a real-world setting. Participants are highly satisfied with the online modality and find this resource useful. The significant improvements observed in GAD-7, PHQ-9, FACIT-F, MAAS, and CWS scores suggest a substantial impact on patients' quality of life. Given the confirmed efficacy of online programs, it is crucial to incorporate these feasible and accessible interventions into routine care to benefit a larger number of patients.

P2-01-11: Supportive Care Service Utilization Among Long Term Metastatic Breast Cancer Survivors

Ashley Pariser Davenport, Chloe Hery, Kayla Williams, Juan Peng, Michelle J. Nauhgton

Background: Patients living with metastatic breast cancer (MBC) have unique psychosocial and medical needs, which often go unrecognized. Many MBC patients are now living years on chronic therapy. Understanding current referral patterns and utilization of supportive care services is a necessary step to improving patient access and aligning services with patient needs. We examined supportive care service utilization among long term MBC survivors to determine sociodemographic, psychosocial, and clinical predictors of

utilization.
Methods: 224 patients from the Ohio State University Stefanie Spielman Comprehensive Breast Center, who had been diagnosed with MBC for ≥1 year, were asked to complete a one-time, online survey to assess their quality of life, self-rated health, symptoms, supportive care needs, and reflections on their cancer diagnosis and treatment. Multivariate logistic regression was used to determine sociodemographic (age, race, education, income, rural/urban residency), psychosocial/quality of life (PROMIS physical component score, PROMIS mental component score, social support), and clinical factors (time since diagnosis, current treatment, metastasis site, fatigue, pain, and sleep) associated with utilization of supportive care services.
Results: The mean age of the participants was 60.0 years old (±12.8 years) and the average time since stage IV diagnosis was 5.9 years (±4.9 years). Most participants were female (n=221), white (92%), non-Hispanic (98%), and about half had a total household income of < $75,000. Approximately 50% had a bachelor's degree or higher, and 71% resided in urban areas and 29% in rural areas in the state. Most participants were currently receiving bone health support (47.8%), endocrine therapy (43.4%), or CDK4 inhibitor therapy (33.3%). About two-thirds of participants had metastases to the bone (66%) and 17% had metastases to the brain. Participants with the highest rate of referral to supportive services were those with metastases to the liver (49%), followed by bone (46.6%), brain (44.7%), lymph nodes (43.6%), and other sites (33.3%). Over 25% of participants used 3 or more services, however, the majority of participants reported not using any supportive care services (55.3%). The three most common referrals among the MBC survivors were for nutrition/dietitian services (19.3%), physical therapy (18.4%), and counseling services (18.0%). However, only 15% of participants actually reported receiving either nutrition/dietitian care (15.4%), physical therapy (14.9%), and/or counseling services (10.5%). Patients receiving services were more likely to be non-white (p=0.008), more highly educated (p=0.02), receiving chemotherapy (p=0.03), and with lower (worse) PROMIS physical and PROMIS mental scores (ps<0.01), higher levels of fatigue and pain (ps<0.02), and lower self-rated quality of life (p=0.005). In multivariate logistic regression models, those with better PROMIS mental health scores also had lower odds of using supportive care services (OR: 0.93, 95% CI: 0.86, 0.99, p=0.04).
Conclusions: Survivors living with MBC in this study reported lower rates of referral and use of supportive care services than expected. Those who engaged with supportive care services often used multiple services compared to only one. Given this dichotomy, future studies are needed to determine if low rates of engagement are due to patient wishes or variability in screening and referral practices. More research is needed to determine processes that equitably and efficiently screen, refer, and engage eligible MBC patients with guideline-based supportive care services.

P2-01-12: Association of Employment Characteristics and Food Insecurity Risks among Women with Breast Cancer

Michael Halpern, David Gimeno Ruiz de Porras

Introduction: Food insecurity (i.e., inconsistent access to nutritionally adequate and safe food) is estimated to occur among 17%-55% of individuals diagnosed with cancer. Little is known about how employment and its characteristics after a cancer diagnosis may mitigate food insecurity risks. We examined associations between food insecurity, employment, and availability of paid sick leave among women diagnosed with breast cancer in the U.S.
Methods: The study sample (n=604) was women aged 18-65 with non-missing employment status and a self-reported history of breast cancer (diagnosed age 18 or older) from the 2020, 2021, and 2022 National Health Interview Survey (NHIS), a nationally representative household survey of the civilian noninstitutionalized U.S. population. Bivariate (Chi-Square) analyses of NHIS food insecurity items by employment status and, among currently employed women, availability of employer-provided sick leave were conducted using PROC SURVEYFREQ in SAS 9.4 adjusting for the complex survey design of the NHIS.
Results: Compared with not currently employed women (n=234), currently employed women (n=370) had higher levels of education and were younger. There were no differences in years since breast cancer diagnosis, marital status, household race/ethnicity composition, or household urban/rural status between the two groups. Currently employed women were less likely ($p<0.05$) to report food insecurity in the past 30 days across multiple domains (less likely that food runs out; food didn't last and didn't have money for more; couldn't afford balanced meals; cut the size of meals, skipped meals, ate less, or went hungry due to money; and lost weight or didn't eat for a whole day because there wasn't enough money for food) and less likely to report overall food insecurity. Among currently employed women, those with paid sick leave were less likely ($p<0.05$) than those without paid sick leave to report that their food didn't last and that they ate less due to money. Those with paid sick leave also reported greater food security overall and had less worry about paying medical bills if they got sick or had an accident.
Conclusions: Continued employment after a breast cancer diagnosis is associated with a significantly decreased risk of food insecurity. Available paid sick leave decreased food insecurity among women continuing employment. Support to facilitate continued employment and return-to-work and workplace accommodations, including paid sick leave can have a positive impact on the well-being of women with a history of breast cancer.

P2-01-13: Palliative Care Use and End-of-Life Care Quality in HR+/HER2- Metastatic Breast Cancer

Julia Cohn, Susan C. Locke, Kris W. Herring, Susan F. Dent, Thomas W. LeBlanc

Background: Metastatic breast cancer (MBC) is incurable, but therapeutic advances have improved clinical outcomes for patients with hormone receptor positive (HR+), human epidermal growth factor-2 negative (HER2-) disease. Palliative care (PC) is recommended to alleviate distress of patients with advanced cancer and reduce administration of aggressive care at the end of life. Intensive end-of-life (EoL) care is associated with greater physical and emotional distress of patients and caregivers. Despite current guidelines, there is limited data in prior literature on PC use and EoL care of patients with MBC benefitting

from therapies such as cyclin-dependent kinase 4/6 inhibitors (CDK4/6i). The aim of this study is to describe referral to PC, hospice utilization, and EoL outcomes, including rate of aggressive EoL care, in patients with HR+/HER2- MBC.
Methods: A secondary analysis of data from a retrospective review of patients with HR+/HER2- MBC treated with endocrine therapy +/- CDK4/6i for first-line MBC at the Duke Cancer Institute between 1/2012 and 12/2017 was performed. Data extracted from the electronic medical record included demographic and clinical characteristics at MBC diagnosis. Variables added for this analysis and abstracted through 3/15/24 included PC involvement, hospice use and duration of care, and EoL care outcomes, including place of death, healthcare utilization in last 30 days of life, and chemotherapy in last 30 and 14 days of life. PC and hospice utilization and EoL care data were analyzed with descriptive statistics.
Results: Of 102 patients in the cohort, 85 died during the study period, 77 of whom had complete EoL care data. Mean age at metastatic diagnosis was 61.9 (SD 12.1; range 27-84 yrs) and mean age at death was 66.0 (11.9; 33-86 yrs). Over half (n=42/77, 55%) received aggressive EoL care. Half of the cohort received some form of PC (51/102, 50%). Among the deceased, rates of aggressive EoL care were comparable between those who engaged with PC (24/45, 53%) and those who did not (18/32, 56%). Of those who received PC, in-hospital referrals were more common (31/51, 61%) than ambulatory referrals (19/51, 37%). Similar proportions engaged with PC in outpatient clinics (28/51, 55%) as those with exclusively inpatient PC encounters (23/51, 45%). Median number of outpatient PC visits was 2 (range 1 – 16 visits among deceased). Among the indicators of aggressive EoL care, multiple emergency department (ED) visits (22/79, 28%) and hospital admissions (18/79, 23%) in the last 30 days of life as well as in-hospital location of death (20/85, 24%) were the most common. Chemotherapy was administered within the last 30 days for 16 patients (16/80, 20%) and within the last 14 days of life for 9 patients (9/80, 11%). Among the 72% (61/85) who enrolled in hospice, 9% (7/82) were on hospice care for ≤ 3 days. Of the 15 patients who received hospice care for more than 3 days and received aggressive EoL care, most had multiple ED visits (n=11) and/or hospital admissions (n=7) in the last 30 days of life.
Conclusion: This real-world study demonstrates that patients with HR+/HER2- MBC receive aggressive care at EoL despite some engaging with PC and many enrolling in hospice care. PC involvement did not appear to impact receipt of aggressive EoL care. This may be a result of the low median number of outpatient PC visits, representing insufficient PC "dosage" to facilitate complex symptom management and advance care planning required to reduce aggressive EoL care. Interventions to enhance PC engagement and decrease aggressive EoL care are needed to reduce in-hospital deaths, frequency of ED visits, hospitalizations, and intensive care unit admissions in the last month of life, and to ensure patients with MBC experience hospice services for a sufficient duration to derive meaningful benefit.

P2-01-14: Impact of Psychological Support on Quality of Life, Coping Strategies, and Anxiety and Depression in Breast Cancer Patients: A Comparative Randomized Study

Angela Di Pasquale, Sabrina Cataldi, Rosanna Lo Coco, Maria Luisa Calagna, Cristiana Duranti, Antonella Ussett, Vita Baldassara Leonardi, Giovanni Sortino, Fabio Aiello, Livio Blasi

Recent advancements in breast cancer treatments have improved survival rates, yet the focus remains primarily on survival outcomes rather than quality of life and psychological factors. This study investigates the impact of psychological support on anxiety, depression, coping strategies, and quality of life in early invasive breast cancer (BC) patients. Conducted at ARNAS Civico hospital in Palermo, Italy, this randomized comparative study assigned patients to either standard care (control group) or standard care supplemented with psychological support (intervention group).
Assessments were conducted pre-surgery and at 8 months post-treatment, coinciding with the completion of a 9-session support program for the intervention group. The study utilized QLQ-C30, QLQ-BR23, HADS, and Brief COPE questionnaires. Data analysis employed two-way repeated measures ANOVA and mixed-effects models to explore temporal trends and group differences over time. Statistical significance was set at p-values below 0.05 and t-values exceeding twice the standard deviation in mixed-effects models. A total of 65 patients participated, with 34 in the intervention group and 31 in the control group. Median age differed significantly between groups (p=0.001). At baseline, significant differences were observed in self-blame (p=0.02) and financial difficulties (p=0.02). Anxiety and depression (HADS-T) increased over time in patients without psychological support (HADS-T = 3.42, t = 3.46), while those receiving psychological support showed reduced levels of anxiety and depression (HADS-T = -6.94, t = -4.87). Emotional functioning (int: 13.69, t=2.72; ctrl: -6.09, t=-1.74), social functioning (int: 14.48, t=2.82; ctrl: -13.72, t=-3.11), cognitive functioning (int: 14.79, t=2.50; ctrl: -17.45, t=-4.25), and insomnia (int=-19.39, t=-2.72; ctrl=11.78, t=2.39) significantly improved over time in the intervention group, while declining in the control group. Global quality of life significantly improved from baseline for patients receiving psychological support (7.33, t=2.1) but declined for those in the standard care group (-7.78, t=-3.22). Patients in the intervention group showed improvements in body image (17.57, t = 3.56) and future perspective (19.65, t = 3.56), and reductions in hair loss (-28.44, t = 2.70) and systemic therapy side effects (-11.51, t = 2.64). In contrast, the control group experienced significant deterioration in these aspects over the study period. Regarding coping strategies, the support group showed significant improvements in problem-focused coping (int: 5.47, t=6.23; ctrl: -4.26, t=-7.03) and emotion-focused coping (int: 3.97, t=4.19; ctrl: -2.57, t=-3.94) at the second assessment. Avoidance behaviors decreased in both groups (int: -0.95, t=-1.56; ctrl: -0.87, t=-2.074). The intervention group showed positive outcomes in informational support (1, t=2.81), planning (1.53, t=5.37), positive reframing (1.75, t=4.89), active coping (1.24, t=4.13), behavioral disengagement (-1.074, t=-3.46), self-distraction (1.37, t=4.51), denial (-1.14, t=-2.94), acceptance (1.61, t=5.64), and emotional support (1.23, t=3.44).

The findings highlight that psychological support significantly enhances various aspects of patient well-being, contributing positively to improving overall quality of life.

P2-01-15: Survivorship attributes in women with hormone receptor positive breast cancer at long term follow-up in the CLEAR Study of Late Recurrence.

Ana Elisa Lohmann, Marguerite Ennis, David W Cescon, Stephen K Chia, Christine Brezden-Masley, Christine Elser, Kamran Fazaee, Carol Townsley, Katarzyna Jerzak, Pamela J Goodwin

Background: Limited data are available on long-term breast cancer (BC) survivorship. We examined this issue in women with hormone receptor positive BC recruited at least 4 years post-diagnosis onto a prospective cohort study that investigates survivorship as well as host and circulating factors associated with risks of late recurrence.
Methods: At study entry (2019-2022), 423 women provided information regarding overall health, marital status, current living situation, vitamin/supplement/alternative therapy use, participation in supportive activities. They also completed the Attachment subscale of the Social Provisions Scale and the Holmes and Rahe Stress Scale.
Results: Mean age was 61.4 ± 9.8 years, 93.6% were post-menopausal. 322 (76.1%) identified as white, 16 (3.8%) black, 70 (16.5%) Asian, and Latin America/Hispanic 9 (2.1%). Mean time from surgery to enrolment 7.5 ± 2.8 years, mean CTS5 score 4.2 ± 0.6 % per year. 100 (23.6%) tumors were HER2+, 368 (87%) received chemotherapy. 274 (64.8%) were still on endocrine therapy (ET): 194 (45.9%) on AIs and 80 (18.9%) on tamoxifen at the time of enrolment. Mean duration of ET 6.5 ± 2.4 years. Mean BMI was 27.3 ± 5.9 kg/m2: 25.8% obese, 34.3% overweight, 38.5% normal weight. 213 (50.4%) consumed alcohol in the last year, mean 5 ± 4.3 drinks per week. 377 (89.1%) used dietary supplements: 328 (77.5%) vitamin D, 93 (22.0%) multivitamins, 80 (18.9%) vitamin C and 172 (40.7%) calcium, 66 (15.6%) reported using alternative supplements, notably cranberry and Coenzyme Q10. 276 (65.2%) were married, 65 (15.4%) separated/divorced, 35 (8.3%) widowed, 47(11.1%) never married. Most lived with a partner 279 (66%); 59 (13.9%) with other family members or friends and 82 (19.4%) lived alone. Overall health during the past year was considered stable or better by 306 (84.2%) subjects. 266 (62.9%) reported engaging in at least 1 of the following supportive activities therapy, meditation, yoga, and group exercise. Mean score on the Attachment subscale of the Social Provisions Scale was 15 + 1.7 (range 0 to 16); 254 (60%) reported the maximum score, indicating excellent close attachment and support. In contrast, 154 (36.4%) scored in the highest risk category (>300) on the Stress Scale. The most frequently endorsed items were changes in family get togethers, social activities, vacations, health of family members and work conditions, likely reflecting the COVID pandemic.
Conclusions: In the CLEAR study, with a mean of 7.5 years post-diagnosis, BC survivors reported strong support, with strong emotional ties and stable overall health. However, they experienced high stress and high alcohol consumption, possibly related to the COVID

pandemic. Further analysis addressing diet, physical activity and medical status, and change over time are ongoing.

P2-01-16: Pharmacogenomic variants and risk of adverse events in breast cancer patients treated with Trastuzumab-deruxtecan: results from the PROCURE project

Rodrigo Sánchez-Bayona, Javier de Nicolás-Hernández, Cristina Saura, Maria Gion, Juan Miguel Cejalvo, Elisenda Llabrés, Javier Cortés, Alejandro Falcón, Sonia Pernas, Alfonso Lopez de Sa, Maria Vidal, Carmen Hinojo, Teresa Curiel, Josefina Cruz, Virginia Martínez, Blanca Cantos, Maria Jose Echarri, Isabel Gallegos, Coralia Bueno, Ana Milena Vargas, Santiago Escrivá-de-Romaní, Bartomeu Fullana, Maria Angeles Cobos, Alicia Arenas, Laia Joval-Ramentol, Tomás Pascual, Carlos Valdivia, Guillermo Villacampa, Eva Ciruelos, Cristina Rodriguez-Antona

Background: Trastuzumab-deruxtecan (T-DXd) has shown an unprecedented clinical benefit in advanced breast cancer. Despite its meaningful anticancer outcomes, around 15-20% of patients have to discontinue T-DXd due to related toxicity (mainly pneumonitis/interstitial lung disease). To date, there is no evidence of the potential impact of pharmacogenomic variants and the risk of treatment-related adverse events (TRAE) in breast cancer patients treated with T-DXd.
Methods: The PROCURE project is a translational research study comprising 26 Spanish institutions that aims to analyze pharmacogenomic variants and risk of toxicity in patients with breast cancer treated with T-DXd. Eligible patients had to receive at least one dose of T-DXd for its current approved indications in advanced HER2+/HER2-low breast cancer, with a minimum follow-up of 3 weeks to collect data on early-onset toxicity. Patients who had discontinued the treatment were also eligible. Patients' demographics and clinical variables were gathered from medical records in an electronic database. Emerging adverse events were registered following CTCAE V.5 guidelines. One blood sample was collected for DNA extraction. Pharmacogenomic analyses included the determination of UGT1A1*28 allele and a massive SNP genotyping array with over 1.9 million genetic markers and enriched in pharmacogenomics variants (Infinium Global Diversity Array with Enhanced PGx, Illumina).
Results: A total of 329 female patients were enrolled in the study from July 2022 to March 2024 with available genetic information. At data cut-off (1 July 2024), clinical data was available for 315 (95.7%). The median age was 56 years and the median duration of T-DXd treatment was 12.0 months (95%CI 10.4–14.2). Regarding UGT1A1 genotypes, 36 patients (11.4%) were *28/*28 homozygous (poor metabolizers), 143 (45.3%) were *1/*28 heterozygous (intermediate metabolizers), 1 (0.3%) was *1/*37 and 135 (42.7%) were *1/*1 (wild type). According to UGT1A1 genotypes (in this order: *1/*1, *1/*28, *28/*28) we observed the following TRAE of any grade: neutropenia (14.0%, 15.3%, 8.3%), anemia (13.2%, 7.6%, 11.1%), thrombocytopenia (4.4%, 4.2%, 11.1%), diarrhea (19.9%, 16.7%, 16.7%), vomiting (16.2%, 14.6%, 13.9%), pneumonitis/ILD (10.3%, 8.3%, 8.3%), dose

reductions (28.9%, 27.8%, 34.8%), and treatment discontinuation (28.9%, 26.7%, 17.4%). We observed a higher incidence of grade 3 gastrointestinal toxicity in poor metabolizers (*28/*28) compared to the other two genotypes: diarrhea (0.7%, 0.7%, 2.8%), and vomiting (0.7%, 0.0%, 5.6%). The incidence of drug-induced pneumonitis/ILD in our study was 9.2% (29/315). We did not find an association between the UGT1A1 variants and the incidence of pneumonitis. In the SNP array, 314 of 315 samples and >95% of SNVs passed quality control. A logistic regression analysis of pneumonitis/ILD revealed more than 25 markers with unadjusted p-value <5x10-5 (additive model). Detailed pharmacogenomic TRAE analyses will be presented during the conference.
Conclusions: Descriptive analyses from the PROCURE project show a similar incidence of all grade TRAE irrespective of UGT1A1 allelic variants. We observed a higher incidence of grade 3 gastrointestinal toxicity in UGT1A1 *28/*28 carriers. Potential pharmacogenomic markers of ILD were identified by a massive SNP genotyping array in unadjusted analysis that warrants further research.

P2-01-17: Genomic predictors of response among patients with hormone receptor-positive (HR+)/HER2- metastatic breast cancer (MBC) receiving the AKT inhibitor (AKTi) ipatasertib combined w/ endocrine therapy & a CDK4/6 inhibitor (CDK4/6i) in TAKTIC trial

Maxwell Lloyd, Geoffrey G. Fell, Elizabeth Scott, Jennifer C. Keenan, Laura M. Spring, Jennifer Shin, Steven J. Isakoff, Lianne Ryan, Sarah Padden, Elizabeth Fisher, Amber Newton, Beverly Moy, Andreas Varkaris, Leif W. Ellisen, Douglas S. Micalizzi, Daniel Haber, Dejan Juric, Aditya Bardia, Seth A. Wander

Background: Treatment of HR+/HER2- MBC often involves an antiestrogen agent and CDK4/6i, and following disease progression, multiple therapies are approved in the second line. Management is increasingly guided by a precision-based approach, including the use of AKTi in tumors harboring an AKT1 or PIK3CA mutation or PTEN loss. However, little is known regarding molecular factors that mediate resistance to AKTi. Results from the TAKTIC trial demonstrated antitumor activity and tolerability of the AKTi ipatasertib with endocrine therapy (ET) +/- palbociclib post-CDK4/6i (Wander et al., 2023). We hypothesize that next-generation sequencing (NGS) of tumors among patients (pts) receiving ipatasertib could inform genomic predictors of response to AKTi.
Methods: TAKTIC was a phase Ib open-label trial evaluating ipatasertib in combination with fulvestrant, an aromatase inhibitor, or fulvestrant + palbociclib, in participants with HR+/HER2- MBC who received ≥1 line of prior therapy for MBC and had exposure to CDK4/6i (NCT03959891). An exploratory objective of TAKTIC was to identify genomic biomarkers that correlate with response to an AKTi-based combination regimen. Blood samples for circulating tumor DNA analysis were drawn at routine timepoints and archival tumor tissue was obtained. Mutational profiling was performed using commercially available NGS-based assays (frequently via Guardant360). Progression free survival (PFS) was estimated using the Kaplan-Meier method, and survival analysis was implemented with

the Breslow approximation for ties. Univariable and multivariable hazard ratio (HR) and 95% confidence interval (CI) analyses were estimated using a cox proportional hazards model.
Results: TAKTIC accrued 77 pts (6/2019 – 2/2022), enrolling 35 on doublet therapy (AKTi + antiestrogen) and 42 on triplet therapy (AKTi, fulvestrant, and palbociclib). Baseline NGS results were available in 58 of 77 pts, and alterations in PI3K/AKT pathway genes were found in PIK3CA (43%), AKT1 (7%), and PTEN (10%). Mutations in ESR1 (29%) were seen at rates consistent with prior studies in MBC post-ET. A subgroup of 20 pts who received the triplet ipatasertib regimen and had baseline NGS data within 60 days of drug start were analyzed. Mutations in PIK3CA (n=7, 35%; n=5 polyclonal) and PTEN (n=4, 20%; n=1 polyclonal) were detected, as were alterations in ESR1 (n=5, 25%), FGFR1 (n=4, 20%), KRAS (n=4, 20%), and ERBB2 (n=3, 15%); no baseline AKT1 mutations were seen in this subgroup. Univariate gene analysis demonstrated that FGFR1 amplification was associated with shorter PFS (HR 5.42, 95% CI 1.3 – 22.1, P=.019), and ERBB2 alteration trended toward worse outcomes (HR 3.38, 95% CI 0.8 – 13.6, P=.086); no significant difference was seen between ESR1 mutant vs. ESR1 wild-type tumors (HR 1.6, 95% CI 0.6 – 4.6, P=.384). Multivariate gene analysis demonstrated that PIK3CA/AKT1/PTEN altered tumors (n=9) had greater response to the AKTi triplet combination compared to tumors without mutations in this pathway (n=11) (median PFS 505 vs. 114 days, HR 0.2, 95% CI 0.1 – 0.7, P=.015). Breast cancers harboring alterations that upregulate RAS pathway signaling (KRAS/NRAS, BRAF, FGFR1/2, ERBB2, EGFR; n=9) showed a trend toward inferior outcomes compared to non-altered disease (n=11) (median PFS 114 vs. 253 days, HR 2.0, 95% CI 0.8 – 5.3, P=.160). Additional analyses at the individual gene and pathway level will be presented at the meeting.
Conclusions: Genomic insights using NGS suggest that MBC post-CDK4/6i is more susceptible to an AKTi-based treatment with ipatasertib in the presence of a PI3K/AKT/PTEN pathway mutation, whereas alterations in FGFR1 are associated with worse outcomes. This effort is one of very few studies prospectively evaluating mediators of AKTi response, an area of active interest given changes in the therapeutic landscape. The results presented here are hypothesis-generating; future work is underway to further expand upon these data.

P2-01-19: Measurement of ADC Targets HER2 and TROP2 in Breast Cancer for Accuracy and Selection

Nay Chan, Katherine M. Bates, Julia Benanto, C. Jack Robbins, Mengni He, Liam Scott, Salisha Hill, Ryan D. Morrison, Daniel Liebler, Regan Fulton, David L. Rimm

Introduction: With over 700 antibody drug conjugates (ADCs) in clinical trials, there are new challenges for protein diagnostics. ADCs have a measurable target and likelihood of response increases with increased target expression. But as multiple ADCs are approved for the same indication, measurement of target also could play a role in sequencing of therapy.

To accurately compare competing ADCs, the targets must be quantitatively measured, not read, as there is broad variability in reading/scoring target expression by conventional semi-quantitative IHC tests. We have previously described a quantitative immunofluorescent (QIF) method (called HS-HER2) to measure HER2 protein in attomoles per square millimeter (amol/mm2). Our new duplex QIF (TROPLEX™) assay measures both HER2 and TROP2 protein targets. We show validation of the TROPLEX assay and a prospective assessment to compare relative levels of target expression. We envision use of this assay to help sequence patients for Trastuzumab deruxtecan (T-DXd) and Sacituzumab govitecan (SG).

Methods: We constructed cell lines microarrays (CMAs) with 9 cell lines expressing different levels of HER2 and TROP2 proteins, then created HER2 and TROP2 standard curves of QIF scores based on targeted mass spectrometry measurements. This provided a conversion from QIF signal to (amol/mm2) for each target. We then tested the TROPLEX assay on a 40 case CLIA lab validation set and a prospectively collected cohort of 93 breast cancer cases. Both validated HS-HER2 and TROPLEX assays were performed using the Leica BOND RX autostainer and imaged with the CyteFinder II HT multiplex fluorescent imaging platform from RareCyte, and molecular compartmental analysis was performed in QuPath with the Qymia extension.

Results: Validation of the TROPLEX assay showed inter-operator reproducibility (R2 = 0.99 for HER2 and R2 = 0.94 for TROP2), inter-assay CVs of 10% for HER2 and 9.8% for TROP2, and intra-assay CVs of 6.4% for HER2 and 6.2% for TROP2. Since the threshold of ADC response is not known for either target, the assays were made as sensitive as possible. The limit of detection (LOD) for HER2 was 360 amol/mm2 and for TROP2 it was 325 amol/mm2. In the TROPLEX prospective trial 2% of the cases were below the LOD for HER2 and 0% for TROP2. Other analytic parameters are in process. Measurement of HER2 protein in 40 cases selected for CLIA lab validation we found a very high correlation (R2 = 0.9) between HER2 measured by the validated HS-HER2 assay compared to the TROPLEX assay. In prospective trials, we found that HER2 expression ranged from about 100 to nearly 7200 amol/mm2 and TROP2 showed a range from about 900 to 22000 amol/mm2. The TROPLEX assay showed no significant correlation between HER2 and TROP2 expression but many cases that are high for one target are low for the other (see figure 1). While TROP2 IHC is not standard of care, we could compare measured levels of HER2 to IHC scores. We found that the first quartile of quantitative HER2 shows 57% cases scored as IHC=0 and 30% cases scored as IHC=1. In the second quartile of quantitative HER2 we found 29% cases scored as IHC=0 and 42% cases scored as IHC=1. This distribution shows the inaccuracy of conventional HER2 IHC compared to quantitative assessment.

Conclusion: Based on our validation and prospective studies, the multiplex QIF TROPLEX assay is highly sensitive for both HER2 and TROP2. The assay was sufficiently accurate and reproducible for validation in a CLIA lab. Studies are underway to determine the threshold for ADC response and to assess the value of this quantitative ranking assay to select between ADCs with the same indication.

P2-01-20: Impact of Exercise on Immune Biomarkers in Benign Breast Tissue from Women with High Mammographic Breast Density (MBD)

Jennifer Ligibel, Douglas Russo, Kun Huang, Anita Giobbie-Hurder, Anna Tanasijevic, Tari A. King, Judy Garber, Myles Brown, Stuart Schnitt, Kornelia Polyak, Rinath Jeselsohn

Background: Increased physical activity (PA) is associated with lower risk of all subtypes of breast cancer in both pre- and post-menopausal women, but the biological mechanisms through which PA impacts breast carcinogenesis are not well understood.

Methods: We conducted a single-arm pilot study to evaluate the impact of an aerobic and strength training PA intervention on tissue biomarkers in inactive women at increased risk of breast cancer due to the presence of increased mammographic breast density (MBD). Eligibility criteria included having at least 50% MBD (BIRADS C or D); engaging in <90 minutes per week of moderate or vigorous PA (MVPA); age <60 years; no concurrent use of hormone replacement therapy, oral/implantable birth control agents, or chemoprevention for breast cancer; and no prior history of breast cancer. Participants (pts) took part in a 12-week aerobic and strength-training intervention including 2 supervised exercise sessions and 1+ session of home-based aerobic exercise. Pts underwent biopsy of benign breast tissue at baseline and 12-weeks of mirror-image sites in opposite breasts. Biopsies were timed to coincide with the luteal phase of the menstrual cycle in pre-menopausal participants. Areas of interest (AOIs) were marked from terminal ductal lobular units (TDLU's), ductal epithelium, and stroma by a breast pathologist and by staining for pan-keratin and CD45. RNA-sequencing of the AOIs was performed using GeoMx platform. Changes over time between pre- and post-intervention biopsies were evaluated using paired t-tests on average (per patient) immune cell type abundances that were estimated from gene expressions using the GeomxTools R package. All p-values were adjusted for multiple testing using the Benjamini-Hochberg procedure. Single cell spatial analysis targeting 20 immune and proliferative markers was performed using Co-detection by indexing (CODEX), a multiplexed imaging method, in 11 paired biopsies with sufficient tissue remaining after gene expression analysis. Analysis included cell segmentation and clustering with deconvolution of cellular populations followed by comparisons between matched samples pre and post exercise. Comparisons differences in number and density of cellular populations, cell-cell interactions and cell neighborhoods.

Results: Thirty pts were enrolled between 10/2018 and 11/2019. Due to the COVID-19 pandemic, 3 participants did not undergo a week-12 biopsy and 1 additional patient was lost to follow up for non-COVID related reasons, leaving 26 participants with paired pre- and post-intervention tissue. Average age of study pts was 47.6 (±5.7) years, average BMI was 29.2 (±6.3) kg/m2, and median minutes of MVPA at baseline was 72.5 (range 0-360). Pts attended an average of 20.4 of 24 exercise training sessions (85% adherence) and increased exercise by a median of 92.5 minutes/week (range -140 to 700). Cell abundance based on gene expression data showed increased CD8+ memory T cells (mean difference (MD)=1.34, standard error (SE)=0.85), neutrophils (MD=2.25, SE=0.83), and NK cells

(MD=1.18,SE=0.57) in the epithelium (N=11 patients) and increased neutrophils (MD=1.00, SE=0.33) in the stroma (N=10 patients) after the 12-week exercise intervention at a 25% FDR threshold. Details of the CODEX analysis will also be presented.

Conclusions: In this single-arm pilot study exploring the impact of an exercise intervention on biomarkers in benign breast tissue in women at increased risk of breast cancer due to elevated MBD, there was evidence of immune changes in post-exercise tissue samples, providing some of the first evidence that exercise could impact gene expression in benign breast tissue. This work provides a foundation for further work exploring the potential pathways through which exercise could prevent breast cancer in at-risk populations.

P2-01-21: Baseline circulating tumor cells (CTCs) predict for progression-free survival (PFS) after ablation on NRG-BR002, a randomized phase II/III study of ablation vs. standard systemic therapy care (SOC) for oligometastatic breast cancer (OMBC).

Wendy Woodward, Jennifer Moughan, Steven Chmura, Peter Kuhn, Anthony Lucci, Virginia F Borges, Joseph K Salama, Hania Al-Hallaq, Martha M Matuszak, Michael T Milano, Nora Jaskowiak, Stephanie N Shishido, Jeremy Mason, Salyna Meas, Carol Hall, Sachin R Jhawar, Robert A Nordal, Gregory N Gan, Diane C Ling, Imran Zoberi, Sobha Kurian, Kathryn Winter, Eleftherios P Mamounas, , Julia R White

Background: NRG-BR002 randomized patients with OMBC to SOC with vs. without ablation (surgery or radiation) of all visible metastases. The phase II PFS go signal for improvement with ablation was not met. Blood for CTCs was collected from consenting patients and sent for the FDA-approved CellSearch CTC assay and High-Definition Single Cell CTC Analysis (HDSCA). The primary CTC objective was that pretreatment CTCs (PreRX CTCs) would be prognostic for PFS. Secondary objectives included baseline CTCs being predictive for the effect of RX on PFS and CTC post-treatment clearance rate correlating with PFS.
Statistical Design and Methods: A secondary endpoint analysis of the prognostic effect of PreRX CTCs on PFS and the interaction between study arm and the PreRX CTCs on PFS were evaluated for both assays using multivariable Cox proportional hazards models (MVA). CellSearch CTCs were dichotomized 0 vs. ≥ 1 and HDSCA CTCs were assessed by < vs. ≥ lowest quartile (Q1). Due to small numbers of CTC+ cases, CTC clearance correlation with PFS was not able to be tested. Descriptive results are presented.
Results: Of 125 phase II eligible patients, 108 (86%) consented to blood collection. Among the cohort with CTC data (n=62 for CellSearch, n=60 for HDSCA), demographic and treatment variables were balanced between study arms and similar to the trial population. Thirty-six (58%) and 26 (42%) had CellSearch CTC = 0 and ≥1, respectively. Fifteen (25%) and 45 (75%) had HDSCA CTCs < Q1 and ≥ Q1, respectively. Median follow up at the time of analysis was 48 months. PreRX CTCs (CellSearch and HDSCA) were not prognostic for PFS. In each of the analyses for PreRX CTC (0 or < Q1) being predictive for PFS, after adjusting for number of metastases (1 v >1), the interaction between study arm and CTCs had a HR >

3, reaching statistical significance for HDSCA (p=0.024; HR 5.58, 95% CI: 1.26, 24.77) and trending towards statistical significance for CellSearch (p=0.063; HR 3.39, 95% CI: 0.94, 12.25). Patients in the ablation arm, with HDSCA PreRX CTCs < Q1, experienced better PFS than those with PreRX CTCs ≥ Q1; 78% vs. 33% at 2 years, respectively, as compared to patients on the control arm (17% vs. 55%). Patients in the ablation arm, with CellSearch PreRX CTCs = 0, also experienced better PFS than those with PreRX CTCs ≥ 1; 54% vs. 27% at 2 years, respectively, as compared to patients on the control arm (35% vs. 61%). For CellSearch only, 19/62 patients (9 SOC and 10 ablation) had positive PreRX and PostRX CTC values. In the SOC arm, clearance of CTCs was seen in 6 patients (all progression-free) and no clearance in 3 (2 progressed/1 died). In the ablation arm, clearance (n=5)/decrease (n=2) of CTCs was seen in 7 patients; however, only 3 remained progression-free; and an increase was seen in 3 patients whose disease progressed. For the 9 patients across both arms with PreRX and PostRX CTCs that progressed, all 9 developed new metastatic sites. Conclusion: Lower PreRX CTCs predicted for improved PFS after ablation using the HDSCA assay. The pre-specified CTC analyses provide consistent results using two independent assays highlighting the robustness of the finding. These hypothesis-generating findings suggest that PFS is improved in CTC negative OMBC patients who are treated with ablation.

P2-01-22: NSABP B-31 confirms the prognostic value of the NeoALTTO-developed S5 genomic classifier

Katherine L. Pogue-Geile, Paolo Verderio, Nan Song, Chiara M. Ciniselli, Patrick G. Gavin, Rim S. Kim, Christos Sotiriou, David Venet, Priya Rastogi, Giancarlo Pruneri, Norman Wolmark, Soonmyung Paik, Sara Pizzamiglio, Serena Di Cosimo

Background: S5 and S18 gene classifiers were generated in the NeoALTTO study and were associated with a poor prognosis in patients treated with trastuzumab + chemotherapy (ESMO 2022). The associations of S5 and S18 with prognosis were confirmed in the Italian GHEA (Group HEreceptin in Adjuvant treatment) expanded access study. Now we report on a pre-planned, retrospective study (NRG Ancillary project AP2220) testing the association of S5 and S18 with the prognosis of patients from NRG Oncology/NSABP B-31 to confirm their prognostic value. NSABP B-31 was a phase III, randomized trial to assess the safety and efficacy of the addition of trastuzumab (H) to doxorubicin and cyclophosphamide followed by paclitaxel (ACT) in patients with operable, node-positive, HER2-positive breast cancer. This analysis benefits from a large patient sample, an extended follow-up duration, and detailed treatment information.

Materials and methods: Among the 2,130 patients who participated in B-31, tissues were available for 1,579. Available Affymetrix gene expression data from 731 patients were used

to associate S5 and S18 with outcomes. The S5 and S18 scores were analyzed as (i) continuous and (ii) dichotomized variables using a median predefined cut-off. Co-primary endpoints for this study were disease-free survival (DFS) and overall survival (OS) as estimated by the Kaplan-Meier method and Cox models.

Results: The patient populations of the original NSABP B-31 trial and the current gene expression study were very similar. The median follow-up time was 7 years. Main patient characteristics were: median age 50 (range 26-78), distribution of positive nodes (58% with 1 to 3, 28% with 4 to 9, and 14% with ≥10), tumor sizes in cm (39% ≤2, 52% >2 to ≤5, and 9% >5), and estrogen receptor (ER) status (53% positive and 47% negative). Of 731 patients, 370 were randomized to ACT and 361 to ACTH. No statistically significant associations with outcomes were observed with the S18 score, but the S5 score was significantly associated with DFS after adjustment for clinical variables (age, tumor size, node and ER status) and treatment, both as continuous and dichotomized variables (C-indexes were 0.65 [95% CI: 0.61-0.69] and 0.66 [95% CI: 0.61-0.70], respectively). The hazard ratio (HR) for dichotomized (high v low) S5 score was 1.50 (95% CI: 1.14-1.99, p=0.004). Notably, patients classified as S5-high also had a higher risk of death with a C-index of 0.69 (95% CI: 0.64-0.75) and HR of 1.42 (95% CI: 0.95-2.12). No significant interaction between the S5 score and the treatment arm or ER status was observed.

Conclusions: In patients with early-stage HER2-positive, node-positive breast cancer, the S5 score was confirmed as an independent prognostic factor, whereas the S18 score was not confirmed. The S5 score might be useful to identify patients with a favorable prognosis who would be suitable for treatment with trastuzumab + chemotherapy alone in the adjuvant setting.

P2-01-23: A 140-gene Machine Learning Classifier Predicts Survival and Response to Chemotherapy and Immunotherapy in 2500 TNBC

Xixuan Zhu, Orsolya Sipos, Katherine A. Hoadley, Jane Bayani, Lucy Kilburn, John M.S. Bartlett, Judith Bliss, David Cameron, Andrew Tutt, Maggie Chon U Cheang

Background: TNBC is molecularly heterogeneous, showing varied responses to therapeutic agents (Txt). We developed a 140-gene classifier (TNBC-ICR) based on random-forest (RF) to cateogorize TNBC into four biological subgroups. It was trained and tested on 551 TNBC (Zhu ESMO Congress 2023), and had better precision in predicting time to recurrence with anthracycline-based (A) txt compared to TNBC-Baylor subtypes (Burstein Clin Cancer Res, 2015) in TACT2 trial (NCT00301925).

Here, we assessed the genomic characteristics and clinical value of TNBC-ICR classifier to predict response for standard of care and emerging Txt.
Methods: TNBC-ICR, consisting of 1000 decision trees, assigned each case to immune-enriched (IM), luminal-AR (LAR), mesenchymal-like (MES) or highly proliferative basal-like (BL-Prolif) based on RF probabilities linked to these subgroup features.
Association with genomic characteristics and prognosis were tested in The Cancer Genome Atlas (n=155, TCGA Nature, 2012), METABRIC (n=269, Curtis Nature, 2012), and SCAN-B (n=571, Saal Genome Med, 2015).
Association with pathological complete response (pCR) was tested across 4 neoadjuvant (NAT) clinical studies: 1) a combined cohort of MDACC, ISPY-1, LBJ/IN/GEI and USO (MDACC, n=188, Hatzis JAMA 2011), 2) CALGB 40603 (n=389, NCT00861705), 3) BrighTNess (n=482, NCT02032277) and 4) ISPY-2 (n=364, NCT01042379). These studies, all including Paclitaxel (P), assessed the additional benefits of Bevacizumab (Bev), Carboplatin (Carbo), PARP inhibitor (V) or Pembrolizumab (Pem), followed by A and Cyclophosphamide (C).
Gene expression data (GE) was available for all studies, with batch correction applied to reduce platform effects before using the TNBC-ICR classifier.
Statisical analyses included multivariable Cox regression models to assess the hazard ratio (HR), chi-squared tests to compare genomic characteristics and pCR rates among the subgroups and logistic regression models to assess the significance and odds ratio (OR) of tumor probabilities to IM, LAR, MES and BL-Prolif related to pCR.
Results: Using whole exome sequencing data from TCGA and METATRIC (n = 306), TP53 was the most frequently mutated gene, observed in IM (88%), MES (76%), BL-Prolif (85%) and LAR (68%, $p = 0.008$), with PIK3CA mutations in LAR (41%) and the others (7%, $p < 0.001$).
The pCR rates for IM, LAR, MES and BL-Prolif were as follows:

MDACC (P+AC), 33% (18/54), 10% (3/30), 25% (9/36) and 48% (29/60), $p = 0.002$;
CALGB 40603 (P+Carbo+AC+Bev), 67% (76/103), 56% (30/54), 36% (31/86) and 54% (73/136), $p < 0.001$;
BrighTNess P+Carbo+V arm: 69% (51/74), 29% (8/28), 62% (34/55) and 43% (34/80), $p < 0.001$; P+Carbo arm: 73% (29/40), 37% (7/19), 62% (13/21) and 48% (20/42), $p = 0.03$; in P arm: 43% (16/37), 17% (3/18), 27% (8/30) and 34% (13/38), $p = 0.21$;
ISPY-2 P arm: 22% (6/27), 50% (5/10), 12% (3/26) and 14% (3/22), $p = 0.06$; P+Pem arm: 100% (8/8), 60% (3/5), 40% (2/5) and 55% (6/11), $p = 0.098$;

In P arms, pCR rate was generally low but addition of either Carbo or V increased pCR rates in IM and MES subtypes and addition of Pem over P increased pCR rates for IM and BL. There was no consistent association of TNBC-Baylor subtypes to pCR in these studies.
Statistical modelling of TNBC-ICR classifier on txt response showed that probability to IM-subgroup predicted pCR (OR = 3.52, $p < 0.001$) in NAT and better recurrence-free survival in adjuvant chemotherapy-treated subgroups of SCAN-B (HR = 0.38, $p = 0.04$) and METABRIC (HR = 0.3, $p = 0.04$).

Conclusion: Tumors with higher IM-features had increased pCR rates after NAT. We validated the reproducibility and clinical validity of TNBC-ICR classifier in predicting differential response to therapies, including taxane and immunotherapy, demonstrating its potential as a practical clinically relevant integrative biology-driven machine learning algorithm.

P2-01-24: Immune activation of tumor cells and microenvironment as assessed by PD-L1 expression and interferon gamma signaling predict long term disease-free and overall survival: Results of the prospective randomized neoadjuvant ABCSG 34 trial

Ulrike M. Heber, Dominik Hlauschek, Christian F. Singer, Daniel Egle, Richard Greil, Ruth Helfgott, Gregor Huber, Elisabeth Müller-Holzner, Cornelia Hauser-Kronberger, Margaretha Rudas, Georg Pfeiler, Rupert Bartsch, Sigurd Lax, Martin Filipits, Gabriel Rinnerthaler, Michael Gnant, Zsuzsanna Bago-Horvath

Background: Novel neoadjuvant treatment options including combinations of chemotherapy with immune-checkpoint inhibitors have improved pathologic complete remission (pCR) rates and long-term outcomes in early-stage breast cancer. To better understand individual risk of relapse and stratify patients for post-neoadjuvant risk-adapted therapeutic interventions beyond the crude dichotomization of pCR, novel predictive factors serving as surrogate for immune-activation and long-term outcome are warranted. The interferon gamma signaling pathway is a key modulator of antitumor immune effects. In the present study, we assessed the role of PD-L1 and the interferon gamma related proteins STAT1 and IRF1 in different tissue compartments as prognostic and predictive biomarkers in the prospective randomized ABCSG 34 trial.
Patients and Methods: In total, 289 tumor samples of 400 patients with early HR+/HER2- or TN breast cancer (BC) or triple-negative BC within the ABCSG 34 trial were available: 210 HR+/HER2 BC and 79 TN patients received neoadjuvant chemotherapy (anthracycline and taxane-based) and endocrine therapy, respectively. Patients were randomized 1:1 to receive either Standard of Care (SoC) or SoC plus the MUC1-based antitumor vaccine tecemotide. Expression of PD-L1 (Immune Score, IC: SP142 clone, Ventana and Combined Positivity Score, CPS: SP263 clone, Ventana), as well as STAT1 and IRF1 (both Cell Signaling Technology) expression at baseline, surgery (where available), and the change in expression during therapy was correlated with patient outcome. Also, STAT1 and IRF1 expression was determined in tumor cells, TILs and stromal fibroblasts. Expression levels were correlated with invasive disease-free (IDFS), distant relapse-free (DRFS) and overall survival (OS). Association with outcomes and use of tecemotide were estimated using univariable stratified (chemotherapy vs endocrine therapy cohort) Cox regression. For continuous markers the hazard ratios (HR) depict the change in hazards for an absolute 10%-point increase of the marker.
Results: Higher PD-L1 IC in biopsy samples was associated with a better DRFS (HR 0.92, 95% CI 0.84 – 1; p = 0.048). In surgical specimens, a positive compared to a negative CPS

was associated with improved DRFS (HR 0.31, 95% CI 0.10 – 0.99; p = 0.048). However, an increase in CPS during neoadjuvant therapy was associated with worse OS (HR 1.03, 95% CI 1 – 1.05; p = 0.032). Pre-therapeutic IRF1 expression in TILs was associated with a better IDFS (HR 0.64, 95% CI 0.42 – 0.98; p = 0.039) and DRFS (HR 0.55, 95% CI 0.34 – 0.88; p = 0.013). Post-therapeutic proportion of IRF1 expressing tumor cells was associated with a better DRFS (HR 0.62, 95% CI 0.42 – 0.92; p = 0.018). STAT1 expression in any of the compartments at any time did not show significant association with long-term outcome. These effects were independent of biological tumor subtype (HR+/HER2- or TNBC). No significant associations between the expression of the investigated biomarkers and any potential tecemotide benefit could be identified.
Conclusion: The results of this study indicate that in the ABCSG 34 trial, PD-L1 positivity as determined by IC and CPS was able to predict better DRFS and OS. However, in patients with residual tumor, an increase in CPS during treatment was associated with decreased OS - a result that needs to be interpreted with caution, since no “post treatment sample” can be accessed in cases of pCR. In addition, IRF1 expression both in tumor cells and TILs predicted an improved IDFS and DRFS. STAT1 expression in any of the tissue compartments did not demonstrate significant association with survival. Despite a limited sample size, these results suggest that immune activation status of tumors and TILs as well as the microenvironment at the beginning of neoadjuvant treatment predict prolonged long-term outcomes, even when RCB/PCR rates remain unchanged.

P2-01-25: Circulating tumor DNA clearance by neoadjuvant chemotherapy or breast surgery detected using an ultrasensitive ctDNA MRD assay in early breast cancer

Luc Cabel, Julia Ah-Reum An, David Kurtz, Dara Ross, Esra Dikoglu, Enrico Moiso, Kevin Murphy, Kathleen Szuhany, Sierra Love Stowell, Dillon Maloney, Giselle Zamora-Chavez, Andre Schultz, Howard I. Scher, Jake Chabon, Mark E Robson, Monica Morrow, Bob T Li, Ash A Alizadeh, Sarat Chandarlapaty, George Plitas, Maximilian Diehn, Pedram Razavi

Introduction: Presence of circulating tumor DNA (ctDNA) after treatment for early-stage breast cancer (EBC) is associated with poor outcomes, yet accurate detection of ctDNA clearance after treatment requires ultrasensitive methods. Here, we describe the clearance of ctDNA in EBC by multiple treatment modalities, including surgery and neoadjuvant chemotherapy (NAC), using an ultrasensitive ctDNA minimum residual disease (MRD) assay.
Methods: The MSK-LINC study prospectively collected blood samples from EBC patients throughout their clinical care at MSK. MRD was monitored using Foresight CLARITY, an ultra-sensitive MRD research assay with LOD95 below 1 part-per-million (ppm). Whole genome sequencing (WGS) of primary tumor and WBC samples was used to identify tumor-derived phased variants. Personalized MRD assays were then designed to detect ctDNA. We assessed the relationship between ctDNA during distinct phases of treatment and clinical outcomes, including NAC, surgery, or adjuvant treatment.

Results: We analyzed 390 samples from 50 EBC patients (Stages: I=22%, II=56%, III=22%) treated with curative-intent surgery for diverse subtypes (62% HR+/HER2-, 24% HER2+, 14% TNBC). Pretreatment ctDNA was present in 72% of patients, with a median variant allele frequency (VAF) of 100 ppm (range 8 - 226,000 ppm). Following neoadjuvant (44%) or adjuvant (48%) chemotherapy, 14% distant relapses were observed.
Among 18 patients with detectable ctDNA before or during NAC, 56% cleared their ctDNA prior to surgery and remained disease free, with 60% of these achieving pathological complete response (pCR). In contrast, 44% of patients were ctDNA MRD positive (ctDNA+) at the last time-point prior to surgery (median 5 ppm, range: 3-12); 50% of these patients experienced disease recurrence and none achieved pCR. Clearance of ctDNA prior to surgery was associated with significantly improved DFS ($p = 0.012$).
When considering the effect of surgery on patients with residual ctDNA after NAC, 63% had undetectable ctDNA at the first post-operative time-point while 38% did not, with ctDNA levels ranging from 0.9 to 322 ppm. All ctDNA+ patients experienced relapse. Among patients who cleared ctDNA at any postoperative timepoint, only one (13%) experienced relapse; ctDNA was detected in the next blood sample, 15 months prior to relapse. All patients experiencing relapse had ctDNA detected prior to recurrence by serial monitoring.
Among evaluable patients not receiving NAC, 15 patients had ctDNA detected pre-surgery (median ctDNA level 40 ppm, range 8-913), with 87% achieving ctDNA clearance post-surgery. The two patients without ctDNA clearance post-surgery (VAF pre- vs post-surgery 124→3.8 ppm and 40→10 ppm) were HR+/HER2- and experienced no relapse. Interestingly, both patients received adjuvant chemotherapy and endocrine therapy, leading to ctDNA clearance at subsequent timepoints. Among 13 cases with ctDNA clearance post-surgery, 92% remain disease free. We observed a single late relapse at 54 mo in a patient with TNBC who cleared ctDNA at the post-operative landmark, with ctDNA detection re-emerging prior to relapse.
Conclusion: In EBC, ctDNA clearance by NAC, surgery, or adjuvant therapy is strongly associated with favorable outcomes. Ultrasensitive MRD analysis demonstrates that surgery also leads to a high rate of ctDNA clearance, suggesting the ability to measure and differentiate responses to both local and systemic therapies. Ultrasensitive ctDNA in EBC is likely to become an important biomarker of response to therapeutic interventions and warrants further study.

P2-01-26: Carboplatin added to neoadjuvant chemotherapy in a randomized phase II study: Complex DNA based biomarkers predict response in hormone receptor positive and triple negative breast cancer.

Olav Engebraaten, Marianne Lislerud Smebye, Arne Valebjørg Pladsen, Øystein Garred, Elin Borgen, Eivind Valen Egeland, Mads Haugland Haugen, Maria Aanesland Dahle, Gunhild Mari Mælandsmo, Eivind Hovig, Sigve Nakken, Anne Alexandra Østgaard, Inger Riise Bergheim, Ellen Schlichting, Helle Skjerven, Anne-Lise Børresen Dale, Erik Wist, Bjørn Naume, Hege Russnes, Ole Christian Lingjærde

Background: Carboplatin (Cb) improves treatment efficacy among patients with triple negative breast cancer (TNBC). However, not all patients need additional chemotherapy and the benefit for patients with hormone receptor positive breast cancer (HR+BC) has not been extensively investigated. Tumor-specific copy number alterations may predict sensitivity to DNA damaging agents such as Cb. The I-BCT-1 (Improved Breast Cancer Therapy – 1) study was designed to discover biomarkers associated with treatment response, in patients with high-risk HR+BC and TNBC.

Methods: Patients with HER2 negative high risk (by Ki67, ER/PgR and/or grade) cT2-4 tumors and no distant metastases were randomized 1:1 to paclitaxel (80 mg/m2, Q1W) alone or in combination with Cb (AUC6 Q3W), for 12 weeks, followed by four cycles of EC90 (epirubicin 90 mg/m2 and cyclophosphamide 600 mg/m2; Q3W). Tumor sampling was performed before treatment start, along the treatment, and at surgery, but only data related to initial sampling is reported here. Complex biomarkers based on somatic copy number alterations (the complex arm-wise aberration index (CAAI), loss of heterozygosity (LOH) and homologous recombination deficiency (HRD)) status were determined based on exome sequencing data. The influence of Cb on chemotherapy delivery and toxicities was analysed.
Results: In the 187 patients randomized, the median follow-up was 4.7 years (range 1.0 – 7.9 years). Among the TNBC patients (n=72), the pCR rate was 69% in the Cb group (n=35) vs. 43% in the control group (n=37; p = 0.036). For HR+BC patients (n=115), the pCR rate was 15% in the Cb group vs. 11% in the control group (n.s.), but the fraction of these patients with residual cancer burden (RCB) 0 or 1 increased from 16 to 35% by Cb treatment (p = 0.033). For TNBC patients, event-free survival (EFS) was significantly improved in the Cb group compared to the control group (p=0.017, HR 0.24, 95% CI 0.07-0.86). For HR+BC patients, no improvement in EFS was observed (p=0.684, HR 1.19, 95% CI 0.52-2.71). The proportion of patients with serious adverse events was 42.1% in the Cb group vs. 18.5% in the control group (p<0.001).
In TNBC patients receiving Cb, high CAAI was associated with an improved pCR rate (p=0.029). HRD has earlier been investigated as a marker for several DNA targeted therapies, including Cb, but no significant difference in pCR was found in the TNBC patients according to HRD status. In HR+BC patients receiving Cb, the pCR rate was significantly higher in patients with HRD tumors vs. patients with non HRD tumors (p=0.002; not associated with germline BRCA status).
In TNBC patients with a low genomic fraction of LOH, the treatment outcome was better in the Cb group than in the control group (p=0.005). In TNBC patients who did not receive Cb, high genomic fraction of LOH was associated with a good prognosis. This was validated in an independent dataset of TNBC patients (n=144, p=0.034), indicating a limited additional effect of Cb for patients with tumor harbouring a high fraction of LOH.

Conclusion: In TNBC patients, Cb improves the pCR rate and EFS. In HRBC patients, Cb improves the favorable outcome with RCB 0/1, but not EFS. The results suggest that different complex DNA based biomarkers predict response in hormone receptor positive

and triple negative breast cancer: HRD should be further investigated as a predictive marker for Cb benefit in hormone receptor positive patients, while genomic fraction of LOH may be an important marker for treatment selection in triple negative breast cancer patients.
Clinical trial identification: EudraCT number: 2013 – 004418 – 17 / ClinicalTrials.gov ID NCT02546232

P2-01-27: Utility of Plasma Circulating DNA Tumor Fraction in Bone-Only Metastatic Breast Cancer: A Real-world Outcomes Study

Deloris Veney, Julia C. F. Quintanilha, Gilbert Bader, Mia Levy, Lincoln W Pasquina, Daniel G. Stover

Introduction: Among the >168,000 women living with metastatic breast cancer (MBC) in the U.S., bone metastases (mets) are common, developing in 50-70% of MBC patients (pts). Notably, approximately one-third of MBC pts develop bone mets without other visceral (V) mets, termed 'bone-only' (BO) MBC. Standard imaging is insufficient to reliably detect and track BO progression, resulting in many BO pts being excluded from clinical trials, and leaving providers lacking valuable knowledge to inform treatment decisions. Evidence suggests that the tumor-derived fraction of circulating DNA (TF) is highly prognostic in MBC. This study aimed to (1) evaluate differences in TF distribution between pts with BO and V MBC; (2) investigate the prognostic value of TF near the time of start of therapy; and (3) determine baseline lab and clinical factors associated with TF.

Methods: This study included MBC pts who underwent Foundation Medicine liquid comprehensive genomic profiling, with samples collected up to 60-days prior to start of therapy. Pts clinical data was obtained by the U.S.-wide de-identified Flatiron Health and Foundation Medicine real-world clinicogenomic breast database (CGDB), from ~280 U.S. cancer clinics (~800 sites of care) between 01/2011 and 12/2023. Real-world overall survival (rwOS) was compared between TF group (<1% vs. 1-10% vs. >10%) and stratified by BO and V (with or without bone) MBC. Multivariable analyses were adjusted for baseline lab and clinical factors, including age, ECOG score, race/ethnicity, hormone receptor statuses, histology, line of therapy, practice type, stage at diagnosis, adjuvant therapy, menopausal status, number of mets, albumin, alkaline phosphatase (ALK), serum creatinine, hemoglobin, lactate dehydrogenase (LDH), and neutrophil-to-lymphocyte ratio. The association between TF and baselined lab and clinical features was performed by linear regression.

Results: A total of 778 pts were included in the study (155 BO and 622 V MBC, 1 missing mets data). Of these, 299 had TF <1% (TF-low), 175 had TF 1-10% (TF-intermediate [int]) and 304 had TF>10% (TF-high). Prior to 1st line of therapy, there was no significant difference in proportion of pts with detectable ctDNA; comparing BO MBC pts to V MBC pts

(n=256, BO 39% TF-low, 18% TF-int, 43% TF-high; and V 38% TF-low, 18% TF-int, and 44% TF-high; p=1.0), a similar distribution was seen among all evaluable samples. Among patients with BO MBC, TF was prognostic: BO MBC pts with TF-low demonstrated improved rwOS relative to TF-int (median not reached vs. 31.1 months, hazard ratio (HR) 2.19, 95% confidence interval (CI) 1.1-4.35) and TF-high (median 23.5 months, HR 2.07, 95% CI 1.12-3.82; log-rank p=0.027). Multivariable analyses confirmed the independent and additive association of TF and less favorable rwOS, including BO vs. V status. In multivariable analyses evaluating clinicopathologic factors associated with TF, V mets were not associated with higher ctDNA TF and, conversely BO MBC was not significantly associated with TF values (p=0.106). Higher TF was independently associated with ECOG PS 1+ (p=0.023), 2+ sites of mets (p<0.001), albumin (p=0.043), ALK (p<0.001), and LDH (p=0.002); lower TF was independently associated with estrogen receptor status positive (p=0.017).

Conclusions: BO MBC Pts are as likely to have detectable circulating tumor DNA as MBC Pts with V mets, – particularly prior to 1st line of therapy when ctDNA levels would be expected to be lowest and in multivariate modeling controlling for clinicopathologic factors. There are no associations between V vs. BO mets and TF groups, and BO Pts with TF <1% have significantly better prognoses than those with TF ranging from 1-10% or >10%. TF is a useful biomarker in BO prognosis offering the same utility in BO as it does in V MBC.

P2-01-28: Expression of Antibody-Drug Conjugate targets in tumor and normal tissue from patients with metastatic breast cancer

Kristien Borremans, Anirudh Pabba, Gitte Zels, Amena Mahdami, Camille Carette, Marion Maetens, Karen Van Baelen, Josephine Van Cauwenberge, Ha Linh Nguyen, Hava Izci, Bram Boeckx, Evy Vanderheyden, Thomas Van Brussel, Patrick Neven, Hans Wildiers, Françoise Derouane, Wouter Van Den Bogaert, Elia Biganzoli, Diether Lambrechts, Giuseppe Floris, François Richard, Christine Desmedt

Background. The ideal Antibody-Drug Conjugate (ADC) target should have a high specificity for an antigen expressed in tumors, with low heterogeneity between tumor sites, and a low expression in normal tissue to avoid on-target toxicity. 72 targets for ADCs are currently being clinically studied in solid tumors with 2 targets (HER2, TROP2) already having an approved indication for metastatic breast cancer (mBC). Here, we investigated the mRNA expression levels of all 72 targets in 910 tumor and normal tissue samples from 30 patients enrolled in our rapid autopsy program UPTIDER (NCT04531696).
Methods. 910 samples (58 primary untreated (P), 753 metastatic (M), 99 normal (N)) from 30 UPTIDER patients underwent bulk mRNA sequencing with data available to study gene expression of 72 targets. 23 patients had HR+/HER2-, 6 triple-negative (TNBC), and 1 HER2 amplified primary BC. 18 patients had invasive breast cancer of no special type (NST), 7 invasive lobular carcinoma (ILC) and 5 mixed (3 NST/ILC, 1 NST/metaplastic, 1 both NST and ILC). Normal samples were selected based on the absence of oncological and non-oncological organ disease and on representation across available organs and patients. M

and N samples from 33 different organ sites were considered for the analysis. Normalized gene expression was reported as a continuous parameter. Weighted Spearman correlation on median gene expression was used to identify co-expressed/mutually exclusive targets. Associations between gene expression and independent co-variate (sample status: M vs P) were assessed by linear mixed quantile regression with random effect on patient ID to correct for inter-and intra-patient heterogeneity. No formal association test was performed between M and N.
Results. The 5 targets with the highest median expression in M are: FN1, MUC1, LAMP1, HER3 and SLC39A6 (median range: 8.46-10.34). TROP2 and HER2 had the 9th and 27th highest expression (median: 7.73 and 4.99). The 5 targets with the highest median expression in N are: FGFR2, SLC39A6, FN1, ALCAM and MUC1 (range: 9.43 and 10.45). TROP2 and HER2 had the 21st and 36th highest expression (median: 5.70 and 4.46). 15 targets had relatively consistent low expression across all normal tissues, which did not include the 5 highest expressed targets in M. Moderate levels of HER2 expression were found across several normal tissues, including bone marrow, heart and kidneys, but not in the lung. For TROP2, higher expression was seen in normal bladder, kidney, lung, pancreas and peritoneum, but not in bone marrow. Intra-patient inter-M heterogeneity, assessed by interquartile range (IQR), was high for MUC1, FN1 and VTCN1 (median IQR: 1.38–1.65) but relatively low for HER2 and HER3. Reduced and higher expression in M vs P was reported for 11 and 4 targets. Almost no differential expression was seen between HR+/HER2- vs TNBC, ILC vs NST and ER+ vs ER- metastases. A strong positive correlation (R>0.6) in M samples was observed for 20 pairs, including HER3-CEACAM5, and a strong negative correlation (R<-0.6) was observed for 6 pairs, including HER2-GPNMB. Organ specific expression was observed for a few targets in bones, brain, lung, muscle, pleura and subcutaneous M but not for M in breast contralateral, liver, lymph nodes, peritoneum and spleen. In N, CA9 was strongly expressed in bladder, CFC1B in bone marrow, DLL3 and ST8SIA1 in brain, CEACAM6 and CLDN18 in lung, DPEP3 in thoracic lymph nodes, CLDN6 in pancreas and CDH6 in peritoneum. No association was observed for age at death, post-mortem interval and changes in target expression in both M and N samples.
Conclusions. Our study brings novel data on the mRNA expression of ADC targets in M and N samples in mBC, both for targets with approved clinical indication (HER2 and TROP2) as for those being clinically investigated.

P2-01-29: Prognostic value of circulating tumor DNA in metastatic breast cancer

Luc Cabel, Emanuela Ferraro, Enrico Moiso, Randy Yeh, Julia Ah-Reum An, Mehnaj Ahmed, Yuan Chen, David Solit, Michael Berger, Mark Robson, Steven Maron, Dara Ross, Sarat Chandarlapaty, Pedram Razavi

Introduction: Circulating tumor DNA (ctDNA) is widely used in the management of metastatic breast cancer (MBC) for tumor genotyping and detection of actionable alterations. Whether detectable ctDNA and its levels are associated with worse prognosis

has not been well established yet in MBC. Available data are limited by small sample sizes and/or suboptimal ctDNA assays. In this study, we aim to evaluate the prognostic value of ctDNA detection in a large cohort of patients (pts) with MBC.
Methods: We integrated clinical and ctDNA sequencing data from MBC pts treated at our institution (MSK) who underwent at least one ctDNA assessment using MSK-ACCESS, a 129-cancer-related gene assay. The assay demonstrated high sensitivity and specificity to detect tumor-derived variants as it utilizes matched WBC sequencing to filter out biological noise originating from clonal hematopoiesis or germline variants. We selected the first ctDNA assessment performed in the metastatic disease course. ctDNA level was defined as the highest variant allele frequency (maxVAF) of the detected tumor-derived variants. In case of no detectable ctDNA mutation, ctDNA level was considered as zero. Association between ctDNA detection and its levels with overall survival (OS) was assessed using uni- and multivariate left-truncation corrected Cox proportional hazard models.
Results: Overall, 766 pts with at least one MSK-ACCESS between 8/2019 and 4/2024 were identified. Of those, 685 pts with complete clinical information were included in the analysis: 72% HR+/HER2-, 15% TNBC, and 13% HER2+. At the data lock, 42% of the pts had died. MSK-ACCESS was performed at or after the metastatic disease diagnosis with a median interval of 15 months (IQR: 1.4-46, 33% within 3 months). ctDNA was detectable in 73% of pts (at least one tumor-derived mutation), with a median maxVAF of 2.4% in ctDNA+ pts (IQR: 0.63-12.7%) and 34% of pts having >2 mutations. Median ctDNA levels were strongly associated with the number of metastatic sites (2.9% for ≥3 sites, 1.6% for 2, 0.7% for 1; p=0.00047), and presence of liver metastases (1.5% vs 0.76%; p=0.0013). ctDNA levels were lower in ctDNA+ pts with HR+/HER2- as compared to TNBC or HER2+ (median 1.9%, 4.2% and 4.6%, respectively, p=0.031). Detection of ctDNA was a strong prognostic factor for OS with a univariate HR of 3.9 (95% CI: 2.7-5.8) and multivariate HR of 3.7 (95% CI: 2.5-5.4). ctDNA levels were also strongly prognostic: ref: not detected, <1%: HR=2.2 (95% CI: 1.4-3.5), 1-10%: HR=3.9 (95% CI: 2.6-5.9), >10%: HR=7.3 (95% CI: 4.8-11.0), p for trend <2e-16. The number of mutations detected was associated with OS; HR=2.8 (95% CI: 1.9-4.2) for 1-2 mutations and HR=5.8 (95% CI: 3.9-8.6) for > 2 mutations, compared to none. In the analysis by receptor subtype, ctDNA levels were prognostic for both HR+/HER2- (p<2e-16) and TNBC (p=0.00045) but not for HER2+ (p=0.32). ctDNA level remained an independent prognostic factor for OS in a multivariable analysis adjusted for visceral metastasis, number of metastatic sites (at the time of metastatic relapse) and receptor subtype (HR=6.7, 95% CI: 4.4-10.2 for maxVAF >10% vs 0). Similar results were obtained using median, mean, and geometric mean VAF to estimate ctDNA levels. When restricting the analysis to HR+/HER2- MBC pts with a ctDNA collected within 3 months from metastatic diagnosis (n=152), ctDNA levels remained an independent prognostic factor for OS after adjusting for presence of visceral metastasis and number of metastatic sites (HR=4.5 95% CI: 1.6-13 for maxVAF >10% vs 0).
Conclusion: In this large cohort of MBC pts, ctDNA detection and levels emerged as strong prognostic indicators for OS, independently from disease burden. Our data suggest that ctDNA levels can provide valuable insight into tumor biology as well as disease burden and may be utilized for early prognostication in MBC.

P2-01-30: Gene Expression patterns in early ER+/HER2- breast cancer treated with neoadjuvant chemotherapy versus CDK4/6 inhibitor therapy: results from the Swedish PREDIX Luminal B trial

Evangelos Tzoras, Michail Sarafidis, Emmanouil G. Sifakis, Dimitrios Salgkamis, Balazs Acs, Wenwen Sun, Ioannis Zerdes, Kang Wang, Jonas Bergh, Thomas Hatschek, Alexios Matikas, Theodoros Foukakis

Introduction: CDK4/6 inhibitors are approved in ER+/HER2- breast cancer at the adjuvant and metastatic settings, however their role as neoadjuvant therapy is still under investigation. The aim of this study was to identify gene expression-based predictive biomarkers for response to the combination of a CDK4/6 inhibitor and endocrine therapy versus chemotherapy in clinically defined high-risk, early luminal breast cancer.
Methods: The PREDIX Luminal B clinical trial (NCT02603679) enrolled ER+/HER2- breast cancer patients with tumor size at least 20mm and/or positive nodal status. Patients were randomized 1:1 to receive preoperatively either weekly paclitaxel for 12 weeks followed by palbociclib and endocrine therapy for 12 weeks (Arm A), or the reverse sequence (Arm B). The primary outcome was the objective radiologic response at 12 weeks (ORR12) while pathologic response to treatment was a secondary outcome. Core needle biopsies were obtained at baseline, after 12 weeks of treatment and at the time of surgery. Total RNA-sequencing was performed using bulk RNA extracted from fresh frozen biopsies from all timepoints. RNA libraries were constructed using the Illumina Stranded Total RNA library prep kit with Ribo-Zero Plus and sequencing was carried out on the Illumina NovaSeq X Plus System. The raw RNA-sequencing data were subjected to pre-processing and quantification using the nf-core/rnaseq bioinformatics pipeline (version 3.3). Differential expression analysis was performed, followed by gene set enrichment analysis (GSEA) using the Hallmark gene sets sourced from the MSigDB database. Finally, single-sample predictor (SSP) models were employed for both classifying patients into one of the five PAM50 subtypes (SSP-PAM50) and estimating the risk of recurrence (ROR) score (SSP-ROR).
Results: The study enrolled a total of 181 patients, with 179 forming the intention-to-treat population (39% premenopausal, 66% node positive). After quality control, 170 patients had evaluable RNA-sequencing data at baseline and 133 of those had matched data for week 12. Residual Cancer Burden (RCB) status was available for 132 patients, with 16 of them having RCB 0/1. In patients treated with palbociclib and endocrine therapy, the ORR12 was higher for the Luminal B intrinsic subtype compared to other subtypes (Odds Ratio (OR)= 2.81, 95% CI 1.03-8.08, p = 0.04) at baseline, but not in patients treated with paclitaxel (OR = 1.50, 95% CI 0.52-4.45, p = 0.43). ROR did not differ between responders and non-responders in either arm (p=0.76 in arm A, p=0.15 in arm B). GSEA showed that responders in chemotherapy arm had tumors with upregulation of immune-related genes and downregulation of the ER-pathway (adjusted $p < 0.05$) at baseline. In contrast, responders in arm B were characterized by upregulation of cell cycle related genes, MYC and E2F program (adjusted $p < 0.05$), and this was confirmed by interaction analysis for ORR12 and arm B for the reference arm A. Patients achieving RCB 0/1 were enriched for immune related pathways at baseline (adjusted $p < 0.05$). Longitudinal analysis between baseline

and week 12 for the Luminal B group revealed a change of intrinsic subtype under treatment and the direction of the change was similar in both arms, with most (93.4%) converting to either Luminal A or Normal-like.
Conclusion: Objective response of ER+/HER2- breast cancer to neoadjuvant palbociclib/endocrine therapy or paclitaxel is governed by different biologic processes. Further translational studies are ongoing to identify predictors of response and the best sequence of treatments.

P2-02-01: Enhancing chemotherapy sensitivity in triple-negative breast cancer through knockdown of the 'Dark' druggable gene SCYL3

Hannah Engebretson, Steven W. Wall, Audra Lane, Sara Savage, Bing Zhang, Gloria V. Echeverria

Triple Negative Breast Cancer (TNBC) is an aggressive subtype of breast cancer with limited targeted therapy options for patients lacking deleterious BRCA1/2 mutations. TNBC has a five-year survival rate of less than 11% once the disease has metastasized which is alarming given that 45% of patients have residual disease after undergoing neoadjuvant chemotherapy (NACT). Therefore, it is crucial to identify therapeutic regimens that increase chemotherapy sensitivity. We previously demonstrated that mitochondrial oxidative phosphorylation (OXPHOS) is elevated in TNBC cells that survive NACT after administration of DNA damaging chemotherapeutics (e.g. doxorubicin [DXR] and carboplatin [CRB]) but not taxane treatments (e.g. docetaxel [DTX] and paclitaxel [PTX]) (PMIDs 30996079 and 36813854). Other groups have provided evidence that induction of mitophagy, a process whereby damaged mitochondria are degraded, can improve taxane sensitivity in TNBC. Thus, identifying mechanisms regulating OXPHOS and mitophagy could lead us to promising therapeutic targets to overcome chemoresistance in TNBC. In 2014, the NIH launched the "Illuminating the Druggable Genome (IDG)" project that identified approximately 4,000 genes with therapeutic potential based on classification of a G-protein coupled receptor, kinase, nuclear receptor, or ion channel domain. Cross-referencing this list across public and proprietary databases to subclassify them based on current knowledge revealed 328 "dark" genes with unknown functions (PMID: 29472638). We determined co-expression of each dark gene in the BRCA proteomics data from the Clinical Proteomic Tumor Analysis Consortium (PMID: 37582339). We then used gene set enrichment analysis to identify positive enrichment of OXPHOS-related metabolic pathways from WikiPathways. Genes co-expressed with Saccharomyces cerevisiae yeast 1 (SCY1) Like Pseudokinase 3 (SCYL3) were enriched for in the electron transport chain and OXPHOS pathways. SCYL3 was previously shown to negatively regulate mitophagy in hepatocellular carcinoma (HCC) (PMID: 36440258). Based on our prior work demonstrating the crucial role of OXPHOS in TNBC and the potential mechanism and relationship between mitophagy and taxane sensitivity, we sought to ascertain the role of SCYL3 in TNBC cell survival, chemotherapeutic resistance, metabolic rewiring, and mitophagy. Transient siRNA-mediated knockdown of SCYL3 in human TNBC cell lines MDA-MB-468 and SUM159 caused no defect in cell survival as

evidenced by cell counting assays. To ascertain the role of SCYL3 in chemotherapeutic resistance, we treated TNBC cells with IC50 doses of conventional chemotherapies and monitored cell numbers following SCYL3 knockdown. Our data provide evidence in the aforementioned cell lines that SCYL3 knockdown increased sensitivity to taxanes but not DNA-damaging agents. Our preliminary findings also indicate that knockdown of SCYL3 in cultured human TNBC cells leads to decreased levels of the negative regulator of mitophagy, Presenilin-associated rhomboid-like (PARL) protein. These findings suggest inhibition of SCYL3 improves taxane sensitivity in TNBC cells, potentially through activation of mitophagy. Continued experimentation will focus on direct measurement of mitophagy rates and functional studies to ascertain the potential role of SCYL3 in mitochondrial phenotypes and chemoresistance.

P2-02-02: CHEMOTHERAPEUTIC TOPOISOMERASE 2 POISONS GENERATE TREX1 RESISTANT DNA FRAGMENTS THAT INDUCE A POTENT cGAS/STING RESPONSE

Kienan Savage, Eliana M. Barros, Richard D.A. Wilkinson, Guido Zagnoli-Viera, Stuart A. McIntosh, Katrina M. Lappin, Oliver Barker, Ieuan L. Morgan, Eileen E. Parkes, Marc A. Fuchs, Nuala McCabe, Roger A. Greenberg, Tim Harrison, Keith W. Caldecott, Richard D. Kennedy

Tumours with genomic instability display enhanced immunogenicity and potential for response to immune checkpoint blockade (ICB). Interestingly, chemotherapy mediated DNA damage can also stimulate the immune system through activation of the cGAS/STING innate immune pathway and therefore, improve clinical outcomes in combination with ICB. Here we set out to compare the ability of classically used chemotherapies to activate innate immunity, as well as characterise the mechanism(s) behind it. We identified topoisomerase 2 (TOP2) poisons, such as anthracyclines, as the most effective activators of cGAS/STING, leading to a potent type I interferon response. Mechanistically, we demonstrate that abortive TOP2cc repair intermediates (dsDNA fragments containing 5'-phosphotyrosyl residues) get encapsulated within micronuclei and activate cGAS, which can be blocked with antimitotic agents (e.g. taxanes). Crucially, we discovered that these 5'-phosphotyrosyl linked fragments are resistant to nuclease degradation by the cytoplasmic nuclease TREX1, which stabilises them, resulting in robust cGAS/STING mediated inflammation. Finally, using in vivo modelling, we confirmed that Top2 poisons enhance anti-tumour responses to ICB in comparison to taxanes. In line with this, using pre and on-treatment breast tumour biopsies, we have shown that anthracycline-based chemotherapy induces a robust type I interferon response in breast tumours, driving tumour lymphocytic infiltration. Moreover, following anthracycline treatment with taxane treatment results in supression of lymphocytic infiltration in these same tumours. Collectively, our findings reveal that TOP2 poison mediated DNA lesions enhance cGAS substrate availability by impairing cytoplasmic dsDNA degradation, highlighting their ability to drive anti-tumour immune responses and enhance the therapeutic efficacy of ICB.

P2-02-03: The RAR gamma nuclear receptor agonist IRX5010 has combination inhibitory effects with an anti-PDL-1 checkpoint inhibitor on the growth of EMT-6 triple negative breast cancer

Martin Sanders, Vidyasagar Vuligonda

Research Objectives and Rationale: We previously presented (2023 SABCS) that monotherapy with the RAR gamma agonist IRX5010 inhibits tumor growth in the triple negative breast cancer EMT-6 syngeneic mouse model; and in a human Her2+ JIMT-1 breast cancer xenograft mouse model. Growth inhibitory effects of IRX5010 in both models were accompanied by increased tumor infiltrating effector memory T-cells. We presented (2024 FASEB Retinoids Conference), effects of monotherapy with IRX5010 on inhibition of tumor growth accompanied by development of tumor infiltrating effector memory T-cells in mouse models of lung, (Lewis Lung Cancer); colorectal (MC38) and prostate cancers (MyC-CaP). We observed in these studies inhibition of tumor infiltration by myeloid derived suppressor cells, suggesting that combination treatment with IRX5010 and checkpoint inhibitors could increase inhibition of tumor growth. We now present data on IRX5010 treatments with anti-PD-1 or anti-PDL-1 monoclonal antibody checkpoint inhibitors in an EMT-6 triple negative breast cancer model.
Experimental Methods: EMT-6 cells were injected into Balb/c mice and allowed to grow to 50-150 mm3. Then treatments were started and maintained until tumors grew to 1500 mm3. Treatment was administered as daily oral doses of IRX5010 at 10 mg/kg/day, or vehicle. Murine monoclonal anti-PD-1 or anti-PDL-1 antibodies were injected ip every three days at 10 mg/kg. Tumor sizes were assessed by calipers every three days. Toxicity assessment was done by weighing the mice every three days. Flow cytometry of harvested tumors for tumor infiltrating T-cell subtypes, and myeloid derived suppressor cells was done at study end.
Results: Monotherapy with either IRX5010 or murine anti-PDL-1 monoclonal antibody had substantial inhibitory effects relative to vehicle on tumor growth in the syngeneic EMT-6 triple negative breast cancer model; -61% for IRX5010, and -75% for murine anti-PDL-1. Monotherapy with murine anti-PD-1 had modest inhibitory effect on tumor growth, -14%. Combination treatment with IRX5010 plus murine anti-PDL-1 had an additive effect resulting in 84% inhibition of tumor growth relative to vehicle, a 9% additional inhibition of tumor growth compared to monotherapy with anti-PDL-1 alone. Combination treatment with IRX5010 plus murine anti-PD-1 had a modest additive effect, resulting in -65% inhibition of tumor growth relative to vehicle, a 4% additional inhibition of tumor growth compared to monotherapy with IRX5010. Flow cytometry for T-cells subsets and myeloid derived suppressor cells was performed. These results are pending at the time of submission of this abstract. The data will be presented at the symposium.
Conclusions: Treatment of the EMT-6 murine model of triple negative breast cancer with the RAR gamma selective agonist compound IRX5010 plus the checkpoint inhibitor monoclonal murine anti-PDL-1 resulted in 84% inhibition of tumor growth, a 9% increase of inhibitory treatment effect over anti-PDL-1 alone. Combination treatment with IRX5010 with monoclonal anti-PD-1 had only modest additive effects on inhibition of EMT-6 tumor

growth. All treatment regimens were well tolerated as assessed by change in weight. These findings are the first demonstration of additive effects of combination treatment with an RAR gamma nuclear receptor agonist and an anti-PDL-1 monoclonal antibody checkpoint inhibitor in a triple negative breast cancer mouse model. They support future translation of combination treatment with IRX5010 plus an anti-PDL-1 monoclonal antibody checkpoint inhibitor into clinical trials in triple negative breast cancer patients.

P2-02-04: Investigating Semaphorin7a in Mammary Gland Involution and Postpartum Breast Tumorigenesis

Lauren Cozzens, Traci R Lyons

Women with postpartum breast cancer (PPBC), breast cancer diagnosed within 10 years post-childbirth, have an increased risk of metastasis and death compared to nulliparous women or women diagnosed during pregnancy. Unfortunately, what causes this increased risk is not well understood. Studies have shown that postpartum involution (INV), the process by which the lactating mammary gland re-models to a morphologically near prepregnant state, is a driving force of tumor progression. Our lab has identified Semaphorin 7a (SEMA7A), a signaling molecule, as upregulated in the mammary gland during INV and in PPBC tumors compared to nulliparous mammary glands or tumors, respectively. SEMA7A promotes both mammary epithelial cell (MEC) survival during INV, and tumor cell survival in models of PPBC. Studies have found that constitutive Sema7a knock-out (KO) mice exhibit a decrease in the proportion of mammary progenitor cells (MPCs) during INV as compared to wild-type (WT) mice. Notably, MPCs have been identified as the cells of origin for many breast cancer tumors. SEMA7A has also been shown to promote progenitor-like phenotypes in vitro in both normal MECs and breast tumor cells. Despite these findings, the mechanism by which SEMA7A promotes progenitor cell phenotypes during INV and how these phenotypes may contribute to PPBC tumorigenesis has yet to be explored. Therefore, we hypothesize that SEMA7A promotes progenitor-like and pro-survival phenotypes in MPCs during involution to contribute to PPBC tumor initiation. To model differentiation during lactation, and cell death programs during INV, we have utilized and characterized in vitro cell models of lactation and INV. Preliminary studies have shown that SEMA7A upregulates expression of the transcription factor SRY-box 2 (SOX2) in both normal MECs during INV and in breast cancer cells. Interestingly, SOX2 has been shown to maintain luminal progenitor cells and breast cancer stem cells and thus may mediate SEMA7A's promotion of progenitor cell phenotypes. SEMA7A is known to signal through integrins to mediate its downstream effects and preliminary work has suggested SEMA7A may facilitate upregulation of SOX2 through MAPK signaling. To test the impact of SEMA7A on SOX2 transcriptional activity during INV, we have begun to utilize a SOX2 reporter vector developed in the laboratory of Dr Lalage Wakefield. To model the impact of SEMA7A on PPBC tumorigenesis in vivo, we have also combined the whey acidic protein-transforming growth factor alpha (WAP-TGF) mouse model with our SEMA7A KO mice. The

goal of these studies is to inform improved prevention and treatment strategies for patients with PPBC.

P2-02-05: Mechanism of action of gedatolisib in combination with fulvestrant and/or palbociclib in estrogen receptor positive breast cancer models

Stefano Rossetti, Aaron Broege, Megan Seibel, Jhomary Molden, Igor Gorbatchevsky, Brian Sullivan, Lance Laing

Background: Therapies targeting PI3K, AKT, and mTOR (PAM) in combination with fulvestrant are approved to treat patients with HR+/HER2- advanced breast cancer. Due to the crosstalk between the PI3K/AKT/mTOR (PAM) pathway and the Estrogen Receptor (ER) and CDK pathways, resistance can arise through compensatory mechanisms when only one of these pathways is inhibited. In a phase 1b clinical trial in patients with HR+/HER2- advanced breast cancer, the combination of gedatolisib, a pan-PI3K/mTOR inhibitor, with endocrine therapy and palbociclib showed promising efficacy and safety compared with the published results for standard-of-care therapies. A Phase 3 trial (VIKTORIA-1) evaluating gedatolisib plus fulvestrant with and without palbociclib is underway in patients with advanced breast cancer. In the present study, we used multiple ER+ breast cancer cell lines to investigate the mechanism of action of gedatolisib and single node PAM inhibitors in combination with fulvestrant and/or palbociclib.
Methods: A panel of breast cancer cell lines with mutated or non-mutated PAM pathway genes (e.g. PIK3CA, PTEN) were evaluated for their responses to gedatolisib and single node PAM inhibitors (PI3K, AKT, mTORC1) alone or in combination with fulvestrant and/or palbociclib. Cell viability, growth rate, and cell death were evaluated by luciferase/fluorescence-based assays. Cell cycle and DNA replication were assessed by EdU incorporation and flow cytometry. ER activity was assessed by analysis of ER-target genes, while CDK pathway activity was assessed by analysis of phospho-RB and E2F-target genes. Breast cancer xenograft studies evaluating gedatolisib plus fulvestrant and/or palbociclib in vivo were also performed.
Results: Gedatolisib significantly reduced cell viability and growth rate in all cell lines tested, and the addition of fulvestrant and/or palbociclib significantly increased its growth-inhibitory effects. Mechanistically, the gedatolisib/palbociclib/fulvestrant triplet demonstrated greater inhibition of DNA replication and counteracted adaptive responses associated with single drug treatment, such as induction of ER activity by gedatolisib and reactivation of CDK signaling after palbociclib treatment. Previously, the in vivo efficacy of the gedatolisib/palbociclib/fulvestrant triplet was confirmed in a breast cancer xenograft model. In comparative studies, gedatolisib plus fulvestrant/palbociclib induced greater growth-inhibition relative to single-node PAM inhibitors plus fulvestrant/palbociclib.
Conclusions: The combination of gedatolisib, fulvestrant, and palbociclib exerted greater growth-inhibitory effects than each drug alone and showed superior efficacy relative to single node PAM inhibitors combined with fulvestrant and palbociclib. This study provides

a strong mechanistic rationale for combining gedatolisib, fulvestrant, and palbociclib for the treatment of advanced breast cancer.

P2-02-06: Molecular heterogeneity in adjacent normal tissue among Chinese breast cancer patients

Hela Koka, Bin Zhu, Priscilla Lee, Kevin Wang, Avraam Tapinos, Difei Wang, Gary M. Tse, Koon-ho Tsang, Cherry Wu, Chad A. Highfill, Kristine Jones, Belynda Hicks, Amy Hutchinson, Montserrat Garcia-Closas, Stephen Chanock, David C. Wedge, Lap Ah Tse, Xiaohong R. Yang

Background: Breast cancer (BC) stands as a prominent contributor to cancer-related fatalities on a global scale. Traditionally, the primary focus in assessing recurrence risk and guiding treatment decisions has revolved around scrutinizing the primary tumor's histopathological characteristics and molecular compositions. However, recent findings suggest that exploring normal tissue adjacent to the tumor (NAT) could unveil valuable insights into the intricate characteristics of BC advancement and patient prognoses. Specifically, in our recent work, we discovered three phylogenetic tree groups of NAT and tumor tissues that were associated with distinct tumor and tumor microenvironment (TME) features using the whole genome sequencing data collected from 43 Hong Kong BC patients (Zhu et al. under review). Here, we aimed to further characterize the molecular heterogeneity of NAT by integrating methylation and gene expression profiling data in an expanded sample set, which may deepen our understanding of tumor evolution.
Methods: Genome-wide DNA was extracted from fresh frozen paired tumor/NAT tissues in 188 patients diagnosed with breast cancer and treated in Hong Kong, China. DNA was then profiled using the Infinium Methylation 850K BeadChip array. Horvath clock was utilized to estimate epigenetic age, and MethylCIBERSORT was used to estimate cellular composition using the methylation data. For a subset of the patients (N= 76), we also analyzed RNA sequencing (RNA-Seq) data and used CIBERSORTx to estimate the proportions of immune cell subpopulations in NAT samples. Risk factor and clinical information was available for most patients.
Results: The uniform manifold approximation and projection (UMAP) identified two distinct clusters of NAT samples (cluster 1, N= 139; cluster 2, N= 49) based on the top 10K most variable methylation probes. The two clusters were recapitulated by unsupervised clustering. The two sets of patients did not differ by chronological age at diagnosis, but when investigating epigenetic aging - as captured by Horvath clock – we found that cluster 2 displayed a lower age acceleration in NAT compared to cluster 1. Among the subset of patients with phylogenetic trees constructed in our previous work, we observed cluster 1 had a higher frequency of patients (64.3%) that showed distinct evolutionary trajectories in matched NAT and tumor samples (multiple-tree group) compared to cluster 2 (33.3%). Consistent with previous findings, we found that cluster 1, enriched with multiple-tree NAT samples, was associated with lower proportions of CD14 cell population (P=1.6x10-6), monocytes (P=7.1x10-6), and M2 macrophages (P=2.3x10-7) compared to cluster 2. Interestingly, genomic features in the matched tumors such as PAM50 subtype, TP53

mutation status, or tumor mutational burden, did not vary significantly between clusters 1 and 2. Lastly, established BC risk factors examined in this study did not show significant differences by this methylation-based cluster assignment.
Conclusion: Using methylation data in an expanded dataset, we extended our previous analysis of paired tumor and NAT samples to characterize breast cancer field effect. Our main findings illuminate the diverse nature of the microenvironment surrounding the tumor and its potential influence on the genomic evolutionary path of the tumor.

P2-02-07: Different effects of gedatolisib versus single-node PI3K/AKT/mTOR pathway inhibitors on breast cancer cell metabolic functions

Stefano Rossetti, Aaron Broege, Jhomary Molden, Ross Kopher, Stephen Schulz, Ky McCracken, Igor Gorbatchevsky, Brian Sullivan, Lance Laing

Background: Currently approved treatment options for patients with HR+/HER2- advanced breast cancer include single-node PI3K/AKT/mTOR (PAM) inhibitors, such as everolimus (mTORC1), capivasertib (AKT), and alpelisib (PI3Kα), in combination with hormonal therapy. In a previous study, we found that comprehensive inhibition of multiple PAM pathway nodes by gedatolisib, a pan-PI3K/mTORC1/mTORC2 inhibitor, exerted greater growth inhibitory effect than single-node PAM inhibitors in breast cancer models, both in vitro and in vivo. Since increased activation of the PAM pathway plays a critical role in driving metabolic adaptations (e.g. increased glycolysis) required by cancer cells to sustain biomass production and proliferation, we hypothesize that gedatolisib exerts a greater effect on key metabolic functions in cancer cells relative to single-node PAM inhibitors.
Methods: A panel of breast cancer cell lines with mutated or non-mutated PAM pathway genes (e.g., PIK3CA, PTEN) were evaluated for their responses to gedatolisib versus single node PAM inhibitors (alpelisib, capivasertib, everolimus). Several metabolic functions were evaluated, including glucose consumption, lactate production (Biosen analysis), and real time oxygen consumption rate (OCR, Resipher analysis). Effects on PAM pathway activation, cell viability, and growth rate were evaluated in parallel by luciferase and flow cytometry assays.
Results: Gedatolisib strongly inhibited PAM pathway activity and reduced cell viability and growth rate in the cell lines tested. Consistent with these effects, significant inhibition of metabolic functions, such as glucose consumption, lactate production, and OCR was also found. Compared to the single-node PAM inhibitors, gedatolisib exhibited more potent and efficacious effects on these metabolic functions regardless of the cell lines' PI3K pathway mutational status. The metabolic changes induced by gedatolisib within the cancer cells also resulted in microenvironmental changes known to improve anti-tumor immune response, such as higher glucose levels, lower lactate levels, and increased oxygen concentration.
Conclusions: By targeting multiple PAM pathway nodes, gedatolisib, inhibited cancer cell metabolic functions more effectively relative to more narrowly targeted PAM inhibitors. A more comprehensive inhibition of PAM-controlled functions, including critical metabolic

functions required to sustain cancer cell proliferation, may explain the greater activity of gedatolisib relative to single node PAM inhibitors in breast cancer cells. Gedatolisib has previously demonstrated promising preliminary clinical efficacy and safety data in combination with hormonal therapy in advanced breast cancer. A Phase 3 study (VIKTORIA-1) evaluating gedatolisib plus fulvestrant with and without palbociclib is underway in patients with HR+/HER2- advanced breast cancer.

P2-02-08: Chromosome 8q gain-related transcription factor MYBL1 is a critical regulator in triple-negative breast cancer

Akihiro Fujimoto, Kazuhiro Ikeda, Keiichi Kinowaki, Hidetaka Kawabata, Akihiko Osaki, Satoshi Inoue, Kuniko Horie

Chromosome arm-level aneuploidies (CAAs) are a common consequence of genomic instability during the evolution of solid tumor and often associated with metastasis and therapy resistance. In breast cancer, chromosome arms 1q and 8q are the frequent amplified regions for CAAs. This study aims to investigate whether critical genes amplified in genomic regions with CAAs contribute to the pathophysiology in triple-negative breast cancer (TNBC). We established multiple long-term culturable TNBC patient-derived cells (PDCs) using spheroid culture technique, which is favorable for the enrichment of cell population with cancer stemness. We performed a genome-wide chromatin immunoprecipitation study for histone H3K27ac and super-enhancer analysis in these TNBC PDCs and cell lines. Super-enhancer analysis revealed that 8q is a substantial chromosomal region with a high density of super-enhancers. Among genes in the vicinity of 8q super-enhancers, we identified that MYB proto-oncogene like 1 (MYBL1) is a transcription factor with high abundance in TNBC PDCs as well as in basal-like BT549 cells. In TCGA breast cancer database, 8q gain is a common genomic feature in MYBL1 gene-amplified breast cancer tissues and MYBL1 expression is substantially correlated with 8q-related genes and proliferation-related genes like MKI67 and BUB1. In TNBC PDCs and cell lines, we showed that MYBL1-specific siRNAs significantly repressed TNBC cell proliferation and migration. RNA sequencing analysis in TNBC cells revealed that MYBL1 silencing substantially downregulated genes involved in the transcription machinery such as nuclear envelope, chromatin dynamics, and DNA replication. In immunohistochemical analysis of clinical TNBC tissues from a Japanese cohort, we showed that a positive MYBL1 immunoreactivity (IR) was significantly associated with shorter disease-free survival (DFS). Among candidate MYBL1 targets, we demonstrated that NCAPH, a subunit of condensin I complex, was a prognostic factor for patients with TNBC based on the immunohistochemistry of clinical TNBC tissues. Notably, patients with double IR positivity for MYBL1 and NCAPH showed shorter DFS than those with MYBL1 or NCAPH positivity alone. MYBL1 has been characterized as an essential transcriptional regulator in male meiosis and in female mammary gland development. Our findings indicate that MYBL1 plays an essential role in the pathophysiology for advanced breast cancers such as TNBC,

and MYBL1 and its downstream genes can be potential diagnostic and therapeutic targets for the disease.

P2-02-09: Novel Intramolecular BRCT Domain Interaction with ECT2 C-terminal Intramolecular Interaction Domain Regulates GEF Activity and Tumorigenesis

Jinyu Lu, Yong-Li Dong, Michelle Pirruccello, Hao Chang, Ming Wu, Thomas Ni, Jose Pastor-Pareja, Xiangyu Zheng, Deyou Zheng, Tian Xu

BRCT domain-containing proteins are a large family of regulators that control diverse biological processes through recruiting effector molecules. Regulation of BRCT effector recruitment is a key modulation step. ECT2 (Epithelial Cell Transforming sequence 2), a BRCT domain-containing Rho/Rac GEF and key regulator of cell division, is frequently upregulated in various human cancers, including breast cancer. Particularly, overexpression of ECT2 is strongly associated with poor prognosis and represents a putative independent prognostic factor for breast cancer.
Through an in vivo genetic screen for mutations driving tumor invasion and metastasis, we identified a group of special mutations in Pebble/ECT2. In this study, we report the discovery of a highly conserved, novel Intramolecular Interaction Domain (IID) in ECT2/Pebble (Pbl), which is frequently mutated in human cancers and contains conserved motifs shared by numerous BRCT domain-containing proteins. The binding of BRCT to RacGAP1 is promoted by intramolecular interaction of BRCT with IID, which is controlled by cell cycle-dependent phosphorylation of IID. Mutations in IID disrupt the intramolecular interaction and consequently prevent assembly of high-affinity Pbl/ECT2-RacGAP1 complexes, thereby causing abnormal Rac1 activation and tumor progression. Our study uncovers a novel intramolecular mechanism that governs the recruitment of BRCT domain effectors and provides potential target for developing novel therapeutic agents against breast cancers.

P2-02-10: Inhibition of the Kif11 mitotic protein kills TP53-mutant triple-negative breast cancer cells

Amanda Lanier, William Tahaney, Cassandra Moyer, Jamal Hill, Darrian Coleman, Banu Arun, Abhijit Mazumdar, Powel H Brown

Background: Triple-negative breast cancer (TNBC) has the poorest prognosis of the breast cancer subtypes, in part due to the lack of targeted therapy options. TNBCs lack the expression of targetable cell surface or nuclear receptors such as estrogen receptor (ER) or HER2 present in other breast cancers. Standard of care for TNBC patients includes surgery, radiation, and non-specific chemotherapy, and very few women with TNBC meet criteria to receive immunotherapy or PARP inhibitors. Thus, new targeted therapies are urgently needed for these aggressive cancers. Nearly all TNBCs harbor TP53 mutations, so our

laboratory has sought to identify molecular vulnerabilities of these TP53-mutant breast cancers. A drug screen identified that the Kif11 inhibitor SB-743921 preferentially killed TP53 mutant breast cancer cells (as compared to TP53-wild type cells). Kif11 is a motor protein critical for proper alignment of the mitotic spindle, and inhibition leads to mitotic defects and cell cycle arrest.
Hypothesis: We hypothesized that Kif11 inhibition causes TP53-mutant TNBC cells to undergo mitotic catastrophe leading to cell death.
Methods: Clinical Data: Data was accessed via cBioPortal or UCSD Xena Browser. Expression was compared between groups using Student's t-tests. For Kaplan-Meier curves, Kif11 expression was dichotomized at the median and survival curves were compared using the Log-Rank test. Cell Proliferation and Cell Death Assays: Cells were treated with SB-743921 or vehicle, stained with Hoechst 33342 and DRAQ7(2D) or Annexin V-FITC and PI (Flow), and imaged on the ImageXpress PICO or analyzed via flow cytometry. Immunofluorescence: Cells were treated with SB-743921 or vehicle, stained with anti-alpha tubulin-AlexaFluor488 and DAPI and imaged on the Nikon Ti2. Mouse xenograft experiments: Cells were injected into the mammary fat pads of nude mice. When tumors reached 50-100 mm3, mice were treated with the Kif11 inhibitor SB-743921 10mg/kg or vehicle i.p. 3 times weekly. Experiments were conducted under IACUC approval.
Results: The Kif11 mitotic kinesin is more highly expressed in TP53 mutant and TNBCs than in TP53 wild-type breast cancers, and high expression is associated with poorer survival. Kif11 inhibition leads to cell cycle arrest and growth suppression in both TP53-wild-type and TP53-mutant breast cancer cells. However, in TP53-mutant cells Kif11 inhibition causes mitotic dysfunction, formation of multinucleated giant cells, and caspase-dependent apoptotic cell death. Furthermore, knockout of TP53 in wild-type breast cancer cells sensitizes them to cell death following Kif11 inhibition. Kif11 inhibition also inhibits the growth of TP53-mutant TNBC xenografts in vivo.
Conclusions: In cells with TP53-mutation or loss, Kif11 inhibition results in mitotic dysfunction and cell death due to mitotic catastrophe, and Kif11 inhibitors suppress in vivo TP53-mutant TNBC growth. These results support further investigation of Kif11 inhibitors as a potential therapeutic in TP53 mutant TNBC.

This work was supported by the John Charles Cain Endowment, Pauline Altman Goldstein Discovery Research Award, and the NCATS of the NIH under Award Numbers TL1TR003169 and UL1TR003167. We also thank the MDACC NORTH Campus Flow Cytometry and Cellular Imaging Core Facility for their assistance.

P2-02-11: Unveiling the subtype-specific role of PTPRK in triple-negative breast cancer: Implications for targeted therapies

Xiangyi Liu, Wen G. Jiang, Lin Ye

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer characterised by the absence of estrogen receptor, progesterone receptor, and HER2 receptor, leading to limited treatment options and poor prognosis. Protein tyrosine phosphatase receptor type K (PTPRK) has been implicated in various cancer-related pathways, such as EGFR and BMPs, but its specific functions within TNBC subtypes remain poorly understood. Elucidating the subtype-specific roles of PTPRK in TNBC could provide crucial insights into its underlying mechanisms and identify potential therapeutic targets, paving the way for more effective and personalised treatment strategies for this challenging breast cancer subtype.
Methods: The transcript level of PTPRK was assessed in 11 breast cancer cell lines using PCR and qPCR. Additionally, its expression in subtype-specific breast tumour tissues from TCGA and in various breast cancer cell lines using Genearray data (E-MTAB-2770) was analysed. The overall survival analysis of PTPRK in different breast cancer subtypes was conducted using Kaplan-Meier test with TCGA RNA-Seq data. Relapse-free survival (RFS) and distant metastasis-free survival (DMFS) data for PTPRK across subtypes were obtained from the KM plotter website (https://kmplot.com/analysis/). Correlation analysis between PTPRK expression and TNM stages and its markers were performed using TCGA data. Lentiviral vectors were utilised to create PTPRK knockdown models in two TNBC cell lines, BT-549 and MDA-MB-468. Cellular function assays, including proliferation, adhesion, invasion, and migration, were conducted using these knockdown cell lines.
Results: PTPRK generally showed high expression in breast cancer cell lines, particularly in HER2+ and TNBC tumour samples from TCGA data, and in TNBC cell lines based on Genearray data. TCGA data revealed that higher PTPRK expression was correlated with longer overall survival in TNBC (P=0.049), while the opposite finding was observed in other subtypes. Similar trends were seen for RFS and DMFS, with high PTPRK expression associated with shorter survival in HER2+ subtypes (RFS: P=0.0058, DMFS: P=0.011) and longer survival in TNBC (RFS: P=0.031, DMFS: P=0.01). Advanced T stages (T3+T4) exhibited lower PTPRK expression compared to early T stages (T1+T2). No significant differences in PTPRK expression were observed with distant metastasis and lymph node status across all breast cancer subtypes. Positive correlations observed between PTPRK expression and CDK6 and KI67 were notably significant in the TNBC subtype. For cellular function assays with PTPRK knockdown models, significant changes were observed in adhesion and invasion tests in both BT-549 and MDA-MB-468 cell lines, with increased adhesive and invasive ability following PTPRK knockdown. Additionally, a significant increase in proliferation was observed in BT-549 PTPRK knockdown cells compared with the control cells, whilst this was not shown in MDA-MB-468 cell line.
Conclusion: PTPRK plays a subtype-specific role in TNBC, influencing survival of patients and cellular functions for cancer cells including adhesion, invasion, and proliferation. These findings highlight the potential of PTPRK as a therapeutic target in TNBC, warranting further investigation into its mechanistic pathways and therapeutic implications.

P2-02-12: Creating well-defined high-throughput breast cancer dormancy models with bioprinting for probing and targeting late recurrence

Lina Pradhan, Alex Wang, Rafael Castro, Dwayne Dexter, April M. Kloxin

Abstract: Late recurrences, especially in estrogen receptor–positive (ER+) breast cancer, often occur in distant metastatic sites like the bone marrow (BM) and are hypothesized to be triggered by local microenvironment interactions that stimulate the growth of dormant disseminated tumor cells (DTCs). Clinically, late recurrences have been observed after trauma, surgery, and aging, suggesting that changes in the microenvironment of dormant DTCs in conjunction with intrinsic factors (e.g., genetics, subtype) lead to reactivation and thereby cancer recurrence. While progress has been made in understanding this complex process, challenges remain in the detection, prevention, and treatment of late recurrences, leading to low survival rates. To enable studies for addressing these needs, in vitro human 3D culture models of breast cancer cell (BCC) dormancy have been developed. However, their broad use is limited by issues with their accessibility, throughput, and variance. Innovative technologies are needed to address several of these challenges and produce well-defined, accessible, high-throughput (HT) human models for mechanistic studies and identifying effective therapeutics to prevent late recurrence.
To address this need, our recent work established a tunable synthetic dynamic three-dimensional culture system for the indirect co-culture of ER+ BCCs with BM niche cells and identified the important role of soluble secreted factors in the dormancy and reactivation of DTCs, benchmarked versus a preclinical animal model. We now are translating this system to a HT human 3D co-culture model utilizing bioprinting technology, specifically the Inventia RASTRUM. Bringing bioprinting into the research framework brings forth three pivotal concepts. With the RASTRUM, we can create biologically-relevant 3D cell culture architectures inspired by the native microenvironment while providing rigor and reproducibility. The bioprinting further provides opportunities for HT cultures that enable screening of therapeutics and accessible methods for increasing model complexity with the integration of a range of BC and niche cells. We have successfully established an innovative dual and triple matrix co-culture systems using the RASTRUM and reproduced our existing ER+ BCC 3D model for the identification of pathways that regulate dormancy and reactivation and relevant drugs targeting these pathways for preventing late recurrence.
HIGHLIGHTS:

Established HT 3D co-culture models of breast cancer dormancy with increasing complexity for evaluating therapeutics to prevent late cancer recurrence.
Identified treatment strategies for modulating cancer cell dormancy/activation and preventing survival and re-activation of dormant BCCs in vitro and in vivo.

P2-02-13: Metformin prevents tumor cell growth and invasion of human hormone receptor positive breast cancer (HR+BC) cells via FOXA1 inhibition

SeungBaek Lee, Dawa Jung, Val Lowe, Tuba Kendi

Women with type 2 diabetes (T2D) have a higher risk of being diagnosed with breast cancer and have worse survival if they do develop breast cancer, than non-diabetic women. However, more research is needed to elucidate the biological underpinnings of these relationships. Here, we found that Forkhead Box A1 (FOXA1) and metformin (1,1-dimethylbiguanide hydrochloride), a medication used to treat T2D, may impact hormone receptor-positive (HR+) breast cancer (BC) tumor cell growth and metastasis. Indeed, fourteen diabetes-related genes are highly expressed in three HR+ breast cancer cell lines but not in other breast cancer subtypes using a 53,805 gene database obtained from NCBI GEO. Among the diabetes-related genes, FOXA1, MTA3, PAK4, FGFR3, and KIF22 were highly expressed in HR+ breast cancer from 4,032 breast cancer patient tissue samples using the Breast Cancer Gene Expression Omnibus. Specifically, the high expression of FOXA1 correlated to a worse overall survival for patients with ER+/PR+ breast cancer. Consistent with this, the loss of FOXA1 inhibited tumor proliferation and invasion of MCF-7 and T47D HR+ breast cancer cell lines in vitro. Metformin conspicuously inhibits the tumor cell growth in MCF-7 human hormonal breast cancer cells. Metformin or FOXA1 deletion enhanced tamoxifen-mediated tumor growth inhibition in HR+ breast cancer cell lines through the ex vivo three-dimensional (3D) organoid model. Therefore, metformin and FOXA1 inhibition might be a new treatment for patients with HR+ breast cancer when combined with tamoxifen, an endocrine therapy.

P2-02-14: C1QL1 inhibits breast cancer through HSP90α/VCP-ERS/UPR axis

Ningning Zhang, Qing shao, Tingxiu Xiang, Xiaohua Zeng

Our earlier research discovered that C1QL1 was expressed less in breast cancer (BrCa) tissues than in normal breast tissues by analyzing the gene profile of RNA sequences. However, up to now, the biological function of C1QL1 and its molecular mechanism in BrCa remains unknow. Public database analysis, qRT-PCR, western blot, immunohistochemistry, and quantitative methylation specific PCR were used to analyze C1QL1 expression and promoter methylation. The effects of C1QL1 on breast cancer proliferation, cell cycle, apoptosis, metastasis, were assessed using CCK8, flow cytometry analysis, TUNEL assays, transwell in vitro and nude mice experiments in vivo. LC-MS/MS, CoIP and western blot were performed to identify factors that mediate effects of C1QL1. In BrCa, C1QL1 is often silenced due to promoter methylation, and its expression is favorably connected with prognosis. Overexpression of C1QL1 inhibits BrCa cell proliferation, metastasis and promotes cancer cell apoptosis both in vitro and in vivo. Conversely, C1QL1 knockdown increases the proliferation and spread of BrCa cells. Mechanistically, C1QL1 is located at

endoplasmic reticulum (ER) and interacts with HSP90α and VCP to facilitate their ubiquitin-mediated degradation. This leads to the caspase-dependent apoptosis that occurs in breast cancer cells as a result of ER stress (ERS)/unfolded protein response (UPR). Our results support that C1QL1 can act as a tumor suppressor of BrCa by modulating C1QL1/HSP90α/VCP-ERS/UPR pathway, implying that the promoter methylation status of C1QL1 or the expression of C1QL1 may represent a potential marker for the diagnosis or prognosis of BrCa.

P2-02-15: Engineered macrophages secreting TRAIL achieve immunotherapy for triple-negative breast cancer by inhibiting the Wnt/β-catenin signaling pathway

Chuangui Song

Macrophages play a critical role in the body's defense against cancer by phagocytosing tumor cells, presenting antigens, and activating adaptive T cells. However, macrophages are intrinsically incapable of delivering targeted cancer immunotherapies. Engineered adoptive cell therapy introduces new targeting and antitumor capabilities by modifying macrophages to enhance the innate immune response of cells and improve clinical efficacy. TNF-related apoptosis-inducing ligand (TRAIL) is a member of the TNF superfamily that can either induce cell death or activate survival pathways after binding to death receptors (DRs) DR4 or DR5. In this study, we constructed engineered macrophages secreting mono-TRAIL and tri-TRAIL via viral transfection. The results showed that both types of TRAIL-secreting engineered macrophages could significantly kill triple-negative breast cancer (TNBC) cells and inhibit the proliferation of TNBC cells. The tri-TRAIL-secreting engineered macrophages (Tri-TRAIL-M) exhibited a more significant tumor-suppressive effect compared to the mono-TRAIL-secreting engineered macrophages (Mono-TRAIL-M). Additionally, the study results indicated that TRAIL-secreting engineered macrophages induced the M1 phenotype in macrophages by upregulating DR4 and downregulating DR5 expression. TRAIL, upon entering TNBC cells, could inhibit the tumor cell cycle by suppressing the Wnt/β-catenin signaling pathway. In conclusion, the tri-TRAIL-secreting engineered macrophages provide a novel strategy for constructing engineered macrophages for the immunotherapy of triple-negative breast cancer.

P2-02-16: Therapeutic Decision-Making in Breast Cancer: The Contribution of Artificial Intelligence

Vita Baldassara Leonardi, Fabio Aiello, Antonella Ussett, Giovanni Sortino, Salvatore Mirlocca, Marina Campione

Background: There is a growing effort to explore the benefits and risks associated with the application of large language models (LLMs) across various domains, including personalized medicine, clinical decision-making, and healthcare. This study aims to evaluate

the accuracy and interpretability of responses provided by artificial intelligence (AI) models, specifically in the context of metastatic breast cancer. By integrating advanced AI systems, our goal is to assess their potential impact on real-life patient care and their applicability in clinical practice. Our system integrates several cutting-edge components, including a GPT-4-based reasoning engine, a vector-based semantic search engine (QDrant), a specialized web search engine for PubMed (filtered for clinical studies), and utilizes the ReAct prompt paradigm. The Retrieval-Augmented Generation (RAG) facilitated the integration of the latest guidelines from the Italian Association of Medical Oncology (AIOM) and NCCN into QDrant.
Methods: A total of 43 patients with metastatic breast cancer treated at ARNAS Civico Hospital in Palermo, Italy, were randomly selected from clinical practice and included in the study. The median age was 68 years, with 58% of patients being older than 65 years. Comorbidities were present in 65% of patients, including cardiac problems (40%), hypercholesterolemia (14%), hepatitis (18%), and diabetes (17%). At diagnosis, 41% had metastatic cancer. Tumor types included luminal A (36%), luminal B HER2-negative (57%), and HER2-positive (8%). The AI model analyzed the patients' medical records to make therapeutic recommendations. The accuracy of these recommendations was assessed by comparing them to the AIOM guidelines. Three physicians independently reviewed and compared the AI model's therapeutic recommendations against the AIOM guidelines, rating the explainability of the model's responses on a scale from 1 (poor) to 5 (excellent).
Results: For 81% of patients, questions concerned first-line metastatic treatment, while 18% were in later lines of therapy. The concordance rate with AIOM guidelines was 91%, and the overall explainability score given by the physicians was 4.7. LLMs enabled the provision of concise summaries of patients' electronic medical records, generating comprehensive synopses of the patient's current condition by summarizing their therapeutic journey. The model made considerations regarding the patient's comorbidities, issuing alerts about therapy continuation for patients with critical test values. Notably, the AI model considered the patient's clinical course, adjusted treatment based on comorbidities, changed therapy at disease progression, and provided recommendations for complementary (e.g., radiotherapy) and supportive care.
Conclusion: The AI model demonstrates high concordance with clinical guidelines and provides explainable, comprehensive treatment recommendations that account for patient comorbidities and disease progression. These findings suggest a potential role for AI in supporting oncological treatment decisions in metastatic breast cancer.

P2-02-17: Race and outcomes in HR+/HER2- breast cancer: how tissue morphology and molecular pathways contribute to worse outcomes in Black women

Daniel Cook, Zach Cacini, John A. Cole, Kimberly A. Kelly, Yara Abdou

Background: Black women with breast cancer (BC) have a 40% higher relative risk of BC death than White women. Previous analyses from the RxPonder study have shown that

differences in tumor biology, particularly higher proliferation axis scores in tumors from Black women, may contribute to these poorer outcomes (Abdou et al. ASCO24). However, a comprehensive understanding of the underlying tumor biology necessitates further investigation. To this end, we conducted an in-depth analysis of tissue morphology and molecular pathways in Black and White women with early-stage hormone receptor-positive (HR+) BC, aiming to elucidate the biological factors driving these disparities.

Methods: We used the SIMBIOSYS PhenoScope Discovery software suite to investigate (HR+) BCs using paired MRIs and gene expression data from the ISPY-2 trial (N = 309 patients, 272 White and 37 Black). PhenoScope Discovery uses an AI-based algorithm to automatically segment tumors and surrounding tissues from MRIs and calculates morphological features associated with tumor biology. These morphological features, including features describing the tumor size, shape, and vascularity are then integrated via a machine learning model into a composite score called the the TumorSight Risk score, which has been shown to be prognostic of event-free survival (EFS) in early-stage breast cancer. Additionally, PhenoScope Discovery uses genome-scale metabolic modeling to simulate tumor metabolic pathway usage and dependency from gene expression data. We integrated the multi-scale outputs of PhenoScope Discovery to compare tumor morphology, simulated metabolism, and risk of recurrence amongst Black and White patients.

Results: We used the TumorSight Risk score to stratify patients based on their tumor morphology characteristics into recurrence high-risk and low-risk groups. We found Black women with (HR+) BC are more likely to have high-risk tumors than White women with (HR+) BC – 43% of tumors in Black women were high-risk; compared to only 29% of tumors in White women. Furthermore, integrating results from our metabolic modeling, we found that high-risk tumors were more likely to be dependent on mitochondrial fatty acid metabolism, suggesting a mechanistic connection between recurrence risk and breast adiposity.

We also directly compared tumor metabolism simulated from our metabolic model between Black and White women. We found that the tumors in Black women had a higher proliferation rate than tumors in White women ($p = 0.001$), indicating more aggressive tumors in Black women. This increased proliferation rate was driven by an increase in Warburg metabolism (characterized by higher glucose uptake, more use of the glycolysis pathway, and higher lactate secretion in tumors in Black women).

Conclusions: In this cohort of patients with (HR+) BC, tumors in Black women had a higher proliferation rate and a higher likelihood of being classified as high-risk of recurrence (using TumorSight Risk). Additional analyses of cellular signaling, tumor vascularity, and tumor perfusion are underway to try to further understand these disparities.

P2-02-18: Agreement Across 10 Artificial Intelligence Models in Assessing HER2 in Breast Cancer Whole Slide Images: Findings from the Friends of Cancer Research Digital PATH Project

Brittany McKelvey, Pedro A. Torres-Saavedra, Jessica Li, Glenn Broeckx, Frederik Deman, Siraj Ali, Hillary S. Andrews, Salim Arslan, Santhosh Balasubramanian, J. Carl Barrett, Peter Caie, Ming Chen, Daniel Cohen, Tathagata Dasgupta, Brandon Gallas, George Green, Mark Gustavson, Sarah Hersey, Ana Hidalgo Sastre, Shahanawaz Jiwani, Wonkyung Jung, Kimary Kulig, Vladimir Kushnarev, Xiaoxian Li, Meredith Lodge, Joan Mancuso, Mike Montalto, Satabhisa Mukhopadhyay, Matthew Oberley, Pahini Pandya, Oscar Puig, Edward Richardson, Alexander Sarachakov, Or Shaked, Mark Stewart, Lisa M. McShane, Roberto Salgado, Jeff Allen

Recent successes of HER2 antibody-drug conjugates (ADCs) have expanded patient eligibility for HER2-targeted therapy; therefore, accurate and consistent identification of patients who may benefit from ADCs is more critical than ever. Previous studies of agreement between pathologists highlight areas of discordance, but little is known about the reproducibility of assessments by emerging artificial intelligence (AI) models, particularly at low levels of HER2 expression. These models have the potential to deliver more quantitative and reproducible HER2 assessments than visual scoring by pathologists, but large-scale comparative evaluations to understand their variability are lacking.
Friends of Cancer Research created a research partnership to describe and evaluate the agreement of HER2 biomarker assessment across independently developed AI models. Both H&E and HER2 IHC whole-slide images (WSIs, N=1,124) from 733 patients diagnosed with breast cancer in 2021 were obtained from a single laboratory (ZAS Hospital, Antwerp, Belgium). Available pathology and specimen data include three pathologists' HER2 readings and details on slide processing and digitization. Ten AI models assessed HER2 status on all cases. Blinded, independent analyses were performed by statisticians from the National Cancer Institute.
Of the 10 AI models, seven used HER2 IHC WSIs, two used H&E WSIs, and one used both stains as inputs to determine HER2 score and/or status. The primary analysis focused on the seven models (6 using IHC, 1 using IHC and H&E) providing HER2 scores based on the ASCO/CAP 2018 categories (0, 1+, 2+, 3+). Absent a defined reference standard, agreement was evaluated for all possible pairings of models across all samples, resulting in a median (interquartile range, IQR) pairwise overall percent agreement (OPA) of 65.1% (60.3-69.1%) and unweighted Cohen's kappa of 0.51 (0.45-0.55). When defining binary HER2 scores as 3+ vs. not 3+, the median (IQR) pairwise agreement measures were: OPA 97.3% (95.9-97.9%), average positive agreement (APA) 87.3% (84.1-90.9%), average negative agreement (ANA) 98.5% (97.7-98.8%), and kappa 0.86 (0.82-0.90). Conversely, when defining HER2 scores as 0 vs. not 0, the median (IQR) pairwise measures were: OPA 85.6% (82.4-88.0%), APA 91.3% (87.4-92.6%), ANA 65.2% (59.9-69.7%), and kappa 0.57 (0.51-0.61). Ongoing analyses aim to assess the association of between-model agreement with patient, specimen, and model characteristics as well as the agreement between models and pathologist readings.
These findings highlight variability in HER2 biomarker scoring across models, with the least

variability and a higher level of agreement in reporting 3+ cases and larger inter-model variations in evaluating HER2 low tumors, similar to agreement measures between pathologists observed in published studies. Further work is needed to understand the variability in ascribing lower HER2 scores and to evaluate performance in the context of clinical application, especially given the evolving treatment landscape and clinical implications of HER2 scores. This ongoing research partnership will enable a greater understanding of the variability in AI models and support best practices for using these models for measuring and reporting AI driven biomarker assessments in drug development and clinical practice. This dataset also has potential value for creating reference sets for future model development.

P2-02-19: Virtual Multiplex Immunofluorescence Identifies Lymphocyte Subsets Predictive of Response to Neoadjuvant Therapy

Anran Li, Madeleine Torcasso, Anna Woodard, Hanna Hieromnimon, James Dolezal, Rebecca Abraham, Marcus R. Clark, Yuanyuan Zha, Alexander T. Pearson, Frederick M. Howard

Background: Multiplex immunofluorescence (mIF) captures spatial relationships within the tumor microenvironment and predicts response to therapy. However, cost and complexity limit real-world clinical application. We evaluated generative artificial intelligence approaches to recreate virtual mIF images from routine hematoxylin and eosin (H&E) stained pathology.
Methods: Core-needle biopsies from a cohort of triple-negative breast cancer underwent staining and mIF imaging. H&E and a composite mIF image for DAPI, pan-CK, CD3, CD4, CD8, and CD20 were aligned. We designed a pipeline, multiplex Synthetic Immunofluorescence Generated through H&E Translation (mSIGHT), which integrates a trainable registration network to overcome alignment issues in pairs of H&E and mIF images. Pairs of image tiles were extracted to train the mSIGHT pipeline, and the results were compared to Pix2Pix and CycleGAN image translation approaches. The mean squared error (MSE) between the six image channels was compared across generators using a paired t-test in the validation cohort, and Frechet Inception Distance (FID) was also compared. Cells were segmented and clustered into tumor cells, B-cells, CD4+ T-cells, and CD8+ T-cells. The accuracy of cell classification was measured using Spearman's correlation coefficient between real and generated classifications, as well as the area under the receiver operating characteristic curve (AUROC) for the prediction of real cell density in the top tertile of images from the validation set. The association of predicted immune cell subsets with pathologic complete response (pCR) was evaluated using an adjusted logistic regression model in a retrospective cohort of patients receiving neoadjuvant therapy, controlling for hormone receptor status and grade.
Results: Fifteen core needle biopsies yielding 418 image tiles were used for training, and two biopsies yielding 160 images were used for validation of image generation and cell classification. The mSIGHT pipeline (MSE 0.11, 95% CI 0.10 - 0.12, FID 125.7) outperformed Pix2Pix (MSE 0.31, 95% CI 0.28 - 0.33, $p < 0.001$ vs mSIGHT; FID 322.0) and CycleGAN (MSE

0.14, 95% CI 0.13 - 0.15, p = 0.019 vs mSIGHT; FID 167.0) in average pixel level accuracy across all channels. Generated images provided significant correlations for all immune cell subtypes, although accuracy ranged from Spearman rho 0.49 (95% CI 0.37 – 0.60), AUROC 0.77 (95% CI 0.69 – 0.85) for CD4+ T-cells to Spearman rho 0.20 (95% CI 0.05 – 0.35), AUROC 0.61 (95% CI 0.51 – 0.71) for CD8+ T-cells. In a cohort of 310 cases treated with neoadjuvant therapy with digital H&E images available, the predicted density of CD8+ T-cells was significantly associated with pCR (adjusted odds ratio [aOR] 1.34, 95% CI 1.16 – 1.62), whereas among spatial metrics derived from virtual mIF, proximity of CD4+ T-cells within 20 microns of B-cells was negatively associated with pCR (aOR 0.63, 95% CI 0.44 – 0.91).
Conclusions: The mSIGHT pipeline may be used to gain insight into clinically relevant spatial immune features directly from H&E images. Compared to other image translation pipelines, mSIGHT demonstrated superior predictive accuracy for identification of immune cell subsets. Additional study of this approach using larger datasets is ongoing.

P2-02-20: Prediction of Axillary Lymph Node Metastasis in Breast Cancer using Intraoperative Fluorescence Multi-modal Imaging

He Sun, Xiaobo Zhu, Jiaqian Li, Zhenyu Liu, Yu An, Jie Tian

Axillary lymph node (ALN) status serves as a crucial prognostic indicator in breast cancer (BC). Currently, sentinel lymph node biopsy (SLNB) and axillary lymph node dissection (ALND) are the standard methods for predicting and evaluating ALN status; however, intraoperative frozen section and pathological analysis are both time-consuming and laborious, and there is a certain false-positive rate. Therefore, there is a need for a method that can rapidly and accurately assess the status of ALN metastasis (ALNM) during surgery. To address the above clinical needs, this study combined near-infrared fluorescence imaging technology during BC surgery with advanced deep learning strategies to build a predictive model called "Multi-modal Fluorescence Imaging Feature Fusion Prediction" (MFI-FFP). For the multi-modal imaging data obtained during BC surgery, including white light imaging (WLI), near-infrared fluorescence imaging (FI), and pseudo-color imaging (PCI), we selectively customized feature extraction networks for each imaging modality to fully explore and utilized the complementary information between different modalities. We designed a multi-modal feature fusion module that effectively integrates features extracted from each modality by combining global and local information. Additionally, due to the common issues of class imbalance and classification challenges in real-world clinical datasets, we also designed a novel loss function to enhance the recognition of minority class instances. Through the above design, MFI-FFP can quickly and accurately determine the positive or negative of ALNM in surgery, reducing diagnostic time and costs, and ultimately improving patient outcomes.
The BC lymph node image database used in this study was derived from intraoperative fluorescence videos of 93 patients. During the surgical procedure, 312 excised lymph nodes were obtained from these 93 patients. with 35 lymph nodes testing positive for metastasis.

The ratio of negative samples to positive samples was approximately 8:1. During data preprocessing, key frames of each lymph node in the videos were captured and extracted as intraoperative fluorescence images. Each captured frame contained the three modes of data which include WLI, FI, and PCI. A total of 936 imaging data were captured, with 312 images corresponding to each mode.
Experimental evaluations demonstrated that the MFI-FFP model achieved remarkable performance in predicting ALNM, with an area under the ROC curve (AUC) of 0.7512 and an accuracy (ACC) of 0.8617, significantly outperforming single-modality models (WLI: AUC 0.5810; FI: AUC 0.5226; PCI: AUC 0.5601) and dual-modality models (WLI+FI: AUC 0.6786; FI+PCI: AUC 0.6089; WLI+PCI: AUC 0.6571). Given the absence of dedicated multimodal models for intraoperative fluorescence data from BC lymph nodes, we concatenated multi-modal features and input them into models that excel in natural image classification tasks, including resnet18, swin_transformer, convNeXt, efficientnet_v2, mobilenet_v3. Experimental results indicated that our model significantly outperforms the best-performing model in natural image classification, MobileNet_v3, with an AUC value of 0.6595.
This study not only validated the precision and reliability of the MFI-FFP model in predicting the status of ALNM in BC but also highlighted its substantial potential in assisting clinical decision-making and enabling real-time diagnosis of ALNM.

P2-02-21: Predicting HER2-targeting antibody-drug conjugate dosing regimens and quantifying immune system contributions to efficacy using agent-based computational modeling

Melissa Calopiz, Greg M. Thurber, Jennifer J. Linderman

Antibody-drug conjugates (ADCs) have proven to be successful in the clinic with 12 FDA approvals, including 7 approved within the last 5 years. ADCs combine a targeting monoclonal antibody backbone conjugated with a cytotoxic payload via a specific linker. Every component of an ADC must be designed and optimized for a particular target to ensure efficacy. The complexity of ADC design makes it challenging to study experimentally, as variability across experimental models, target expression, and heterogeneity make design and optimization both time-consuming and expensive. Computational modeling can be advantageous in ADC design and testing due to the ability to simulate a large range of ADC features to narrow down the optimal properties, and here we use our validated computational model, SimADC, to evaluate the efficacy of several ADCs. Specifically, we study trastuzumab, a HER2-targeting antibody used in 2 FDA-approved ADCs, conjugated to several types of payloads in different environments including ADC-induced immune responses.
SimADC captures heterogeneous ADC distribution, individual cell responses, and ADC efficacy, allowing us to study a wide variety of conditions and parameters, and generate/test new hypotheses efficiently. In this work, we first simulate different ADCs with a trastuzumab backbone to study the impact of a carrier dose (co-administering the ADC

with its unconjugated antibody backbone) on ADC intratumoral distribution. Studies have shown that ADCs tend to localize around perivascular areas but leave other areas of the tumor untreated, thereby reducing efficacy. Adding a carrier dose creates partial competition with the ADC for binding sites, which can improve distribution and therefore efficacy. For the ADCs tested, it was determined that co-dosing the ADC with enough carrier to saturate all cell receptors in the tumor results in the best possible efficacy.
Next, we used SimADC to study the impact of and immune response during ADC therapy. Data support a role for the immune system in ADC efficacy, although the relative importance and mechanisms operating between ADCs and immune cells are currently unclear. We build upon SimADC by incorporating the immune system, specifically CD8+ T cells and macrophages, to quantify the contribution of immune cells when dosing Enhertu (trastuzumab deruxtecan) in low-expressing systems. Enhertu is known to be efficacious in these low-expressing systems, but the role of the immune system versus payload cell killing is unclear. Using SimADC, we can set bounds on the HER2 expression level needed (receptors/cell) to attribute efficacy to payload cell killing versus the need for an immune response. The relative role of payload release from macrophages and systemic uptake of free payload is also included. Understanding the relationship between ADCs and the immune system can allow for the design of treatment regimens that target immune cell activation to aid in tumor treatment instead of relying on high doses of drug, resulting in less drug toxicity for the patient.

P2-02-22: BCM PDX Insights Portal: An Intuitive Web-based Tool for Patient-Derived Xenograft Collection Management to Facilitate Pre-clinical Studies in Breast Cancer

Heidi Dowst, Apollo McOwiti, Fei Zheng, Ramakrishnan Rajaram Srinivasan, Anadulce Hernandez-Herrera, Nino Rainusso, Lisa Brubaker, Qizhi Cathy Yao, Michelle Redell, Alexandra Stevens, Seth Lerner, Sarah Woodfield, Andres F. Espinoza, John D. Landua, Susan G. Hilsenbeck, Michael T. Lewis

Objective: Mouse Patient-Derived Xenograft (PDX) models are essential tools for evaluating experimental therapeutics. Baylor College of Medicine (BCM) established a PDX Core to provide technical support and infrastructure for PDX-based research. To manage PDX collections effectively, de-identified patient clinical and omics data, as well as PDX-related information and omics data, must be curated and stored. Data must then be analyzed and visualized for each case. To enhance PDX collection management and data dissemination, the BCM Biomedical Informatics Core created the BCM PDX Insights portal (https://pdxportal.research.bcm.edu/).
Materials and Methods: Patient clinical data are abstracted from medical records for each PDX and stored in a central database. Annotations are reviewed by a clinician and de-identified. PDX development method and biomarker expression are annotated. DNAseq, RNAseq, and proteomics data are processed through standardized pipelines and stored. PDX gene expression (mRNA/protein), copy number alterations, and mutations can be

searched in combination with clinical markers to identify models potentially useful as a PDX cohort.
Results: PDX collection management and PDX selection of models for drug evaluation are facilitated using the PDX Portal. Users identify models for studies by querying DNA mutation, copy number variations and gene expression. Model selection is further narrowed by viewing the patient clinical timeline, indicating staging, disease progression and response to treatments. A large breast cancer collection of 300 PDX models is accessible in the portal from multiple institutions including BCM, MD Anderson, and Huntsman Cancer Institute. Models from this collection with the assistance of data collected in the portal have been utilized to execute drug sensitivity studies with breast cancer avatars presenting specific molecular signatures and patient resistance to first line therapies resulting in evidence for alternative treatments.
Discussion: Successful preclinical studies provide critical evidence for well-designed clinical trials. To closely simulate real world conditions in preclinical PDX studies, methods that capture and display multiple features of the patient clinical and molecular data are needed which operate at scale. Selection of models for studies should be representative of the patient cohort from which they originated while also being standardized to allow for aggregation of models from various sources to achieve an adequate representation of uncommon cancer subtypes. At BCM, our PDX core and collaborators across Texas have found value in using the PDX Insights portal to manage, standardize, query, aggregate and disseminate PDX annotations.
Conclusion: The BCM PDX Insights portal is a highly effective PDX collection management tool allowing data access in a visual, intuitive manner which has been shown to be effective in facilitating breast cancer preclinical studies.

P2-02-24: Evaluating ChatGPT as an educational resource for patients with Breast cancer: A preliminary investigation

Zunairah Shah, Arya Mariam Roy, Varsha Gupta, Nerea Lopetegui Lia, Dionisia Quiroga, Gilbert Bader, Sheheryar Kabraji, Lubna N. Chaudhary, Ellis Levine, Shipra Gandhi

Introduction: Breast cancer (BC) is the most commonly diagnosed cancer among women in the United States, representing about 30% of new cases annually. Patients with BC encounter various challenges, such as understanding the disease, exploring treatment options, managing prognosis, coping with side effects, and accessing supportive care. Educating patients is crucial for empowering them to make informed healthcare decisions. With the evolution of artificial intelligence (AI), there is potential to leverage these technologies for patient education. ChatGPT, an AI-based language model, is a promising avenue in this regard. While ChatGPT has been applied across diverse domains, its potential in medicine is currently under exploration. This study aims to evaluate ChatGPT's effectiveness as an educational tool for BC patients, assessing its accuracy and safety in delivering medical information.
Methods: We designed a comprehensive questionnaire with 22 questions covering various

aspects of breast cancer—from diagnosis to treatment options and prognosis. This questionnaire served as the prompt for our study utilizing OpenAI's ChatGPT version 3.5.0 to generate responses. The accuracy of these responses was meticulously evaluated by nine Breast Medical Oncologists (BMOs): four from Roswell Park Comprehensive Cancer Center, four from Ohio State University, and one from the Medical College of Wisconsin. Each expert independently assessed the responses provided by ChatGPT and categorized them as accurate, inaccurate, or harmful.
Results: We found that sixteen of these questions (16/22) 73% received unanimous agreement from all BMOs for accuracy. Only one question (1/22) 4% was deemed harmful, and five questions (5/22) 23% graded as inaccurate by some of BMOs due to insufficient or misleading information. The response to questions that received criticism were “Are there any alternative or complementary therapies that may help with breast cancer?” it was flagged harmful by (2/9) 22% BMO and inaccurate by (2/9) 22%. Another question, asking about the different types of breast cancer, was graded inaccurate by (6/9) 67% of experts as it was missing a few breast cancer types. Additionally, (3/9) 33% of BMOs found the response regarding dietary recommendations for breast cancer patients inaccurate, highlighting the lack of evidence supporting dietary interventions in metastatic breast cancer. The advice on preserving hair during chemotherapy was rated as inaccurate by (3/9) 33% of experts due to concerns that some of the recommendations, such as maintaining a good diet and using a mild shampoo, do not effectively prevent chemotherapy-induced alopecia and could potentially raise false hopes among patients. Similarly, explanations about HER2-positive breast cancer and its prognosis were labeled as inaccurate by (2/9) 22% of BMOs due to misleading statements about recurrence rates. Lastly, (3/9) 33% of experts criticized the discussion on potential side effects of treatment modalities for omitting important information, such as cardiovascular toxicity associated with chemotherapy.
There are some limitations to our study, such as small sample size, subjective evaluation criteria, and rapid evolution of ChatGPT and other large language models.
Conclusion: While ChatGPT shows potential as an educational resource for BC patients with 73% of answers graded accurate by all BMOs, it is essential to recognize its limitations and the indispensable role of human medical expertise. These findings underscore the variability in accuracy and appropriateness of AI-generated responses in medical contexts, highlighting the importance of refining and validating AI tools for patient education and information dissemination. A few of the safety considerations are the use of complex medical terminology in responses and, the dissemination of sensitive information without empathy and emotional support.

P2-02-25: Predicting the response of triple negative breast cancer to neoadjuvant systemic therapy via biology-based modeling and habitat analysis

Casey Stowers, Chengyue Wu, Zhan Xu, Clinton Yam, Jong Bum Son, Jingfei Ma, Gaiane M. Rauch, Thomas E. Yankeelov

Introduction: Neoadjuvant systemic therapy (NAT) is the standard of care for the treatment of locally advanced triple-negative breast cancer (TNBC) [1]. Unfortunately, only 50-65% of TNBC patients who receive NAT attain a pathological complete response [2]. Our goal is to improve methods for predicting treatment response early during NAT to allow for better patient outcomes. Biology-based mathematical models calibrated to magnetic resonance imaging (MRI) data have proven accurate in predicting NAT response, but they require hundreds of locally calibrated parameters to achieve highly accurate predictions of voxel-wise tumor cellularity [3]. Fitting so many parameters is computationally expensive and may suffer from overfitting of the data. Here, we combine biology-based mathematical models with habitat analysis to dramatically reduce the number of parameters to be calibrated within our biology-based model, and then test the accuracy of the subsequent predictions.

Methods: Data acquisition – This study used 138 patients from the ARTEMIS trail (NCT02276443) who received Adriamycin/Cytoxan (A/C) followed by Paclitaxel. Each patient received MRI pre- (V1), post two cycles (V2), and post four cycles A/C (V3).

Defining habitats –We applied habitat analysis on the apparent diffusion coefficient (ADC) map obtained from diffusion weighted MRI and the positive enhancement integral (PEI) map obtained from dynamic contrast enhanced MRI. To do so, we constructed a vector of ADC and PEI at V1 and V2 for every tumor bearing voxel in every patient. We then pooled these vectors across the cohort and applied k-means clustering to identify habitats.

Mathematical model - Our biology-based mathematical model captures the spatio-development of tumor cellularity at each voxel location within the breast as the sum of tumor cell diffusion (controlled by a fixed diffusivity), proliferation (controlled by a calibrated proliferation rate), and death due to NAT (controlled by a calibrated drug efficacy rate). These parameters can be calibrated globally (one value per tumor) or locally (one value per tumor voxel). We calibrated the models to V1 and V2 data, after which the calibrated model is used to predict tumor status at V3.

Habitat-informed model calibration – Habitats allow us to calibrate one drug efficacy value per habitat, as opposed to one value per tumor voxel. We first identified and calibrated for two habitats, and then gradually increased the number of habitats up to 16. We report preliminary results for three models, all of which calibrated for a global proliferation rate, but differ in how they handled drug efficacy: (A) global drug efficacy, (B) an efficacy value for each of ten habitats, and (C) local drug efficacy.

Results: To evaluate the quality of the model calibrations we compare the median (interquartile range) of the absolute difference between the modeled and measured percent change in total tumor cellularity (%ΔTTC) across the cohort for each calibration. When calibrating from V1 to V2, we obtained %ΔTTC's of 19 (5.0-25) %, 12 (7.7-15) %, and 2.0 (0.42-4.1) % for models A, B, and C, respectively. We repeat the analysis for predicting

%ΔTTC at V3 and obtained 6.5 (0.90-20) %, 5.5 (2.8-12) %, and 15 (5.8-23) %, for models A, B, and C, respectively.

Summary and Discussion: The accuracy of the calibrated V1 to V2 %ΔTTC increased as we increased the number of calibrated drug efficacy parameters due to the larger number of free parameters. However, the accuracy of models A and B for predicting %ΔTTC at V3 is superior to model C, which is also more computationally expensive. The more accurate and efficient models could support personalized treatment optimization, in which the calibrated model is used to predict patient response to a variety of treatment schedules.

P2-02-26: Development of AI diagnosis of immunohistochemistry for ER and HER2 in breast cancer.

Kaori Terata, Teppei Konishi, Eriko Takahashi, Ayuko Yamaguchi, Masaaki Onji, Hikari Konno, Hiroshi Nanjo, Yusuke Sato, Kazuhiro Imai

Background: Breast cancer is the most common cancer among women worldwide, and subtype estimation by immunohistochemistry (IHC) is essential in the process of treatment decision making. In recent years, the importance of basic IHC diagnosis has further increased, as multigene assays have been used to predict the efficacy and prognosis of chemotherapy in hormone receptor-positive human epidermal growth factor receptor 2 (HER2) -negative breast cancer and HER2 low diagnosis is used to determine the indication for T-DXd. On the other hand, however, the effort required for routine IHC diagnosis is enormous and complicated, and there is a need to reduce effort in clinical practice. Therefore, we developed an automated diagnosis system using artificial intelligence (AI) for IHC of estrogen receptor (ER) and HER2, which is necessary to determine the treatment strategy for breast cancer. Methods: We retrospectively extracted 236 IHC preparate of ER and HER2 of breast cancer in Akita University Hospital consecutively. Each pathology image was divided into patches, the data was expanded for each patch, the expanded patches were trained by Convolutional Neural Network (CNN), and Train, Validation, and Test were performed to calculate sensitivity, specificity, positive diagnostic rate, and AUC for ER with more than 50% and less than 50% occupancy and for HER2 Sensitivity, specificity, positive diagnostic rate, and AUC were calculated for four classes based on the HER2 score for HER2; for HER2, training and evaluation were also performed using open data. In addition, the time required to diagnose one image was examined. Results: In ER, based on 3536 training data and 884 test data, sensitivity was 96%, specificity was 93%, accuracy was 95%, and AUC was 0.99 for less than 50% of ER expression and 0.99 for more than 50% of ER expression, based on 3272 training data and 818 test data, sensitivity was 82%, specificity was 87%, accuracy was 71%, and AUC was 0.79 for HER2 score 0,1, 0.80 for HER2 score 2,

and 0.89 for HER2 score 2. Diagnostic accuracy was slightly lower in the low score situation. On the other hand, in the open data study (data: score 0;65, score 1;60, score 2;101, score 3;113), the accuracy was 94.2% when scores were divided into 4 classes. It took less than one second to diagnose one image. Conclusions: In this study, we have developed an AI diagnosis system that speedily assists pathologists in diagnosing IHC. In breast cancer treatment, IHC diagnosis of ER and HER2 is indispensable for treatment decision making, and rapid and precise diagnosis is desired. On the other hand, it is desirable to reduce the potential labor required to perform complicated IHC diagnosis of ER and HER2 in a large number of breast cancer patients. The present AI system for IHC diagnosis of ER and HER2 showed a certain high accuracy as a numerical value, although no similar study has been reported in the past as far as we could find. Although discrepancies in the diagnosis of HER2 between pathologists have been a problem, more reproducible diagnosis is needed to determine the indication of T-DXd for HER2 low. In this study, high accuracy was obtained by AI diagnosis based on open data. The results of further additional analyses will also be reported. Furthermore, we are currently marketing an in vitro diagnostic device system that enables IHC in a short time with reproducibility. As a future prospect, we are developing a system to enable faster and more accurate diagnostic support in combination with this AI diagnosis.

P2-02-27: Automating Breast Cancer Relapse Identification in Pathology Reports Using Natural Language Processing

Jaimie Lee, Andres Zepeda, Gregory Arbour, Kathryn Isaac, Raymond Ng, Alan Nichol

Background: Relapse is a major concern for breast cancer survivors and oncologists. However, population-wide cancer registries fall short in systematic relapse monitoring due to logistical challenges and prohibitive costs. Recent advancements in Natural Language Processing (NLP) have created new opportunities to address these limitations. Hence, we investigated Bidirectional Encoder Representations from Transformers (BERT), a state-of-the-art NLP language model, to automate relapse identification in the text of pathology reports. Methods: Follow-up pathology reports from breast cancer patients diagnosed between January 1, 2005, and December 31, 2014, were included. These reports were gathered within a 120-day window of a known relapse finding. The presence or absence of local, regional, and distant breast cancer relapses were annotated by trained staff. We selected BlueBERT as our base model, a transformer pre-trained on PubMed abstracts and MIMIC-III clinical notes that is commonly used for medical text classification. To fine-tune our BlueBERT models, pathology reports were divided into training (80%), validation (10%), and test (10%) sets. Model performance was evaluated using accuracy, sensitivity, specificity and respective 95% confidence intervals [CI]. Results: The study cohort comprised 1,375 breast cancer patients with a median age at breast cancer diagnosis of 58 years (range 23-94 years). A total of 1,896 pathology reports were included from these patients, with 673 (35.5%) describing local relapses, 295 (15.6%) regional relapses, and 643 (33.9%) distant relapses. The local-relapse model achieved 93.1% [91.8-94.4] accuracy,

91.3% [89.0-93.6] sensitivity, and 94.2% [92.7-95.7] specificity. The regional-relapse model showed 91.4% [90.0-92.8] accuracy, 81.9% [77.0-86.8] sensitivity, and 93.2% [91.8-94.6] specificity. Finally, the distant-relapse model demonstrated 90.6% [89.1-92.1] accuracy, 82.8% [79.3-86.3] sensitivity, and 94.1% [92.7-95.5] specificity. Conclusion: We used BlueBERT-based NLP models to identify breast cancer relapse in pathology reports. These models demonstrated excellent performance across all relapse types. When applied retrospectively, the automation of breast cancer relapse identification has the potential to enrich cancer registries with information on patient outcomes. When used prospectively, this technology holds the potential to enhance patient care by facilitating timely relapse identification.

P2-02-28: Challenges and Opportunities in Early Diagnosis of Breast Cancer: Utilizing Clinical Decision Support Platforms for Improved Detection

Bea Bakshi, Seema Dadhania, Brian Herrick, Edwin Lee, Greg Joondeph-Breidbart, Miles Payling

Introduction: Breast cancer is the most common cancer diagnosed worldwide. Despite a widely adopted screening program in most countries, many patients are missed and present symptomatically. In the US, symptomatic breast cancer patients are reported to represent 30-40% of patients with breast cancer. However, while the percentage between screen-detected cancer and symptomatic breast cancer has been improving over the last three decades, evidence suggests the total number of patients diagnosed with symptomatic breast cancer has increased by over two thirds during this period. In addition, the number of patients with late stage disease has not significantly fallen. This therefore highlights that early detection of symptomatic breast cancer remains a critical challenge in healthcare in order to optimize outcomes.
Utilizing the extensive data available in Electronic Medical Records (EMRs) offers a valuable opportunity to pinpoint high-risk patients with symptomatic breast cancer for early intervention. In this study, we investigate the effectiveness of utilizing the C the Signs AI Prediction Model to identify patients at risk of breast cancer and explore the time to diagnosis relative to primary care physician detection.
Methods: A retrospective analysis was conducted on 900,601 patients within the Mayo Clinic Data Platform between 1st January 2002 and 31st December 2021. 19,879 individual patients were diagnosed with breast cancer during this interval. We utilized the C the Signs AI Prediction Model to match relevant factors from the EMR record (e.g. breast lump, nipple changes etc) and calculate if a patient was at risk of breast cancer according to the model's algorithms.
A sensitivity analysis was performed to evaluate the platform's effectiveness in early detection. In addition, we examined the timing of breast cancer diagnosis relative to primary care physician detection to assess the potential for earlier identification. Staging data for patients with breast cancer diagnosed was not available so could not be assessed.

Results: The sensitivity of the C the Signs platform for detecting breast cancer was 76.8%, with a specificity of 79.5%. The positive predictive value was 7.8% and the negative predictive value was 99.3%. Remarkably, 20.7% of patients with breast cancer were diagnosed up to 5 years before their diagnosis by primary care physicians. Of interest, with the sensitivity being at 76.8%, the vast majority of patients with breast cancer within the Mayo Clinic Data Platform were symptomatic at presentation which is at odds with previously reported screening detected cancer proportions (which the C the Signs AI Prediction Model would not have been able detect in this configuration).
Conclusion: Our findings establish the potential of AI Prediction Models, such as C the Signs, to address the challenge of identifying patients with symptomatic breast cancer at the earliest stages of the disease. By leveraging EMR data and advanced algorithms, these platforms can enhance the identification of at-risk patients and enable earlier intervention. The evidence of this study may also suggest that the proportion of asymptomatic patients who are currently detected through mammography alone, may be much smaller than previously assumed (<30% compared to the currently assumed 60-70%). Further research and integration of such platforms into clinical practice are warranted to realize their full potential in improving breast cancer diagnosis and confirm stage shift.

P2-02-29: AI-based Clinical Decision Support System (CDSS) for predicting response to primary systemic therapy in early breast cancer: multimodal modeling and pathology contribution.

Barbara Bussels, Sandra Steyaert, Francesca Dedeurwaerdere, Isabelle Kindts, Philip Poortmans, Adelheid Roelstraete, Frederik Deman, Caroline De Beukelaar, Mona Bové, Sander Goossens, Peter De Jaeger

$ The BreaCS Consortium is a collaborative research effort between four Belgian EUSOMA-certified hospitals and Endare as external partner.

Background: Accurate prediction of tumor response to primary systemic therapy (PST) in early breast cancer is crucial for optimizing treatment decisions. The Breacs consortium developed an AI-based CDSS that integrates digital pathology data and pre-operative clinical variables to predict pathological complete response (pCR) in early breast cancer patients. Deciphering the factors on which the model relies to make these predictions may provide valuable new insights.

Material and methods: A multimodal predictive model was developed using data from the BreaCS consortium, encompassing a cohort of 550 patients who underwent PST.
The dataset included digital pathology data from biopsies and more than 100 pre-operative clinical variables from the standardised EUSOMA database.
The data was split into a training and a test sets (80-20 stratified split on patient level).
Model evaluation metrics included the area under the operator curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

Quantitative cell segmentation analysis was conducted on the test set to identify histopathological features influencing the model's predictions. Cell type fractions were compared across 4 different groups (true positives, false positives, false negatives, true negatives) within the confusion matrix.

Results: The unimodal model based on pathology data achieved an AUC of 0.70 (training) and 0.81 (test). The model using only EUSOMA clinical data scored an AUC of 0.88 (training) and 0.82 (test). The multimodal model, incorporating both pathology and clinical data, demonstrated superior performance with an AUC of 0.91 (training) and 0.84 (test).
The multimodal model demonstrated a significant improvement in sensitivity, NPV and PPV compared to the unimodal models, with specificity remaining relatively unchanged.
The test set confusion matrix showed 72 true negatives (TN), 11 false negatives (FN), 14 true positives (TP), and 9 false positives (FP).
The cell segmentation in the group of the TP (predicted and obtained complete remission) shows an excess in the fraction of tumor cells compared to the TN. The TN (non-responders) on the other hand have an excess in the fraction of connective tissue compared to the TP.

Conclusions: The AI-based CDSS demonstrates promising predictive capabilities for response to PST in early breast cancer, with the multimodal approach showing enhanced predictive accuracy. This study underscores the importance of integrating multimodal data in predictive models.
The observed differences in cellular composition between TP and TN reveals distinct cellular compositions and may suggest potential refinements for improving model accuracy.

P2-03-01: Sexual health in unpartnered women after breast cancer: Report from a joint analysis of two international multi-site prospective cohorts of young breast cancer survivors

Sharon Bober, Eleonora Pagan, Monica Ruggeri, Shari Gelber, Vincenzo Bagnardi, Ann Partridge, Olivia Pagani, Shoshana Rosenberg, Karin Ribi

Objectives: Sexual dysfunction is a distressing potential side effect of breast cancer (BC) treatment. However, little is known about the experience of unpartnered young women whose concerns may differ from partnered peers. Helping Ourselves, Helping Others: The Young Women's Breast Cancer Study (YWS-HOHO) investigates gaps in knowledge about young BC survivors in 2 multi-site prospective cohorts. Methods: The North American (USA, Canada) and European (Italy, Switzerland) YWS-HOHO cohorts jointly enrolled 1602 women. Participants were ≤40 yrs. and diagnosed with stage 0-IV BC <6 months before enrollment. Serial surveys were completed every 6 months for the first 3 yrs. and annually thereafter. Surveys included assessment of body image, sexual health, menopausal symptoms (using the CARES and BCPT scales, score range: 0-4, with higher scores indicating greater severity) and menopausal concerns. Unpartnered and partnered women

were compared at baseline and 2-yrs. post-enrollment using T-tests. Results: A total of 1342 women were included in this analysis (1054 from N.A., 288 from Europe). The median age at enrollment was 37 yrs. (IQR 33-39), 81% of women had stage 0-2 disease. Most women (n = 1000, 74.5%) had received chemotherapy, 63.8% (n = 856) had undergone mastectomy. At baseline, 13% of women were unpartnered (n=180). Unpartnered young women reported significantly higher body image concerns than partnered peers at baseline (mean CARES body image scale 1.28 vs 1.09, p-value=0.04) but not at 2-yrs (1.17 vs 1.08, p-value=0.35). Concern about general sexual function was comparable for unpartnered and partnered women at baseline (1.97 vs 1.81, p-value=0.11) and at 2-yrs (1.43 vs 1.42, p-value=0.92). For example, >47% of both unpartnered and partnered women endorsed a loss of sexual interest at baseline and >36% of both groups also at 2-yrs. Unpartnered women reported fewer vaginal symptoms (e.g., vaginal dryness, pain with intercourse) than partnered women at both timepoints (mean BCPT vaginal scale at baseline 0.53 vs 0.83, p-value<0.001; at 2-yrs 0.74 vs 1.01, p-value=0.002), while there were no differences in hot flashes and urinary symptoms at either timepoint. Greater than 50% of both unpartnered and partnered women reported concern about becoming post-menopausal at both timepoints. Approximately half of unpartnered women reported difficulty with dating at both timepoints, including difficulty with initiating contact with potential partners and difficulty with discloser about their cancer experience. Conclusion and Implications: Unpartnered young BC survivors report similar levels of sexual dysfunction as partnered peers as well as distinct concerns about body image and dating. These findings underscore the need to routinely address sexual health regardless of partner status and to better investigate specific concerns of unpartnered women such as dating and relationship-building.

P2-03-02: Fertility and ovarian function preservation in young women with breast cancer: A comparative analysis of two prospective cohort studies in Mexico and Italy

Fernanda Mesa-Chavez, Maria Grazia Razeti, Eva Blondeaux, Alejandra Platas, Virginia Delucchi, Alan Fonseca, Valeria Fontana, Marlid Cruz-Ramos, Paola Anserini, Manuel Rolando García Garza, Edoardo Chiappe, Alejandro Mohar, Laura Orlando, Enrique Bargallo-Rocha, Saverio Cinieri, Lucia Del Mastro, Cynthia Villarreal-Garza, Matteo Lambertini

Background: Due to their age and life stage, young women with breast cancer (YWBC) encounter distinct challenges related to their diagnosis and treatment. Unmet parity along with potential premature ovarian insufficiency represent a notable concern among this group of patients. Effective strategies to address this issue include fertility preservation techniques, as well as temporary ovarian suppression with gonadotropin-releasing hormone agonists (GnRHa) for ovarian protection during cytotoxic treatments.
Here we report a comparative analysis of two prospective studies describing the rates and factors associated with fertility and ovarian function preservation choices in YWBC from two countries.

Methods: Women with BC at an age ≤40 years were prospectively accrued in the Joven & Fuerte and PREFER multicenter cohorts in Mexico and Italy, respectively. These studies provide early referrals to fertility and/or ovarian function preservation strategies at diagnosis as needed. This analysis comprised YWBC diagnosed from 2014-2019 whose treatment included chemotherapy (CT) with the objective of identifying their uptake of fertility and ovarian function preservation options. Patients' characteristics within and across cohorts were compared using chi-squared, Fisher's exact, and Wilcoxon tests. Simple logistic regression was conducted to calculate the likelihood of undergoing fertility preservation.

Results:In total, 485 patients were included: 361 (74%) in Mexico and 124 (26%) in Italy. Median age at diagnosis was 35 years (IQR 32-38) in both cohorts. A higher proportion of Mexican patients had a partner compared to Italian patients (65% vs 59%, p=.04). Patients' median number of children at diagnosis was also higher in Mexico than in Italy (1 [IQR 0-2] vs 2 [IQR 1-3], p<.001). Patients' distribution by clinical stage (p<.001), timing of CT (p=.01), hormone receptor status (p=.04), and HER2 status (p=.002) also differed between cohorts: Mexican patients were more frequently diagnosed with stage III BC and received neoadjuvant CT, while Italian patients more commonly had positive hormone receptors or HER2 overexpression.

Regarding fertility preservation, a technique was used in 8% and 25% of patients in Mexico and Italy, respectively (p<.001). Methods comprised oocyte (50% in Mexico vs 87% in Italy), embryo (53% vs 0%; this strategy is forbidden by law in Italy), and ovarian tissue cryopreservation (0% vs 16%). GnRHa for ovarian protection were used in nearly all Italian patients (98%) but in a minority of Mexican patients (6%).

Not undergoing fertility preservation was mainly due to lack of interest (47-50%), urgency to start treatment (4-6%), and personal reasons (3-5%). Fertility preservation uptake was associated with younger age (OR 1.2, 95%CI 1.1-1.2), unpartnered status (OR 3.4, 95%CI 1.9-5.9), childlessness (OR 21.8, 95%CI 10.0-47.6), private healthcare coverage in Mexico (OR 3.0, 95%CI 1.1-8.1), stage I-II BC (OR 3.1, 95%CI 1.5-6.3), positive hormone receptors (OR 2.3, 95%CI 1.2-4.6), and adjuvant CT (OR 2.4, 95%CI 1.4-4.3).

Conclusions: This comparative analysis of two prospective studies in Mexico and Italy showed that a significant distinct proportion of YWBC had access to the available fertility and ovarian function preservation techniques in these countries, possibly reflecting the different social and healthcare contexts.

Although all women should receive a complete oncofertility counseling, patients who are younger, unpartnered, childless, and have earlier-stage BC appear to be those who particularly benefit from being offered fertility preservation options. This study underscores the need to enhance awareness and access to oncofertility services in order to provide comprehensive, patient-centered care to this young population.

P2-03-03: Aromatase inhibitor (AI) use in a phase I, single arm, prospective study to evaluate the treatment of genitourinary syndrome of menopause (GSM) with platelet rich plasma (PRP) in women with a history of breast cancer.

Anita Chen, Johnny Yi, Emanuel Trabuco, Jacqueline Thielen, Jeffrey Cornella, Shane Shapiro, Reagan Dukes, Jennifer Arthurs, Michael Heckman, Sophia Blumenfeld, Saranya Chumsri

Background: GSM is a constellation of symptoms and signs associated with a decrease in estrogen involving changes to the external genitalia, vagina, urethra, and bladder. The syndrome may include dryness, burning, and irritation of the vagina and vulva. Sexual dysfunction may be caused by lack of lubrication, discomfort or pain, and impaired function. Urinary symptoms of urgency, dysuria, and recurrent urinary tract infections are also commonly described with GSM.

Breast cancer is the most common cancer among women worldwide, and GSM is an extremely challenging, unique issue for breast cancer survivors especially those taking AI where the goal is to lower estrogen levels. It is estimated that more than 2 million US survivors of breast cancer are affected by GSM, the majority receiving no treatment. There is overwhelming evidence to support the use of vaginal estrogen to treat GSM, but many patients with breast cancer and their providers are hesitant due to the concern of exogenous hormones. In addition, these painful symptoms may result in discontinuation of adjuvant endocrine therapy (ET). GSM symptoms typically do not resolve without treatment and may worsen with time.

PRP is theorized to induce angiogenesis and restore the effects of growth factors. It has been used for various conditions including GSM.

Objective: To assess the effect of AI treatment on breast cancer survivors who underwent injection of autologous PRP to the vaginal canal for treatment of GSM.
Design: Breast cancer survivors (stage 0-III) who reported GSM symptoms of vaginal dryness with or without dyspareunia underwent a single treatment of autologous PRP injected throughout the vaginal canal and posterior fourchette. The primary outcome was to assess the safety and feasibility of the treatment. Secondary outcomes included the efficacy of treatment. Vaginal atrophy was measured by vaginal maturation index (VMI) and vaginal health index (VHI), vaginal and vulvar symptoms with assessment scales (VAS/VuAS), quality of life with the day-to-day impact of vaginal aging questionnaire (DIVA), sexual function with the female sexual function index (FSFI), and urinary symptoms with the urogenital distress index (UDI-6). VMI was obtained at baseline and 6 months. All other measures were obtained at baseline, 1, 3, and 6 months. Patient global impression of improvement (PGI-I) was assessed with a 7- point Likert scale.
Results: Mean age was 53 years (range 40-66) and body mass index was 27.2 kg/m2 (range 20-36.6). All completed the planned injection protocol with a mean visual analogue scale

(VAS) pain score of 3.9(range1-7). Of the 20 participants, 11 were on endocrine therapy with an aromatase inhibitor. There was no statistical difference between the AI group and no AI group in regards to safety, feasibility, or efficacy. Interestingly, 81.8 % in the AI group noted “much better” and “very much better” on PGI-I versus 66.6% in the no AI group. All patients remained compliant with adjuvant ET.
Conclusion: Adjuvant ET is proven to reduce the risk of recurrence and mortality in patients with hormone receptor positive breast cancer; however up to 20% of patients discontinue treatment prematurely due to gynecologic side effects. In this phase I trial sub-analysis of participants on AI, we found that PRP treatment significantly improved GSM symptoms, sexual function, urinary symptoms, and quality of life in breast cancer survivors regardless of AI status. There was a trend towards more AI participants reporting improvement of symptoms. All participants demonstrated adherence to AI treatment, a key component to improved disease-free survival. Future randomized controlled Phase 2 trials are warranted to further validate these promising findings.

P2-03-04: Assessing and Addressing the Distinct Psychosocial Needs of Young Women with Breast Cancer

Shari Goldfarb, Alanna Jamner, Cassandra Chang, Padmapriya Subramanian, Jeannie Englehardt, Morgan Moy, Mary Gemignani

Background/Objective: Although young women under 45 represent only 11% of newly diagnosed breast cancer patients annually in the US, their physical and psychosocial experiences are distinct. Diagnosis often raises concerns about fertility, family planning, sexual function, body image, acceptance by partner(s) and family, and career trajectory. In 2023, MSKCC launched the Young Women with Breast Cancer Program (YWBCP) to provide streamlined comprehensive care, support, education, and research opportunities tailored for women 45 and younger.
Methods: The YWBCP administered an online 35-question patient-reported intake survey to women 45 and younger with newly diagnosed breast cancer. It assesses psychological status, fertility and family history, sexual health, and body image before treatment. All women registered at MSKCC for new appointments received the option to participate. Quantitative analysis was performed.
Results: From 5/2023- 5/2024, 72.2% (600/820) of women with stage 0-IV breast cancer ages 19-45 completed the YWBCP Intake Survey on MSK Engage within six weeks of their initial visit. 78.2% (469/600) remained at MSKCC for primary treatment. The mean and median age of participants was 38.7 and 40 years, respectively.
51% (305/595) of women reported experiencing high levels (very much or quite a bit) of anxiety in the previous 28 days. 58% (171/298) reported being very much or quite a bit worried about how cancer will affect their friends/family and 52% (76/180) were very much or quite a bit worried about discussing cancer with friends/family. 46% (71/155) were very much or quite a bit worried about trouble with school or work and 43% (48/110) were very much or quite a bit worried about trouble parenting. 41% (38/92)

were very or quite a bit worried about relationships and 58% (98/169) about money problems. 22% (130/586) reported wanting to speak to a social worker about how to discuss their diagnosis with their children, parents, and friends. Patients reported preference for individual therapy 34%(206/600), support groups 32% (189/600), support for family 30% (177/600), recreational programs 19% (112/600), peer-to-peer programs 18% (109/600), and other mental health resources 17% (103/600).
37% (224/581) of women were very or quite a bit concerned that their cancer would affect their ability to be physically intimate. Regarding fertility, 17% (100/595) already protected future fertility, 27%(159/595) had not yet, but wanted to and 56% (336/595) were not interested. 41% (245/600) wanted more info about having children in the future.
Conclusion: The YWBCP tailors its services to meet the needs reported by newly diagnosed breast cancer patients ages 45 and younger. Expert social work and educational services were developed to address the needs of these women given their significant anxiety and distress. Likewise, reproductive and sexual health counseling are key components of our program. The YWBCP will continue to develop programs and services to help address the concerns of these young women. Further analysis of the six-month and one-year surveys will be crucial in identifying programmatic and service gaps and guide the development of evidence-based interventions.

P2-03-05: AI-Powered Breast Cancer Survivorship Support: A Comparative Analysis of ChatGPT and Gemini in Providing Evidence-Based Lifestyle Guidance

Jasmin Hundal, Asfand Yar Cheema, Amna Zaheer, Mishaal Munir, Baidehi Maiti

Background: Breast cancer survivors are a growing population in the United States, with an increasing number of women facing challenges in navigating the complexities of post-treatment care. However, the transition to survivorship is often challenging, as many women struggle to adhere to recommended lifestyle guidelines, which are crucial for long-term health and well-being. As highlighted in a recent survey study of cancer survivorship programs accredited by the American College of Surgeons Commission on Cancer (CoC), there are significant gaps in the provision of certain services, particularly those related to sexual health and fertility1. Additionally, low patient awareness and lack of referrals remain barriers to accessing available resources. Integrating innovative solutions like large language models (LLMs) into breast cancer care could address these challenges and empower survivors to actively participate in their health and wellness journeys. This study aims to evaluate the potential of AI-powered chatbots, specifically ChatGPT and Gemini, to provide personalized, evidence-based guidance on exercise, diet, and weight management, consequently improving long-term health outcomes for breast cancer survivors.
Methods: This study utilized the Exercise, Diet, and Weight Management During Cancer Treatment guidelines from the American Society of Clinical Oncology (ASCO) and the National Comprehensive Cancer Network (NCCN) to formulate 22 questions focused on preventive health, physical activity, nutrition, and weight management for cancer survivors.

These questions were posed to ChatGPT-4 and Gemini. Responses were evaluated independently by 2 physicians who graded each response on 5 criteria: factual accuracy, relevance, completeness, clarity, and coherence, using a scale from 1 (poor) to 5 (excellent). Grading was analyzed and compared to determine their alignment with ASCO and NCCN guidelines.
Results: ChatGPT demonstrated high performance in factual accuracy, with an average score of 4.52/5. Gemini exhibited a lower average score of 4.38 but achieved 75% of responses rated 4 or higher. In terms of relevance, ChatGPT maintained an average score of 4.43/5. Gemini performed well in relevance, with an average score of 4.29. For completeness, ChatGPTachieved an average score of 4.38/5. Gemini showed slightly higher performance in this criterion, with an average score of 4.48/5. Both models excelled in clarity, each attaining an average score of 4.57/5, with high ratings and minimal ambiguity in their responses. For coherence, both ChatGPT and Gemini demonstrated logical structuring, with average scores of 4.33/5.
Conclusion: The findings highlight the potential of integrating LLMs into oncology for survivorship care. Both models demonstrated robust performance across all criteria. ChatGPT excelled in factual accuracy and relevance, while Gemini showed slightly better completeness. Both models achieved high clarity and coherence scores, indicating their ability to provide clear, comprehensive, and logically structured responses. This integration can significantly enhance adherence to survivorship guidelines, offering personalized, real-time support that improves patient education, risk communication, behavior modification, and systematic follow-up. Continued development and refinement of these models, with a focus on addressing specific needs and concerns of breast cancer survivors, could revolutionize survivorship care, leading to improved adherence to guidelines, better quality of life, and, improved long-term outcomes.

1 - Stal J, Miller KA, Mullett TW, et al. Cancer Survivorship Care in the United States at Facilities Accredited by the Commission on Cancer. JAMA Netw Open. 2024;7(7):e2418736. doi:10.1001/jamanetworkopen.2024.18736

P2-03-06: Factors Associated with Pregnancy and Postpartum Treatment After Endocrine Therapy Interruption in Breast Cancer Patients

Risa Kasahara, Atsuko Kitano, Kumiko Kida, Fumi Akitani, Kyoko Shiota, Asaka Wada, Junko Takei, Atsushi Yoshida

Background: We previously retrospectively analyzed the long-term prognosis of patients who interrupted endocrine therapy in an attempt to achieve pregnancy after breast cancer treatment. We reported that there was no significant difference in the risk of breast cancer related events between the endocrine therapy interruption and continuation groups (at 110 months postoperatively were 25.7% in the continuation group vs. 20.0% in the interruption group, $p = 0.5$). The study also reported that 58% of the patients in the interruption group became pregnant (14.6% in the continuation group, $p<0.05$), indicating that interruption of

endocrine therapy is significantly increases pregnancy rates. In this study, we aimed to examine factors that predispose to pregnancy after interruption of endocrine therapy and postpartum breast cancer treatment.

Methods: This was a retrospective study using surveying of medical chart data between June 2007 and November 2015 at St. Luke's International Hospital. Patients with stage I-III ER-positive breast cancer who visited a reproductive center before starting treatment for breast cancer and interrupted endocrine therapy for less than 120 months were included in this study. Patients who attempted to conceive after discontinuing endocrine therapy were divided into two groups: those who became pregnant and those who did not. The factors associated with achieving pregnancy and postpartum treatment were compared between the two groups. Statistical analysis was performed using the chi-square test and t-test.[Result] Patients who interrupted treatment within 120 months of endocrine therapy and became pregnant were 20/33 patients (60.1%). The median age was 35 years in the pregnancy group and 40 years in the non-pregnancy group. In the pregnancy group, 18 patients (90%) were 39 years old or younger, and in non-pregnancy group, 7 patients (53.8%) were 39 years old or younger ($p<0.05$). The number of patients who were married or had a partner was 16 (80%) in the pregnancy group and 11 (85%) in the non-pregnancy group. Chemotherapy was administered in 9 (45%) of the pregnancy group and 6 (46.2%) of the non-pregnancy group and GnRHa for fertility purpose during chemotherapy was used for four patients (4/9, 44.4%) in the pregnancy group and two patients (2/6, 33%) in the non-pregnancy group. Fertility procedures included duplicate cases: 17 cases preserved embryos (85%) and 5 preserved oocytes (25%) in the pregnancy group, 8 cases preserved embryos (61.5%), 3 preserved oocytes (23.1%), 2 preserved ovaries (15.4%) and 1 (7.7%) could not be frozen in the non- pregnancy group. Of the 20 cases in the pregnancy group, 18 had delivered and 20 children were born. (Two cases gave birth twice.) and two were currently in the process of conceiving. The median time from interruption of endocrine therapy to delivery was 23 months (median); 21 months for those under 35 years of age and 27 months for those 35-40 years of age. Endocrine therapy was resumed after delivery in 9 cases (9/20, 45%), with a median of 8 months (0-19 months) between delivery and resumption of endocrine therapy. The 11 cases who did not resume endocrine therapy after childbirth included 6 cases who had completed 5 years of endocrine therapy, 2 cases who did not resume endocrine therapy because their hormone receptors were originally weakly positive, and 3 cases for unknown reasons.

Discussion and Conclusion:Pregnancy after interruption of endocrine therapy was significantly associated with age <35 years at the time of fertility preservation. This age factor was not related to other factors. While many patients resumed endocrine therapy after delivery, there were instances of non-resumption, highlighting the need for clearer guides and communication regarding postpartum treatment decisions. The findings can inform clinical practice and patient counseling regarding fertility preservation and treatment decisions.

P2-03-07: Neoadjuvant (Z)-endoxifen for Premenopausal Estrogen Receptor (ER)+, Human Epidermal Growth Factor Receptor 2 (HER2)- Breast Cancer (BC): Evaluation of Quality of Life (QOL) measures in the EVANGELINE Study

Sarah K. Premji, Vera J. Suman, Lida A. Mina, Pooja P. Advani, Arezoo Mirad, Roberto Leon-Ferre, Karthik V. Giridhar, Felipe Batalini, Swaathi Jayaraman, Patricia Cronin, Mara Piltin, Amy Degnim, James N. Ingle, Tufia C. Haddad, Amye J. Tevaarwerk, Jason M. Jones, Daniel Flora, Harjinder Singh, Nusayba A. Bagegni, Katie N. Hunt, Judy C. Boughey, Joel M. Reid, Matthew Schellenberg, John R. Hawse, Steven Carl Quay, Matthew P. Goetz

Background: Premenopausal women (PrW) with ER+, HER2- breast cancer (BC) are commonly treated with aromatase inhibitors (AI) with ovarian function suppression (OFS) or tamoxifen (tam) +/- OFS. Common adverse effects (AE) include musculoskeletal symptoms, hot flashes, night sweats, mood changes, and sexual side effects that may seriously impact quality of life (QOL). In SOFT, compared to tam alone, pts treated with tam + OFS had more hot flashes, loss of sexual interest, sleep disturbances, and vaginal dryness. In the combined SOFT/TEXT analysis, pts receiving exemestane + OFS had greater bone/joint pain, vaginal dryness, and loss of sexual interest, whereas pts receiving tam + OFS had more hot flushes and sweats. In the premenopausal setting, E1/E2 levels differ based on type of endocrine therapy regimen, with menopausal E1/E2 levels following OFS, but increases with tam monotherapy. EVANGELINE (NCT05607004) is an ongoing phase 2 multicenter neoadjuvant study assessing (Z)-endoxifen (ENDX), a potent tam metabolite that dually targets ERα and PKCβ, in PrW with ER+/HER2- BC. Prior to the randomized phase II, a PK run-in was designed to identify a dose wherein 28-day ENDX Css > 500 ng/ml in ≥ 5/6 pts and to assess antitumor activity and toxicity when ENDX is dosed at 40 mg/day (monotherapy) and 80 mg/day (+/- OFS). Pts with endocrine sensitive disease (ESD) defined as 4-week Ki67 ≤ 10% continue treatment (tx) for 24 weeks followed by surgery. Here, we report the menopausal symptoms for pts enrolled onto 40 mg/day cohort. Methods: All eligible pts who completed baseline and at least one tx questionnaire or toxicity evaluation are included. Data captured by the medical team using Common Terminology Criteria for Adverse Events (CTCAE) and self-reported symptoms are reported in pts menstrual diary or on the Menopause-Specific Quality of Life (MENQOL) questionnaire administered at baseline, end of week 4, 12, and 24. MENQOL bothersomeness level was categorized as mild (score 0-1), moderate (2-4), and high (5-6). Estradiol and estrone levels were assessed for the 40 mg/day dose at week 4 and 24. Results: For the 40 mg/day cohort, 7 PrW (6 White, 1 Asian) aged 28-51 (median 46) received ENDX. One pt discontinued due to week 4 Ki-67 > 10%. The remaining 6 had ESD, and after 24 weeks underwent surgery. Over the course of tx, relevant AEs reported as possibly, probably or definitely attributed to ENDX included: amenorrhea (G2-n=5); dysmenorrhea (G2-n=1; G1-n=1), hot flashes (G2-n=1; G1-n=5), hyperhidrosis (G1-n=1), hypomenorrhea (G1-n=1), irregular menstruation (G1-n=2), and libido decrease (G2-n=1). Menses did not occur on tx for 4 pts. No dose reductions occurred. Among the remaining 3

pts, dysmenorrhea was described as mild/moderate. MENQOL after 4 wks of tx revealed that hot flashes developed in 4 pts (moderately bothersome -3 pts, not bothersome -1 pt). One pt began venlafaxine for hot flashes. Three pts reported 'being impatient with others' as moderately bothersome. The median (range) baseline estrone (n=5) was 54 pg/mL (19-114) with median (range) fold increase from baseline of 9.0 (1.3-23.2 pg/mL) at wk4 and 4.7 (0.4 - 25.9 pg/mL) at wk24. The median baseline estradiol level (n=5) was 29 pg/mL (19-209) with median fold increases from baseline of 17.9 (0.4-57.0 pg/mL) at wk4 and 8.1 (0.04 - 56.6 ng/mL) at wk24. Currently, 12 pts are enrolled to either 80 mg/day monotherapy or 80 mg/day + OFS.
Conclusions: This is the first report of menopausal side effects in PrW women treated with ENDX 40 mg/day without OFS. Most side effects were low grade and amenorrhea was common. ENDX induced marked increases in E1/E2 levels that peaked at 4 weeks and then declined. MENQOL data from the 80 mg/day monotherapy and 80 mg/day + OFS cohort will be reported at the meeting.

P2-03-08: Influence of Work Schedule Flexibility on Nutrition and Physical Activity Among Employed Breast Cancer Survivors

Jasmin Hundal, Zorie Jones, Narayani Ballambat, Alicia Dugan, Helen Swede

Introduction: Healthful dietary and physical activity behaviors are essential for breast cancer survivors after treatment to enhance recovery and perception of physical well-being. These interventions are critical because they can reduce fatigue, improve cardiorespiratory fitness, strength, health-related quality of life, and reduce morbidity and mortality among breast cancer survivors. Prior studies suggest that survivorship care plans should incorporate physical activity, as even moderate activity can be vital for improving health-related quality of life. However, it is unknown for those in the workforce if employment-related stressors affect compliance and/or self-perception of overall health. This is the first study to evaluate these factors among employed breast cancer survivors.
Methods: We analyzed cross-sectional survey data (self-completed) from 156 employed breast cancer survivors in central Connecticut. Age-adjusted linear regressions were performed using Likert scale questions (5-point or 10-point). Independent variables included adherence to nutrition recommendations (e.g., half of each meal consisting of fruits and vegetables) and physical activity (e.g., strength training twice per week plus other activities to raise heart rate several days per week). The dependent variable was the perception of overall physical health. We conducted stratified analyses based on a dichotomized Likert variable representing the perceived level of control over one's work schedule (Agree/Strongly Agree vs. Disagree/Strongly Disagree, with the central neutral value assigned to Agree). Future analyses are planned to examine overall mental health as the dependent variable using multivariate linear regression and a structural equation model with multiple predictors.
Result: Among the full sample, age-adjusted linear regression revealed a strong positive correlation between adherence to nutrition recommendations and the perception of

physical health (B=0.61, p<0.001). In stratified analyses, we observed that those who reported more control over their work schedule exhibited a slightly stronger relationship compared to those who reported less control (B=0.64, p<0.001; B=0.53, p=0.08, respectively). Similarly, the correlation between adherence to physical activity guidelines and perceived overall physical health was high in the full sample (B=0.61, p<0.001). A notable difference in this association was observed between those who perceived more control over their work schedule compared to those who did not (B=0.72, p<0.001; B=0.32, p=0.18, respectively).
Conclusion: Reduced control over work schedules might significantly affect compliance with healthful behaviors and, concomitant perception of health, particularly for engagement in physical activity. This presents a crucial point of intervention for health care providers. Physicians should recognize and address the impact of work-related stressors on health behaviors to better support their patients in maintaining healthy lifestyles post-treatment. Tailoring survivorship care plans for healthful behaviors that account for work schedules can potentially improve both health outcomes and quality of life in this patient group. Further research is needed to explore the underlying mechanisms and develop interventions to mitigate the negative effects of work-related stress on adherence to healthful behaviors.

P2-03-09: Breast Cancer Surgery and Its Quality-of-Life Outcomes: A Study of São Paulo Public Employees

Marcelo Antonini, Andre Mattar, Mylena Scheneider Becale, Arthur Gaia Duarte Peixoto, Denise Joffily Pereira da Costa Pinheiro, Renata Arakelian, Felipe Zerwes, Eduardo de Camargo Millen, Francisco Pimentel Cavalcante, Antônio Luiz Frasson, Fabrício Palermo Brenelli, Odair Ferraro, Reginaldo Guedes Coelho Lopes

Objective: To evaluate the quality of life (QoL) of breast cancer patients' post-surgery, compare conservative, radical, and oncoplastic surgical outcomes, and identify symptoms and treatment-related factors that negatively impact QoL.
MethodsThis observational, cross-sectional, descriptive study was conducted at the Hospital do Servidor Público Estadual de São Paulo (HSPE) from October 2021 to December 2022. We assessed the QoL of female state public servants presenting in situ or non-metastatic invasive breast cancer who underwent surgical treatment and completed the EORTC QLQ-C30 questionnaire. Inclusion criteria encompassed female patients over 18 years, diagnosed with breast cancer, undergoing surgical treatment, employed as public servants in São Paulo, and actively working at diagnosis. Exclusion criteria included refusal to respond to the questionnaire and metastatic breast cancer at the study's outset or progression within six months of diagnosis. Ethical approval was obtained from the HSPE Research Ethics Committee (CAAE 68337823.4.0000.5463), and all participants signed informed consent forms.
Results: The study included 300 patients with a mean age of 56.6 years. Most participants had a partner (55.69%) and higher education (72.15%). The EORTC QLQ-C30 scores

indicated a reasonable overall quality of life, with an average score of 70.6. Physical (76.6), social (87.1), and role functioning (78.3) scored high. Most patients did not experience bed confinement, did not need assistance with daily activities, and were able to maintain their leisure activities. Emotional functioning had the lowest score (65.1), indicating some level of tension, irritability, depression, or worry. On the symptom scale, insomnia (33.3), pain (30.0), and fatigue (28.3) were the most prevalent, while nausea and vomiting (5.7), dyspnea (7.2), and diarrhea (8.0) scored low, suggesting little interference with daily activities. There was some financial difficulty due to the physical condition and treatment (15.6). In the QLQ-BR23, the score for side effects was 18.5, indicating few adverse effects from systemic treatments. Concerns about hair loss (35.9), arm symptoms (25.2), and breast symptoms (22.4) were the most affected. Body image acceptance was good (74.9), indicating that most patients did not feel less attractive or feminine. Sexual function scored high (82.5), but sexual satisfaction was lower (57.4), showing that although sexual activity continued, satisfaction was impaired. Patients who underwent conservative surgery had better overall quality of life (73.2) compared to radical (66.7) and oncoplastic surgery (55.2) ($p=0.033$). Cognitive function was better preserved in conservative surgery (79.5) compared to oncoplastic (56.3) ($p=0.045$). Social function was also better with conservative surgery (90.7) compared to oncoplastic (70.8) and radical (78.3) ($p=0.017$). More advanced clinical staging was negatively correlated with quality of life, especially in role functioning ($p=0.006$), social function ($p=0.004$), and body image ($p=0.002$). Patients with triple-negative tumors reported greater limitations in activities, while those with HER-2 expression had better role functioning scores ($p=0.094$). Neoadjuvant chemotherapy was associated with lower body image satisfaction (60.3 vs. 78.9; $p=0.033$) and greater concern about hair loss (58.3 vs. 30.1; $p=0.014$). Adjuvant radiotherapy was associated with better overall quality of life (73.0) and social function (89.3) scores ($p=0.007$ and $p=0.033$, respectively), as well as lower pain symptoms (8.5 vs. 25.0; $p=0.007$).
Conclusion: Breast cancer patients demonstrated that while the overall quality of life was reasonable, emotional functioning remained a challenge. Conservative surgery yielded better outcomes in quality of life, cognitive, and social functions compared to radical and oncoplastic surgeries. Advanced clinical staging and triple-negative tumors were linked to greater limitations, whereas HER-2 positive patients showed better role functioning. Neoadjuvant chemotherapy negatively impacted body image and increased concern about hair loss, while adjuvant radiotherapy improved overall quality of life and reduced pain. These findings underscore the need for tailored supportive care to address the emotional and specific functional challenges faced by breast cancer patients.

P2-03-10: Functional Disability and Adverse Mental Health Outcomes among Breast Cancer Survivors: A US National Survey Study

Jincong Freeman, Xinyi Li, Yong Gun Lee, Victoria Umutoni

Background: Breast cancer diagnosis and treatment can have a negative impact on patients' mental health and well-being. Disability adds another layer of adverse effects to

survivorship, and cancer survivors with disabilities may bear heavier burdens of mental health symptoms. However, little is known about the relationships between disability and adverse mental health outcomes among breast cancer survivors in the US.
Methods: We analyzed data from the 2022 National Health Interview Survey that used multistage probability sampling to interview US adults. This study was restricted to adults with a breast cancer history. Any disability (yes/no) was defined by the Washington Group Composite Disability Indicator measuring the self-reported level of difficulty in 6 functional domains: vision, hearing, mobility, communication, cognition, and self-care. Ever having anxiety was per self-report (yes/no), and level of severity in the past 2 weeks was assessed using the 7-item Generalized Anxiety Disorder scale (none-minimal, mild, moderate, and severe). Participants self-reported ever having depression (yes/no), and level of severity in the past 2 weeks was assessed using the 8-item Patient Health Questionnaire depression scale (none-minimal, mild, moderate, and severe). We compared weighted proportions using Rao-Scott Chi-squared tests and calculated P-trends using the Cochran-Armitage test. Multivariable weighted logistic regression was used to estimate adjusted odds ratios (AOR). All statistical analyses accounted for complex design and survey weights.
Results: The unweighted sample size was 644, representing a weighted sample of 4,234,520 US breast cancer survivors. The mean age was 68 years; 79.8% were White, followed by 9.7% Black, 6.3% Hispanic, and 3.6% Asian. Overall, 21.2% had any disability, and they were older than those without disabilities (73 vs. 67 years). Black survivors reported a higher proportion of having any disability than White survivors (27.3% [95% CI: 13.9-40.6%] vs. 21.8% [95% CI: 17.8-25.7%]). Of the total, 25.9% (95% CI: 21.8-30.1%) and 21.3% (95% CI: 17.5-25.1%) have ever experienced depression and anxiety disorder, respectively. Survivors with any disability reported a higher percentage of depression than those without (35.3% [95% CI: 25.3-45.2%] vs. 23.5% [19.0-27.9%], P=.023). The proportion of anxiety was higher among survivors with any disability than those without (32.3% [95% CI: 22.5-42.1%] vs. 18.3% [14.3-22.3%], P=.004). After controlling for demographic and socioeconomic factors, survivors with any disability had greater odds of depression than those without (AOR 1.90, 95% CI: 1.08-3.36). The odds of anxiety were much greater among survivors with any disability than those without (AOR 2.47, 95% CI: 1.35-4.50). In addition, compared with survivors without disabilities, those with any disability were more likely to experience mild (25.1% vs. 15.5%), moderate (20.3% vs. 4.1%) or severe (2.7% vs. 0.8%) depression (P-trend<.001). Similarly, survivors with any disability tended to experience mild (19.6% vs. 8.9%), moderate (8.4% vs. 3.4%), or severe (4.1% vs. 2.0%) anxiety than those without (P-trend<.001).
Conclusions: In this US national sample of breast cancer survivors, 1 in 5 had any functional disability, 1 in 4 experienced depression, and 1 in 5 experienced anxiety. Survivors with any disability had a greater likelihood of lifetime depression or anxiety and an increased level of severity of recent mental health symptoms than those without. Early and routine screening for these symptoms in this population is needed. Oncology programs should identify unmet needs, provide appropriate supportive care or services for cancer-related disability, and improve mental health among breast cancer survivors, particularly those with functional disabilities.

P2-03-11: Health-Related Quality of Life in BREAST trial (Brazilian outcome for Metastatic Breast Cancer): clinical outcomes of HR+, HER2+ breast cancer and its relationship with access to healthcare in Brazil

Luciola Leite de Barros, Vanessa Monteiro Sanvido, Rachel HV Machado, Marina L Nicola, Jackeline O Gomes, Leticia G Barbante, Alexandre B Cavalcanti, Maria SIlvia Petty Moutinho, Afonso CP Nazario

Introduction: Cyclin-dependent kinase 4 and 6 inhibitors (CDK 4/6i) in combination with endocrine therapies have become standard of care in hormone receptor positive (HR+) and human epidermal growth factor receptor 2 negative (Her2-) advanced/metastatic breast cancer. However, in Brazil, women have limited access to CDK 4/6i, notably in public healthy system. Evaluation of health-related quality of life (HR-QoL) among cancer patients has gained an increasing importance and is now a key determinant of anticancer treatments' value. Several trials show that HR-QoL was generally maintained with CDK4/6i. Objective: This study evaluated HRQoL by EQ-5D questionnaire in the first 12 months follow up in patiens from the BREAST trial, comparing their results in the public and private health care systems. Methods and Materials: BREAST trial is a multicenter, prospective observational study that included 300 patients divided into two groups: the public and the private health system, with the ratio of 1 patient in the private for every 2 patients in the public health system. For evaluating HRQoL, the EQ-5D questionnaire was applied by telephone contact at baseline, 3,6, 12 and 24 months. Results: A total of 300 patients were evaluated, with 199 (66.3%) in the public and 101 (33.7%) in the private service. The mean age was 58 years and 76.2% were postmenopausal. In terms of metastatic sites, 84.7% had non-visceral disease, predominantly with bone as the main site. The use of CDK 4/6i at any point of the treatment was 6% in the public health system versus 90.1% in the private setting. At baseline, the EQ5D score was similar between the groups, with median of 0.69 in public (0.52-0.79) and 0.74 (0.64-1) in private system. When evaluation the burden of symptoms, a significant higher proportion of patients from the public system reported problems in one or more EQ-5D dimensions at baseline, most frequently pain/discomfort (70.3%), followed by anxiety/depression (61%), usual activities (42.1%), mobility (34.9%), and self-care (17.9%). At 12-months follow up, the score remained stable in both groups, with median of 0.69 in public (0.54-0.79) and 0.79 (0.65-1) in private; no deterioration was seen in the private setting, despite the fact that the patients received a more intense treatment. In longitudinal analysis, the changes in domains between baseline and 12-months showed an improvement for about 1/3 of the patients, regardless of the health care system, notably for pain and discomfort, this item, however, more prounounced in patients receiving CDK4/6i. The global burden of symptons remained higher at the patients from the public system. Of note, with a median follow up of 31 months, a difference in overall survival was demonstrated, with a mortality rate of 8.9% in the private sector and 19.6% in the public system (p=0.02). Conclusions: The results of our study highlights the disparity in the treatment of metastatic breast cancer among patients in relation to access to health care, with patients dependent on the public system experiencing higher mortality

rates and worse HRQol regarding the burden of symptons at diagnosis and at 12-months follow up.

P2-03-12: Reducing Stress and Improving Quality of Life for Adult Breast Cancer Patients via delivery of monthly non-medical essential services for up to six months during treatment

Danna Remen, Christina Jurrissen; Emily Magnavita, Jeffrey Feldgoise, Meredith Mendelson, Nekia Clark, Aditi Hazra, Amy Comander

Introduction: Ellie Fund provides essential support services for breast cancer patients to ease the stresses of everyday life, allowing the focus to be on family, recovery and healing. In 2019, Ellie Fund launched an Outcomes Measurement Program to empirically measure the impact of its services on patients' physical, emotional and financial health and show improved quality of life (QOL).
Methods: Patients apply for services via an online application, selecting 2 services such as grocery gift cards, prepared/delivered meals, transport to/from medical appointments, childcare, housekeeping and integrative therapies. Services are delivered monthly, for 3 months for curative patients and 6 months for metastatic (mets) patients. Impact data are gathered via voluntary surveys administered before and after services delivery, and tracking fundamental metrics contributing to patients' health and well being. Surveys are composed of the Perceived Stress Scale (PSS), the most widely used public health tool for measuring personal stress. PSS-14 is used (14 standard questions), and each response is assigned a numeric value which is compiled into a final PSS score. Twelve additional survey questions assess QOL changes using a 4-point Likert Scale.
Survey 1 (S1) is mailed to each patient upon entering the service program to establish a baseline stress level. Survey 2 (S2) is mailed upon services completion. S1 and S2 data are recorded, tabulated and compared to determine changes by metric. For this study, analysis was limited to surveys returned from patients who began services in 2022 or 2023 and returned both surveys. Differences between S1 and S2 were evaluated using the 2-sided Chi-Square test.
Results: In 2022 and 2023, 2061 patients received services. 806 recipients returned S1, and 567 recipients returned S2. Survey questions were evaluated based on a 4-point Likert Scale ranging from "a lot" to "none." The largest changes were: patients feeling "a lot" of emotional stress decreased 10.8% (54.1%→43.3%; S1 n=389, S2 n=284, p=0.006); patients feeling "a lot" of disruption of daily life decreased 7.6% (44.0%→36.4%; S1 n=387, S2 n=286, p=0.048); patients feeling "a lot" of ability to focus on family increased 13.7% (31.5%→45.2%; S1 n=321, S2 n=321, p=0.0003); patients feeling "a lot" of ability to access food increased 18% (55.3%→68.3%; S1 n=324, S2 n=325, p=0.0002); and patients feeling "a lot" of ability to care for themselves increased 9.8% (19.9%→29.7%; S1 n=326, S2 n=320, p=0.0018). All 13 measures showed QOL improvement. On the PSS assessment, patients reporting high perceived stress decreased by 6.2% (56.2%→50.0%; S1 n=333, S2 n=336, p>0.05).

PSS scores from 2019 through present were also analyzed. For both mets and curative patients who returned both surveys, patients reporting high perceived stress decreased 11.2% (59.3%→48.1%; S1 n=754, S2 n=755, p<0.00001). Mets patients reporting high perceived stress decreased 18.4% (62.8%→44.4%; S1 n=129, S2 n=124, p=0.0032), and curative patients reporting high perceived stress decreased 9.8% (58.6%→48.8%; S1 n=625, S2 n=631, p=0.0005).
Conclusion: Ellie Fund's non-medical services reduce stress and improve QOL for breast cancer patients during treatment, which other research shows to positively impact health outcomes. Mets patients experienced greater relief from high perceived stress than did curative patients, suggesting a need for supportive services over a longer time period. Data by race and income level need further examination. The data can also inform service effectiveness and program improvement; e.g., a metric showing surprisingly low impact was "Ability to Get To/From Appointments" which increased just 1.3%, suggesting Ellie Fund's transportation service requires improvement.
Limitations
Study strengths: high survey response rate, meeting a broad need for QOL data for cancer patients. Limitations: sampling bias; not every question is answered per returned survey.

P2-03-13: Quality of life in young Hispanic women with breast cancer: Long-term results from a large prospective cohort

Fernanda Mesa-Chavez, Ana Ferrigno Guajardo, Hatem Azim Jr, Federico Rotolo, Alejandra Platas, Alan Fonseca, Marlid Cruz ramos, Ana Rodriguez, Alejandro Mohar, Cynthia Villarreal-Garza

Background: Young women with breast cancer (YWBC) are a unique group of patients facing diverse challenges, including tumors with aggressive pathological features, intensive treatment strategies, career concerns, and family and motherhood issues. These factors can have a significant impact on their quality of life (QoL). While most studies have focused on postmenopausal women, there is limited information on how QoL evolves in young patients. Here we report longitudinal variations in QoL and the associated predictors in YWBC.
Methods: We included patients aged ≤40 with non-metastatic BC accrued in the Joven & Fuerte cohort. YWBC completed sociodemographic information and the EORTC QLQ-BR23 questionnaire at diagnosis and during four follow-up visits (approximately at month 6 and years 1, 2-3, and 4-5 post-enrollment). We also collected clinical and treatment information. To analyze the main patterns of QoL, we used group-based multivariate trajectory modeling, which identified two groups of patients that we labeled 'good' and 'poor' based on their functional and symptom scores. We used the Chi-squared, Fisher's exact, Kruskal-Wallis tests, and binomial logistic models to explore the relationship between baseline characteristics and trajectory group classification.
Results: In total, 477 women with a median age of 36 years were included in the analysis. The majority had public health insurance (87%) and stages II (49%) or III (39%) BC. Among them, 52% had HR-positive HER2-negative BC, 22% had HER2-positive BC, and 26% had

TNBC. Most patients received anthracycline-based chemotherapy (82%). Up to 62% of YWBC were clustered in the poor trajectory group, while 38% were in the good trajectory group. Both groups had similar sociodemographic, clinical, and treatment characteristics. From baseline to year 5, the mean body image score declined from 92.8 to 89.7 in the good trajectory group and from 75.4 to 64.7 in the poor trajectory group. Sexual functioning scores also deteriorated from baseline to year 5 in the good (29.3 vs. 27.8) and poor trajectory groups (30.6 vs. 25.6). Sexual enjoyment mean scores remained unchanged from baseline values in the good trajectory group (51.4), while they deteriorated at year 5 in the poor trajectory group (51 vs. 37.3). Regarding YWBC's future perspective, the good (56.4 vs. 79) and poor trajectory group (39.3 vs. 57.2) showed improvement in mean values from diagnosis to year 5 of follow-up. Compared to initial scores, the good trajectory group reported better systemic therapy side effects at year 5 (16.4 vs. 14.3), while the poor trajectory group had worse scores (25.7 vs. 27.9). Breast symptoms improved from baseline to year 5 in both the good (16.9 vs. 10.4) and poor trajectory groups (27.3 vs. 14). Compared to baseline values, arm symptoms in the good trajectory group improved at year 5 (8.2 vs. 7.1), whereas they worsened in the poor trajectory group (17.6 vs. 20.1). Regarding being upset by hair loss, the good (36.3 vs. 27) and poor trajectory groups (43.4 vs. 31.2) showed improvement in mean values from baseline to year 5 of follow-up. In a multivariable logistic model, patients with HER2-positive BC (aOR=0.57 95%CI 0.35-0.94; p=0.028) and those with public health insurance (aOR=0.41 95%CI 0.16-0.90; p=0.035) were less likely to belong to the poor trajectory group.
Conclusions: Most of our patients had a poor QoL over time. Key areas that are of concern for YWBC include body image, sexuality, and their outlook on future health. Additionally, oncologists should prioritize using available strategies to minimize treatment-related side effects and enhance patients' QoL. Future studies should identify which therapies impact the QoL in YWBC and establish effective approaches to improving their QoL.

P2-03-14: PATIENT REPORTED OUTCOMES AND LYMPHEDEMA IN NODE-POSITIVE BREAST CANCER IN THE EARLY POSTOPERATIVE PERIOD AFTER NEOADJUVANT CHEMOTHERAPY IN THE PROSPECTIVE NEOSENTITURK-trial MF18-03

Neslihan Cabioglu, Halime Gül Kılıç, Atilla Bozdoğan, Birce Rumisa Kılıç, Yasemin Uslu, Ekin Özgörgü, Selman Emiroğlu, Mustafa Tükenmez, H Karanlık, Mahmut Müslümanoğlu, C Uras, Yeliz E Ersoy, Ebru Sen, Atilla Çelik, MA Gulcelik, Ecenur Varol, Ayşe Altınok, Inci Akman, Taner Kıvılcım, Ahmet Dağ, Lütfi Doğan, ,Niyazi Karaman, L. Yeniay, A. Igci, V Ozmen, D Sindel, Ayfer Kamalı Polat, A Soran, A Oral

Abstract: The Neosenti-Türk/MF-18-03 is a prospective study that evaluates the outcome and whether breast cancer-related lymphedema (BCRL). patient-reported arm and shoulder morbidity and quality of life are affected by axillary surgery type in patients with node-positive breast cancer who underwent surgery following neoadjuvant chemotherapy (NAC). The present study investigated the risk factors associated with lymphedema, and how

quality of life is affected by axillary surgery type in the early postoperative period.
Methods: Patients were evaluated by the SF-12 quality of life and QUICK-DASH hand, arm, and shoulder range of motion questionnaires. Circumferential tape measurements of the arm width were performed to evaluate the postoperative lymphedema.The volume difference of 10% or more in the operated arm compared to the healthy arm was considered as lymphedema. Patients were treated either with sentinel lymph node biopsy /targeted axillary dissection (SLNB/TAD, n=243) or axillary lymph node dissection (ALND, n=130).
Results: Of 373 patients from 15 centers, breast cancer related lymphedema (BCRL) was detected in 41 (11%) patients at the 12-month follow-up. Treating with SLNB/TAD-alone (5.8% vs 20.8, p<0.001), removal <6 lymph nodes (5.6% vs 18.1, p<0.001), or cT1-2 (8.5% vs 19.1%, p=0.005), were found as significant factors associated with decreased lymphedema risk. Even though decreased lymphedema has been observed in those aged <50 (8.6% vs 14.9%, p=0.06), with cN1 (9.8% vs 18.8%, p=0.066) and breast conserving surgery (8.7% vs 13.9%, p= 0.113), these differences did not reach the statistical significance.
In the assessment of SF-12 quality of life questionnaire. patients with SLNB/TAD were more likely to have improved bodily pain scores (35.68±12.37 vs 32.35±14.76, p=0.045) compared to those with ALND. Furthermore, patients with ALNB/TAD were more likely to have a better arm and shoulder function as assessed with the QUICK-DASH questionnaire with decreasing scores at the 12th month (29.22±18.47 vs 34.85±20.35, p=0.011). Moreover. patients with SLNB/TAD were found to have an improved SF-12 bodily pain scores. Even though, there were improvements in role physical and role emotional scores in the SLNB/TAD group compared to the ALND-group, these changes did not reach the statistical significance. However, no significant differences could be found in other parameters including general health, physical functioning, vitality, social functioning and mental health of SF-12 test scores between patients with SLNB or ALND in terms of axillary surgery type.
Conclusion: These findings suggest that a more conservative axillary surgery with omitting axillary dissection and with axillary lymph node excision not more than 6 lymph nodes, are factors associated with decreased risk of BCRL in the present cohort. Patients with ALND were more likely to have impaired arm and shoulder function compared to those without ALND, and presence of lymphedema was found to be associated with decreased quality of life. Therefore, precautions such as early postoperative exercise and early diagnosis of preclinical lymphedema should be considered to prevent the BCRL in the first year after surgery.

P2-03-15: Identifying pre-habilitation targets for the mitigation of long-term side effects of chemotherapy in patients with early breast cancer

Lyndsay Cooper, Sasha Knowlton, Kirsten Nyrop, Allison Deal, Coral Aman, Annie Page, Hyman Muss

Background: There is a need to identify pre-treatment characteristics of women with early breast cancer that are associated with persistent fatigue or suboptimal health-related quality of life (HRQOL) post-chemotherapy as potential targets for pre-habilitation interventions: Patients and Methods: Ancillary analysis of previously collected data from patients with newly diagnosed Stage I-III breast cancer scheduled to receive chemotherapy with curative intent. The objective was to identify baseline (pre-chemotherapy) variables associated with meaningful deteriorations in fatigue and other measures of HRQOL from pre-treatment to 6 months after chemotherapy completion. Percentages are reported along with unadjusted and adjusted relative risks.
Results: In a sample of 249 women post-chemotherapy, 32% reported worsening fatigue (FACIT-F), 35% worsening Physical Well-Being (PWB), 16% worsening Functional Well-Being (FWB), 8% worsening Emotional Well-Being (EWB), and 30% worsening Social Well-Being (SWB). In multivariable (MV) analysis, variables that were significant in univariate analysis – Black race, high BMI, and baseline poorer EWB – remained significant for worsening post-chemotherapy fatigue (FACIT-F). In MV analysis that included race, education, falls and baseline EWB, Black race and a positive falls history remained significant for worsening PWB. In MV analysis inclusive of race, SPPB and FWB, lower SPPB and FWB remained significant predictors of worsening FWB. In MV analysis that included baseline Mental Health Index-Anxiety, EWB and SWB, a higher SWB and lower EWB remained significant for worsening SWB.
Conclusion: Pre-chemotherapy characteristics in women with early-stage breast cancer that are associated with increased fatigue and reduced HRQOL post-treatment could be used to identify patients who may benefit from pre-habilitation interventions.
Keywords: breast cancer, pre-habilitation, cancer-related fatigue, chemotherapy, long-term toxicity,

P2-03-16: Prevalence of PIK3CA/AKT1/PTEN and other genomic alterations in primary and recurrent tumor tissue: exploratory analysis from the Phase 3 CAPItello-291 clinical trial

Javier Cortés, Hope S. Rugo, Mafalda Oliveira, Sacha J. Howell, Florence Dalenc, Henry L. Gomez, Xichun Hu, Komal Jhaveri, Petr Krivorotko, Sibylle Loibl, Meena Okera, Yeon Hee Park, Joo-Hyuk Sohn, Masakazu Toi, Eriko Tokunaga, Lyudmila Zhukova, Agostina Nardone, Elza C. de Bruin, Robert McEwen, Marta Fulford, Nicholas C. Turner

Background: Based on the positive results from the CAPItello-291 trial, capivasertib plus fulvestrant is a treatment option for adult patients with HR+/HER2− locally advanced or metastatic breast cancer who have progressed on an endocrine-based regimen and whose tumors harbor one or more alterations in PIK3CA, AKT1, or PTEN. In CAPItello-291, participants were requested to provide a formalin-fixed, paraffin-embedded tumor sample from the most recently collected tumor tissue for next-generation sequencing (NGS) testing at the stage of either primary or recurrent disease. Overall, 48% of samples with a valid NGS

test result had a PIK3CA/AKT1/PTEN alteration. In this exploratory analysis, we assessed the prevalence of PIK3CA/AKT1/PTEN alterations in tissue samples from primary versus recurrent disease and explored the broader molecular profiles between cohorts.
Methods: A retrospective review of molecular profiles of non-matched primary and recurrent breast cancer samples from CAPItello-291 was performed to assess the prevalence of PIK3CA/AKT1/PTEN alterations in tissue from the primary tumor versus recurrent disease. Based on the tissue requisition forms, samples were classified as primary if the type of tissue provided was reported as 'primary' and had breast/lymph node as the anatomic site, while samples were classified as 'recurrent' if the tissue provided was reported as 'recurrence' and the anatomic site was not breast. Analysis for pathogenic/likely pathogenic genes with alteration prevalence of ≥2% captured by FoundationOne®CDx was carried out by primary/recurrent and PIK3CA/AKT1/PTEN-altered/non-altered status. Statistical analyses were performed using chi-square or Fisher exact test. All analyses were exploratory.
Results: A total of 381/594 (64.1%) of the analyzed samples were defined as primary, 156/594 (26.3%) were defined as recurrent, and 57/594 (9.6%) were defined as unknown/not valid and excluded from further analysis. Prevalence of PIK3CA/AKT1/PTEN alterations was similar in primary and recurrent cohorts, overall (50.7% primary vs 46.2% recurrent, p=0.39) and by gene (PIK3CA: 36.2% primary vs 30.8% recurrent, p=0.27; AKT1: 5.5% primary vs 6.4% recurrent, p=0.84; PTEN: 5.7% primary vs 6.4% recurrent, p=0.94). Compared with primary samples, recurrent samples were enriched for alterations in ESR1 (5% vs 17%, p≤0.001), BRCA2 (5% vs 11%, p=0.02), GATA3 (17% vs 24%, p=0.04), CDKN2A (2% vs 6%, p=0.04), and SMAD4 (1% vs 4%, p=0.04). Notably, ESR1 mutations were enriched at recurrence in both the PIK3CA/AKT1/PTEN-altered and non-altered cohorts, whereas GATA3 alterations were enriched in the PIK3CA/AKT1/PTEN non-altered cohort and CDKN2A alterations in the PIK3CA/AKT1/PTEN-altered cohort at recurrence. When comparing the overall PIK3CA/AKT1/PTEN-altered versus the non-altered cohorts, the altered cohort had more alterations in CDH1, MAP3K1, TBX3, CBFB, and BCL6, whereas the non-altered cohort had more alterations in genes associated with cell cycle, such as GATA3, CCND1, and MYC.
Conclusions: Overall, the prevalence of PIK3CA/AKT1/PTEN alterations was comparable between non-matched tumor tissue samples collected at primary or recurrent disease used for NGS testing in CAPItello-291, in line with their role as oncogenic drivers in HR+/HER2− breast cancer. Consistent with the literature, recurrent tissues were enriched for ESR1, BRCA2, GATA3, CDKN2A, and SMAD4 alterations, indicating a potential role for these gene alterations in driving disease recurrence. The PIK3CA/AKT1/PTEN-altered cohort was enriched for CDH1 mutations while the non-altered cohort was enriched for alterations in cell cycle-related genes previously associated with endocrine and cyclin-dependent kinase 4/6 inhibitor resistance.

P2-03-17: Targeting NR2F2 overcomes multiple forms of endocrine resistance

Yanyan Cai, Peihua Zhao, Fan Wu, Huiyong Zhao, Hong Shao, Antonio Marra, Payal Patel, Elizabeth O'Connell, Emma Fink, Matthew M Miele, Zhuoning Li, Elisa De Stanchina, Emiliano Cocco, Pedram Razavi, Eneda Toska, Sean W Fanning, Guotai Xu, Anna A Sablina, Sarat Chandarlapaty

Endocrine resistance is frequently encountered in the clinic through a variety of mechanisms such as NF1 loss that induce alternative survival pathways and suppress estrogen responsiveness. While targeting the induced pathways such as the RAS-MAPK pathway can have antitumor effects, it can also incur toxicities. To identify novel and potentially more specific therapeutic vulnerabilities in this context, we performed CRISPR/Cas9 screens in wildtype and NF1 knockout isogenic ER+ models and identified NR2F2, an orphan nuclear receptor, to be essential specifically in NF1 loss cells. Our in vitro and in vivo results revealed that NR2F2 is a critical regulator of the estrogen signaling pathway, largely playing a repressive role. We found that NF1 loss could upregulate NR2F2 expression level in ER+ breast cancer cells through the activation of the MAPK pathway. NR2F2 overexpression by itself conferred endocrine resistance, while genetic knockout and pharmacologic inhibition of NR2F2 sensitized ER+ breast cancer cells to endocrine therapies and attenuated resistance across multiple endocrine refractory tumor models including those driven by NF1 loss, ARID1A loss, and PTEN loss. These results reveal upregulation of NR2F2 to be a recurrent mechanism whereby hormone responsiveness is suppressed. At a mechanistic level, investigation into chromatin accessibility and transcription revealed that altered NR2F2 expression modulates genome-wide chromatin accessibility including ER-regulated loci and modulates ER transcriptional activity through its direct interactions with ER and its transcriptional coregulators. Collectively, our data unveil a critical mechanism whereby endocrine resistance occurs through the repression of estrogen responsiveness and highlight a new therapeutic approach to restore endocrine response through pharmacologic inhibition of NR2F2.

P2-03-18: Lymph node metastasis of breast cancer: subclonal selection for high lipid metabolism from the primary tumor

Yue Zhou, Zehao Wang, Zhishuang Gao, Xiaoting Chen, Bingqiu Xiu, Jingyan Xue, Jiong Wu

Background: Lymph node metastasis is the most prevalent site of breast cancer dissemination and significantly influences patient prognosis and survival. Accurate prediction of axillary lymph node metastasis (ALNM) is crucial for tailoring surgical and pharmacological treatments. Understanding the underlying characteristics of lymph node metastasis can improve risk prediction and treatment strategies. Methods: We integrated single-cell transcriptomic data from 13 pairs of primary breast tumors and their matched lymph node metastases, sourced from our institution and public databases. Epithelial cells were clustered to explore the characteristics, and inferCNV was applied to trace the

evolutionary lineage of metastatic cells. We validated the association between LNM-signature and lymph node metastasis using TCGA breast cancer data. Results: Single-cell transcriptomics identified lymph node metastatic cells with heightened lipid metabolism, emphasizing fatty acid synthesis and membrane related metabolism. Immunohistochemistry of expanded clinical cohorts and a murine model corroborated the findings. Analysis of the inferCNV evolutionary tree revealed that the main ancestors of metastases in the primary tumor were clones exhibiting elevated lipid metabolism compared to others. This suggested that nodal metastasis was driven by subclonal selection rather than emerging adaptation. This association between primary tumors and lymph node metastases was further reinforced by bulk RNA-Seq data from breast cancer patients in the TCGA dataset. We generated a LNM-signature from the nodal metastasis associated cluster. The signature score increased with higher N stage and the area under the curve (AUC) for the signature score reached 0.65 (95%IC 0.61~0.71) within patients with the same T stage. Conclusions: Our findings indicate that lymph node metastasis arises from subclonal selection for high lipid metabolism from primary tumors. The corresponding signature score is a valuable predictor of nodal metastasis risk.

P2-03-19: Capivasertib-fulvestrant for patients w/ HR-pos/HER2-negative advanced breast cancer who had relapsed or progressed during or after aromatase inhibitor treatment: exploratory analysis of PTEN deficiency by IHC from phase III CAPItello-291 trial

Komal Jhaveri, Hope S. Rugo, Javier Cortes, Mafalda Oliveira, Sacha J. Howell, Florence Dalenc, Henry L. Gomez, Xichun Hu, Petr Krivorotko, Sibylle Loibl, Meena Okera, Yeon Hee Park, Joo-Hyuk Sohn, Masakazu Toi, Eriko Tokunaga, Lyudmila Zhukova, Agostina Nardone, Elza C. de Bruin, Ian Wadsworth, Celina D'Cruz, Nicholas C. Turner

Background: In the phase III CAPItello-291 trial in patients with HR-positive/HER2-negative advanced breast cancer (ABC) who had relapsed or progressed during or after aromatase inhibitor (AI) treatment, the addition of capivasertib (a potent, selective pan-AKT inhibitor) to fulvestrant significantly improved progression-free survival (PFS) compared with placebo-fulvestrant in the overall population (hazard ratio: 0.60; 95% confidence interval [CI]: 0.51–0.71; p<0.001) and in patients with PIK3CA/AKT1/PTEN-altered tumors detected by next-generation sequencing (NGS; hazard ratio: 0.50; 95% CI: 0.38–0.65; p<0.001). Previous exploratory analysis also showed consistent PFS benefit across each alteration detected, including in patients with PTEN-altered tumors (n=50; hazard ratio: 0.45; 95% CI: 0.24–0.84). Here, we report a prespecified exploratory analysis of alteration prevalence and PFS in patients with deficient PTEN expression as detected by immunohistochemistry (IHC). Methods: In CAPItello-291, eligible pre-/peri- or postmenopausal women or men with HR-positive/HER2-negative ABC that had recurred or progressed on or after AI treatment with or without a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) were randomized 1:1 to receive fulvestrant (500 mg intramuscularly on days 1 and 15 of cycle 1, and day 1 of each subsequent 28-day cycle) with either placebo or

capivasertib (400 mg twice daily; 4 days on, 3 days off). PIK3CA/AKT1/PTEN alteration status was determined post-randomization using NGS in tumor tissue collected prior to study enrollment. Available samples were processed centrally to determine deficient PTEN protein expression by IHC using the VENTANA® PTEN SP218 antibody and a prespecified cutoff for this study of <10% staining of tumor cells. Hazard ratios for PFS were calculated using Cox proportional hazards models stratified by prior use of CDK4/6i. Data cutoff: August 15, 2022. Results: In total, PTEN results by IHC were obtained from 373/708 (53%) patient tumor samples. Baseline characteristics were broadly balanced between those with and without PTEN testing results. 71/373 (19%) patient tumor samples were identified as PTEN deficient by IHC; of these, 55% (n=39) had PIK3CA/AKT1/PTEN-altered tumors by NGS (26% PIK3CA [PIK3CA only n=15; PIK3CA and PTEN n=4]; 1% AKT1 [AKT only n=1]; 32% PTEN [PTEN only n=19; PIK3CA and PTEN n=4]), 30% (n=21) had PIK3CA/AKT1/PTEN-non-altered tumors by NGS, and 15% (n=11) had unknown NGS results. For tumors PTEN proficient by IHC 302/373 (81%), 164 (55%) were non-altered and 128 (42%) were altered by NGS (107/302, 35% PIK3CA, 6% AKT1, 3% PTEN) and 10 (3%) had unknown NGS result. Within samples with both NGS and IHC data, all samples with homozygous deletions or large rearrangements of PTEN by NGS were PTEN deficient by IHC. In patients with PTEN-deficient tumors by IHC, 34/71 (48%) received capivasertib-fulvestrant and 37/71 (52%) received placebo-fulvestrant. In this group, PFS benefit was observed with capivasertib-fulvestrant versus placebo-fulvestrant: median PFS: 9.3 months versus 3.7 months; hazard ratio: 0.52 (95% CI: 0.28–0.93). Conclusions: In this CAPItello-291 exploratory analysis, 19% of patient tumor samples that were available for central IHC testing were PTEN deficient by IHC. Within this subgroup of PTEN-deficient tumors, over half also had PIK3CA/AKT1/PTEN alterations detected by NGS. In the PTEN-deficient by IHC cohort, PFS benefit was noted with capivasertib-fulvestrant versus placebo-fulvestrant, although results are exploratory.

P2-03-20: Correlation of cell cycle arrest and intrinsic subtype with pathologic nodal status after neoadjuvant endocrine therapy – results from the Palbociclib and Endocrine therapy for Lobular breast cancer Preoperative Study

Anna Weiss, Qingchun Jin, Patrick Kurnia, Douglas Russo, Jorge Gomez Tegeda Zanudo, Eileen Wrabel, Michelle DeMeo, Jamie Carter, Steven Come, Caroline Block, Michael Constantine, Meredith Faggen, K.M Steve Lo, Mary Anne Fenton, Denise Yardley, Laura Kennedy, Isabella Bedrosian, Hilal Hachem, Nabihah Tayob, Tari A. King, Otto Metzger Filho, Rinath Jeselsohn

Background: Biomarkers to predict response to neoadjuvant chemotherapy have been well-studied; however, for patients with estrogen receptor-positive disease receiving neoadjuvant endocrine therapy (NET), this remains an area of need. Here we examine cell cycle arrest (CCA) and intrinsic subtype (PAM50) as potential biomarkers of nodal response in the Palbociclib and Endocrine therapy for LObular breast cancer Preoperative Study

(PELOPS) trial.
Methods: PELOPS enrolled women with cT >1.5cm, N0-3, hormone receptor-positive HER2-negative breast cancer, stratifying based on histological subtype. The first 120 postmenopausal participants (60 with invasive ductal carcinoma [IDC] and 60 with invasive lobular carcinoma [ILC]) were randomized to letrozole versus tamoxifen for a 2-week window phase; all patients were then randomized 2:1 to a 24-week treatment phase of NET +/- Palbociclib (Palbo). CCA was defined as a Ki67 staining level ≤2.7% at day 15. For most, CCA measurement was after 2 weeks of NET; the only patients with CCA measured after Palbo were enrolled directly to the treatment phase with NET + Palbo. PAM50 was performed at baseline using RNASeq and the Genefu algorithm. ypN rates were compared by CCA and by intrinsic subtype using chi-square tests.
Results: 188 patients were included. 110 (58.5%) patients had T2 tumors, 82 (43.6%) had lobular histology and 96 (51.1%) were moderately differentiated. 99 (52.7%) patients were cN0, 84 (44.7%) patients were cN+, and 5 (2.7%) unknown. ypN0 and ypN+ rates were similar among patients with IDC and ILC histology. Among IDC patients who underwent axillary surgery, 37 (40.2%) were ypN0 and 55 (59.8%) were ypN+. Among ILC patients who underwent axillary surgery, 28 (34.6%) were ypN0 and 53 (65.4%) were ypN+.
Of 161 patients with complete Ki67 staining and ypN information, 93 (57.8%) had evidence of CCA and 68 (42.2%) did not, 62 (38.5%) were ypN0 and 99 (61.5%) were ypN+. CCA was not correlated with ypN status among patients with IDC (OR 0.84 [0.24-2.88], p=1, and 0.59 [0.13-2.60], p=0.708, for patients enrolled to window+treatment or directly to treatment phase, respectively) or ILC (OR 0.89 [0.26-3.17], p=1, and 1.23 [0.17-10.91], p=1, respectively). There was also no correlation between CCA and ypN status in each treatment arm: window+treatment (NET + Palbo, CCA measured after NET-only in window phase) OR 0.68 (0.24-1.87), p=0.458; window+treatment (NET) 0.86 (0.20-3.55), p=0.832; treatment (NET + Palbo), 0.27 (0.04-1.40), p=0.140; and treatment (NET) 2.25 (0.26-23.97) p=0.468.
Of 93 patients with available PAM50 and ypN data, 32 (34.4%) were luminal A, 57 (61.3%) luminal B, 3 (3.2%) HER2, and 1 (1.1%) normal. Luminal A versus B subtype did not correlate with ypN status overall (OR 0.63 [0.25-1.52], p=0.372), among patients with IDC (OR 0.5 [0.13-1.79], p=0.345) or ILC (1.15 [0.29-4.55], p=1), or among patients treated with NET + Palbo (OR 0.83 [0.27-2.44], p=0.786) or NET alone (0.37 [0.07-1.69], p=0.274).
Conclusions: Among patients treated with NET +/- Palbo, 43.6% of whom had ILC, 57.8% exhibited CCA. Most patients with available PAM50 results had luminal B subtype (61.3%). Cell cycle arrest after NET and baseline intrinsic subtype did not correlate with ypN status among patients treated with NET +/- Palbo. Alternative biomarkers of nodal status after NET need to be investigated.

P2-03-21: Longitudinal Monitoring of ctDNA for Disease Surveillance in Older Women with ER+ Breast Cancer on Primary Endocrine Therapy to Facilitate Surgical De-Escalation: A Prospective, Pragmatic, Hybrid-Decentralized Trial with Correlative Analyses

Neil Carleton, Alexander Chang, Fangyuan Chen, Hunter Waltermire, Michael S Cowher, Kristin Lupinacci, Emilia J Diego, Julia Foldi, Shannon L Puhalla, Quratulain Sabih, Ronald R Johnson, Monica Malhotra, Amanda Laubenthal, Vikram Gorantla, Marija Balic, Antony Tin, Catherine Bridges, Ekaterina Kalashnikova, Angel Rodriguez, Minetta C Liu, Steffi Oesterreich, Adrian V Lee, Priscilla F McAuliffe

Background: Older patients (pts) with ER+ breast cancer (BC) are at risk for both over- and under-treatment due to competing comorbidities. Those who opt to forego surgery in favor of primary endocrine therapy (pET) have approximate risks of 3% for BC-related mortality and 20% for progressive disease. Circulating tumor DNA (ctDNA) is associated with recurrence and progression across multiple solid tumors and may be particularly useful for disease surveillance in these pts.
Methods: The primary objective of this prospective, pragmatic, hybrid-decentralized clinical trial (NCT05914792) was to evaluate the rate of ctDNA positivity in pts ≥ 70 years with early-stage ER+ BC receiving pET and to investigate the clinical significance of ctDNA through longitudinal ctDNA analysis. Pts with ER- and/or HER2+ BC or M1 disease were excluded. This study used a clinically validated, tumor-informed multiplex PCR-NGS assay (SignateraTM, Natera, Inc.) to longitudinally monitor changes in ctDNA levels in pts on pET. Core needle biopsies at diagnosis served as the source of tumor DNA to generate the bespoke ctDNA assay. Blood samples were collected every 3-6mo during follow up. To make the study more accessible to the older population, pts were offered Natera's mobile phlebotomy service to complete blood draws at home. Progressive disease was defined using RECIST 1.1 criteria based on serial ultrasonography imaging. Pt- and caregiver-reported outcomes (PRO/CRO) were collected at each time point. Correlative studies utilizing spatial gene and protein expression assays, multispectral IHC (mIHC), and bulk RNA-seq were completed on a unique set of matched diagnostic core biopsy and surgical specimens treated with long-term endocrine monotherapy to investigate phenotypes of acquired aromatase inhibitor (AI) resistance.
Results: Of 39 pts enrolled to date (median age: 86 yrs, range: 75-94), 64% had stage II/III disease, 28% had regional nodal involvement, and 92% received AI alone for pET. Median follow up was 14mo (range: 2-29mo), with 7 pts (18%) deceased from a non-breast cancer related cause within 16mo of diagnosis, reflecting the advanced age and comorbidities of the cohort. PROs indicated that 75% pts were at least a little bit concerned about the possibility of tumor progression, and 80% felt that ctDNA testing helped inform their treatment plan. Nearly 80% of caregivers indicated that their daily activities often centered around caring for the pt, and they thought ctDNA testing could alleviate some follow up visits. Of 30 pts who had a pre-treatment blood draw, 33% were ctDNA-positive. By the second ctDNA draw (median time to second draw: 6mo), all pts who cleared ctDNA had

sustained responses to ET (stable disease or partial response), whereas all pts who did not clear ctDNA experienced tumor progression (cumulative risk of progression was 50% over 1.5 years, $p < 0.0001$ compared to those who had ctDNA-negativity or cleared at 6mo). Of 20 pts with negative pre-treatment ctDNA, all remained ctDNA-negative on subsequent blood draws without evidence of progression, and ultrasound imaging responses were concordant with ctDNA results (Cohen's kappa=1). Surgery was completed for progression on imaging (n=2) and for patient choice (responding to AI, n=4). Correlative studies on these specimens revealed immunosuppressive macrophage-fibroblast interactions that mediate tumor progression, with enrichment for ARG1+ macrophages and decreased effector T cells in progressing tumors.
Conclusions: This study enrolled older pts, in whom "right-sizing" therapies for ER+ BC is critical. ctDNA results were highly associated with disease outcome, and persistent ctDNA positivity conferred significant risk for progression. ctDNA monitoring may help identify those pts with indolent disease who may be safely followed on pET and those who may be at risk for AI resistance. Both patients and caregivers thought ctDNA was helpful in informing the treatment plan.

P2-03-22: Shallow whole genome sequencing of cell free DNA to predict response to CDK4/6 inhibitor treatment in ER+/HER2- metastatic breast cancer

Olga O|ikonomidou, Fiona Semple, John P. Thomson, Natalie Wilson

Background: Cell-free plasma DNA (cfDNA) from cancer patients contains tumour-derived DNA fragments (ctDNA), allowing a non-invasive method for analysing tumour molecular information in the blood of cancer patients. This allows genetic tracking of tumours and the identification of patients that may not respond or stop responding to treatments.
CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy are the standard of care first-line treatment in ER+/HER2-negative advanced breast cancer. Clinical trials showed improvement of PFS and OS with the use of CDK4/6i. Currently there are no robust biomarkers of response or resistance to CDK4/6i and a rapid disease progression is often seen following failure of response to CDK4/6i. Early identification of response is crucial and has multiple clinical and financial implications. Here, we use shallow whole genome sequencing (sWGS) to detect copy number alterations (CNAs) and calculate a Genome Instability (GI) score with the aim to investigate correlations of GI with CDK4/6i treatment and clinical outcomes.
Methods: Blood samples were collected from a small cohort of metastatic ER+/HER2 negative breast cancer patients (n=36), including patients on CDK4/6i and patients on chemotherapy following progression on treatment with aromatase inhibitor. Bloods were processed to collect the plasma containing the cfDNA which was extracted, quantified and analysed using Agilent Bioanalysis. Samples demonstrating a clean cfDNA profile with minimal contaminating larger sized leukocyte DNA were taken forward for library preparation and sequencing. The resulting genomic data were normalised following binning

and background correction resulting in genome wide copy number patterns. GI scores were calculated as a read out of genomic disruption with respect to control samples. Analysis of PFS and OS were carried out with respect to treatment type and GI score thresholds.
Results: Patients receiving chemotherapy demonstrated significantly higher GI scores than those treated with CDK4/6i (median chemotherapy = 319.5, CDK4/6i = 263.7, T-test P-value = 0.02), evident particularly over chromosomes 3,4,5 & 21. Additionally, patients on CDK4/6i for <1 year demonstrated significantly higher GI scores than patients on CDK4/6i for >1 year (Poor response with <1year on CDKI = 328.7, good response and remain on CDKI > 1 year = 231.7). Survival analysis showed that patients on CDK4/6i for <1 year also demonstrated worse progression free survival (PFS) and overall survival (OS) then those who remained on CDK4/6i for >1 year (median difference PFS = 630 days; OS = 377 days).
Conclusion: Preliminary results examining the GIN scores from our sWGS of cfDNA suggest that high GI scores were associated with shorter progression free survival on CDK4/6i plus endocrine treatment. Patients with higher GI scores at the time of diagnosis are less likely to respond well to CDK4/6i predicting poor clinical outcomes.

P2-03-23: Charting the longitudinal mutational landscape of triple negative breast cancer

Olga O|ikonomidou, Fiona Semple, Devin Bendixsen, Alastair Ironside, Natalie Wilson, Ailith Ewing, Colin Semple

Background: Triple Negative Breast Cancer (TNBC) is characterised by extensive intra-tumour heterogeneity (ITH) where clonal lineages diverge from distinct subpopulations over time, impacting treatment resistance and influencing metastasis. However, the mutational dynamics underlying these lineages are poorly studied. Most TNBC patients with early or locally advanced disease receive neoadjuvant chemotherapy (NACT). Pathological complete response (pCR) to NACT is considered as a surrogate for good prognosis but patient response differs greatly. Both SNVs (short nucleotide variants) and copy number variants (CNVs) have been implicated as drivers of the adaptive response to chemotherapy and metastasis in TNBC. Here, we comprehensively investigated the mutational landscapes in a longitudinally sampled TNBC cohort, relating SNV and CNV patterns during the course of the disease to patient outcomes.
Methods: All TNBC patients selected for the study were undergoing NACT. Samples included preNACT treatment (PreT), surgical postNACT treatment (PostT) and recurrence samples. Residual Cancer Burden (RCB) scores and tumour infiltrating lymphocytes (TILs) were reported by a breast cancer pathologist. DNA was extracted from FFPE tumour samples where homogenous tumour regions had been identified by the pathologist. Multiple regions of the PostT recurrence samples were selected for DNA extraction, resulting in 96 samples in total. Following whole exome sequencing, the raw sequencing reads were processed to identify germline and somatic variants. In addition, we optimised an affordable approach to profile genome wide CNVs in longitudinal samples. Bioinformatic analysis of SNV and CNV data then studied the dominant mutational patterns over time, and identified likely driver

variants and disrupted pathways.
Results: Our results demonstrate that low RCB score correlates with higher levels of TILs in the PreT samples. Tumour mutational burden (TMB) varied from 1-27 per Mb and was lowest in 2 patients with known germline mutations. SNV analysis identified variants in 69 genes previously reported to play roles in the progression of TNBC, the most frequently mutated being TP53. We also found suggestive evidence for novel driver variants under positive selection in the MICA gene. Overall, we identified an enrichment of mutations in genes associated with nucleic acid metabolic processes. The longitudinal sampling also allowed the detection of relatively early PreT mutations, showing enrichment in pathways involved in double-strand break repair and apoptotic signaling. Subsequently many of these early variants were found to be 'conserved' as mutations retained from PreT to PostT in samples from the same patient. In addition, we identified a novel class of SNVs that appear to arise only at later stages of the disease. In the CNV landscape, we identified regions that were commonly amplified or deleted in PreT samples, particularly a recurrent amplification of 8q. For some patients, the CNV landscape changed dramatically over the course of TNBC disease progression, with frequently altered genes differing markedly from those impacted by SNVs.
Conclusions: We have developed relatively inexpensive profiling techniques to identify disease-associated variants in TNBC patients, allowing us to study their dynamics over the course of the disease. We present mutational profiles from before and after NACT from the same patient, which can be compared to reveal the variants that are gained or lost genome-wide during the evolution of a tumour. Ultimately, specific SNVs and CNVs associated with survival, recurrence and metastasis can be identified. These data will direct larger scale follow-up studies for biomarker validation and treatment stratification.

P2-03-24: Cost-Effectiveness of CYP2D6 Genotyping in the Management of Tamoxifen Therapy for Breast Cancer Patients: A Focus on Adverse Events

Isabel Blancas, Xando Díaz-Villamarín, Carlos José Rodríguez-González, Rocío Morón-Romero, Fernando Rodríguez-Serrano

Background: Tamoxifen, an antiestrogen prodrug, is widely used in treating hormone receptor-positive breast cancer. Its efficacy largely depends on its conversion to the active metabolite endoxifen by the CYP2D6 enzyme, which exhibits varying levels of activity based on genetic polymorphisms. Current clinical practice guidelines recommend an initial gynecological examination with transvaginal ultrasound before starting tamoxifen. If no abnormalities are detected, the patient begins tamoxifen without additional gynecological follow-up unless symptomatic (e.g., spotting or vaginal bleeding). This study explores the cost-effectiveness of CYP2D6 genotyping to predict patients at higher risk of toxicity.
Methods: This analysis utilized data from our dose escalation trial (EudraCT: 2007-002942-40), where poor metabolizers (PM) received increased doses of tamoxifen. All women were treated with 20 mg/day of tamoxifen for 5 years, except PM, who received 20 mg/day for 4 months, 40 mg/day for the next 4 months, and 60 mg/day for another 4 months before

returning to 20 mg/day for the remainder of the 5 years. The costs for managing adverse events, updated in May 2024, were obtained from the Andalusian Health Service. These costs provide a detailed financial perspective based on public data, including costs for consultations, diagnostic procedures, follow-up treatments, and hospitalization, reflecting Grade 2 complexity. Additionally, we calculated the cost of CYP2D6 genotyping, covering expenses for DNA extraction, analysis using KASP assays, and proration of personnel and equipment costs. We analyzed the incidence of specific side effects: osteoarticular pain, hot flashes, asthenia, and gynecological alterations.
Results: Only gynecological alterations showed significant differences between CYP2D6 phenotypes. The incidence of gynecological adverse events was significantly higher in slow metabolizer (SM) patients (44.8%) compared to rapid metabolizer (RM) patients (15.2%, p=0.001). Adverse events quantified as average cost per patient include endometrial hyperplasia (€8544,81), endometrial polyps (€1834,56), adenocarcinoma (€9467,96), and endometrial thickening (€1132,27). Although costs related to medications, secondary events, extended hospital stays, or patient evolution were not included, our study recorded an average of 0.75 emergency visits per patient (range: 0-4), each costing €208.47 without hospital admission or observation. The cost of CYP2D6 genotyping is minimal (€10.98) compared to managing gynecological adverse events.
Conclusion: Considering the significant impact of CYP2D6 polymorphisms on the occurrence of gynecological adverse events and the substantial cost of managing these events, our results advocate for the implementation of CYP2D6 genotyping. Given its demonstrated cost-effectiveness, we propose CYP2D6 genotyping for all patients scheduled to receive tamoxifen. For those with a predicted SM phenotype, we recommend protocolized gynecological follow-up at least once a year, along with thorough clinical monitoring. Any emerging symptoms should prompt immediate referral to gynecology for evaluation and examination. This approach not only enhances the quality of care but also aligns with healthcare efficiency objectives.

P2-03-25: Characterization of patritumab deruxtecan activity in breast cancer (BC) patient-derived xenograft (PDX) models

Andreu Òdena, Laia Monserrat, Fara Brasó-Maristany, Cristina Molina-Guitiérrez, Marta Guzmán, Olga Rodríguez, Sarat Chandarlapaty, Fumitaka Suto, Pang-Dian Fan, Mafalda Oliveira, Aleix Prat, Violeta Serra

Background: HER3 is overexpressed in 30-50% of breast cancers and is associated with poor prognosis. Patritumab deruxtecan (HER3-DXd; MK-1022) is a HER3-directed ADC with a potent topoisomerase I (TOP1) inhibitor payload. Clinical trials have demonstrated promising antitumor activity of HER3-DXd in metastatic and treatment-naïve breast cancer in all major subtypes (NCT02980341, NCT04610528), showing clinical activity across baseline levels of HER3 protein or mRNA expression. The identification of relevant biomarkers of response for this treatment remains an unmet clinical need. Here, we aimed to study the activity of HER3-DXd in breast cancer PDX models to explore potential

biomarkers of response.
Methods: The antitumor activity of HER3-DXd (10 mg/kg or 3 mg/kg dosed once weekly, 4 doses in total; Q1W x 4) was assessed in 30 BC PDX models (21 ER+/HER2- and 9 triple negative [TNBC]) and compared to the antitumor activity of the clinically approved TOP1 inhibitor irinotecan (50 mg/kg dosed once weekly; Q1W). PDX models that achieved a complete response to HER3-DXd that lasted longer than 120 days were classified as non-relapsed models. Genetic alterations harbored by PDX models were determined using the MSK-IMPACTTM targeted exome panel that also includes selected intronic regions. nCounter platform was used to assess PAM50 subtype classification and the proliferation score. HER3 expression was assessed by immunohistochemistry (IHC). Tumor samples from PDXs were collected 24h or 7 days (7d) after a single dose of HER3-DXd for pharmacodynamic (PD) experiments. DNA damage induction and replication stress were evaluated in untreated/treated PD samples by quantification of γH2AX and phospho-RPA32 (S4/S8) nuclear foci formation by immunofluorescence (IF), respectively. Chi-squared test was used to evaluate the association between HER3-DXd response and different variables.
Results: 13 out of 30 (43%) PDXs exhibited a profound and sustained response to HER3-DXd 10 mg/kg. Antitumor activity of HER3-DXd was observed across baseline levels of HER3/ERBB3 expression. Basal-like PAM50 intrinsic subtype (p=0.001) and PTEN (p=0.035), RB1 (p=0.014) and TP53 (p=0.008) alterations were associated with long-term response (non-relapse). High concordance was observed between HER3-DXd and irinotecan response (p=0.019). Mechanistically, HER3-DXd induced higher transient HER3 membrane downmodulation in non-relapsed BC PDXs models (p=0.037). In addition, treatment with HER3-DXd resulted in a mild transient antiproliferative effect based on proliferation score accompanied by a sustained higher S-phase DNA damage measured as γH2AX nuclear foci in non-relapsed models versus the relapsed ones (p<0.001). Low-dose HER3-DXd (3mg/kg) showed high efficacy in BRCA1/2-altered PARPi-resistant PDX models (p=0.035), sustained higher S-phase DNA damage and induction of replication stress marker p-RPA32 (S4/S8) in non-relapsed models.
Conclusions: HER3-DXd exerts a potent antitumor response in BC PDXs across baseline levels of HER3/ERBB3 expression in ER+/HER2- and TNBC models. Based on our data, basal-like PDX models were more likely to show long-term responses to HER3-DXd than luminal B PDX models. Results also suggest that BRCA1/2-altered PARPi-resistant tumors will show high benefit with HER3-DXd treatment.

P2-03-26: Real-world prevalence of PD-L1 positivity in early-stage/metastatic triple-negative breast cancer (eTNBC/mTNBC): primary results and pathology insights from the global retrospective observational VANESSA study

Corrado D'Arrigo, Sitki Tuzlali, Romualdo Barroso-Sousa, Nagi El Saghir, Rebecca Dent, Nataša Medić-Milijić, Gyungyub Gong, Shahin Sayed, Tu Thai Anh, Alisan Zirtiloglu, Götz Hartleben, Paula Toro, Iman Estaytieh, Ehsan Masoudi, João Mouta, Lazar Popovic

Background: Most recent phase 3 trials in eTNBC/mTNBC have included central laboratory testing to determine PD-L1 status using protocol-defined assays and scoring methods, varying according to the investigational agent. Applicability to routine clinical practice is poorly understood. In the VANESSA study, conducted in 39 sites across 19 countries, we assessed the global prevalence of PD-L1+ status in eTNBC/mTNBC using the Ventana PD-L1 (SP142) assay retrospectively in real-world clinical practice, and explored diagnostic factors and patient/disease characteristics potentially affecting detection of PD-L1+ status.
Patients and methods: The multicenter retrospective observational VANESSA study consecutively and uniformly enrolled patients treated with systemic therapy for eTNBC or mTNBC (assessed locally per ASCO/CAP guidelines) newly diagnosed between Jan 1, 2014, and Dec 31, 2017. An archival formalin-fixed paraffin-embedded tumor tissue sample was required from all patients. PD-L1 status was retrospectively assessed locally and at a central laboratory by pathologists certified specifically for TNBC on the Ventana platform. The primary objective was to determine the prevalence of PD-L1 positivity (PD-L1 expression on tumor-infiltrating immune cells [ICs] covering ≥1% of the tumor area using the Ventana PD-L1 [SP142] immunohistochemistry assay per local assessment) on primary or metastatic tumor tissue from patients with eTNBC or mTNBC. The secondary objective was to evaluate inter-observer concordance between local and central PD-L1 testing. Prespecified exploratory objectives included comparison of PD-L1+ status in subgroups according to sample size (<5 vs >5 mm), scoring method (digital slides vs light microscopy), and (in mTNBC only) sample origin (primary vs metastatic).
Results: Among 2054 eligible patients, the PD-L1+ prevalence by local assessment was 38% (95% CI 36–41%) in eTNBC (n=1902) and 20% (95% CI 14–27%) in mTNBC (n=152). The prevalence of PD-L1+ status was higher by central than local assessment (eTNBC: 55% [1007/1822] vs 38%; mTNBC: 26% [38/145] vs 20%), and comprised 35% IC1, 13% IC2, and 7% IC3 in the eTNBC cohort and 20% IC1, 6% IC2, and 0% IC3 in the mTNBC cohort. There was 75% overall percentage agreement (PA) between local and central laboratories (62% positive PA, 91% negative PA; Cohen's κ coefficient 0.52, 95% CI 0.48–0.55). Concordance was similar regardless of cohort (eTNBC vs mTNBC), sample type (biopsy vs resection), or sample origin (primary vs metastatic), but lower in 116 samples scored from digital slides. According to local assessment, PD-L1 positivity was more common in larger (>5 mm) than smaller (<5 mm) samples (eTNBC: 43% vs 16%; mTNBC 24% vs 13%). In the mTNBC cohort, the PD-L1+ prevalence was 19% (95% CI 12–27%) in 116 primary tissue samples and 23% (95% CI 10–40%) in 35 metastatic samples. Centrally assessed positive status for PD-L1 ICs and stromal tumor-infiltrating lymphocytes (TILs) was broadly overlapping (Spearman correlation 0.36 for eTNBC, 0.31 for mTNBC).
Conclusion: The PD-L1+ prevalence in real-world samples by SP142 was lower in mTNBC vs eTNBC, by local vs central assessment, and in smaller vs larger samples. We observed lower PD-L1+ prevalence in the VANESSA real-world study than in reported prospective clinical trials assessing PD-L1 status centrally. These findings underline the importance of robust PD-L1 assessment to ensure optimal selection for therapies targeting PD-1/PD-L1 in patients with mTNBC.

P2-03-27: Prevalence of actionable genomic alterations (GA) and predictive value of tumor mutational burden (TMB) for immune checkpoint inhibitor (ICI) effectiveness in HR(+)HER2(-) metastatic breast cancer (MBC)

Mariya Rozenblit, Julia C. F. Quintanilha, Jeffrey S. Ross, Mia Levy, Ryon P. Graf

Background: Pembrolizumab, an anti-PD1 antibody ICI is an FDA-approved option for patients with HR(+)HER2(-) MBC who have exhausted standard of care options and have high TMB (≥10 mut/mb, FoundationOne®CDx). No clinical trials or comparative effectiveness analyses have been performed to compare ICI vs. chemotherapy (chemo) using the FDA-approved TMB biomarker. We sought to perform subgroup analyses of ICI and chemo by TMB level and characterize the prevalence of established actionable GA in tissue (TBx) and liquid (LBx) biopsies of HR(+)HER2(-) MBC patients (pts).
Methods: MBC pts who underwent genomic testing using Foundation Medicine tissue or liquid comprehensive genomic profiling (CGP) assays were included. Patient clinical data was obtained by the US-wide-de-identified Flatiron Health and Foundation Medicine real-world clinicogenomic breast database (CGDB) originated from ~280 US cancer clinics (~800 sites of care) between 01/2011 and 12/2023. The prevalence of mutations (mut) in ESR1, PIK3CA, AKT1, PTEN, BRCA1/2, and PALB2, homozygous copy loss (loss) in PTEN and BRCA1/2, and fusions in NTRK and RET was determined in TBx and LBx. TMB, microsatellite instability-high (MSI-H) and homologous recombination deficiency signature (HRDsig) were determined in TBx. Progression-free survival (PFS), and real-world overall survival (rwOS) were compared in pts receiving single-agent ICI between TMB <10 mut/Mb vs. TMB >=10 mut/Mb (TMB<10 vs. TMB10+) by Cox models. Multivariable analyses were performed adjusted for prognostic features. PFS and rwOS were also compared between pts receiving single-agent ICI vs. chemo, adjusted for propensity scores accounting for metastatic site, number of metastatic sites, ECOG performance status, use of opioid pre-therapy, and line of therapy.
Results: A total of 5,825 TBx and 1,801 LBx were evaluated. At least one actionable GA was detected in 70.6% of TBx and 58.4% of LBx [84.8% in samples with circulating tumor (ct)DNA tumor fraction (TF)>=1% and 34.6% in TF <1%]. The most prevalent GA was PIK3CAmut (42.3% TBx / 33.6% LBx: 51.9% in TF>=1% and 17.2% in TF <1%), followed by ESR1mut (16.7% TBx / 29.7% LBx: 48.4% in TF>=1% and 12.8% in TF<1%) and PTENmut (6.4% TBx / 7.8% LBx: 12.9% in TF>=1% and 3.3% in TF<1%). GA losses were more prevalent in TBx, with PTENloss detected in 4.2% of TBx and 0.7% of LBx and BRCA1/2loss in 0.9% of TBx and 0.2% of LBx. HRDsig was detected in 10.8%, TMB10+ in 8.5% and MSI-H in 0.4% of TBx. Of the 5,825 pts with TBx, 89 received ICI (49 TMB<10 and 40 TMB10+) and 1,835 received chemo (1,711 TMB<10 and 1,835 TMB10+). Pts receiving ICI TMB10+ vs. TMB<10 had more favorable PFS [median 2.9 vs. 1.7 months (mo), hazard ratio (HR) 0.61, 95% confidence interval (CI) 0.39-0.95, p=.029] and rwOS (median 12.9 vs. 3.2 mo, HR 0.53, 95% CI 0.32-0.88, p=.014). Pts receiving chemo TMB10+ vs. TMB<10 had similar PFS (median 4.6 vs. 4.6 mo, HR 0.96, 95% CI 0.8-1.16, p=.677) and rwOS (median 8.9 vs. 12.6

mo, HR 1.04, 95% CI 0.85-1.28, p=0.695). The multivariable analyses confirmed the independent association of TMB and PFS and rwOS in pts receiving ICI. Pts TMB10+ receiving ICI vs. chemo had numerically less favorable PFS (median 2.9 vs. 4.3 mo, HR 1.07, 95% CI 0.65-1.75, p=.797) and more favorable rwOS (median 12.9 vs. 8.5 mo, 95% CI 0.41-1.28, p=.268). Pts TMB <10 receiving ICI vs. chemo had less favorable PFS (median 1.8 vs. 4.1 mo, HR 1.56, 95% CI 1.09-2.25, p=.016) and rwOS (median 3.1 vs. 12 mo, HR 1.73, 95% CI 1.19-2.51, p=.004).
Conclusion: About 70% of TBx harbor at least one GA with established clinical utility. Pts with TMB10+ vs. TMB<10 had more favorable PFS and rwOS on ICI. This study supports ICI use in pts with TMB10+ determined by FDA-approved CGP test and highlights CGP role in identifying a wide range of actionable GA.

P2-03-28: Immune-based gene expression signature determines clinical efficacy of CDK4/6i in HR+HER2- breast cancer

Eudald Felip, Sara Cabrero-De las Heras, Edurne Garcia-Vidal, Adrià Bernat-Peguera, Beatriz Cirauqui, Milana Bergamino, Vanessa Quiroga, Iris Teruel, Angelica Ferrando, Anna Pous, Assumpció López, Laia Boronat, Marga Romeu, Ricard Mesía, Pedro Luis Fernández, Bonaventura Clotet, Eva Riveira-Muñoz, Anna Martínez-Cardús, Ester Ballana, Mireia Margelí

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) have emerged as effective treatments for patients with hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2–) advanced breast cancer and more recently in adjuvant setting. Trials in neoadjuvant scenario are ongoing. Dedicated research efforts have been undertaken to find predictive biomarkers of response or resistance to these therapies although no molecular biomarkers have reached the clinic so far. Methods. Here, we performed a single-center prospective study to provide insights into the clinical and tumor characteristics determining the efficacy of CDK4/6i in metastatic breast cancer (n=100). Gene expression in tumors was performed using nCounter Breast 360 (BC360TM) panel. Clinical and biological data were correlated using logistic cox regression analysis. Transcriptomic data from NeoPalAna trial (GSE93204) was used as a validation dataset. Results. Taking into account clinical characteristics determining CDK4/6i efficacy, we developed a clinical stratification algorithm that allowed the dichotomic classification of the cohort based on CDK4/6i efficacy. The two resulting efficacy groups were used to identify and characterize the molecular pathways involved in CDK4/6i efficacy through the standardized tissue-based transcriptomic analysis in pre-treatment biopsies. When considering expression signatures implemented into the BC360TM panel, we identified 19 that were differentially expressed, presenting a significant enrichment of overexpressed immune-related signatures in the bad efficacy group (13/19). Multivariate Cox survival analysis indicated that elevated expression levels of the Treg, IFNGamma, PD1 and TIS signatures were independently associated to PFS only in first-line patients, overall suggesting that immune function might be a key factor determining CDK4/6i efficacy. To

further delineate the immunologic features determining CDK4/6i efficacy, we evaluated differences in single gene expression in first-line patients, resulting in the identification of a 14-gene group exhibiting at least a 50% significant expression difference between good and bad efficacy groups. Unsupervised consensus clustering, allowed us to further define a 9 immune-gene signature that successfully clustered together 90% of patients from the good efficacy group (19/21). Indeed, mean expression of the 9-gene signature was significantly different between good and bad efficacy groups, both considering first-line patients (p=0,004) or the entire cohort (p=0,003), being always upregulated in the bad efficacy patients. More importantly, multivariate Cox survival analysis indicated that elevated expression levels of the 9-gene signature were associated to poorer PFS and OS independent of treatment line (p=0,033 and p=0,034, respectively), improving predictive capacity compared to the BC360TM signatures. The predictive value of our 9-gene signatures was further confirmed using the data from NeoPalAna clinical trial, where a significant difference in the 9-gene signature expression was also observed between sensitive and resistant tumors (p=0.026). Conclusions: Our results identify a novel 9-gene immune-based signature that predicts CDK4/6i efficacy in breast cancer patients, with easy implementation in daily clinical practice. Overall, our data further strengths the key role of immune response as a valuable predictive factor for CDK4/6i efficacy in breast cancer.

P2-03-29: Upregulation of senescence signatures and interferon-signalling after short-term pre-operative CDK4/6 inhibitor – gene expression analysis from the POP and ABC-POP trials

Julia Dixon-Douglas, Bastien Job, Monica Arnedos, Alicia Tran-Dien, Benjamin Verret, David Gentien, Audrey Rapinat, Diep T.N. Tran, Damien Drubay, Stefan Michiels, Fabrice André

Background: CDK4/6 inhibitors (CDK4/6i) have been shown to induce senescence in pre-clinical models, however the extent to which this occurs in patients, and its clinical relevance, is unknown. Senescence is known to modulate adaptive anti-tumour immunity and may be implicated in CDK4/6i induced immune response. We evaluated expression of senescence-associated transcriptomic signatures in patients with early stage hormone-receptor positive, HER-2 negative (HR+/HER2-) breast cancer treated with 14 days of CDK4/6i monotherapy and assessed differential gene expression according to anti-proliferative response.
Methods: Pre- and on-treatment transcriptomic profiles of HR+/HER2- tumours from patients treated with palbociclib on the POP trial (NCT02008734) and abemaciclib on the ABC-POP trial (NCT02831530) were evaluated for on-treatment expression of senescence-associated gene signatures, compared to pre-treatment expression. In both trials, patients with previously untreated, operable, early stage breast cancer were randomised 3:1 to receive 14 days of a CDK4/6 inhibitor or no treatment, and underwent biopsy prior to treatment and at surgery (day 15). Response was defined as the natural log of on-treatment Ki67 (at day 15) < 1, previously shown to be significantly associated with recurrence free survival and breast cancer specific survival in HR+/HER2- breast cancer. Microarray

(Affymetrix Human Gene Chip 2.1ST) of RNA extracted from fresh-frozen tissue obtained from pre-treatment core biopsy and on-treatment surgical specimens was used to generate transcriptomic profiles. Differential gene expression and gene set enrichment analysis were performed.
Results: RNA data was available for 57 pre-treatment and 50 on-treatment samples from patients treated with palbociclib, and for 62 pre-treatment and 57 on-treatment samples from patients treated with abemaciclib. Expression of four senescence-associated gene signatures (SenMAYO, Fridman_UP, Purcell, Purcell RED) was significantly upregulated following 14 days of treatment with palbociclib (SenMAYO normalised enrichment score [NES] 2.41, adj. p-value < 0.01; Fridman NES 2.13, p < 0.01, Purcell_RED NES 1.90, p < 0.01, Purcell NES 1,85, p < 0.01) and abemaciclib (SenMAYO NES 2.43, p <0.01, Purcell_RED NES 2.01, p < 0.001, Purcell NES 1.88, p < 0.01, Fridman NES 1.71, p < 0.01). Both palbociclib and abemaciclib treatment were associated with upregulation of immune hallmarks including TNF-alpha signalling via NFKB, interferon (IFN)-gamma response, IFN-alpha response, and inflammatory response, as well as down-regulation of genes and pathways associated with cell cycle (G2M checkpoints, E2F targets, mitotic spindle hallmarks). Paradoxically, expression of IFN-alpha and IFN-gamma response pathways was suppressed in responders compared to non-responders, at baseline and after treatment.
Conclusion: This data provides evidence that CDK4/6i induce senescence and upregulate interferon signalling in patients with early ER+/HER2 negative breast cancer. Consistent with previous studies, high baseline and on-treatment interferon signalling appears to be related to treatment resistance. The relationship between senescence and interferon signalling in this context, and the potential therapeutic implications of this require further investigation.

P2-03-30: Association of ctDNA in patients with long-term outcome of breast cancer patients undergoing neoadjuvant treatment in the randomized ABCSG 34 clinical trial

Daniel Egle, Dominik Hlauschek, Simon Gampenrieder, Gabriel Rinnerthaler, Christian Singer, Georg Pfeiler, Rupert Bartsch, Gregor Huber, Angelika Pichler, Edgar Petru, ZsuZsanna Bago-Horvath, Anna Kermanidis, Christian Fesl, Ricarda Graf, Sabrina Weber, Nadia Dandachi, Martin Filipits, Michael Gnant, Ellen Heitzer, Marija Balic

Introduction: Circulating tumor DNA (ctDNA) represents a minimally invasive assessment of tumor response based on longitudinal ctDNA analyses. In the neoadjuvant prospective ABCSG 34 trial, we have previously shown that lacking ctDNA clearance correlated with poor response to neoadjuvant systemic treatment (NST) assessed as pathological response (pCR) and residual cancer burden (RCB). In a follow-up analysis, we investigate the impact of ctDNA detection and clearance (or lack thereof) on long-term outcome invasive disease free survival (iDFS), distant recurrence free survival (DRFS), and overall survival (OS).
Experimental design: Previously, tumor-informed assays based on analyses of 93 genes in tissue were designed for 145 patients with sufficient plasma cell free DNA, and ctDNA

presence/absence/clearance in plasma was evaluated before (BL, baseline) , during (MT, mid-therapy), and at the end of neoadjuvant treatment (EOT). In the present analyses, follow up data on invasive disease free survival (IDFS), distant recurrence free survival (DRFS) and overall survival (OS) were available from 109 patients. Association of [DH1] BL, MT and EOT ctDNA status with outcomes was analyzed. Median FU starting from surgery was 7.1 years.
Results: Twenty of 49 patients (40.8%) with detectable ctDNA at BL had an IDFS event, while out of 60 patients who were ctDNA negative at baseline, 19 (31.7%) experienced an IDFS event (HR 1.53 (0.81 - 2.86, p=0.187). IDFS rate at 7 years was 58.5% vs. 70.8%. DRFS rate was 60.9% in patients with detectable baseline ctDNA vs. 77.9% in ctDNA negative patients (HR 1.98, 95% CI 0.99 - 3.95, p=0.053). OS rate at 7 years was 62.7% for ctDNA+ compared with 81.2% in ctDNA- patients (HR 2.12, 95% CI 1.02 - 4.41, p=0.043), respectively. In contrast to BL there was no significant association of ctDNA status with IDFS, DRFS and OS at MT or EOT, even though the HR are comparable, due to smaller numbers significance could not be reached. [DH2] [DE3]
Conclusions: Overall, our results demonstrate that in our cohort the detection of ctDNA at BL was associated with IDFS, DRFS and OS. [DH4] [DE5] Limited numbers of available MT and EOT samples reduced the power of analyses of ctDNA dynamic changes under treatment and their association with long term outcome, therefore results didn't reach significance. In summary, BL ctDNA assessment is useful to assess long-term prognosis in patients receiving neoadjuvant NST.

P2-04-01: MUC1-C integrates aerobic glycolysis with suppression of oxidative phosphorylation in triple-negative breast cancer stem cells

Nami Yamashita, Henry Withers, Yoshihiro Morimoto, Atrayee Bhattacharya, Naoki Haratake, Atsushi Fushimi, Mark D. Long, Donald Kufe, Takayuki Ueno

Triple-negative breast cancer (TNBC) is a recalcitrant malignancy largely unresponsive to cytotoxic, targeted and immunotherapeutic agents. The Mucin1 (MUC1) transmembrane heterodimeric protein, which is aberrantly expressed in TNBCs, evolved in mammals to provide protection of epithelia from the external environment. With loss of homeostasis, the (i) MUC1 N-terminal (MUC1-N) subunit is shed and released into serum as detected by the CA15-3 assay, and (ii) MUC1 C-terminal (MUC1-C) subunit is activated and thereby promotes lineage plasticity, epigenetic reprogramming, and the cancer stem cell (CSC) state. However, little is known in regard to the regulation of TNBC CSC metabolism.

Studies of TNBC CSCs have been hampered by challenges using cell surface markers in purifying this cell population. Accordingly, we enriched TNBC CSC populations by serial passage of mammospheres. The present studies performed on enriched populations of TNBC CSCs demonstrate that MUC1-C is essential for integrating activation of glycolytic pathway genes with self-renewal and tumorigenicity. Based on the importance of GLUT1 and HK2 in driving glycolysis and tumorigenicity, we confirmed their upregulation in

passaged mammosphere cells. Here, we found that silencing MUC1-C in passaged mammosphere cells decreases MYC occupancy of the GLUT1 PLS and HK2 PLS, in support of MUC1-C dependency in the activation of GLUT1 and HK2 expression. Moreover, treatment with the 2-deoxy-D-glucose (2DG) , HK2 inhibitor, markedly decreased mammosphere formation in concordance with dependence of CSCs on MUC1-C-induced activation of the glycolytic pathway.

Futhermore, we found that suppression by targeting MUC1-C with silencing and GO-203 treatment MUC1-C further integrates the glycolytic pathway with suppression of mitochondrial DNA (mtDNA) genes encoding components of mitochondrial Complexes I–V. The repression of mtDNA genes is explained by MUC1-C-mediated downregulation of the mitochondrial transcription factor A (TFAM) required for mtDNA transcription and induction of the mitochondrial transcription termination factor 3 (mTERF3). In support of pathogenesis that suppresses mitochondrial ROS production, targeting MUC1-C increases (i) mtDNA gene transcription, (ii) mitochondrial ROS levels, and (iii) loss of self-renewal capacity.

In summary, our findings in TNBC cells indicate that MUC1-C drives CSC self-renewal by integrating the activation of glycolysis in certain subpopulations with suppression of oxidative phospholylation.

P2-04-02: TRIB3 regulates lipophagy and drives the metastasis of triple negative breast cancer by activation of PI3K/AKT/mTOR pathway

Zirong iang, Yushuai Yu, Qing Wang, Mingyao Huang, Shiping Luo, Xin Yu, Xiewei Huang, Chuangui Song, Jun Liu

Background: The balance of lipophagy is critical for maintaining oncogenic signaling pathways. However, the mechanisms by which lipophagy promotes progression and metastasis in triple-negative breast cancer (TNBC) are currently unknown. In this study, we investigated the clinical significance and biological involvement of the pseudokinase protein TRIB3 in TNBC.
Methods: Target genes associated with lipophagy were identified by GSEA database screening and tested in tissues and cell lines. The biological functions of TRIB3 in TNBC were investigated using gain-of-function/loss-of-function assays. Western blotting, laser confocal microscopy, transmission electron microscopy and immunoprecipitation were used to detect and analyze lipophagy. ChIP and luciferase reporter gene assays were used to evaluate the relationship between TRIB3 and FOXA1. Next-generation sequencing technology was applied to screen out the possible downstream molecule MSI2 of TRIB3 and verify the regulatory relationship between the two.
Results: Increased expression of TRIB3 was found in TNBC compared with paired peritumoral tissues. It was more signifcant in TNBC with metastasis and correlated with worse overall survival. Upregulation of TRIB3 accelerated TNBC cells colony formation,

migration and invasion. Mechanically, RNAseq-based analysis showed enrichment of autophagy-related pathways in TRIB3 lowly-expressed TNBC. Next, TRIB3 was demonstrated to interact and stabilize MSI2, amplify PI3K/AKT/mTOR-mediated lipophagy and then promote TNBC growth and metastasis. Moreover, FOXA1 was upregulated and transcriptionally increased TRIB3 expression in TNBC cells. Furthermore, These phenotypes could be reversed by the lipophagy inhibitor chloroquine.
Conclusions: Our fndings suggested that TRIB3 is a key pseudokinase molecule for tumor progression and metastasis and may be an effective target for TNBC patients.

P2-04-03: Progesterone Receptor-Stimulated MicroRNAs Regulate Breast Cancer Proliferation

Motoki Takaku, Annika Price, Jill Goodman, Edward Looker

Background: Breast cancer development is closely linked to the activity of hormone receptors, including estrogen receptors (ER) and progesterone receptors (PR). While the role of ER in breast cancer and its targeted therapies are well-understood and established in clinical practice, the function of PR remains underexplored. This is despite its presence in approximately 70% of breast cancers and the promising inhibitory effects of progesterone treatment. This knowledge gap, along with the dual role of progesterone in both promoting and inhibiting breast cancer, underscores the urgent need for more detailed investigations into PR mechanisms.
Methods: We conducted a microRNA (miRNA) expression analysis and identified 41 differentially expressed miRNAs upon progesterone stimulation. Many upregulated miRNAs are predicted to target cell cycle regulatory genes, suggesting that PR may regulate breast cancer proliferation through miRNAs. Consequently, we employed a CRISPR knockout screening to explore the roles of these progesterone-stimulated miRNAs. In this screening, T47D luminal breast cancer cells were treated with progesterone for one month, and resistant clones were isolated for downstream analysis.
Results: The CRISPR screening indicated enrichment of gRNAs targeting four miRNAs post-progesterone exposure. PR binding was observed near these miRNAs, suggesting direct regulation by PR. The depletion of these miRNAs in T47D cells led to resistance to progesterone treatment. Notably, among these, the expression of miR-30a correlates with PR expression and patient prognosis in breast cancer clinical data.
Conclusion: This study identifies PR-stimulated miRNAs that are crucial for inhibiting growth in luminal breast cancer cells. These findings shed light on how progesterone-activated PR may inhibit tumor growth in breast cancer, providing new insights for potential therapeutic targets.

P2-04-04: Integrated stress response-upregulated mitochondrial SLC1A5var enhances glucose dependency of human breast cancer cells

Sheng-Fan Wang, Yu-Chieh Ho, Pei-Chen Wu, Chian-Ying Chou, Yuh-Lih Chang, Hsin-Chen Lee, Ling-Ming Tseng

Breast cancer ranks as the most frequently diagnosed cancer among women. The proliferation of triple-negative breast cancer (TNBC) cells relies on glucose. The integrated stress response (ISR) represents a cellular reaction to glucose deficiency or other stress. Under glucose scarcity, the ISR-solute carrier family 7 member 11 pathway is activated, contributing to glucose dependency by reducing intracellular glutamate levels. Solute carrier family 1 member 5 (SLC1A5) and mitochondrial solute carrier family 1 member 5 variant (SLC1A5var) are glutamine transporters that play crucial roles in reprogramming cancer metabolism. However, the regulation of mitochondrial SLC1A5var by ISR and its impact on glucose dependency remains to be fully elucidated.
Our investigation indicated that activating transcription factor-4 (ATF4), triggered by glucose depletion, oligomycin (an inhibitor of mitochondrial ATP synthase), and salubrinal (an ISR activator) stimulation, induces the expression of SLC1A5var. The role of ATF4 in SLC1A5var regulation is pivotal, as it binds to specific regulatory elements in the promoter. Knockdown of SLC1A5var diminishes glucose depletion-induced cell death, while overexpression of SLC1A5var enhances it in TNBC cells. Additionally, SLC1A5var knockdown curtails cancer cell proliferation, colony formation, and migration, while SLC1A5var overexpression enhances cell proliferation and migration in TNBC cells. Furthermore, SLC1A5var knockdown reduces the oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) and heightens the maximal OCR and ECAR under glucose depletion. These findings suggest that ISR-activated upregulation of SLC1A5var potentially modulates mitochondrial oxidative phosphorylation and glycolysis characteristics to augment glucose depletion-induced cell death.
In conclusion, SLC1A5var plays a pivotal role in the metabolic reprogramming process and may represent a promising target for breast cancer therapy.

P2-04-05: The dynein regulator LIS1 maintains cell cycle progression and DNA integrity in TNBC, and can be targeted to improve paclitaxel response

Parth Majmudar, Ruth Keri

Triple-negative breast cancer (TNBC) is a highly aggressive disease that typically exhibits faster growth and higher metastatic spread than other subtypes. There is a paucity of treatments available for TNBC, further contributing to poor patient prognosis. The rapid growth of TNBC cells makes mitosis a compelling target; indeed, a current mainstay of treatment is Paclitaxel (Ptx), a taxane that stabilizes microtubules during mitotic progression. Despite being initially effective, acquired resistance to Ptx is common. Moreover, additional antimitotic therapies can be similarly rendered ineffective due to

resistance, toxicity, or a lack of efficacy, underscoring the need for new therapeutic approaches. One understudied class of potential targets is the motor protein dynein and its associated regulatory proteins. Of these, LIS1 was highly ranked in several essentiality screens for breast cancer cell growth. LIS1 regulates mitotic spindle orientation and chromosome movement during neurodevelopment, yet little is known regarding its function in breast cancer. We found that suppressing LIS1 expression in TNBC cells, but not in non-transformed cells, reduces cell number. Live cell imaging indicates that reducing LIS1 alters cell cycle dynamics, increasing mitotic duration due to an accumulation of cells blocked in the G2/M phase. Such accumulation is commonly caused by activation of the spindle assembly checkpoint (SAC) or increased levels of DNA damage. Indeed, LIS1-silenced cells exhibit higher levels of Cyclin B1, a marker of SAC activation. Moreover, loss of LIS1 increases DNA double-strand breaks, highlighting a novel role for LIS1 in TNBC. Lastly, we found that the loss of LIS1 substantially enhances these defects in cells that are resistant to Ptx and sensitizes both parental and Ptx-resistant TNBC cells to Ptx treatment. As such, LIS1 represents a novel anti-mitotic target for treating TNBC, particularly in the context of paclitaxel resistance.

P2-04-06: Enhancement of TGF-β Receptor Inhibitor Efficacy through CD44 Suppression in Claudin-low Breast Cancer

Ryoichi Matsunuma, Sae Imada, Shoko Sato, Ryosuke Hayami, Michiko Tsuneizumi

Introduction: CD44 expression is implicated in various signaling pathways and has been reported to influence cancer proliferation and invasion. Claudin-low breast cancer is characterized by the properties of cancer stem cells, specifically CD44+/CD24- phenotype, and exhibits high expression of EMT markers. We focused on the involvement of CD44 and TGF-β receptors in EMT, investigating the combined effect of CD44 suppression and TGF-β receptor inhibitors in Claudin-low breast cancer. Our aim was to evaluate the potential of this dual approach as a novel therapeutic strategy for Claudin-low breast cancer.
Materials and Methods: We utilized the claudin-low breast cancer cell lines SUM159 and MDA-MB-231 to establish CD44 knockdown cells. The effects of CD44 knockdown and TGF-β receptor inhibitors on proliferation, invasion, and downstream signaling were investigated. Additionally, the potential synergistic effects of CD44 suppression combined with TGF-β receptor inhibitors were examined.
Results: CD44 was found to interact with TGF-β receptor I, but not with TGF-β receptor II. Additionally, CD44 knockdown did not affect the expression levels of TGF-β receptor I/II. In both SUM159 and MDA-MB-231 cells, CD44 knockdown resulted in suppressed proliferation, yet invasion was not inhibited, and phosphorylation of Smad2 was enhanced. However, when combined with TGF-β receptor inhibitors, CD44 knockdown led to synergistic suppression of proliferation, inhibition of invasion, and complete control of Smad2 phosphorylation.
Conclusion:
In CD44-positive Claudin-low breast cancer cells, CD44 knockdown exhibited a

proliferation-suppressive effect. The addition of TGF-β receptor inhibitors produced a synergistic effect in proliferation suppression and controlled Smad2 phosphorylation, thereby inhibiting invasion. This suggests that targeting CD44 in combination with TGF-β receptor inhibitors could provide a novel therapeutic strategy for Claudin-low breast cancer.

P2-04-07: Dual function of PRAK in TP53-associated breast cancer metastasis

Jingjing Liu, Xu Liu, Shaorong Zhao, Jin Zhang

The p53 mutation is the most common mutation in breast cancer, characterized by rapid proliferation, easy metastasis and poor prognosis. MAPK activated protein kinase 5, also named as PRAK, has been reported to function as either an oncogen or a tumor suppressor in different types of human cancers. The role of PRAK in breast cancer carcinogenesis and progression is still unknown. Our previous research found that PRAK function as a tumor suppressor in p53 wild breast cancer and function as an oncogene in p53 mutated breast cancer. In addition, PRAK influenced extracellular matrix (ECM) degradation and metastasis in breast by regulation of MMP9 expression. However, the molecular mechanism is still unknown. ChIP-seq combined with RNA-seq and protein profiling revealed that PRAK could bind to transcriptional factor CREB1 and wild p53. Moreover, we also observed the binding of PRAK to the MMP9 enhancer region. GST-pull down and IP were verified to bind from in vitro and in vivo; Transwell, scratch test and collagen contraction assay were used to evaluate the malignant phenotype of cells in vitro; inoculated SCID mice were observed to grow and metastasize in vivo by in vivo imaging; IHC was used to detect the protein expression of breast cancer tissues with different p53 statuses; and the correlation of its expression and its relationship to clinicopathological factors and prognosis were analyzed in the light of clinical data. In this study, we has found that in p53 wild-type breast cancer, PRAK binds to p53, and the activated p53 binds to the MMP9 promoter, which transcriptionally inhibits the expression of MMP9, prevents the degradation of extracellular matrix (ECM), and inhibits the metastasis of breast cancer; in p53 mutant breast cancer, PRAK binds to the MMP9 enhancer, CREB1 binds to the MMP9 promoter, and the combination of PRAK and CREB1 alters the conformation of the MMP9 genome, transcriptionally activates the expression of MMP9, induces the degradation of ECM, and promotes breast cancer metastasis. Ultimately, we elucidated the mechanism of PRAK in breast cancer with different p53 status and provide a theoretical basis for the development of therapeutic drugs in p53 mutated breast cancer.

P2-04-08: Functions of KLF5 in the cell cycle and breast cancer cell proliferation

Xiaoyun Mao, Jian Sun, Ceshi Chen

As a transcription factor associated with the regulation of growth, development, and maintenance of stemness, the expression and transcriptional activity of the KLF5 protein are influenced by the Hippo signaling pathway. This study aims to investigate the spatiotemporal expression characteristics of KLF5 during the development of breast cancer and further explore the molecular mechanisms by which KLF5, in coordination with the TAZ factor in the Hippo signaling pathway, controls cell growth and proliferation, potentially elucidating mechanisms underlying breast cancer initiation and progression. Results showed that the KLF5/AP1/TAZ/TEAD4 (KATT complex) is highly expressed in triple-negative breast cancer (TNBC), particularly in the basal subtype, regulating the transcription of downstream genes associated with stem cells and lipid metabolism, thus promoting lipid synthesis. Gel filtration chromatography and immunofluorescence staining confirmed the presence of the KATT complex in TNBC. Using knockdown experiments of the KATT complex and transcriptome sequencing analysis, we found that the KATT complex can collectively regulate the expression of lipid metabolism and stem cell-related genes. ChIP-seq analysis revealed mutual regulation among KATT complex members through super-enhancers, forming a core regulatory loop in TNBC. Furthermore, we found that the KATT complex promotes the synthesis of lipid metabolism products (lipidomics), significantly enhancing the synthesis of medium- and long-chain fatty acids (GC-MS). Knockdown of the KATT complex inhibited lipid droplet formation (Nile red staining) and suppressed cholesterol formation and distribution (cholesterol staining). Under cell culture conditions of human breast cells during the metaphase of mitosis, eGFP-KLF5 and endogenous TAZ form phase-separated granules with excellent co-localization characteristics. Similar to reported TAZ behavior, purified KLF5 protein exhibited phase separation capability in vitro. Upon formation of complexes with related transcription factors such as AP1 and TEAD4, it can collectively regulate the transcriptional expression of downstream target genes. Furthermore, we discovered that KLF5 protein undergoes liquid-liquid phase separation during the G2/M phase of the cell cycle and preliminarily found that the transcription factor KLF5 forms phase-separated granules with TAZ and participates in cell proliferation regulation. These data collectively demonstrate that KLF5 protein plays a crucial role in promoting cell cycle progression during the cell cycle process, thereby exerting significant effects on the rapid proliferation of triple-negative breast cancer cells.

P2-04-09: A Novel Role of IP6K2 in Regulating Host Cell Death through p21-mediated cell cycle arrest during HSV-1 oncolytic virus Therapy

Zhijian Huang, Xiaoting Qiu, Cuifeng Sun, Zirong Jiang

Introduction: Oncolytic virus therapy (OVT), specifically Herpes Simplex Virus type 1 (HSV-1)-based therapies, represents a promising frontier in cancer treatment. Despite its efficacy in clinical trials, variability in patient response, particularly resistance development, highlights the need for tailored therapeutic strategies. This study focuses on the role of Inositol Hexakisphosphate Kinase 2 (IP6K2) in modulating HSV-1 oncolytic virus infection, with an emphasis on understanding its influence on viral replication and host cell apoptosis.

Methods: The virus titer was measured on Vero cells using classical fluorescent plaque assay. The gene knock out was all carried by CRISPR/Cas9 system. qPCR and WB were conducted to evaluate biomarkers of apoptosis and relevant pathway. Attachment assay was conducted to verify the binding ability of virus to the host cells. Cell proliferation was assessed using CCK8 and apoptosis was assessed using flow cytometry. Subcutaneous xenograft model was used to evaluate IP6K2 knock out influence in vivo. cBioPortal and TCGA database were applied to analyze genomic alterations in pan-cancer. Results: The results revealed that HSV-1 infection induced significant apoptosis in targeted cells, characterized by enhanced apoptosis markers, p53 stabilization, and activation of the apoptotic signaling cascade including NOXA and PUMA upregulation. Knocking out IP6K2 resulted in attenuated HSV-1-induced apoptosis cell death and lower viral proliferation, but not binding ability of virus to the host cells. We further elucidated IP6K2 prevented apoptosis through p21 - mediated cell cycle G1 phase arrest by both rescue experiment and p21 CRISPR/Cas9 deletion. In vivo experiments also showed marked reduction in the efficacy of HSV-1 oncolytic virus-induced cell death, with decreased tumor regression and viral replication. Analysis of cBioPortal and TCGA databases corroborated the potential resistance stemming from IP6K2 mutations across various cancer types, underscoring the necessity for pre-treatment IP6K2 status assessment. Conclusion: This study underscores the role of IP6K2 as potential markers of resistance opens avenues for precision medicine approaches in OVT. Pre-treatment screening for IP6K2 mutations could significantly enhance patient selection processes, ensuring that individuals most likely to benefit from therapy are accurately identified.

P2-04-10: ARL3 Promotes Hormone Receptor Positive Breast Cancer Progression and Tamoxifen Resistance through ERα Stablization

Han Li, Yang Liu, Zehao Cai, Dan Shu, Yang Peng, Kang Li, Shengchun Liu

Background: Hormone Receptor Positive (HR+) breast cancer is predominantly managed with endocrine therapies that target the Estrogen Receptor Alpha (ERα), a key mediator of estrogen's role in promoting tumor growth. However, the emergence of endocrine resistance poses a significant clinical challenge, limiting the efficacy of these treatments and impeding optimal patient outcomes. Understanding the mechanisms behind ERα's importance and the development of resistance is crucial for advancing therapeutic strategies against HR+ breast cancer.
Methods: In our study, we utilized the GEO database to identify ADP-Ribosylation Factor-Like GTPase 3 (ARL3) as a gene associated with tamoxifen resistance in HR+ breast cancer. We constructed cell lines with ARL3 knockout and overexpression to assess the impact of ARL3 on cell proliferation, migration, and tamoxifen sensitivity. RNA sequencing (RNA-seq) and liquid chromatography-mass spectrometry (LC/MS) were employed to demonstrate the influence of ARL3 knockout on downstream ERα pathways. Furthermore, co-immunoprecipitation (CO-IP), immunofluorescence and Western blot (WB) assays confirmed the role of ARL3 in the ubiquitination and degradation pathway of ERα.

Results: In our analysis of TCGA breast cancer subtypes, we also observed that ARL3 is highly expressed in luminal breast cancer. Additionally, our collection of breast cancer tissue mRNA and immunohistochemistry data revealed that ARL3 expression is elevated in HR+ breast cancer, indicating a correlation with estrogen receptors. We found that ARL3 promotes the proliferation and migration of HR+ breast cancer. Furthermore, overexpression of ARL3 was associated with reduced sensitivity to tamoxifen, and in vivo tumorigenesis in nude mice showed that tumor volume and weight were significantly decreased compared to the control group. To investigate the underlying mechanisms, RNA-seq analysis of ARL3 knockout and control groups revealed a pronounced inhibition of the MYC pathway. Western blot (WB) validation confirmed that ARL3 knockout suppresses the expression of downstream pathways of ERα. Our data suggest that the association between ARL3 and ERα primarily occurs in the cytoplasm, mainly binding to the ligand-binding domain (LBD) of ERα, which is consistent with ARL3 not being recruited to the promoters occupied by ERα. We also discovered that the ARL3/ERα cascade promotes mitochondrial autophagy to enhance mitochondrial oxidative phosphorylation. In summary, our study establishes a non-genomic mechanism whereby ARL3 controls the transcription of estrogen-dependent genes associated with breast cancer cell proliferation by stabilizing ERα levels.
Conclusion: In our study, we posit that ADP-ribosylation factor-like GTPase 3 (ARL3) exerts a pivotal influence on the proliferative capacity, metastatic potential, and responsiveness to endocrine therapies in hormone receptor-positive (HR+) breast cancer. ARL3 modulates the stability of estrogen receptor alpha (ERα), thereby regulating the activation of downstream signaling cascades and the mitochondrial functionality within neoplastic cells.
Our findings suggest that ARL3 represents a promising therapeutic target for HR+ breast cancer. We envision that in-depth investigation into the molecular underpinnings of ARL3's role could pave the way for the development of innovative pharmacological agents capable of overcoming endocrine resistance in patients, ultimately enhancing their clinical outcomes and survival rates.

P2-04-11: Selective Pre-clinical Targeting of CD44+ ADAR1+ Triple Negative Breast Cancer

Wenxue Ma, Jessica Pham, Emma Klacking, Inge van der Werf, Neha Katragadda, Jenna Sneifer, Peggy Wentworth, Kendale Wirtjes, Ethan Lam, Sheldon Morris, James La Clair, Michael Burkart, Catriona Jamieson

Background: Triple-negative breast cancer (TNBC) represents a challenging subtype in breast cancer with limited therapeutic options. Both CD44 and ADAR1 are biomarkers associated with tumor progression, metastasis, and therapeutic resistance in TNBC. This study evaluates the efficacy of Rebecsinib, an experimental small-molecule anti-cancer drug designed to inhibit the splicing-mediated activation of the enzyme ADAR1 (adenosine deaminase acting on RNA 1), in targeting CD44+ and ADAR1+ cells in TNBC preclinical humanized mouse models.

Methods: Triple-negative breast cancer MDA-MB-231 cell line-derived xenograft (CDX) models were established in Rag2-/-gc-/- and NSG-SGM3 mice. First, MDA-MB-231 cells were lentivirally transduced with an ADAR-nanoluciferase-GFP reporter. Following in vivo imaging (IVIS, Caliper) to detect ADAR1-nanoluciferase reporter activity, engrafted mice were treated with DMSO vehicle control, Rebecsinib at a dose of 10 mg/kg by intravenous (IV), or Rebecsinib at a dose of 15 mg/kg by oral (PO) gavage, twice a week for two weeks. Tumor burden was assessed using in vivo imaging system (IVIS) 200. Single-cell suspensions from peripheral blood, lung, liver, spleen, and bone marrow were analyzed by flow cytometry (FACS) to determine the percentages of CD44+ and ADAR1+ cells.
Results: Both IV and oral administration of Rebecsinib significantly reduced CD44+ cells in peripheral blood ($p < 0.05$), lung ($p < 0.01$), liver ($p < 0.01$), and spleen ($p < 0.05$) in Rag2-/-gc-/- models (Student t test). A similar reduction in ADAR1+ cells was also observed in the lung ($p < 0.05$), liver ($p < 0.01$), and spleen ($p < 0.01$) following Rebecsinib treatment in NSG-SGM3 models (Student t test). IVIS imaging revealed a substantial decrease in tumor signals in Rebecsinib-treated groups compared to the controls ($p = 0.02$, student t test). Combination therapy of Rebecsinib with Fedratinib demonstrated enhanced inhibition of tumor cell proliferation, suggesting a synergistic effect ($p < 0.05$, student t test).
Conclusion: Rebecsinib effectively targets CD44+ and ADAR1+ breast cancer cells in preclinical TNBC models, demonstrating potential as a therapeutic option. These findings support further investigation of Rebecsinib in combination with other agents for treating TNBC.

P2-04-12: JAM A expression and its clinical/prognostic value in breast cancer

Yufei Lou, Johannes Benedikt, Wen G. Jiang, Tracey A. Martin

Background: Junctional adhesion molecules (JAMs) are a family of transmembrane proteins that localize in tight junctions at the apical and lateral membrane. JAM-A was the first family member to be described and functions in the cell as both a cell-cell adhesion protein and in the regulation of, barrier function contributing to the establishment of tight junction formation and epithelial polarity. Tight Junction proteins have been shown to be an important factor in the progression and metastatic progression. This study aimed to determine the role of JAM A in human breast cancer,

Method: The gene transcript expression levels of Jam A in human breast tumour and normal tissues were quantitatively determined in a Cardiff cohort of human breast cancer tissues (151 samples), supported by clinical, pathological information. Expression was analysed against the clinical and pathological parameters, together with clinical outcome of the patients including recurrence, metastasis and breast cancer related death. Statistical methods used were Mann Whitney U test for comparisons, logistic regression and Kaplan-Meier's methods for survival analyses.

Result: JAM A demonstrated an aberrant pattern of high expression in breast tumours compared with normal breast control tissues both in our own samples (p=0.06) and when analyses using the TCGA (The Cancer Genome Atlas) public database (P<0.001). Considering that our clinical sample size is not large, it is reasonable to consider both results as consistent. Our own clinical samples and TCGA samples both indicate that low levels of JAM A are related to longer overall survival (P=0.038 and P=0.003 respectively). In addition, our own samples show that for NPI (Nottingham Prognostic Index), JAM A has high expression in NPI3 group compared with NPI1 and NPI2 groups, the expression value for NPI3 group is 0.01 and the expression value for NPI1 and NPI2 group are 0.0052 and 0.0053 respectively. Though the P-value is greater than 0.05, it's still shows the expression trend. Our data also suggest that in the disease-free group, the expression of JAM A declines with ER positive status. GEPIA (Gene Expression Profiling Interactive Analysis) website analysis that JAM A correlates with ESR1(Estrogen Receptor 1) (R=0.22, P<0.001) and ESR2 (Estrogen Receptor 2) (R= -0.31, P<0.001). These results indicate that JAM A may be related to the regulation of ER expression. In addition, JAM A works as an activity regulator in TGF-beta receptor signalling in EMT (epithelial to mesenchymal transition) as assessed using the Pathcards website analysis. When considering co-expression in breast cancer, the results obtained via cBioPortal indicated that Nectin4 and DEDD were significantly correlated with JAM A (R=0.66, P<0.001 and R=0.65, P<0.001). Nectin4 is also located within the tight junction complex and DEDD (Death Effector Domain Containing) is a scaffold protein that directs CASP3 to certain substrates and facilitates their ordered degradation during apoptosis.

Conclusion: JAM A is aberrantly expressed in clinical breast cancer and is significantly correlated with predicting progression of breast cancer and outcome for patients. It can be suggested that JAM A, together with ER status could be a prognostic indicator in breast cancer and that JAM A could potentially be a future target for breast cancer treatment.

P2-04-13: DIFFERENTIAL SUSCEPTIBILITY OFMESENCHYMAL-LIKE AND BASAL-LIKE TRIPLE NEGATIVE BREAST CANCER CELLS TO STANDARD OF CARE TREATMENT

Ngoc Bao Vuong, Olga Korolkova, Michael Izban, Amos Sakwe

Triple-negative breast cancer (TNBC) is a subtype of breast cancer with negative expression of estrogen, progesterone, and HER-2 receptors. Clinically established chemotherapy is the main systemic treatment option; however, tumor heterogeneity and lack of biomarkers represent the significant challenges in TNBC therapeutic resistance and relapse. Therefore, it is important to identify the molecular mechanisms which underlie drug resistance in TNBC treatment. Our study focuses on the hypothesis that the breast tumors consist of mesenchymal-like (MSL) cells which show strong resistance to chemotherapies and basal-like (BSL) cells, which are sensitive to chemotherapy treatment. MSL tumor cells are

identified by the expression of high Vimentin and the Ca2+-dependent membrane binding Annexin A6 (AnxA6) while BSL TNBC cells are identified by low expression of AnxA6 and high Ki67 index. In this study, we develop in vitro models of chemotherapy-resistant MSL and BSL TNBC cell lines using three chemotherapeutic agents over 6 months. We aim to demonstrate that the frequent resistance of TNBC tumors to chemotherapy is driven by specific genes and/or secreted biomarkers in MSL and BSL TNBC subpopulations. We anticipate that AnxA6-high MSL cells will become resistant to treatment while AnxA6-low BSL cells will be responsive to chemotherapy. Hence, a comprehensive treatment response will depend on the proportion of MSL cells in a given TNBC tumor.

P2-04-14: Activation of Target X by Del-1 regulates the progression of TNBC

Byeongju Kang, Seol-Hwa Jeong, Soo Jung Lee, Jeeyeon Lee, In Hee Lee, Jin Hyang Jung, Eun Ae Kim, Jieun Kang, Ho Yong Park, Yee Soo Chae

Purpose: Developmental Endothelial Locus-1 (DEL-1), also known as EGF Like Repeats and Discoidin Domains 3 or Edil-3, is widely expressed and notably enriched in extracellular vesicles circulating in the plasma of breast cancer patients. Various papers have suggested that DEL-1 might be important in Triple Negative Breast Cancer (TNBC), the subtype with the highest mortality rate, even though it only accounts for 15%-20% of all breast cancers. Despite its importance, little is known about how DEL-1 regulates TNBC. Here, we report that target X, promoted by Del-1, stimulates proliferation and invasion in TNBC cells.

Methods: We performed a western blotting assay to clarify the relationship between DEL-1 and target X. To examine the effect of DEL-1 to target X, we used CRISPR/Cas9 genome editing DEL-1 knockout cell lines and pharmacological activator of X. In addition, the effects of DEL-1 and X to TNBC cells were analyzed using MTT, MTS, BrdU and Matrigel transwell assays.

Results: In TNBC cells, the expression levels of DEL-1 and target X were significantly upregulated. Both overexpression of DEL-1 and pharmacological activation of target X stimulated proliferation and invasion, whereas CRISPR/Cas9 genome editing Del-1 knockout inhibited target X and blocked proliferation and invasion. In addition, overexpression of DEL-1 increases target X, but the X activator did not have any effect on DEL-1

Conclusions: Altogether, we suggest that DEL-1-mediated activation of target X regulates TNBC proliferation and invasion.

P2-04-15: Diagnostic potential of disseminated and circulating cancer cells: A case study of a 34-years-old patient with rapidly progressing breast cancer.

Jonas Roth, Clara Chaiban, Lukas Wöhrl, Kirsten Utpatel, Valeria Gerthofer, Julian Schornbaum, Christian Werno, Olaf Ortmann, Stephan Seitz, Zbigniew Czyz, Christoph A. Klein

Presenting the case of a 34-year-old patient diagnosed with early breast cancer NST stage cT2, cN+, G3, M0, ER IRS4, PR IRS3, Her2neu 1+, Ki67 75% in July 2022 with rapidly progressing disease, we are exploring the diagnostic potential of disseminated and circulating cancer cells. Before and during the treatment of the patient, disseminated cancer cells (DCCs) were isolated using cytokeratin staining of bone marrow aspirates. Furthermore, the number of circulating cancer cells (CTCs) in 7,5 ml of blood was measured at different timepoints using the CellSearch® CTC-Assay. Single DCCs and CTCs were isolated using a micromanipulator. By comparing the number of CTCs with clinical data, we noted a correlation between the number of CTCs with treatment response, but also disease progression. As not only enumeration of CTC but also their molecular profiling may provide important information, we analyzed the mutational landscape of CTCs using the newly developed single cell IMPACT-Assay. This panel sequencing approach captures around 470 actionably or therapeutically relevant genetic changes. Based on the sequencing results we are currently performing an in vitro drug screen using 35 single drugs and drug combinations on cancer cells isolated from a pleural effusion of the patient. We will ask whether the mutational or the functional assays allow predicting the clinical response of the patient and provide a novel rational that could support decision making of the molecular tumor board. The results will be presented on the poster.

P2-04-16: Artificial intelligence can extract important features for diagnosing axillary lymph node metastasis in early breast cancer using contrast-enhanced ultrasonography

Tomohiro Oshino, Ken Enda, Hirokazu Shimizu, Megumi Sato, Mutsumi Nishida, Fumi Kato, Mitsuchika Hosoda, Kohsuke Kudo, Norimasa Iwasaki, Masato Takahashi

Background: Axillary lymph node (ALN) metastasis in early breast cancer affects the prognosis and accurate identification of ALN metastasis in early breast cancer is important for determining the treatment. Conventional ultrasonography (cUS) of breast cancer is used worldwide because it is inexpensive, simple, and does not involve radiation exposure and is not invasive. However, cUS is insufficient to evaluate ALN status accurately. Contrast-enhanced US (CEUS) improves the performance of predicting ALN metastasis, so at our facility, CEUS is performed routinely. However, there are many diagnostic indicators, and standard imaging and image interpretation methods have not yet been established, resulting in difficulty of use. To make CEUS universal and effective, we evaluate the ability of

predicting ALN metastasis and importance features, using deep learning (DL) models or weighted decision tree (WDT) model with ALN CEUS imaging data and tabular formatted data.
Methods：In this retrospective study, 788 CEUS images of ALNs were collected from 788 patients (mean age 59.7 [range, 25–90] years) , who underwent breast surgery between January 2013 and December 2021. First, CEUS images were inputted into the DL models, EfficientNet B0, B4, and B8 and VisionTransformer Base/16, which yielded an image-based predictive covariate (iP : 0–1) for ALN metastasis. Second, the tabular formatted data of primary tumor and ALN of cUS and CEUS was inputted into light gradient boosting machine (LightGBM), one of the WDT models. This data was including diameter of primary tumor and ALN evaluated by cUS and CEUS, 10 findings of primary tumor which could be evaluated by only CEUS, 9 findings of ALN evaluated by both cUS and CEUS, and 6 findings of ALN evaluated by only CEUS. These findings were evaluated by two breast surgery specialists. We also used iP for lightGBM models. Labeling data was histopathologic diagnosis of ALN surgical specimen divided into two groups pN0 or pN1mi and more.
Results： In the analysis of DL models, the area under the receiver operating characteristic curve (AUC) was highest for the EfficientNet B8 model at 0.69, which was used as the iP. In the analysis of LightGBM, the AUC for CEUS was 0.93 (0.88-0.98), significantly higher than that for cUS alone of 0.76 (0.68-0.85) ($p < 0.001$, DeLong test). Top feature importance for predicting of ALN metastasis was “heterogeneous enhancement pattern, “diffuse cortical thickening”, and “eccentric cortical thickening >3 mm”.
Conclusion：LightGBM model, an AI model, was able to extract CEUS findings that are important in predicting ALN metastasis in early breast cancer.

P2-04-17: The MIRACCL Portal for Comparing Patient and PDX Response Using Cancer Image Features and Genomics in Co-Clinical Breast Cancer Trials

Heidi Dowst, Fei Zheng, Emel Alkim, Apollo McOwiti, Ram Rajaram Srinivasan, David Hormuth, Thomas Yankeelov, Daniel Rubin, Michael T. Lewis

Introduction: The Molecular and Imaging Response Analysis of Co-Clinical Trials (MIRACCL, https://miraccl.research.bcm.edu/) platform was developed beginning three years ago to support the co-clinical breast cancer RESPONSE trial at Baylor College of Medicine. The goal of MIRACCL is to enable parallel studies which apply the same protocol to patients in a clinical trial and patient-derived xenograft (PDX) cohorts. MIRACCL evaluates treatment response by electronically measuring the changes in serial MRI. The response assessments include the measurement of multiple imagine features such as apparent diffusion coefficient (ADC) and signal enhancement ratio (SER) at pre-treatment and post-treatment along with samples taken for assessment of the genomic changes.
Methods: To achieve this goal, we employee the use of web-technologies to enable visual and quantitative comparison of the imaging and genomics. Investigators at Baylor College of Medicine leveraged their expertise in patient derived xenograft development and model

study implementation to generate the PDX imaging dataset and collect the model samples for sequencing. The University of Texas at Austin provided centralized patient and PDX image normalization, segmentation, and analysis while the Biomedical Informatics team at Stanford University provided the image visualization tool and imaging response assessment. Due to the difference in data modalities, data sources, and temporal collection of data it was necessary to place the data within the context of the study design and provide visual and quantitative comparisons of the study outcomes for various time points. The MIRACCL features created to achieve this goal include tabular cohort annotations, a side-by-side visualization of imaging response distributions, and a comparison of the upregulated and down regulated gene expression between cohorts. One of the imaging methods deployed in MIRACCL to assess treatment response measures response by tumor longest diameter which is then categorized by RECIST. Additional imaging comparison methods include signal enhancement ratio (SER), apparent diffusion coefficient (ADC), and tumor volume. Samples for sequencing taken at pre-treatment and throughout the design of the study are used to identify gene expression changes brought about by treatment. In the Omics module of MIRACCL, the 500 most frequently upregulated and 500 down regulated genes for each cohort are displayed based on user selected time points and imaging feature of interest. A Venn diagram is generated to identify the genes which are commonly regulated in both cohorts.
Results & Conclusion: While these features have provided multiple methods of comparing the outcome of co-clinical trials, the research team desired to know the significance of these correlations and differences between the two cohorts. Consequently, the Analytic module was implemented in MIRACCL this past year. The analytics module focuses on two hypotheses: 1) PDX models of similar subtyping will respond in a similar manner to the patients enrolled in the trial and 2) Response can be predicted while on-treatment to determine if changes to treatment are warranted. The change in tumor quantifications from on-treatment to baseline were statistically correlated to changes in tumor quantifications from post-treatment to baseline to determine if response could be determined while currently on-treatment. The p value and r value of the spearman correlation are provided to determine the significance and clustering of the cohort. The enhancements afforded by MIRACCL's Analytics module summarize the treatment response of the patient and PDX cohorts and effectively address the hypothesis of the REPONSE trial. MIRACCL is now available for expansion as a tool for other trials co-clinical trials.

P2-04-18: Unlocking the Complete Blood Count as a Risk Stratification Tool for Breast Cancer Using Machine Learning: A Large Scale Retrospective Study

Pedro Henrique Souza, Daniella Castro Araujo, Bruno Aragão Rocha, Karina Braga Gomes, Daniel Noce da Silva, Vinicius Moura Ribeiro, Marco Aurelio Kohara, Fernanda Marana, Renata Andrade Bitar, Adriano Alonso Veloso, Maria Carolina Tostes Pintao, Flavia Helena da Silva, Celso Ferraz Viana

Optimizing early breast cancer (BC) detection requires effective risk assessment tools. This retrospective study from Brazil showcases the efficacy of machine learning in discerning complex patterns within routine blood tests, presenting a globally accessible and cost-effective approach for risk evaluation. We analyzed complete blood count (CBC) tests from 396,848 women aged 40-70, who underwent breast imaging or biopsies within six months after their CBC test. Of these, 2,861 (0.72%) were identified as cases: 1,882 with BC confirmed by anatomopathological tests, and 979 with highly suspicious imaging (BI-RADS 5). The remaining 393,987 participants (99.28%) were classified as controls, with BI-RADS 1 or 2 results.

The database was divided into modeling (including training and validation) and testing sets based on diagnostic certainty. The testing set comprised cases confirmed by anatomopathology and controls cancer-free for 4.5 to 6.5 years post-CBC. While our dataset lacked specific indicators for identifying metastasis and lymph node status required for TNM staging, the BC study population in the testing set primarily consisted of early-stage carcinomas, as reflected by the fact that 24% of the identified carcinomas were in situ and 95% of the recorded invasive T stages were at T1-2.

Statistical analysis revealed that age, hematocrit, hemoglobin, mean corpuscular hemoglobin (MCH), mean corpuscular volume (MCV), neutrophils-lymphocyte ratio (NLR), derived neutrophils-lymphocyte ratio (dNLR), platelet-lymphocyte ratio (PLR), systemic immune-inflammation index (SII), systemic inflammation response index (SIRI), and aggregate index of systemic inflammation (AISI) were significantly elevated in women with BC, whereas lymphocytes and the lymphocyte-monocyte ratio (LMR) were markedly lower. Given the statistical significance of all CBC-derived ratios, they present a valuable opportunity as cost-effective predictive biomarkers in BC. Furthermore, by harnessing Artificial Intelligence (AI), we developed a ridge regression model incorporating age, NLR, and RBC, achieving an AUC of 0.64 (95% CI 0.64-0.65), demonstrating superior performance over more complex models like LightGBM, while offering full interpretability. The explanatory analysis indicates that higher age and NLR, along with lower RBC levels, may increase BC risk. Age correlates with BC due to cumulative exposure, genetic mutations, and cellular aging. High NLR suggests inflammation, potentially impairing immune response and promoting tumor growth, while low RBC might indicate a chronic inflammatory state conducive to cancer progression.

To emulate the use of a risk stratification tool, using the probabilistic output from this model, we divided the study population into four risk groups: high, moderate, average, and low risk, which obtained relative ratios of BC of 1.99, 1.32, 1.02, and 0.42, respectively. The aim of this stratification was to streamline prioritization, potentially improving the early detection of breast cancer, particularly in resource-limited environments. As a risk stratification tool, this model offers the potential for personalized breast cancer screening by prioritizing women based on their individual risk, thereby indicating a shift from a broad population strategy. To support its clinical application, external validation with diverse populations is of paramount importance.

P2-04-19: Identification and Validation of Novel Necroptosis-Related lncRNAs for Prognostic Prediction in Breast Cancer

Zhijian Huang, Xiaoting Qiu, Cuifeng Zheng, Yi Zeng

Background: Breast Cancer (BC) is the most common cancer in the world. The rapid development of tumor immunotherapy and necroptosis has brought new directions to the treatment of breast cancer. To improve the situation, this project aims to identify biomarkers that can help predict prognosis and determine a precise treatment.
Method: The Cancer Genome Atlas (TCGA) data was analyzed for coexpression relationships and univariate Cox regressions to identify lncRNAs associated with necroptosis. In addition, differential expression analysis, prognostic analysis, and time-dependent receiver operating characteristics (ROC) analysis were performed to determine whether Necroptosis-related lncRNA is an independent prognostic factor. Then, based on the risk model, principal component analysis (PCA), immune cell infiltration, immune functions, prediction of the half-maximal inhibitory concentration (IC50), and immune checkpoints were evaluated. Additionally, we divided the entire set into two clusters based on immunotherapy response between cold and hot tumors.
Results: We developed a signature consisting of seven necroptosis-related LncRNAs. Over 1, 3, and 5 years, the area's OS under the ROC curve (AUC) was 0.748, 0.753, and 0.714, respectively. High-risk group immune cells were infiltrated less frequently and had lower immune functions than low-risk group immune cells. In addition, using clusters as a means to make a distinction between a cold tumor and a hot tumor could provide more precise treatment options. In Cluster 2, the tumor is considered to be hot tumor, which is more sensitive to immunotherapy drugs.
Conclusion: According to our findings, necroptosis-related lncRNA can be used to predict prognosis and to distinguish cold and hot tumors in BC, thereby optimizing individual treatment.

P2-04-20: Advances and Detection Methods of Metachronous Bilateral Breast Cancer Detection Using AI-Assisted Mammography for Japanese women

Mio Adachi, Toshiyuki Ishiba, Tomoyuki Fujioka, Sakiko Maryua, Kumiko Hayashi, Leona Katsuta, Yuichi Kumaki, Emi Yamaga, Du Hao, Mikael Hartman, Feng Mengling, Goshi Oda

Background: Patients after unilateral breast cancer(BC) are at higher risk for bilateral BC. After unilateral BC, diagnosis by mammography (MG) is more difficult because the lack of comparison with contralateral side. In this study, we examined the diagnostic status of metachronous bilateral BC and tested whether the artificial intelligence (AI) system in MG can detect BC correctly or at an earlier than human diagnose.
Methods: The subjects were patients who underwent metachronous bilateral BC surgery between 2014 and 2022. We reviewed the medical records retrospectively. The AI system is FxMammo® (FathomX Pte Ltd, Singapore). FxMammo® is based on deep learning and has

been put into practical use in some countries. The AI was created by collecting 17,769 cases (of which 45% were malignant) from 10 institutions in Asia. Our institution was involved in the development of the system. The AI system analyzed four MG images (craniocaudal [CC], mediolateral oblique [MLO], left and right) The AI system indicated the probability of malignancy for each of imaging s as a percentage. The threshold value was set as 40.0 %, (Sensitivity was set at 91.5 %and specificity was 82.0%). In addition, region of interest was displayed in color on a heat map.
Results: Among the 1101 patients who underwent surgery, there were 36 cases of metachronous bilateral BC. Twenty cases (56%) were detected during postoperative surveillance for BC, 9 cases (25%) by subjective symptoms, 3 cases (8%) by screening, and 4 cases (11%) during follow-up for other diseases. Of the cases detected by subjective symptoms, except in one case, more than 10 years had passed since the initial surgery at the time of diagnosis of the contralateral BC. In 22 cases (61%), lesions were noted in both MG and ultrasonography (US), in 2 cases (5%) only in MG, and in 10 cases (28%) only in US. One case (3%) had no lesions in both MG and US and underwent Magnetic Resonance Imaging (MRI)-guided biopsy. One case (3%) had a preoperative diagnosis of Paget's disease with no abnormality and final pathology was ductal carcinoma in situ (DCIS). We used the AI system to examine MG in 10 patients who were undergoing surveillance at our hospital after partial resection for unilateral BC. The AI system diagnosed 6 of 10 cases (60%) as malignant. In 2 of these cases (20%), the radiologists diagnosed no malignancy. The AI system also diagnosed malignant in the year prior to the diagnosis of malignancy in these 2 cases. In both cases, small invasive carcinomas were found within extensive DCIS. Of the 4 cases that the AI system diagnosed as not possibly malignant, in 1 case the radiologists diagnosed malignant with MLO only. In 3 of the 10 cases, both the AI system and radiologists diagnosed MG with no malignancy.
Conclusions: Although postoperative unilateral BC is considered a high risk for birateral BC, some cases were detected by physical examinations. While MG is recommended for postoperative surveillance, there were cases that could be identified by only US. There was one case in which only MRI was effective. In some cases, the AI system diagnosed malignant even when the radiologists diagnosed no malignancy. This AI system has the potential to detect contralateral breast cancer earlier and accurately.

P2-04-21: Dynamic reporting of treatment related symptoms via ePROs can reversely identify the type of underlying cancer

Andreas Trojan, Hans-Friedrich Witschel, Gerd Kullak-Ublick, Michael Kiessling, Nora Asper

Background: Digital symptom reporting through cancer patients (ePRO) undergoing systemic treatment has demonstrated detection of symptoms, equivalent side effects regarding similar drugs, reduction of unplanned admissions, and machine learning (ML) may predict when patients will require emergency treatments. We examined whether dynamic reporting of treatment related symptoms via ePROs can reversely identify the type of underlying cancer.

Methods: 226 patients on treatment had self-reported on presence and severity (according to CTCAE) of more than 90 available symptoms via the medidux app (formerly consilium care). For a balanced analysis we used data from 25 patients treated for breast cancer, 19 for cancer of lung, 16 for colon, 12 for lymphoma and 7 for prostate cancer, respectively. Patients` symptoms over the entire study period were aggregated by counting the days on which a particular symptom was reported. Thus, each patient was represented by a vector of symptoms indicating how often the given symptom occurred. A human-interpretable ML logistic regression model was applied to predict the primary tumor of the patient from his/her respective symptom vector. All symptoms with positive coefficient above a certain threshold (0.1) were collected and then graphically displayed for association between symptoms and cancer type.
Results: The ML model was not able to recognize the prostate and blood-lymph patients in retrospect since their number was too small. Analysis for three remaining cancer types revealed a mean area under the curve (AUC) score of 0.72 (breast cancer AUC 0.74, CI: 0.62–0.85; gut cancer AUC 0.78, CI: 0.66–0.89; lung cancer AUC 0.63, CI: 0.50–0.77). Results indicate that ML performs "fair" and significantly better than random guessing (which would result in AUC = 0.5) for the reverse identification of the underlying cancer upon ePRO reporting from patients.
Conclusion: Cloud aggregation of patient reported symptoms and ML harbor the potential in identifying the type of cancer for which patients receive systemic treatment. Whether associations can be made from dynamic changes of reported symptoms, regarding the underlying cancer and adherence to oral medication shall be explored in prospective studies. Finally, ML and the anticipation of specific side effects might be a cost-effective tool in decentralized clinical trials and registries, enabling a more nuanced understanding of symptom associations with different cancer types.

P2-04-22: Predictive Modeling of Cancer Treatment-Related Cardiac Events in Breast Cancer Patients: Utilizing Dosiomic and Radiomic Features with Machine Learning

Sefika Dincer, Sefika Dincer, Muge Akmansu

Purpose: Conventional clinical study consists of clinical, radiological and dosimetric data and follow-up for many years. In the last decade, personalized medicine has become the main subject of scientific research with genome maps and biomarker discoveries. This study focused on predicting treatment-associated cardiac side effects in breast cancer patients, before they occur, using cardiac related biomarkers (hs-TopT, radiomics, dosiomics). This is the first study of heart-segmented dosiomics in breast cancer patients.
Methods: In this retrospective study, clinical and dosimetric data, along with radiomic and dosiomic features extracted from medical imaging, were analyzed for 42 women diagnosed with localized breast cancer (patients whose blood troponin levels were measured 2-3 weeks following the completion of radiotherapy). Patients with pre-existing cardiac comorbidities or previous troponin-T elevation were excluded from the study. The cutoff

value of heart specific troponin T levels at 2-3 weeks following radiotherapy was determined 14 ng/L, and the patients were classified into two groups. Those above this limit value were considered to be associated with a cancer treatment-related cardiac event. For the extraction of radiomic and dosiomic features, an open-source Python package PyRadiomics was utilized. In this study, we employed the TPOT (Tree-based Pipeline Optimization Tool) to select and optimize machine learning models and hyperparameters. This process led us to identify the 'Gradient Boosted Classification Algorithm' as the algorithm that would yield the best performance. Gradient boosted recursive feature elimination, a hybrid method, was used to select important features for prediction. Gradient boosted classification algorithm, an embedded method, was used to create and test the model. 5-layer cross-validation and nonparametric permutation testing were performed to evaluate model generalizability and randomness. The area under the curve (AUC) method was used to evaluate model performance.
Results: In total, 111 dosimic and 119 radiomic features were extracted for each patient. A total of 6 different models were created with different feature groups (clinical, dosimetric, radiomics, dosiomics). The highest prediction model was obtained with clinical + dosiomics + radiomics parameters (test set-AUC = 0.96). This value was much lower for the clinical + dosimetric model (test set-AUC = 0.67). These two models were found to be non-coincidence based on confirmation from nonparametric permutation tests ($p<0,05$). Other models were considered random based on permutation testing ($p>0,05$). Cross-validation analyses for the clinical+ dosiomic+ radiomics model showed that the generalizable performance of the model was relatively lower but still fair-to-good (mean AUC value 80.33 ± 21%).
Discussion: This study can demonstrates that imaging biomarkers, specifically radiomics and dosimics, exhibit superior predictive capability for treatment-related cardiac events in breast cancer patients compared to traditional clinical and dosimetric parameters (96% vs. 67%). Incorporating radiomics and dosiomics parameters into future clinical practice can serve as critical indicators. Fundamentally altering treatment approaches and follow-up strategies by achieving nearly perfect predictive success (96%) in anticipating cardiac side effects before their occurrence. This may suggests that high statistical imaging biomarkers should be integrated into personalized clinical practice. Further investigation is needed.

P2-04-23: Analytical validation of a high-definition tumor-informed MRD assay demonstrates robust detection at low tumor fractions common in breast cancer

Ashley Acevedo, Kyle Trettin, Nafei Xu, Matt LaBella, CJ Battey, Ravi Patel, Kiefer Haug, Elise Buser, Shalee Carlson, Thanh Tran, Britney Sadler, Abby Tucker, Genevieve Gould, Dale Muzzey

Background: Molecular residual disease (MRD) refers to the small number of tumor cells remaining in the body during or after cancer treatment. These tumor cells shed DNA into the bloodstream, resulting in circulating tumor DNA (ctDNA). ctDNA can be identified in

plasma-derived cell-free DNA (cfDNA) via the presence of tumor-specific somatic variants. We have developed a second-generation tumor-informed MRD assay to detect the presence and quantity of ctDNA in the plasma of breast-cancer patients with residual disease or tumor recurrence. Our assay detects the presence of ctDNA using a hybrid-capture based sequencing panel, targeting tumor-specific somatic variants. Each panel is designed with up to 1000 carefully selected somatic variant targets identified based on tumor profiling by matched tumor and normal whole genome sequencing and is optimized to provide high sensitivity and specificity at low tumor fraction, which is particularly important because many breast tumors have low shedding of ctDNA. Targeted sequence data is fit to a statistical model that incorporates panel-specific and sample-specific parameters to provide a robust estimate of the ctDNA fraction with a rigorous assessment of confidence for each test result. Here, we evaluated the performance of our assay at low ctDNA fraction.
Methods: Contrived mixtures of matched tumor and normal breast cancer cell lines and healthy donor plasma were were evaluated over a range of tumor DNA concentrations from 1 part per million (ppm) to 10,000 ppm, and were processed across multiple days, reagent lots, operators and instruments.
Results: Analysis of healthy donor samples paired with non-patient matched panels demonstrated the Limit of Blank (LoB) at a 95% specificity threshold—i.e., the threshold at which 95% of negative samples return a negative result—to be 0.3 ppm. When the LoB was used as the detection threshold, we found the Limit of Detection with 95% sensitivity (LoD95) to be <5ppm. Using a more stringent detection threshold of 1.4 ppm—corresponding to a specificity of 99.615%—we found the LoD95 to be 10 ppm. Both PPV and NPV were 100% when assessed with 56 positive samples at 50 ppm and 126 negative samples. Additionally, quantification of ctDNA fraction was linear over the entire range of tumor DNA concentrations assessed.
Conclusions: Overall, our assay demonstrated high sensitivity, specificity and measurement accuracy, which, together, will facilitate improved resolution in residual-disease detection and extend lead times in recurrence detection.

P2-04-24: CINDERELLA Clinical Trial (NCT05196269): initial Insights into Patient Engagement with an Artificial Intelligence-Based Healthcare Application for Enhancing Breast Cancer Locoregional Treatment Decisions

André Pfob, Eduard-Alexandru Bonci, Marília Antunes, Martin Mika, Maciej Bobowicz, Ludovica Borsoi, Jaime S. Cardoso, Oriana Ciani, Helena Cruz, Rosa Di Micco, Marcin Ekman, Oreste Gentilini, Tiago Gonçalves, Pedro Gouveia, Jörg Heil, Pawel Kabata, Orit Kaidar-Person, Elisabetta Listorti, Henrique Martins, Carlos Mavioso, Hélder P. Oliveira, André Pfob, Miguel Romariz, Natalie Romem, Giovani Silva, Timo Schinköthe, Maria-Joao Cardoso, on behalf of the CINDERELLA Consortium

Background: The CINDERELLA Project introduces an innovative artificial intelligence (AI)-based tool, the CINDERELLA APP, designed to enhance the shared decision-making process

in breast cancer treatment. This clinical trial aims to assess the Digital Health intervention's effectiveness in improving patient satisfaction with locoregional treatment aesthetic outcomes, aligning patient expectations with actual results, and evaluating its influence on overall quality of life and psychological well-being. The adoption and utilization of digital health applications in this context have not been extensively explored, making this study crucial for evaluating the app's acceptability, usability, clinical impact and patients' satisfaction. This work specifically addresses patient engagement and usage patterns of the CINDERELLA APP within the interventional arm of the trial during the first ten months of recruitment.
Methods: The CINDERELLA Trial is an international, multicenter, interventional, randomized, controlled, open-label clinical study. Patients with a diagnosis of primary breast cancer and no signs of systemic disease are enrolled and randomly assigned to the intervention or control group. The intervention arm utilizes the CINDERELLA APP, which leverages AI and digital health technologies to provide patients with comprehensive information (i.e., text, images, videos) about existing and proposed locoregional treatments, including photographs of similar cases treated with the same surgical techniques. Data collection encompassed patient demographics and app usage metrics (i.e., duration, logins, content engagement). Comparative analyses of app usage time across different patient subgroups were conducted using the Wilcoxon or Kruskal-Wallis rank-sum test. Statistical analysis was conducted using R 4.4.1 for Windows and RStudio (2024.04.2). The CANKADO platform was the primary digital platform for physicians to manage the app content and collect data, ensuring adherence to privacy, data protection, and ethical guidelines in AI applications.
Results: The clinical trial recruited 474 patients from August 8, 2023, to June 30, 2024, across seven study sites in five countries. Of these, 246 patients, with a median age of 53 years, were randomized to the interventional arm. The average app usage duration was 19.25 minutes (min) with a median of 4 logins/user, over a median follow-up period of 3.2 months. Israel recorded the lowest app usage time with an average of 10.26 min and a median of 1.5 logins/user, while Poland recorded the highest with 24.68 min and a median of 6 logins/user. There were no statistically significant differences in median app usage time based on age groups (<40 years, 6.55 min vs. 40-60 years, 11.8 min vs. >60 years, 14.17 min, p=0.136) or estimated type of surgery (11.58 min for breast-conserving surgery vs. 11.68 min for mastectomy with reconstruction, p=0.721). Noteworthy, patients expected to undergo radiotherapy used the app longer than their counterparts (12.81 min vs 9.06 min, p=0.034). The "Frequently Asked Questions" section was the most accessed part of the app, accounting for 44.61% of the total 3201 hits.
Conclusions: Initial data indicate good engagement with the CINDERELLA APP. The presence of only minor differences in usage patterns across countries, age groups, and treatment types suggests that the app may play a role in filling the informative gaps related to patients' characteristics. The CINDERELLA Trial is ongoing, with final results predicted to be published in 2026 once recruitment and follow-up have been concluded. These initial findings regarding the app's usability, together with the trial's final results will inform enhancements to design AI-based clinical decision support systems to better meet patient

needs and improve decision-making processes in breast cancer treatment.
Funding. European Union grant HORIZON-HLTH-2021-DISEASE-04-04 Agreement No. 101057389.

P2-04-25: Different Pyroptosis Phenotype within Breast Cancer Possess Distinctive Prognosis and Tumor Immune Microenvironment

Ye Hong, Qianqian Lei, Nan Li

Pyroptosis, a type of programmed cell death that was involved in tumorigenesis, progression, and tumor immune microenvironment (TME). However, little is known about the pyroptosis phenotype of breast cancer (BC) and its' role in the prognosis and TME. Here, we acquired BC data and performed comprehensive analyses to dissect BC's pyroptosis patterns and corresponding characteristics. Based on transcriptomic data, we identified three types of pyroptosis patterns (type 1-3), which possessed distinctive prognosis, immunologic features, genomic alterations, and clinical characteristics. Type 3 with lowest pyroptosis activity showed worst prognosis, highest tumor purity, and coldest TME (significantly downregulation of cancer antigen presentation, infiltration of immune cells into tumors, recognition of cancer cells by T cells, killing of cancer cells, and so on). Type 2 with highest pyroptosis activity had better prognosis and hotter TME. Further analyses demonstrated the difference in anti-tumor immune among three pyroptosis patterns and identified CACNA1B, a potential crucial molecular that caused different prognosis and immune microenvironment. Taken together, our study firstly uncovered three types of pyroptosis patterns in patients with BC and their molecular features, which provided reference into further study targeting pyroptosis and its role in immune microenvironment.

P2-04-26: Predicting the prognosis and immunotherapeutic response of triple-negative breast cancer by constructing a prognostic model based on CD8T cell-related immune genes

Zhijian Huang, Yunyun Han, Xiaoting Qiu

Background: triple-negative breast cancer (TNBC) posed significant challenges in terms of treatment efficacy. CD8+ T cells, pivotal immune cells, can be effectively analyzed for gene expression differentials across diverse cell populations owing to the rapid advancements in sequencing technology. Leveraging these genes, our objective was to develop a prognostic model that accurately predicted the prognosis of TNBC patients and their responsiveness to immunotherapy.
Methods: The sample information and clinical data of triple-negative breast cancer (TNBC) were sourced from the TCGA database and METABRIC database. In the initial stage, we identified 67 differentially expressed genes associated with immune response in CD8+ T cells. Subsequently, we narrowed down our focus to three key genes: CXCL13, GBP2, and GZMB, which were utilized for constructing our prognostic model. The accuracy of the

model was assessed using validation set data and receiver operating characteristic (ROC) curves. Furthermore, we employed various methods including KEGG pathway analysis, immune infiltration analysis, and correlation analysis with CD274 to explore the model's predictive efficacy in immunotherapeutic responses. Additionally, we investigated the potential underlying biological pathways that contribute to divergent treatment responses.
Results: In the initial stage, we identified 67 differentially expressed genes associated with immune response in CD8+ T cells. Subsequently, we narrowed down our focus to three key genes: CXCL13, GBP2, and GZMB, which were utilized for constructing our prognostic model. We successfully developed a prognostic model capable of predicting the prognosis of TNBC patients. The area under the curve (AUC) values for 1, 3, and 5-year survival predictions were determined to be 0.618, 0.652, and 0.826, respectively. Employing this risk model, we stratified the samples into two distinct groups: high-risk and low-risk group. Through KEGG enrichment analysis, we observed that the high-risk group predominantly exhibited enrichment in metabolic-related pathways, such as drug metabolism and chlorophyll metabolism, whereas the low-risk group demonstrated significant enrichment in cytokine pathways. Furthermore, immune landscape analysis revealed noteworthy variations between CD274 expression and risk scores, indicating that our model effectively predicted the response to immune-based treatments in patients.
Conclusion: In conclusion, our study demonstrated the potential of CXCL13, GBP2, and GZMB as prognostic indicators for clinical outcomes and immunotherapy response in patients with triple-negative breast cancer. These findings provided valuable insights and present a novel avenue for immunotherapeutic approaches targeting triple-negative breast cancer.

P2-04-27: Development & Validation of RSC4All: an Artificial Intelligence-driven Machine Learning Nomogram Enhanced with Synthetic Data to Predict RSClin® Results & Guide Adjuvant Treatment of Node-negative HR-positive/HER2-negative Early Breast Cancer

Flavia Jacobs, Saverio D'Amico, Emanuela Ferraro, Elisa Agostinetto, Carlo Tondini, Mariangela Gaudio, Chiara Benvenuti, Riccardo Gerosa, Giuseppe Saltalamacchia, Rita De Santis, Matteo Giovanni Della Porta, Armando Santoro, Monica Fornier, Evandro De Azambuja, Alberto Zambelli

Background: RSClin™ is a proprietary algorithm that combines clinicopathological (CP) factors (age, tumor size and grade) with genomic risk to refine the prognosis of distant recurrence (DR) and chemotherapy (CT) benefit in patients with Node-negative (N0) Hormone Receptor Positive (HR+)/Human Epidermal Growth Factor Receptor Negative (HER2-) Early Breast Cancer (eBC). Since RSClin™ is only available in the USA, we aimed to develop an automated ML-based nomogram, RSC4All, to predict RSClin™ outcomes and provide free access to this predictive tool via a web-based link. Additionally, we generated synthetic data (SD) using Generative Adversarial Networks (GANs) to augment the initial dataset and enhance the tool's predictive accuracy.

Methods: We retrospective collect CP and genomic data from 290 patients with N0 HR+/HER2- eBC who underwent OncotypeDX from 2020 to 2022 at Italian and Belgian hospitals, with available RS and RSClin™ outputs of DR risk and CT benefit. Patients were randomly split into 2 groups, 70% allocated to the training set and 30% to the validation set. The ML-nomogram was developed using classification and regression models, including linear and logistic regression, to predict the categories (high vs mid/low for DR and yes vs no for CT) as well as the precise value for DR and CT benefit. Additionally, 177 synthetic patient records were generated through GANs and included in the training set to enhance the tool's predictive capability.
Results: Compared to RSClin™ outcomes, the classification model for DR, trained on the original dataset, achieved a ROC AUC of 0.97, while for CT benefit achieved a score of 0.99. The regression analyses for DR and CT benefit yielded significant R2 scores of 0.84 and 0.72, respectively. The inclusion of SD improved the dataset's diversity and representativeness, closely mirroring the real cohort's characteristics. Incorporating SD improved both classification and regression metrics, notably increasing the regression accuracy for predicting precise DR and CT benefit values. A web application was developed to provide easy and free access to the developed ML models (https://rsc4all.streamlit.app).
Conclusions: RSC4All accurately reproduces RSClin™ results to support treatment decisions for patients with N0 HR+/HER2- eBC. The incorporation of SD further enhanced the predictive accuracy of the ML tool, supporting the value of AI-driven data augmentation in oncology.

P2-04-28: Signal Processing Techniques for Investigating the role of Viral Infections in APOBEC3 Enzymes in Tumor Tissue Biopsies

Mohadeseh Soleimanpour, Jake Lehle, Diako Ebrahimi

The National Cancer Institute has designated several viruses such as EBV, HBV, HCV, HIV, HPV, and HTLV as agents that either cause cancer or increase the risk of developing cancer. However, extensive analyses of tumor genome and transcriptome datasets have identified numerous additional virus types, the functional implications of which remain largely unknown. Viral infection often dysregulates unique molecular processes within tumor cells and alters the composition of immune cells in the tumor-microenvironment. For instance, HPV-positive tumors have been shown to exhibit a significantly elevated expression of the DNA editing enzyme APOBEC3B compared to HPV-negative tumors. Furthermore, HPV positive tumors display and increased number of C-to-T mutations induced by this protein. The genome and transcriptome of tumor tissue biopsies contain a wealth of information about these virus-associated signatures. However, advanced signal processing approaches are needed to extract these viral signatures from complex tumor datasets, and elucidate their specific roles in cancer. Here, we developed a quantitative approach to investigate the link between viral infection and dysregulation of a seven-membered A3 enzyme family. The primary role of these enzymes is to restrict viral infections by inducing C-to-U mutations in viral genomes. However, at least three members of this enzyme family (A3A/B/H) can also

induce mutations in cellular DNA, and drive tumor formation and evolution. We used NMF (Nonnegative Matrix Factorization) to deconvolute the expression profiles of A3 enzymes in >10,000 bulk RNAseq datasets from diverse TCGA tumors. This analysis revealed the expression profiles of A3 enzymes within tumor and tumor microenvironment cells including various immune cells. Next, we conducted an association analysis to identify the link between the presence of viral infection and the proportion of each of these tumor and tumor microenvironment expression profiles. As expected, our analyses revealed strong associations between tumor-specific A3 expression profiles and infections by oncolytic viruses such as HPV. Notably, and somewhat unexpectedly, our analyses also revealed associations with viruses about which little is known in the field of cancer. Taken together, our analyses provide evidence for the link between A3dysregulation and infection by viruses including bacteriophages.

P2-04-29: Predictive model of prognosis index for invasive micropapillary carcinoma of the breast based on machine learning: A SEER population-based study

Zirong Jiang, Yushuai Yu, Xin Yu, Qing Wang, Kaiyan Huang, Mingyao Huang, Chuangui Song

Background: Invasive micropapillary carcinoma (IMPC) is a rare subtype of breast cancer. Its epidemiological features, treatment principles, and prognostic factors remain controversial.
Objective: This study aimed to develop an improved machine learning-based model to predict the prognosis of patients with invasive micropapillary carcinoma.
Methods: A total of 1123 patients diagnosed with IMPC after surgery between 1998 and 2019 were identified from the Surveillance, Epidemiology, and End Results (SEER) database for survival analysis. Univariate and multivariate analyses were performed to explore independent prognostic factors for the overall and disease-specific survival of patients with IMPC. Five machine learning algorithms were developed to predict the 5-year survival of these patients.
Results: Cox regression analysis indicated that patients aged >65 years had a significantly worse prognosis than those younger in age, while unmarried patients had a better prognosis than married patients. Patients diagnosed between 2001 and 2005 had a significant risk reduction of mortality compared with other periods. The XGBoost model outperformed the other models with a precision of 0.818 and an area under the curve of 0.863.
Conclusions: A machine learning model for IMPC in patients with breast cancer was developed to estimate the 5-year OS. The XGBoost model had a promising performance and can help clinicians determine the early prognosis of patients with IMPC; therefore, the model can improve clinical outcomes by influencing management strategies and patient health care decisions.

P2-04-30: Harnessing Technology: A Comparative Study of AI versus Manual Scoring in HER2 Ultra-low Breast Cancer

Xu Xuan Lim, Angela Cramer, Jeppe Thagaard, Thomas Wichmand Ramsing, Pedro Oliveira

Background: The advent of targeted therapies using the HER2 receptor as a delivery mechanism in breast cancer, introduced a need for re-evaluation HER2 scoring in previously classified negative cases (2+ ISH -ve; and 1+), as patients with these tumours may benefit from these innovative treatments. At The Christie Hospital. Manchester, U.K., our specialised unit (BTRU) has been exclusively reporting ER, PR, and HER2 status in breast cancers for the past 25 years with a dedicated staff, adhering to consistent technical guidelines and stringent UKAS accreditation standards, with an annual assessment of approximately 1,600 cases. This study aimed to evaluate the performance of an AI solution in the identification of HER2 ultra-low compared to a cohort of reported HER1+ and 0 cases that were manually scored by the BTRU.
Methods: We retrieved a cohort of 288 cases reported as HER1+ or 0 during 2023 (IHC assay: VENTANA Pathway anti-HER2/neu (4B5) rabbit monoclonal primary antibody). The original slides were digitised, scanned at x40, and submitted anonymised to Visiopharm for analysis. No re-scoring of the cases was conducted. The AI system not only provided HER2 scoring but also detailed the total number of tumour cells evaluated, the completeness of membrane staining (complete/incomplete/negative), and staining intensity (weak/moderate/strong).
Results: A total concordance of 85.7% (247 cases) was observed between the AI and previously reported results. The AI upgraded the manual scores in 6 cases from 1+ to 2+ and in 24 cases from 0 to 1+. Conversely, 11 cases originally scored as 1+ were re-evaluated by AI and scored as 0. No significant differences in tumour cell content were noted between concordant and discordant cases.
Conclusions: Overall, there was strong agreement between the two methodologies; however, the AI solution outperformed manual scoring in 24 cases (8.3%), which would otherwise be deemed unsuitable for treatment. Notably, the membrane staining in the 11 cases re-scored by AI as 0, was just bellow the 10% threshold currently established by UK and ASCO/CAP guidelines, underscoring the challenges in achieving precision in borderline cases through manual scoring. Given the unique nature of our unit, it is anticipated that a greater number of discordant cases may be identified in different clinical settings. These findings suggest that incorporating AI tools into pathology practice could enhance patient selection for new therapies, as well as optimising cut-offs for identifying potential responders in future clinical trials.

P2-05-01: Telemedicine in physical therapy after axillary surgery for early breast cancer

Hans-Christian Kolberg, Johanna Schmitz, Isabella Swienty, Leyla Akpolat-Basci, Özlem Yüksel, Abdrhman Maguz, Carsten Lehment, Miltiades Stephanou, Cornelia Kolberg-Liedtke

Background: Reduction of long-term side effects of axillary surgery for early breast cancer is still an unmet medical need. Although axillary surgery is increasingly perceived as a diagnostic rather than a therapeutic tool there will always be patients for whom the removal of axillary lymph nodes is a necessary intervention. The onset of physical exercise for the prevention of shoulder-arm morbidity immediately after axillary surgery is recommended in national and international guidelines and is usually part of the routine work-up during the inpatient stay after breast cancer surgery. However, in times when breast cancer surgery becomes an outpatient procedure, limited access to qualified physiotherapy could lead to a higher risk of shoulder-arm morbidity. Approaches including telemedicine solutions as part of the physiotherapy concept could be an option when physical therapy in person is not possible. Here we are presenting the results of a non-randomized two-arm proof-of-concept trial comparing standard physiotherapy and a telemedicine approach.
Methods: Patients scheduled for axillary surgery for early breast cancer were prospectively recruited. All received a brief introduction to 4 physical exercises for the prevention of shoulder arm-morbidity and were handed tablets with the pre-installed EvoCare®-app. During 4 weeks, they exercised at home and took videos of themselves. Physiotherapists watched the videos and gave feedback via the app. After 4 weeks, all patients answered questionnaires with items from the BREAST Q® and the Quick Dash® instruments. The questions covered social activities, sleep, arm function and lymphedema. For the control group patients who had received the standard physiotherapy after axillary surgery including the same 4 exercises were invited to take part in the retrospective part of the study and to answer the same questionnaires. Results were compared using the t-test. A two-sided p of </= 0.05 was considered statistically significant.
Results: 41 patients were included in the analysis, 21 in the telemedicine group and 20 in the standard physiotherapy group. The groups were well balanced with no statistically significant difference regarding age (p=0.24), breast conservation (p=0.74), mastectomy (p=0.95), sentinel node biopsy (p=0.09), axillary dissection (p=0.28), targeted axillary dissection (p=0.16), ER (p=0.68), PR (p=0.78), HER2neu status (0.68), neoadjuvant chemotherapy (p=0.24) and number of involved lymph nodes (p=0.39). There was a statistically significant difference regarding the number of removed lymph nodes (p=0.03) with 3.7 (SD 4.02) in the telemedicine group and 7.1 (SD 5.39) in the standard physiotherapy group mainly resulting from the different standards regarding the postneoadjuvant management of the axilla at the different timepoints the two groups were treated.
The results of the two groups demonstrated neither statistically significant differences in the BREAST Q®items “sleeping disorders” (p=0.135), “lymphedema” (p=0.07) and “difficulties lifting something” (p=0.58) nor in the Quick Dash® items “carrying a bag” (p=0.31), “social activity” (p=0.15) and “physical limitations at work” (p=0.21).
Conclusion: Standard physiotherapy and the telemedicine approach yielded comparable results regarding lymphedema, shoulder-arm-morbidity, sleep and social activity. Telemedicine could be an option after outpatient breast cancer surgery, in settings where patients have to travel long distances to the next physiotherapy unit or where the lack of

resources leads to the omission of physical therapy after axillary surgery for early breast cancer.

P2-05-02: IDENTIFICATION OF MOST COMMON CONCERNS IN BREAST CANCER SURVIVORS FROM 2019-2023 IN THE MRW LIFE SURVIVORSHIP PROGRAM

Carol A Rosenberg, Anisha Patel, Poornima Saha

Background: The number of breast cancer survivors continues to increase. Unfortunately, many survivors experience late or long-term physical and/or psychosocial effects of cancer treatments. The National Comprehensive Cancer Network (NCCN) has established guidelines on survivorship care to help healthcare professionals address the complex and varied needs of cancer survivors and has recommended screening for common survivorship concerns. The MRW Living in the Future (LIFE) Cancer Survivorship Program at Endeavor Health offers a comprehensive educational program that includes a risk-adapted visit (RAV) during which an individualized survivorship care plan (SCP) is provided and discussed. In this report, we evaluate the pre-visit assessment as an effective way to help survivors self-identify their most meaningful concerns during their cancer journey.
MethodsOnce patients with breast cancer have completed their active treatment with chemotherapy, surgery, and radiation, they are offered a RAV facilitated by an advanced practice oncology nurse through the MRW LIFE Cancer Survivorship program. During this visit, an individualized SCP is provided and discussed. At the time of visit, each patient is also provided a pre-visit concerns assessment which surveys patients at the time of survivorship as to their immediate concerns. The questionnaire collects data as to the patient's type of cancer, age at diagnosis, time of treatment completion as well as a detailed checklist of potential concerns.
Results: From January 2019 to December 2023, two thousand one hundred ninety-nine (2,199) breast cancer survivors were referred to the MRW LIFE Cancer Survivorship Program and had a SCP completed. One thousand seven hundred forty four (1,744) breast cancer patients completed a pre-visit assessment. Of the respondents, all were female and ages ranged from 21-91 years old. Over 97% reported they had a primary care physician (PCP) as part of their care team. All respondents identified at least one or more concerns and > 95% endorsed two or more concerns. The most commonly identified concerns by ≥ 70% of breast cancer survivors were fear of recurrence, long term effects of treatments, cancer prevention/early detection, and nutrition/physical activity/weight management. Other concerns cited by ≥ 30% of breast cancer survivors were fatigue, memory/cognition, and anxiety/stress. From 2019 to 2023, we saw a steady increase in breast cancer patients attending a survivorship visit and the number of pre-visit assessments completed. The top 10 concerns identified by breast cancer survivors remained similar over time.
Conclusion: Completing a survivorship concerns assessment following treatment helps breast cancer survivors self-identify the most important concerns they have during their

cancer journey. Combined with an individualized SCP, a needs assessment can be a useful construct to gain better understanding of their cancer experience and promote self-management of symptoms and shared decision making with their care team. A better understanding of the most important concerns of breast cancer patients during survivorship is critical for the entire care team. Opportunities for targeted interventions such as referrals to supportive care and additional resources can be facilitated with use of a needs assessment. An ongoing educational curriculum geared towards the most identified needs of our breast cancer survivors is implemented year round through Evenings of Survivorship and include such topics as Fear of Recurrence, Nutrition Myth Busters, Coping with Chemo brain – all based on the greatest needs expressed by our breast cancer survivors.

P2-05-03: Work Reintegration After Breast Cancer Surgery in São Paulo Public Employees: a cross-sectional observational study.

Marcelo Antonini, Andre Mattar, Arthur Gaia Duarte Peixoto, Mylena Scheneider Becale, Denise Joffily Pereira da Costa Pinheiro, Felipe Zerwes, Andressa Gonçalves Amorim, Odair Ferraro, Renata Arakelian, Marina Diógenes Teixeirab, Eduardo de Camargo Millen, Fabrício Palermo Brenelli, Francisco Pimentel Cavalcante, Antônio Luiz Frasson, Reginaldo Guedes Coelho Lopes

Objective: This study aims to evaluate the return-to-work (RTW) rate among state public employees in São Paulo with breast cancer who underwent surgical treatment at a single institution. Additionally, it compares RTW rates in relation to different oncological treatments and examines factors such as education, family income, perceived employer support and/or discrimination, workplace adjustments, and personal job satisfaction.
Methodology: This is an observational, descriptive, cross-sectional study conducted at a single institution, involving public employees with non-metastatic breast cancer who underwent surgical treatment at the State Public Servant Hospital of São Paulo from October 2021 to December 2022. Patients included in the study met the following criteria: diagnosed with breast cancer (either carcinoma in situ or invasive), female, over the age of 18, undergoing surgical treatment for breast cancer, employed as public servants in the State of São Paulo, and actively working at the time of diagnosis. Patients who declined to respond to the questionnaire and those with metastatic breast cancer at the time of the study or who progressed to a metastatic condition within six months of diagnosis were excluded. To assess quality of life, the following instruments were used: the European Organization for Research and Treatment of Cancer 30-Item Quality of Life Questionnaire (EORTC QLQ-30), version 3.0 in Portuguese, and its specific module for breast cancer: Quality of Life Questionnaire Breast Cancer - 23 (QLQ-BR 23). The study was submitted through Plataforma Brasil to the Research Ethics Committee (CEP) of Hospital do Servidor Público Estadual and approved (CAAE 68337823.4.0000.5463), and all patients signed the informed consent form.
Results: A total of 420 questionnaires were sent out after initial contact via telephone, with

355 responses received (response rate of 84.5%). Sixteen responses (3.8%) were excluded as they were completed by dependents of the state public servant. Among the 339 eligible patients, 300 (88.2%) were still working at the time of diagnosis. The RTW rate in this study was 74.41%. A significant majority of patients (80.6%) resumed employment within six months, while 15.1% returned between six to twelve months, and 12.8% between twelve to eighteen months. The predominant reason cited for RTW was personal satisfaction with financial necessity being a driving factor. A vast majority (93.8%) resumed their original positions. Upon their return, 62.5% of participants indicated no decline in work performance or productivity. In the assessment of global quality of life, patients who returned to work had higher scores compared to those who did not return, averaging 73.2 versus 51.5, respectively ($p < 0.001$). In the EORTC BR-23 subquestionnaire, patients who returned to work had higher scores in body image assessment, averaging 76.0 versus 52.3 for those who did not return to work ($p = 0.032$), as well as a more optimistic future outlook. It was found that the type of surgical treatment impacts the RTW rate ($p < 0.001$). Among patients who returned to work, 87.5% underwent breast-conserving surgery (BCS) compared to 9.1% of those who did not return to work. Additionally, 45.5% of those who returned underwent radical and oncoplastic surgery. Adjuvant treatment also correlated with RTW; patients undergoing adjuvant chemotherapy had a 6.25-fold increased risk of not returning to work compared to those who did not undergo adjuvant chemotherapy.
Conclusion: The RTW rate among state public employees in São Paulo was 74.41%. Oncological treatment (surgical, chemotherapy, and radiotherapy) was found to have a statistically significant association with RTW rates. Socially, employer-provided adjustments influenced the RTW decision, in addition to the patient's personal and work satisfaction. Returning to work is associated with improved quality of life for women surviving breast cancer.

P2-05-04: Associations between Hearing/Vestibular Problems and Levels of Physical Function Impairment among Breast Cancer Survivors in a Multiethnic Study Cohort

Jincong Freeman, Fangyuan Zhao, Wenji Guo, Megan J. Huisingh-Scheetz, Jayant M. Pinto, Olufunmilayo I. Olopade, Dezheng Huo

Background: Cancer treatment such as chemotherapy and radiotherapy can cause hearing/vestibular problems including tinnitus, hearing loss, and vertigo or persistent dizziness. A recent study has revealed that hearing loss is more prevalent among cancer survivors than in the general population in the US. Further, hearing/vestibular problems can continue through survivorship, which can negatively affect cancer survivors' quality of life. However, research remains scarce concerning these symptoms and physical function specifically among breast cancer patients and survivors.
Methods: Between July and September 2023, we surveyed patients enrolled in the Chicago Multiethnic Epidemiologic Breast Cancer Cohort regarding whether they experienced tinnitus, hearing loss, and/or vertigo. Level of physical function impairment was measured

using a 10-item assessment of daily activities (i.e., moderate/vigorous activities, lifting, climbing, bending, walking, and bathing/dressing) adopted from the Nurses' Health Study. The total score ranges from 0 to 20, with higher scores indicating more physical function impairment. To examine correlations between hearing/vestibular problems and levels of physical function impairment, we fit separate multivariable linear regression models, controlling for age at breast cancer diagnosis, duration from breast cancer diagnosis to survey, race/ethnicity, insurance type, AJCC stage, histology, receptor status, the Charlson-Deyo Comorbidity Index, and treatment modality. Adjusted regression coefficients (β) and standard error (se) were calculated.
Results: Of the 1,462 participants surveyed, the mean age was 54.2 years (SD 11.4) and the median duration from diagnosis to survey was 8.2 years (IQR: 5.0-12.4); 69.8% identified as White, 22.7% as Black, 3.8% as Asian or Pacific Islander, and 3.7% as Hispanic; and 46.0% received chemotherapy. Overall, 15.1%, 13.6%, and 7.7% reported experiencing tinnitus, hearing loss, and vertigo, respectively. The overall mean score for levels of physical function was 4.0 (SD 5.0). Patients who experienced tinnitus had a higher average physical function score than those who did not (5.2 vs. 3.7, $p < 0.001$). Compared with patients who did not experience hearing loss, those who did had a higher mean score (5.3 vs. 3.6, $p < 0.001$). Similarly, the physical function score was higher among patients who experienced vertigo than those who did not (6.4 vs. 3.8, $p < 0.001$). After covariate adjustment, experiencing tinnitus was correlated with a greater level of physical function impairment ($\beta = 0.967$, se = 0.469, $p = 0.035$). Experiencing vertigo was also correlated with a greater level of physical function impairment ($\beta = 2.034$, se = 0.604, $p < 0.001$). The level of physical function impairment was only marginally significantly different between patients who experienced hearing loss and those who did not ($\beta = 1.053$, se = 0.548, $p = 0.055$). Additionally, in the same adjusted models, older age, Black race, having a Charlson-Deyo Comorbidity Index of 1 or ≥2, having stage III-IV tumors, and having Medicaid or Medicare were associated with higher levels of physical function impairment.
Conclusions: In this multiethnic cohort of breast cancer survivors, hearing/vestibular problems were prevalent, and patients who experienced these symptoms were more likely to have reduced levels of physical functioning. Our findings also highlight racial and socioeconomic disparities in physical function impairment. To improve the quality of life of breast cancer survivors, oncology programs should consider early and routine screening for hearing/vestibular problems and address disparities in physical function and unmet needs for survivorship care.

P2-05-05: Associations among BMI and patient-reported body image dissatisfaction during immediate autologous breast reconstruction: A prospective longitudinal evaluation

Sara Bouhali, Tzuan A. Chen, Gregory P. Reece, Mia K. Markey, Fatima A. Merchant, Deepti Chopra

Introduction: Cancer-related breast reconstruction is a process that can take months to years to complete, potentially impacting a patient's psychosocial well-being. Body habitus may influence a patient's adaptation to bodily changes resulting from breast cancer treatment, considering the association between obesity and body image dissatisfaction1. Thus, we investigated the association between body mass index (BMI) categorized as overweight or obese and patient-reported body image dissatisfaction at specific time points during immediate autologous breast reconstruction.
Material and Methods: The study sample included 40 patients who were enrolled in an IRB approved study from 2011 to 2014 at The University of Texas MD Anderson Cancer Center and had completed immediate autologous (DIEP/TRAM) reconstruction. Participants completed health-related quality of life measures including Body Image Scale (BIS), Brief Symptom Inventory (BSI-18), and BREAST-Q preoperatively (baseline) and at least once postoperatively at 3, 6, 9, 18, or 18+ months after reconstruction. Given sufficient abdominal fat tissue is a prerequisite for any abdominal-based tissue reconstruction, patients with baseline BMI over 25 Kg/m2 were included. Linear mixed models were conducted to investigate the effect of baseline BMI category on BIS scores and BREAST-Q physical well-being of the abdomen scores (PWBAS) during reconstruction. Post hoc analyses were conducted when a significant interaction effect of baseline BMI category and time effect was found. Baseline age, depression score, marital status, race, and ethnicity were included as control variables. Analyses were performed using SAS 9.4 and the level of significance was set at $p < 0.05$.
Results: There were no statistically significant changes in BMI across the study visits. Baseline age was significantly associated with BIS scores (ß = -0.31, p = 0.0072), with increased age associated with lower levels of dissatisfaction. Baseline depression was significantly associated with BIS scores (ß = 0.78, p = 0.0058), with higher baseline depression linked to greater body dissatisfaction. Marital status, race, and ethnicity were not statistically significantly associated with BIS scores. Obese patients reported statistically significant improvements in BIS postoperatively, whereas overweight patients had no statistically significant changes in BIS over time. At baseline, obese patients had significantly higher body image dissatisfaction compared to overweight patients (p = 0.0128) and continued to report higher dissatisfaction at follow-up visits, although the difference was not statistically significantly higher than overweight patients after the baseline visit.
Baseline depression, marital status, age, race, and ethnicity were not statistically significantly associated with PWBAS. Both BMI groups reported high abdominal satisfaction preoperatively. However, obese patients experienced a significant decrease in abdominal satisfaction at 9 months (p = 0.0482) compared to baseline, while overweight patients saw significant decreases at 3 and 6 months ($p < 0.0001$). No statistically significant longitudinal differences were observed between BMI groups for PWBAS, except at 6 months, when obese patients had significantly higher abdominal satisfaction (p = 0.0167). Abdominal satisfaction improved by the final visits, yet it remained below baseline levels.
Conclusion: Obese and overweight patients may benefit from additional body image counseling. Screening for depression and making appropriate referrals may be important

for postoperative body image adjustment. Further, these patients can benefit from preoperative counseling about early postoperative physical changes to the abdomen.

P2-05-06: Contemporary media – highlighting a podcast hosted by a breast cancer survivor – to disseminate breast cancer education in a credible, patient-friendly format.

Molly Lindquist, Samira Daswani, Douglas W. Blayney

Background: Most individuals and families facing a health-related decision will attempt to self-educate on their situation. Yet, the National Assessment of Adult Literacy found only 12% of Americans to have proficient health-based literacy. Individuals are searching for information on their diagnoses and ways to improve health, but accessible information that is both credible and contextualized to one's situation is often lost in noise. Many use internet search channels, with Google reporting 70,000 health-related queries per minute, and a January 2024 study of YouTube users reported that 87.6% of respondents watch health related content (HRC) and 84.7% make decisions based on what they watch. According to a 2019 study in Consumer Informatics and Digital Health, 9 out of 10 adults in the US use at least one online social network. In addition, the podcast channel has seen significant growth in recent years; the number of people listening to podcasts has doubled since 2013 to over 177 million listening monthly (Deal, 2022).

Methods: As a survivor who self-identifies as a "patient from hell," Samira Daswani found navigating the cancer care system challenging and frustrating. She led the development of a podcast to disseminate information important to cancer patients and families. Within the first 7 months of our Patient from Hell podcast launch in May of 2022, we ranked within the top 10% of podcasts shared globally (Spotify, 2022) and podcast followers have doubled since the beginning of 2024.

One of the primary areas the podcast has covered is breast cancer via interviews with oncologists, researchers, patients and survivors. A new episode is released bi-weekly on all podcast channels, with social media clips of the episode posted 2-3 times per week via Instagram, YouTube and TikTok for the week after the launch of an episode. The podcast was funded in May 2023 by the Patient Centered Outcomes Research Institute to disseminate PCORI-funded research projects and has featured guests such as Dr. Fumiko Chino, Dr. Karen Wernli, among others.

Findings: Of the 36 episodes published in the last twelve months (July 2023-June 2024), 33% (12 episodes) have been breast cancer specific (vs. more general cancer topics that are applicable to a wider audience of cancer patients, survivors and caregivers). Those 12 breast cancer specific episodes have garnered 81,468 impressions on Spotify, YouTube, Instagram, LinkedIn, TikTok, and Twitter and via our newsletter. We started to share one

minute clips via YouTube shorts in March of 2024 and have generated over 5,000 views of those “key highlight” short clips in just 3 months for the breast cancer focused episodes and our YouTube channel subscribers have nearly doubled since we started running the “Shorts.”
Discussion: The podcast medium is a novel and effective way of disseminating breast cancer information in a form that is both approachable and actionable. In addition to providing an opportunity to glean information by listening to full podcast episodes, we have learned that amplifying key messages and takeaways via short episode clips on social media platforms helps to further disseminate credible, science-backed information as well as key patient learnings to a wider audience of people impacted by breast cancer. The podcast is one patient and family education tool we are developing (JCO 42(16), E13064).

P2-05-07: Combination treatment to prevent and treat oxidative damage to neuronal cells

Matthew Koury, Kathryn J. Fleck, Alisha P. Maity, Zonera A. Ali, Erik L. Zeger, Aarti L. Shevade, Arezoo Ghaneie, Deric C. Savior, U. Margaretha Wallon

Introduction: Chemotherapy-induced peripheral neuropathy (CIPN) is a common dose-limiting side-effect of taxanes, platinum agents, vinca alkaloids, bortezomib and thalidomide. These regimens are first-line treatment for common cancers such as breast, colorectal, lung and lymphoma and used in both early-stage and metastatic cancer therapy. Therefore, numerous patients, both young and old, are at risk for developing CIPN. The symptoms have a negative impact on routine activities, functions, and behaviors in the domestic, work, and social lives of cancer patients, adversely affecting the quality of their survivorship.
A meta-analysis of 31 CIPN studies revealed an aggregated prevalence of 48%. In contrast to other adverse effects, such as hematological side effects, the symptoms of CIPN can be irreversible and there are currently no effective managements to prevent, alleviate or reverse these symptoms. As the number of cancer survivors increases, new research needs to focus on prevention and treatment of this long-term adverse effect to improve patients’ function and quality-of-life.
We have previously shown that personal biochemical responses to oxidative stress, induced by chemotherapeutic agents, during the early cycles of treatment are associated with development of CIPN. Therefore, we have tested a series of antioxidants and components of neuronal signaling transduction for their ability to prevent and/or reverse damage induced by oxidative stress in neuronal cell cultures.
Methods: All experiments were performed using the well-defined mouse neuronal model cell-line Neuro2A and the human peripheral nerve sheath cell-line S462. Cells were treated with retinoic acid in low serum conditions to induce differentiation prior to experiments. Oxidative stress was induced by adding hydrogen peroxide to cultures pre- or post-addition of antioxidant agents at various concentrations. Differentiation was followed by microscopy to determine neurite outgrowth and cell counts to demonstrate cell cycle exit. Cell viability

and membrane damage was tested using the MTT and LDH assays, respectively. PCR and Western blotting was performed to examine changes in KEAP-NRF2 pathway, Caspase-3, SOD, and NLRP3 using commercially available antibodies and reagents.
Results: To date, we have test the monosialoglycospingolipid, GM1, and two antioxidants, not listed by ASCO as unsuitable for prevention/treatment of CIPN, for their effect on hydrogen peroxide triggered neuronal cell damage. Damage to mouse Neuro2A cells could not be prevented or rescued by single agent treatment at doses ranging from 10μM to 50μM. However, when combining GM1 with one of the antioxidants, all doses were able to prevent damage while high dose could treat existing cell damage. Cell damage to the human S462 could be prevented and treated if using high dose GM1 as single agent. In contrast to the Neuro2A experiments, when combining with GM1 with an antioxidant all doses ranging from 10μM to 50μM had a therapeutic effect. The strongest response was observed using the combination treatment in both cell lines.
Discussion and Conclusions: We have been using GM1, a well-tolerated agent, but with reported mixed responses in clinical trials when used to prevent or treat CIPN. Based on our previous data and reports in the literature demonstrating the possible initiation of cell damage resulting in CIPN by oxidative stress, we have performed as series of test using GM1 as single agent and in combination with known antioxidants in cell culture experiment to select optimal treatment options prior to testing in animal models. Using existing therapeutic agents with low toxicity profiles could result in a rapid transition into clinical use for prevention and/or treatment of CIPN for cancer patients.

P2-05-08: QUALITY OF LIFE OF PATIENTS UNDERGOING NEOADJUVANT CHEMOTHERAPY: A LOOK AT SEXUALITY

Fabiana Makdissi, Isabela Rodrigues Neves, Silvana Soares dos Santos, Solange Moraes Sanches

Introduction: The sexual quality of life (QoL) of women with breast cancer (BC) during systemic therapy is one of the most disturbing aspects, not only because of the physical changes caused by the antineoplastic agents, such as fatigue, decreased libido and dyspareunia, but mainly because of the woman's intrapsychic experience of her own body, such as altered self-perception of attractiveness, body image and femininity, aspects that can further worsen the QoL of this population. Objective: To assess the impact on women's sexual QoL during neoadjuvant chemotherapy/NEOCT treatment. Methods: Prospective cohort study, carried out from July 2022 to July 2023 at A.C. Camargo Cancer Center. The study included 149 participants with non-metastatic breast cancer who underwent chemoradiation therapy; all of them signed an informed consent form approved by the local Research Ethics Committee. The assessment tool was the "Sexual Well-Being" scale, translated into Portuguese, from the BREAST_Q Portfolio (https://qportfolio.org/breast-q/). Data was collected at M0 (pre-NEOCT), M1 (halfway through the protocol) and M2 (end of NEOCT). For data analysis, we considered $p < 0.05$. Results: Of the women interviewed, 73.9% were aged between 45-59 and 68.5% were married or living with a partner. On the

question "sexually attractive when you have your clothes on", there was an increase in the "none or a few times" answers, from 13.8% to 32.9% at the end of the NEOCT; while there was a drop in the "most of the time or all of the time" answers, from 60.7% to 38.5%. A similar pattern was observed for the question "sexually attractive when you have your clothes off": an increase for the answers "none or a few times" (from 15.2% to 38.7%) and a drop for the answers "most of the time or all of the time" (from 66.9% to 44.3%). The question "satisfaction with your sex life" also followed the trend already observed: an increase for the answers "none or a few times" (from 21.5% to 50.8%) and a drop for the answers "most of the time or all of the time" (from 67.0% to 33.6%). Analysis of the median total scores on the "Sexual well-Being" scale showed p=0.000 between M0 and M1 and between M0 and M2; however, p=0.144 between M1 and M2.
Discussion and Conclusion: There was clearly a negative impact on sexual well-being throughout the course of the NEOCT, which can be explained by the side effects of the drugs: fatigue, central and peripheral neuropathy, loss of sensation, abnormal genital sensation, tingling, numbness, decreased libido, anorgasmia and vaginal dryness, as well as alopecia, edema and emesis. In addition to the physical effects, there is also anxiety, fear and stress, which can influence perception and coping with reality. However, it is interesting to note that even before chemotherapy began, 40% of women no longer felt sexually attractive. It is therefore important to analyze these aspects even before treatment begins and throughout it, so that women can be welcomed and the negative impacts on their quality of life and sexuality can be adequately reduced.

P2-05-09: Mindfulness as effective complementary therapy in the management of Breast Cancer (BC)

Maria-Eva Perez-Lopez, Iria Fernandez-Somme, Cristina Reboredo, Beatriz Alonso, Silvia Antolin, Patricia Cordeiro, Lourdes Calvo

Background: Breast cancer associates a broad variety of psychological and physical symptoms with a significant impact on quality of life. Mindfulness therapies (MBIs), such as MBSR (Mindfulness-Based Stress Reduction) and MBCT (Mindfulness-Based Cognitive Therapy) have been related with better control of this daily routine signs, achieving better emotional regulation, decreasing internal dialogue, increasing awareness of body sensations (posture, breathing...) and slowing down of mental processes. Mindfulness is a psychological technique that tries to reach a state of full consciousness. It is useful on the treatment and prevention of several diseases by different mechanisms. The brain areas linked to MBIs are: the insular cortex, related to body and emotional awareness; the hippocampus, involved in memory organization; the secondary somatosensory cortex and anterior cingulate, related to pain and the bilateral superior parietal lobe and left superior frontal gyrus, involved in attention. MBI is also related with an increase in telomeric length, increased expression of the hTERT (human telomerase reverse transcriptase) and HTR (human telomerase RNA) genes and a decrease in the level of methylation of the hTERT promoter regions (implying increased gene expression). These changes have potential

effect to delay cellular aging. There is a relationship between long-term meditation practice and a loss of methylation of CpG nucleotides and epigenetic changes in the tumor necrosis factor (TNF) and beta neurotrophic factor (NF-κß) signaling pathway.
PURPOSE:The aim of this study is to compile the effects of different mindfulness therapies on the symptoms associated with breast cancer, both in women with active disease and in survivors.
Methods: a systematic review was conducted using PubMed, PsycINFO, Cochrane library and Web of Science. Thirteen studies, published in the last seven years (between January 1st, 2017 and December 31st, 2023), were included: 10 on patients with "active disease" and 3 on "survivors".
Results: MBIs produce statistically and significant benefits in the short and medium term, on depressive symptoms, anxiety and stress. Among physical symptoms, a significant effect is seen about the reduction of fatigue with MBSR therapies. Other symptoms such as cognitive function and sleep quality also improve with these therapies. Regarding quality of life, only short-term improvements are been observed. MBCT protocols are included in few works. Its role in BC survivors is limited because the low number of researches and the lack of a homogeneous definition of "survivor".
Conclusion: Because of the benefit that mindfulness therapies (MBIs) (specially MBSR and MBCT) have on anxiety, stress, depressive symptoms, fatigue and other symptoms associated with breast cancer, it is proposed to use it as a complementary therapy in the management of these patients.

P2-05-10: Depression and anxiety in patients with breast cancer receiving radiotherapy: A prospective longitudinal study

Shi-Jia Wang, Feng Xin, Wei Zhang, Yan Liu, Hong-Xia Gao, Hao Jing, Yi-Rui Zhai, Wen-Wen Zhang, Hui Fang, Yu Tang, Yong-Wen Song, Yue-Ping Liu, Bo Chen, Shu-Nan Qi, Yuan Tang, Ning-Ning Lu, Fu-Kui Huan, Ye-Xiong Li, Shu-Lian Wang

Purpose: To evaluate the prevalence and changes in depression and anxiety symptoms from pre-radiotherapy (RT) to 6 months post-RT in patients with breast cancer receiving RT; and to identify risk factors for depression and anxiety at baseline and for an increase of depression and anxiety over time.
Methods: This prospective, longitudinal observational study was conducted in China between August 2022 and August 2023. Depression and anxiety symptoms were measured by the 9-item Patient Health Questionnaire (PHQ-9) and the 7-item Generalized Anxiety Disorder (GAD-7) before and during RT, at the end of RT, 1 month and 6 months after RT. Uni-variable and multi-variable logistic regression analyses were performed to explore risk factors for baseline depression and anxiety. Generalized estimating equations were performed to evaluate changes in depression and anxiety over time and predictors of an increase of depression and anxiety over time.
Results: A total of 504 patients completed baseline questionnaires, and 458 (90.9%) patients completed all five-time assessments. Depression and anxiety decreased

significantly over time, with the prevalence decreasing from 37.3% and 26.0% before RT to 28.4% and 20.3% at 6 months after radiotherapy. However, daily insomnia (PHQ-9 Q3) and fatigue (PHQ-9 Q4) showed high scores from pre-RT to 6 months post-RT. In terms of GAD-7, feeling nervous (Q1), worrying too much (Q3), and becoming easily annoyed (Q6) showed high scores. Patients with a family history of cancer and receiving anti-HER2 targeted therapy were independently associated with depression before RT, and patients with premenopausal status, poor family income, and menopausal symptoms were independently associated with both depression and anxiety before RT. Patients receiving anti-HER2 targeted therapy, with a monthly personal income ≤8000 Yuan, and living in rural area were associated with an increase in depression level over time, while patients with poor family income and menopausal symptoms were associated with an increase in anxiety level over time.
Conclusions: Depression and anxiety levels were high among patients with breast cancer receiving RT and decreased over time from pre-RT to 6 months post-RT. Routine psychological assessments of these patients were necessary, especially for those with targeted therapy, poor financial status, and menopausal symptoms.

P2-05-11: A prospective cohort study of real-world patient-reported outcomes in HER2-positive early breast cancer patients receiving (neo) adjuvant anti-HER2 based therapy: the preliminary results at 2-cycle treatment

Ke-Da Yu, Wen-bin Zhou, Yan-wu Zhang, Bo-jian Xie, Xiao-peng Ma, Chao-yang Xu, Jin-hua Ding, You Meng, Heng-yu Li

Background: Anti-HER2-based regimens are the mainstay of treatment for patients with HER2-positive breast cancer. While these treatments significantly improve survival, there is growing concern about the quality of life (QoL) of breast cancer survivors during therapy. Here, we reported the preliminary results of 2-cycle treatments versus baseline and aimed to identify baseline characteristics associated with deterioration of QoL after 2-cycle (neo) adjuvant therapy in patients with HER2-positive early breast cancer.
Method: This prospective, longitudinal cohort study enrolling patients with stage I-III HER2-positive breast cancer was conducted in nine cancer centers across China. Patients eligible for (neo) adjuvant anti-HER2-based therapy have been enrolled in this study, and the treating physician has made treatment decisions according to CACA-CBCS (China Anti-Cancer Association, Committee of Breast Cancer Society) guidelines. The electronic patient-reported outcomes (ePRO) were collected at baseline (T0), during chemo (T1, after two cycles of chemo), 1-month after completion of chemo (T2), and at 12-month follow-up (T3). The ePRO instruments included EORTC QLQ-C30, PDQ-5, PHQ-9, GAD-7, and ISI to evaluate the quality of life, cognition, emotion, and insomnia. Changes ≥10 points from T0 to T1 were clinically meaningful in EORTC QLQ-C30. Univariate logistic regression was performed to explore risk factors of worsening.
Results: From November 2023 to June 2024, 600 patients with HER2-positive early-stage

breast cancer were enrolled (Median age: 51 years). By June 2024, questionnaire compliance rates were 98.7% (592/600) at T0, 86.2% (458/531) at T1, and 75.9% (236/311) at T2. General health status and functional QoL were high at T0, with worsening QoL in summary score, nausea and vomiting, diarrhea, fatigue, and appetite loss domains during treatment. The summary scores at T0 and T1 were significantly different, with a worsening rate of 38.4%, while the deteriorating rate in nausea and vomiting, diarrhea, fatigue, and appetite loss domains was 54.4%, 45.4%, 53.1%, and 55.5%, respectively. The scores in the above domains at T0 and T1 were significantly different (all $P < 0.001$). Over 50 years old (OR: 2.251, 95%CI: 1.508-3.361), post-menopausal (OR: 1.848, 95%CI: 1.259-2.712), hormone receptor-positive (OR: 0.677, 95%CI: 0.464-0.988), and histological grade 3 (OR: 1.665, 95%CI: 1.107-2.504) were associated with worsening QoL. The score varied without clinical meaning in PDQ-5, PHQ-9, GAD-7, and ISI.
Conclusion: For patients with HER2-positive early breast cancer, more than one-third of patients experienced a worsening QoL, mainly due to symptoms like nausea, vomiting, appetite loss, diarrhea, and fatigue. Patients in this prospective study are still in follow-up, and the results of influences of anti-HER2 treatment after chemotherapy on QoL are immature.

P2-05-12: Experience and perceptions with a phone-based weight loss intervention among survivors of breast cancer (BC) in France: a qualitative study within a randomized clinical trial (RCT).

Antonio Di Meglio, Laurence Vanlemmens, Carine Segura-Djezzar, Carole Bouleuc, Olivier Tredan, Barbara Pistilli, Tracy E. Crane, Davide Soldato, Cécile Charles, Aude Barbier, Bruno Raynard, Anthony Mangin, Bernadette Coquet, Guillemette Jacob, Julia Bonastre, Stefan Michiels, Dan Chaltiel, Fabrice André, Jennifer A. Ligibel, Ines Vaz-Luis, Maria Alice Franzoi

Introduction: The MEDEA (NCT04303924) RCT evaluated a phone-based educational and counselling intervention for weight loss (adapted from BWEL A011401) focused on calorie restriction and behavior change among overweight and obese survivors of BC in France. Patient's acceptability and engagement with weight loss interventions can be influenced by cross-country cultural differences related to dietary, social and behavioral habits. We performed a qualitative study to explore these aspects and inform future implementation.
Methods: 220 patients with stage I-III BC within 12 months of primary treatment and BMI ≥25 kg/m2 participated in the MEDEA trial and were randomized to receive the phone-based weight loss intervention delivered by dieticians through 24 semi-structured calls over 12 months vs. a standard health educational program. 20 patients in the intervention arm participated in focus groups to explore barriers and facilitators for uptake and engagement, as well as acceptability, satisfaction, and suggestions of improvement. A thematic content analysis was performed using Nvivo 12 software.
Results: Four focus groups were conducted with patients from diverse sociodemographic and economic backgrounds. Patients had mostly positive representations. Several themes emerged:

1) Patients expressed satisfaction with the objective weight loss and improvement in symptom burden:
“I'm very satisfied with the weight loss, that's for sure.”
“My self-image improved, I find that I'm much more toned, I'm more energetic. I have less pain. I sleep better.”
2) Patients referred to the MEDEA intervention as a catalyzer to sustainable behavior change:
“It helped me a lot because it made me understand that I was eating too much of some food categories and not enough of others. It allowed me to balance my meals.”
“I didn't have motivation anymore and she really coached me, she taught me again to feel like exercise, to boost myself, to walk, and now I've become an addict, I do 2.5 hours of sport per day.”
3) Most of them stressed the convenience of remote intervention:
“It's much better over the phone because it would have been a constraint to free up time to go to in-person meetings.”
Nevertheless, patients highlighted some barriers to uptake and engagement and suggestions for improvement.
1) Need for tools to sustain engagement such as a follow-up call, psychological support and enabling/facilitating self-monitoring:
“If we had a call from the dietician six months after [the end of the intervention], it would help to keep the momentum on which we started.”
“I would have liked to have a summary of my weight loss. A small conclusion on a diagram to see the evolution.”
“I don't know if a psychologist could be included in MEDEA, but in any case it would be a good thing or that the coaches refer to psychologists.”
2) Need for culturally adapted content:
“Sometimes it was more like an American-style method, in terms of food. The menu planning, it's not very French.”
3) Patients advocated for a more patient-centered research ecosystem (e.g. selection of patient-reported outcomes measures, communication and community building):
“I think it would be interesting to have some of the results of the study.”
“I would have liked to meet the women who did the same program, to talk to them.”
“The food questionnaire is horrible to fill out! […] The last one I still haven’t filled it, because it annoys me so much that I forgot.”
Conclusions: The MEDEA intervention was deemed acceptable and positively experienced suggesting that a North American weight loss intervention was scalable and adaptable to a different language and cultural context. This qualitative analysis also informed refinements to optimize weight loss interventions in a European context.

P2-05-13: QUALITY OF SEXUAL LIFE IN YOUNG WOMEN WITH BREAST CANCER IN THE MEDICAL ONCOLOGY SERVICE AT THE HOSPITAL REGIONAL ISSSTE LEON

Carmen Guadalup Bermudez Barrientos

Introduction: Breast cancer is a main public health problem nationally and worldwide. In addition to the increase in prevalence due to the effectiveness of current treatments, young women patients present multiple adverse effects to them, one of them most common are the sexual problems, severe, and persisten. Quality of life and well-being are influenced by different factors such as physical, social, and spiritual. Immediately after the diagnosis of cancer, sexuality becomes less important. Sexual dysfunction is common among women with breast cancer (occurs in 25 - 66% of cases).
Objective: Analyze the quality of sexual life of premenopausal women with diagnostic of breast cancer at the medical oncology service.
Methodology: Cross-sectional, observational, analytical, and descriptive study in patients diagnosed with breast cancer in clinical stage I, II, III or IV with an age ≤ 50 years at diagnosis and with active surveillance and/or treatment, in the medical oncology service at the ISSSTE Regional Hospital León, Gto. Two questionnaires were applied: EORTC SHQ-22 and EORTC QLQ-BR23, both containing questions related to quality of sexual life.
Results: From a total of 210 patients enrolled, a simple linear regression analysis was performed on the variables and scores, which predicted in the QLQ-BR23 questionnaire a higher level of symptomatology due to side effects of systemic therapy after having received chemotherapy (B=10 .15, 95% CI 0.40-19.91, p = 0.04) and living with their partner (B=8.41, 95% CI 2.31-14.50, p = 0.007), perception of Lower BR23 body image after having undergone a radical mastectomy (B=-11.81, 95% CI: -22.79 - -0.84, p = 0.04) and living with their partner (B=-11 .05, 95% CI -19.29 - -2.82, p=0.009), lower future perspective when living with your partner (B=-10.72, 95% CI -20.42 - -1.01, p = 0.031). The correlation of high QLQ-BR23 body image perception score significantly predicted a lower SHQ-22 vaginal dryness score (B=-0.35, 95% CI: -0.60 - -0.10, p=0.006). In the SHQ-22 questionnaire, there were greater problems in sexual activity after having undergone oophorectomy (B=-19.27, 95% CI 1.76-36.78, p=0.03), and fewer problems in sexual activity when living with their partner (95% CI -22.01--1.57, p=0.027) and treatment with adjuvant capecitabine predicted less decreased libido (B=-30.56, 95% CI: -52.16 to -8 .95, p = 0.006).
Discussion: 50% of all patients with BC experience problems with body image, which negatively affects personal relationships and sexual functioning. In our study, having undergone a radical mastectomy and living with their partner makes them feel less attractive, less feminine, it has been difficult to see themselves with their body and they have felt dissatisfied with their body. This correlates with the fact that the impact of surgery is greater when the surgery is radical and when a woman has had less involvement in treatment decisions. Women's body image limits their daily lives and psychological distress reminds them of their illness. BC survivors experience a significant decrease in quality of sexual life compared to survivors of other cancers. Age, time since diagnosis, marital status, educational level, chemotherapy, anti-hormonal therapy, type of breast surgery and body

image are all associated with the quality of sexual life of BC. This It has been previously demonstrated in different studies worldwide and is now demonstrated in this study in Mexican women, so it is imperative to acquire skills to refer to the relevant specialties, as well as have an established route and perform specific interventions for the comprehensive treatment of these patients. This project is still a taboo topic but interest in oncosexuality is growing and the need for specific treatment is increasing but with still insufficient access to specific care.
Conclusion: Premenopausal women with breast cancer present a decrease in their quality of sexual life during cytotoxic treatment and after surgical treatment, which affects their life as a couple.

P2-05-15: Challenges and Communication Gaps in Adjuvant Endocrine Therapy for HR+ Breast Cancer Patients in Russia: Insights from an online Survey

Anastasia Danilova, Daniil Stroykovsky, Irina Nigmatullina, Angelina Osheichik, Laura Malishava

Background: Adjuvant endocrine therapy is crucial in managing hormone receptor-positive breast cancer, significantly reducing recurrence and improving survival. Despite its benefits, adherence to endocrine therapy is often challenged by side effects, including psychological and sexual dysfunction. These issues are rarely discussed during doctor visits in Russia. Understanding patient perspectives on these issues and their communication with healthcare providers is vital for enhancing adherence and patient support.
Materials and Methods: An anonymous online survey was conducted using Google Forms to investigate adherence to adjuvant endocrine therapy, patient-reported side effects, and communication with healthcare providers among breast cancer patients. The survey, distributed via patient advocate groups and online forums, received 920 responses. The survey included questions on adherence, side effects, comfort in discussing side effects with healthcare providers, and whether necessary counseling was received. Data were analyzed to identify key trends and raise questions for further investigation.
Results: Participants: 920 women with breast cancer participated in the survey.HR+ Breast Cancer: 919 (99%) had HR+ breast cancer and were prescribed endocrine therapy.Therapy Context: 777 (84.5%) received adjuvant endocrine therapy, and 143 (15.5%) for metastatic breast cancer.Non-Starters: 40 (4.25%) did not start endocrine therapy.
Reasons for not starting:Concerned with side effects: 35%Unfavorable harm/benefit ratio: 27.5%Concern about potential secondary tumors: 30%Discomfort with taking pills: 2.5%Concerned with the cost: 5%Median Age: 48 years, with participants from various parts of Russia.Disease Stage:

Never discussed adverse events: 23.9%Attempted discussion: 31.3%Discussed: 44.8%Comfortable discussing issues: 35.1%Felt physician underscored side effects: 40.4%Felt doctor was rushed: 21.3%Management Suggestions:
No suggestion: 65.8%Lifestyle modification (diet and exercise): 35.8%Referral to other physicians: 23.6%Prescribed medications: 16.4%Offered to switch endocrine drug: 4.7%Therapy Discontinuation: 23% reported stopping endocrine therapy earlier than planned with the healthcare team.ConclusionsThe survey reveals significant challenges in adherence to adjuvant endocrine therapy among breast cancer patients in Russia, primarily due to side effects and insufficient communication with healthcare providers. A substantial number of patients do not discuss adverse effects with their physicians, and many feel their concerns are not adequately addressed. Improved patient-physician communication and better management strategies for side effects are essential to enhance adherence and support for patients undergoing endocrine therapy. Further studies are needed to develop interventions that can mitigate these issues and improve patient outcomes.

P2-05-16: Interrogating serum thymidine kinase activity with CDK4/6 inhibitor-based therapies: real-world experience in the metastatic and adjuvant setting

Agnieszka Witkiewicz, Emily Schultz, Erik S. Knudsen, Ellis Levine

Background: CDK4/6 inhibitors have become widely deployed in the treatment of HR+/HER2- breast cancer. In the metastatic setting, a number of different CDK4/6 inhibitors are approved in combination with endocrine therapy and lead to a general doubling of progression-free survival (PFS). The CDK4/6 inhibitor abemaciclib is also employed in the adjuvant setting in the treatment of HR+/HER2- tumors at high risk for recurrence. The duration of response to these treatments is variable between individual patients supporting the use of biomarkers to predict time to progression/recurrence. Here, we investigated the DiviTum® TKa assay relative to response to CDK4/6 inhibitor-based therapies using plasma samples from the prospective observational Roswell Park Ciclib Study (NCT04526587) of patients receiving CDK4/6 inhibitor-based therapy as standard of care.
Methods: The TKa assay was employed longitudinally on 69 metastatic and 20 high risk patients that were enrolled in the Roswell Park Ciclib Study. Samples collected at baseline, on treatment, and post-progression were analyzed using the DiviTum® TKa assay (Biovica). The TKa levels >50 DuA (DiviTum unit of Activity) were evaluated as a continuous variable

in association with different features of disease in either the metastatic or high-risk setting.
Results: The TKa levels in the baseline samples were inversely associated with the duration of PFS in the metastatic setting (R=-0.684, p=0.005). Furthermore, when comparing evaluable TKa levels in baseline samples to on treatment Cycles 1 and 2, there was a significant reduction in TKa levels (158.3 DuA vs. 47.6DuA, p=0.038) for patients that experienced a durable response to therapy ≥20 months. However, in patients with shorter duration of response to therapy ≤8 months, the average on treatment Cycles 1 and 2 TKa levels were (243.1DuA). Post progression TKa levels were considerably elevated across the cohort (925.3 DuA). Longitudinal analyses of individual cases illustrated dynamic features of TKa with treatment and emergence of resistance. In the adjuvant setting, there was significant reduction in TKa from baseline to Cycles 1 and 2 (87.8 DuA to 27.55 DuA, p=6.49e-11). While relatively few patients have recurred to date, elevated TKa levels were observed with disease progression.
Conclusions: These findings further support the utilization of the DiviTum® TKa assay to monitor response to CDK4/6 inhibitor-based therapy in the standard of care setting. Baseline and the TKa reduction early on treatment could be predictive of duration of PFS. Further study in the high-risk setting is warranted to predict associations with recurrence.

P2-05-17: The predictive and prognostic value of 18F-FES PET/CT in patients with advanced breast cancer treated with endocrine therapy with cyclin-dependent kinase 4/6 inhibitor

Hyehyun Jeong, Jeongryul Ryu, Sangwon Han, Jaewon Hyung, Sae Byul Lee, Tae-Kyung Robyn Yoo, Jisun Kim, Hee Jeong Kim, Il Yong Chung, Beom Seok Ko, Jong Won Lee, Byung Ho Son, Jin-Hee Ahn, Kyung Hae Jung, Sung-Bae Kim, Dae Hyuk Moon

Introduction: Estrogen receptor (ER) expression and its heterogeneity affect endocrine therapy efficacy. Tumor biopsy is a standard method for determining ER status but has limitations in analyzing ER heterogeneity. 18F-fluoroestradiol (18F-FES) PET/CT is an effective, non-invasive method to analyze systematic ER expression. This study aimed to analyze the predictive and prognostic value of 18F-FES PET/CT in patients treated with endocrine therapy with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors.
Methods: Patients included in this study were identified from a prospective 18F-FES PET/CT cohort, comprising patients who underwent 18F-FES-PET/CT between April 2021 and April 2023 at Asan Medical Center. For the current study, patients with ER-positive, HER2-negative advanced breast cancer who received palliative endocrine therapy with CDK4/6 inhibitors and had pretreatment 18F-FES PET/CT were included.
Results: A total of 127 females were included. The median age was 57 years (range, 28-86). Endocrine therapy comprised aromatase inhibitors in 75.6% (N = 96) and fulvestrant in 24.4% (N = 31). A total of 25 (19.7%) presented “with FES-negative” lesions, of which 22 were mixed with FES-positive lesions, and 3 were entirely negative. The remaining 75.6% (N = 96) had “FES-positive” lesions only. 18F-FES status (FES-positive vs. with FES-negative) correlated with progression-free survival (PFS) to endocrine therapy with

CDK4/6 inhibitors, as well as overall survival (For with FES-negative, hazard ratio [HR] for PFS, 3.9 [95% confidence interval (CI), 2.1-7.2], p<0.001; HR for OS, 3.7 [95% CI, 1.3–10.2], p=0.008). 18F-FES status was predictive for PFS both in weak ER-positive and strong ER-positive tumors in biopsy specimens, showing the least benefit of endocrine therapy in ER weak-positive and with FES-negative lesions. 18F-FES status was consistently predictive for PFS across subgroups, including age, menopausal status, clinically determined endocrine sensitivity, and choice of endocrine therapy.
Conclusion: ER status assessed by 18F-FES PET/CT predicts the efficacy of CDK4/6i-based endocrine therapy and is prognostic for survival in advanced ER-positive, HER2-negative breast cancer. Integrating 18F-FES PET/CT with clinical variables, particularly tumor biopsy, may help further predict the benefit of endocrine therapy.

P2-05-18: Molecular effects of short pre-operative endocrine therapy in hormone receptor-positive and HER2-negative early breast cancer

Raquel Gómez-Bravo, Barbara Adamo, Benjamin Walbaum, Esther Sanfeliu, Blanca González-Farré, Francesco Schettini, Olga Martínez-Sáez, Elia Seguí, Isabel García-Fructuoso, Paula Blasco, Oleguer Castillo, Ángela Aguirre, Valeria Sirenko, Pol Giménez, María Rey, Jordi Canes, Patricia Galván, Tomás Pascual, Maria Vidal, Adela Rodriguez Hernandez, Eva Ciruelos, Meritxell Bellet, Aleix Prat, Montserrat Muñoz, Fara Brasó-Maristany

Background: The identification of biomarkers for evaluating sensitivity to endocrine therapy in early breast cancer (EBC) is critical. Assessing the dynamic biological changes in the tumor caused by brief pre-operative endocrine therapy (POET) can guide decisions on reducing or intensifying treatment. In this study, we examined the molecular changes induced by short-term POET and their correlation with the treatment's effectiveness.
Methods:This is a retrospective study of paired samples from patients (pts) with hormone receptor-positive and HER2-negative (HR+/HER2-) EBC treated at Hospital Clinic of Barcelona between 2014 and 2023 and from the letrozole arm of SOLTI-1501 VENTANA trial (Adamo et al. BCR 2019; NCT02802748). All pts received POET for 2 to 12 weeks prior to surgery, with tamoxifen or aromatase inhibitors (AI), administered according to menopausal status. RNA expression was assessed in baseline and surgery samples, including PAM50 and HER2DX signatures. Treatment response was defined as a value of Ki67≤10% at surgery. Logistic regression models explored the association between baseline gene expression and response. Gene expression changes were analyzed using paired SAM analysis and t-tests.
Results: A total 111 pts with both baseline and surgery samples available were included. Median age was 63 years-old (61.8-66.4) and most of the tumors were cT1 (68.5%) and cN0 (97.3%) at diagnosis. 19 pts (17.1%) were premenopausal and 92 (82.9%) postmenopausal. The median baseline Ki67 was 18% (14-25%). After POET, the median Ki67 value was 4% (1-10). 81 pts (73%) reached Ki67≤10% at surgery and 41 (37%) Ki67≤ 2.7% (complete cell cycle arrest). At baseline, PAM50 molecular subtype distribution was: 79 pts (71.2%) Luminal A, 23 (20.7%) Luminal B, 4 (3.6%) HER2-enriched, 3 (2.7%) Normal-like, 2 (1.8%)

Basal-like. At surgery, there were 82 (73.9%) Luminal A, 23 (20.7%) Normal-like, and 6 (5.4%) Basal-like tumors. In the univariate analysis, baseline clinicopathological variables associated with response were age (odds ratio [OR]=1.04, p=0.028), percentage of estrogen receptor (OR=1.03, p=0.025), Ki67 value (OR=0.95, p=0.003) and type of endocrine therapy (tamoxifen vs AI, OR=0.17, p<0.001). In terms of baseline gene expression, high Luminal A signature (OR=7.72, p<0.001) and luminal-related genes (e.g.: FOXA1 [OR=1.46, p=0.021] or ESR1 [OR=1.38, p=0.001]) were associated with response, while high Basal-like (OR=0.19, p=0.009), PAM50 proliferation (OR=0.30, p=0.005) and HER2DX proliferation (OR=0.24, p=0.037) signatures and proliferation-related genes (e.g.: MYBL2 [OR=0.58, p<0.003] or MKI67 [OR=0.71, p=0.004]) were associated with no response. After POET, all genes and signatures were up- or downregulated significantly. In particular, we observed a significant decrease of the PAM50 Luminal and proliferation signatures, as well as the HER2DX proliferation and luminal signatures, with an increase of the HER2DX immune (IGG) and HER2 amplicon signatures, both in responders and non-responders (FDR<5%).
Conclusion: POET is a simple and secure treatment that can be administrated before surgery in HR+/HER2- EBC. The molecular profiling and dynamic evaluation of biological changes induced by POET could offer opportunities for a better understanding of the tumor´s sensitivity to endocrine therapy and could help guide and optimize treatment strategies in HR+/HER2- EBC.

P2-05-19: An ICG-labeled Novel Trop2 Targeting Peptide for In Vivo and Ex Vivo NIR-II Fluorescence Imaging-guided Breast Cancer Precise Surgery

Kangliang Lou, Jingwen Bai, Linling Lin, Yiyang Gao, Chengxi Li, Yifei Pei, Shengjie Lin, Yixin Chen, Guojun Zhang

Purpose: Positive surgical margins are closely associated with local recurrence in breast-conserving surgery. Meanwhile, accurately assessing sentinel lymph node (LN) metastasis can determine the scope of axillary LNs dissection and minimize unnecessary LN removal. Indocyanine green (ICG)-based near-infrared (NIR) fluorescence imaging provides real-time visualization for surgeons with the potential to reduce the positive margins rates and improve the detection rate of SLN, particularly imaging in the second near-infrared (NIR-II) region with enhanced contrast and deeper tissue penetration. Additionally, owing to the overexpression of Trop2 in breast cancer and the exceptional effectiveness of anti-Trop2 antibody-drug conjugates in breast cancer therapy, Trop2 has emerged as a promising tumor target. In this study, we screened a cyclopeptide (TTP) with a high affinity to Trop2, labeled with ICG, to enable more efficient intraoperative navigation under NIR-II fluorescence imaging.
Methods: TTP was screened via phage display technology, and ICG-NHS was labeled by NHS reaction to create a novel NIR-II probe called TTP-ICG. Its tumor-targeting efficiency were validated in vitro and in vivo. Subsequently, various mice models were utilized to evaluate the efficacy of in vivo NIR-II imaging-guided surgery. Finally, the ex vivo tumors and metastatic LNs were incubated with TTP-ICG to assess the validity of ex vivo NIR-II imaging-

guided surgery.
Results: With a high affinity of Trop2 (KD = 9.829 × 10-10 M), TTP was successfully screened and labeled with ICG-NHS, whose cellular uptake was 2.88-fold higher than control peptide (CP)-ICG in the MDA-MB-231-Luc-Trop2 cells with high Trop2 expression ($p < 0.0001$). Meanwhile, MDA-MB-231-Luc-Trop2 cells showed 6.33-fold higher mean fluorescence intensity (MFI) compared to MDA-MB-231-Luc-NC with rare Trop2-expression ($p < 0.0001$), which could be effectively blocked by free TTP (3.75 ± 0.06 vs 1.75 ± 0.03, $p < 0.0001$). Interestingly, when incubating the mixed cells MDA-MB-231-Luc-GFP (with rare Trop2 expression) and MDA-MB-231-Luc-Trop2 with TTP-ICG probes, cells with stronger ICG fluorescence showed minimal GFP fluorescence.
Then, in MDA-MB-231-Luc-Trop2 subcutaneous tumor models, the TTP-ICG group exhibited a 2.2-fold higher maximum signal-to-background ratio (SBR) compared to the CP-ICG group ($p < 0.0001$). Additionally, TTP-ICG showed a 2.3-fold higher aggregation in MDA-MB-231-Luc-Trop2 tumors than the MDA-MB-231-Luc-NC tumors ($p < 0.001$). Furthermore, NIR-II fluorescence guidance allowed for precise identification of microtumors (with a minimum diameter of less than 2 mm) in the multiple microtumors model with an accuracy rate of 100%. Moreover, it also effectively differentiated malignant and normal tissue with an AUC of 0.932 in the MMTV-PyVT transgenic model. Notably, this approach also facilitated complete tumor resection and improved overall survival compared to conventional white light surgery in intramuscular tumor-invasion models.
Subsequently, after footpad injection of different probes in dual 4T1-Luc-Trop2 SLN metastasis models, the TTP-ICG group showed significantly higher MFI than CP-ICG group (6266.3 ± 1866.7 vs 2260.0 ± 966.5, $p < 0.01$). Besides, a higher MFI was observed in metastasis LN than normal LN after footpad injection of TTP-ICG (6257.5 ± 569.6 vs 2979.3 ± 806.3, $p < 0.001$).
In addition, via co-incubation of TTP-ICG, the 4T1-Luc-Trop2 tumor exhibited a higher MFI relative to 4T1-Luc-NC and muscle with an AUC of 0.917 ($p < 0.0001$). Meanwhile, when co-incubating breast malignant and benign tumor from patients with TTP-ICG, malignant tumor also showed higher MFI (3.2 ± 0.7 vs 1.2 ± 0.3, $p < 0.05$). Finally, the MFI of metastatic LNs was 2.62-fold higher than that of normal LNs after TTP-ICG incubation ($p < 0.01$).
Conclusion: In this study, we successfully developed a novel TTP-ICG probe with efficient Trop2-targeting and excellent bio-compatibility. This probe demonstrates great potential for clinical translation as an effective tool for NIR-II fluorescence-guided breast surgery, which is expected to improve surgical outcomes and patient recovery.

P2-05-20: Tissue-free minimal residual disease testing in 2,000 consecutive patients with breast cancer: real-world data and case report

Tanmayi Pai, Sonam Sonam, Miglena K. Komforti, D.O., Vishal Patel, Derek Dustin, Xiaotong Zuo, Courtney Lewis, Saranya Chumsri

Background: Studies have shown the prognostic impact of circulating tumor DNA (ctDNA) detection following curative-intent therapy in early-stage solid tumors, with detection often

preceding radiologic recurrence. Guardant Reveal™ is a tissue-free assay that interrogates epigenomics to detect minimal residual disease (MRD) with ctDNA and measure tumor fraction (TF). We report the clinical use of the assay in a large, unselected breast cancer (BC) cohort and describe its incorporation into a patient (pt)'s care.

Methods: 2,000 consecutive pts in the United States with stage I-III BC and at least one Guardant Reveal™ test ordered beginning July 9, 2023, were retrospectively queried and assessed through the data cutoff of May 31, 2024. Demographics and clinical variables were obtained from test requisition forms. Fisher's exact test was used for statistical differences. Pt consent was obtained for the case report.

Results: The median age of the 2,000-pt cohort was 61 (range: 26-100); 99.4% were female. 50.3% of pts had > 1 test, representing 3,488 samples. 99.9% passed quality control (QC); the mean turnaround time (TAT) was 10 days.

At the first test, 68% had stage I/II BC, and 32% had stage III BC. BC subtype was available for 97.4% of tested pts, with most being hormone receptor-positive (HR+)/HER2- (58%), followed by triple-negative (TNBC) (19.1%), HR+/HER2+ (14.7%), and HR-/HER2+ (8.2%). Pts with stage III, TNBC, and HR-/HER2+ disease were more likely to have multiple vs. single tests ($p < 0.01$).

Overall, ctDNA was detected in 326 pts (16.3%) and varied by stage. For stage I/II and III pts, the detection rate was 13.5% and 21.8%, respectively. The ctDNA detection rate at any timepoint by subtype was 19.4% in TNBC, 16.5% in HR+/HER2-, 14.9% in HR+/HER2+, and 13.9% in HR-/HER2+ BC. The median TF when ctDNA was detected was 0.12%, with 2.5% having >10% TF.

Case Report: A 42-year-old pt presented with early-stage HR-/ HER2+ BC. Four years after the initial diagnosis, she developed recurrent seizure-like activity and was found to have an isolated brain metastasis without systemic disease. The brain lesion responded well to Gamma Knife. She remained with no evidence of disease on tucatinib, trastuzumab, and capecitabine for over 19 months but developed severe hand-foot syndrome.

In an attempt to de-escalate her treatment, the Guardant Reveal™ test was used for disease monitoring as the patient did not have adequate tumor tissue for sequencing with a tumor-informed MRD assay. As the pt was clinically stable and ctDNA was not detected for the first two blood draws, her capecitabine dose was reduced further. ctDNA was then detected a year later, prompting earlier restaging scans that showed increased enhancement at the treated brain lesion site but no overt progression. Radiologic progression became evident 3 months later. The enlarging brain metastasis was resected, with pathology confirming disease recurrence. The pt's capecitabine dose was increased, and letrozole was added as her resected brain metastasis showed positive progesterone receptor expression. She has had no radiologic evidence of disease progression or ctDNA detection since resection.

Conclusions: This study describes real-world use and results of a tissue-free monitoring test in early-stage BC. The high QC pass rate (99.9%) and rapid 10-day TAT support the feasibility of a tissue-free assay for MRD detection. Results suggest a potential provider preference for monitoring for patients with stage III BC, TNBC, and HR-/HER2+ BC. The pt case shows the potential utility of tissue-free MRD testing in brain-only oligometastatic disease, where radiation necrosis can be hard to discern from true radiologic progression and biopsy can be risky. Further study is needed to explore how pt characteristics influence the use of MRD testing as assays and data continue to evolve.

P2-05-21: BRCA1/2 alterations in circulating tumor DNA: correlation with germline origin and impact on survival in breast cancer.

Letizia Pontolillo, Carolina Reduzzi, Andrew A. Davis, Arielle J. Medford, Emily Podany, Lorenzo Gerratana, Annika Putur,, Surbhi Warrior, Caterina Gianni, Eleonora Nicolò, Katherine Clifton, Whitney L. Hensing, Marko Velimirovic, Laura Munoz-Arcos, Mara S. Serafini, Elisabetta Molteni, Marla Lipsyc-Sharf, Jeannine Donahue, Neelima Vidula, Nadia Bayou, Charles S. Dai, Jennifer C. Keenan, Amir Behdad, William J. Gradishar, Emilio Bria, Cynthia X. Ma, Diana Giannarelli, Aditya Bardia, Massimo Cristofanilli

Background: Circulating tumor (ct) DNA testing is a standard of care approach to evaluate patients (pts) with advanced or metastatic breast cancer (BC) for the detection of resistant and actionable somatic (s) alterations. ctDNA testing could identify incidental germline (g) mutations. While the prognostic and predictive role of known gBRCA1/2 mutation is well established, the significance of sBRCA1/2 alterations is still debated. We aimed to establish a variant allele frequency (VAF) threshold to distinguish germline from somatic mutations and to explore the impact of BRCA1/2 alterations detected by ctDNA on survival outcomes.
Methods: A retrospective multi-institutional cohort of pts with BC and at least one BRCA1/2 mutation detected by standard clinical ctDNA next-generation sequencing (Guardant 360®) for metastatic disease was included in the analysis. The incidence of BRCA1/2 mutation detected by ctDNA and germline testing was analyzed to assess VAF threshold to predict the likelihood of detecting germline mutations. Receiving operating characteristic (ROC) curves were generated to determine the VAF cut-off; differences in survival were tested using the log-rank test.
Results: 294 pts were included in the analysis. BRCA1 and BRCA2 mutations were detected in 104 (35.4%) and 166 (56.5%) pts respectively, while 24 (8.2%) had a co-mutation in BRCA1 and BRCA2 genes. The median age at diagnosis was 50 years (interquartile range [IQR] 44-62), and family history of cancer was known for 45.9% of pts. The most represented subtype was hormone receptor positive/HER2 negative (HR+/HER2-) (70.4%), followed by triple negative (TN) (15.7%) and HER2 positive (13.9%). At the time of the first BRCA1/2 detection in ctDNA, bone (67.1%) and visceral (56.2%) sites were mainly involved. The mean VAF was 10.0% (standard deviation [SD] 19.7%, range 0.02%-84.3%) for BRCA1 and 12.1% (SD 20.1%, range 0.06%-80.3%) for BRCA2 alterations. The most co-

mutated genes were TP53 (58.1%), PIK3CA (35.8%), EGFR (25.1%), ESR1 (23.7%), and ERBB2 (17.2%). The germline testing was available for 157 (53.4%) pts, detecting a gBRCA1 mutation in 16 (10.2%) pts and a gBRCA2 mutation in 37 (23.6%) pts. Comparing the ctDNA and germline testing, 13/16 pts had concordant BRCA1 mutation. In 3 discordant cases, only BRCA2 alteration with different VAF (0.30-80.1%) was detected by ctDNA. All pts with gBRCA2 mutations (37) also had a BRCA2 mutation in ctDNA. An optimal VAF cut-off of 38.4% (AUC 0.99) for BRCA1 and 16.1% (AUC 0.96) for BRCA2 was established as the threshold for the likelihood of a germline mutation detected by ctDNA analysis. For 18 pts with TNBC and 91 pts with HR+/HER2- BC, the detection of BRCA1/2 mutations was at the ctDNA baseline test, before starting a new treatment, with a median of 2 (range 0-9) previous lines of therapy. The median progression-free survival (mPFS) was 7.3 months (mos) (CI 3.9-10.7) for TNBC pts and 8.4 mos (CI 4.5-12.3) for HR+/HER2- pts; no significant survival differences were observed between BRCA1 and BRCA2 mutations. The 2-year overall survival (OS) rate was 69% and 78% in the TN and HR+/HER2- subgroups. Exploring the outcome according to therapy in the HR+/HER2- subgroup, no significant differences were assessed between chemotherapy, CDK4/6 inhibitors plus endocrine therapy, or PARP inhibitors, although a longer mPFS for the latter was observed (4.5 vs. 8.9 vs. 14 mos).
Conclusions: The VAF cut-off identified for the likelihood of a germinal mutation detected by ctDNA resulted lower than expected, underlining the importance of a larger germline BC screening, with considerable impact on therapeutic decision making and germline testing of other family members. Further analysis to explore the interplay of different co-mutations with BRCA1/2 will be performed and validation in additional dataset is needed.

P2-05-22: Plasma proteomic profiling of early recurrence of breast cancer

Anupama Praveen Kumar, Praveen-Kumar Raj-Kumar, Jianfang Liu, Brenda Deyarmin, Brad Mostoller, Caroline Larson, Heather Blackburn, Danette Teeter, Mariano Russo, Leigh Fantacone-Campbell, Jeffrey A Hooke, Craig D. Shriver, Hai Hu, Albert J Kovatich, Xiaoying Lin

Background: Almost 30% of the breast cancer patients who are free of disease after initial treatments may experience disease recurrence later on. Early detection of cancer recurrence during follow-up care improves patient survival. Even though blood-based tests are non-invasive and often considered the most accessible method for monitoring cancer, the dynamic nature of the circulatory system poses a challenge to identifying potential protein targets. In this study, we utilized a highly specific aptamer-based assay, to perform comparative plasma protein profiling of breast cancer patients with known clinical outcome (early recurrence [disease relapse within 5 years after surgery] vs non-recurrence).
Methods: The subjects were enrolled and specimens were collected through the Clinical Breast Care Project using IRB-approved protocols. We analyzed heparinized plasma samples taken at the time of diagnosis from patients who subsequently relapsed within five years after primary tumor diagnosis (n = 65, ipsilateral recurrence/distant metastasis) and those with no relapse reported (n = 65, minimum follow-up: 5 years). Both groups were

matched primarily on race, age, tumor stage, and IHC subtype. The association between sample groups and other clinical features was assessed using Fisher's exact test and logistic regression. SomaScan (7k) assay (SomaLogic, Inc.) was used to measure 6289 unique proteins from the plasma samples. Differential expression analysis of proteins was performed using limma, followed by LASSO regression to identify the top proteins associated with recurrence. Leave-one-out cross-validation (LOOCV) was used for further validation of the identified protein markers. The GSEAPreranked tool was used for gene set enrichment analysis.
Results: There were no significant differences in the distribution of race, age, tumor stage, or IHC subtype between the early recurrence and non-recurrence groups, indicating a balanced cohort. Principal component analysis of protein expression also did not reveal any distinct clusters based on these features, unlike tissue-based studies. Differential expression analysis between the two groups revealed 19 proteins to be significantly differentially expressed (p-value < 0.05, |fold change| > 1.2), with 7 upregulated and 12 downregulated. Some of these proteins like MSMB and OXT are previously-reported plasma protein biomarkers for breast cancer. LOOCV based prediction models, using the 19 proteins' expression, performed moderately (Accuracy = 0.72, Kappa = 0.45). Gene set enrichment analysis revealed key pathways differentially enriched between the two groups, including those related to immune response, embryonic stem cell differentiation, and cancer.
Conclusions: Our study indicated that protein expression in plasma is different compared to that in tumor tissue. We identified 19 proteins that could be potential biomarkers for early recurrence detection. Additional studies need to be performed on a larger sample size to validate these findings.

P2-05-23: Inhibition of de novo fatty acid synthesis demonstrates broad synergistic effects with anti-cancer therapy, alters cellular lipid composition and induces endoplasmic reticulum stress

Naing Lin Shan, Hao-Kuen Lin, Jiawei Dai, Sheila Umlauf, Yulia Surovtseva, Lajos Pusztai

Background: Metabolic rewiring is a characteristic feature of cancers. Our previous study showed metabolic isoenzyme Acetyle-CoA-carboxylase-1 (ACC1/ACACA) is overexpressed in cancer relative to normal tissues. Targeting ACC1 with small molecule inhibitor of ACC1 and ACC2, PF05175157, inhibited breast cancer cell growth and affects metabolic processes including cell membrane structural glycerophospholipids metabolism that are required for cellular membrane synthesis. Unfolded protein response (UPR) restores endoplasmic reticulum (ER) homeostasis and extreme ER stress can induce pro-apoptotic cell death. We hypothesized that PF05175157 displays synergy with anti-cancer agents, induces changes

in the lipid composition of biological membranes and perturb cellular homeostasis leading to ER stress and cell death.
Methods: High-throughput screening was performed using Approved Oncology Drugs Set X (AOD X) available from Developmental Therapeutics Program at National Cancer Institute. The plate set contains 166 FDA-approved anticancer agents (https://wiki.nci.nih.gov/display/NCIDTPdata/Compound+Sets). The compounds were diluted to the final concentrations of 0.05 mM, 0.1 mM, 1 mM and 10 mM using Beckman Biomek NXp. Cell lines tested include BT-20, BT-474, BT-549, HCC1395, HCC1500, MCF7, MDA-MB-231, MDA-MB-468, T47D and ZR-75-1. Hierarchical clustering was performed and heatmap was generated using the aheatmap function from NMF package. Mass spectrometry-based lipid analysis was performed by Lipotype GmbH (Dresden, Germany) and analyzed on a QExactive mass spectrometer (Thermo Scientific) equipped with a TriVersa NanoMate ion source (Advion Biosciences). Data were analyzed with lipid identification software based on LipidXplorer. For western blot analysis, ER Homeostasis Antibody Sampler Kit primary antibodies were purchased from Cell Signaling (#53898) and used at 1:1,000 dilution. Cell viability was assessed using CellTiter-Glo luminescent cell viability assay (Progmega).
Results: To identify active drug combinations enhancing the anticancer effect of PF-05175157, we performed a combinatorial high throughput screen with PF-05175157 (10 μg/ml) and 166 FDA-approved anticancer drugs for 72 hours. We observed broad synergy across different compounds, more prominently noticeable among tyrosine kinase inhibitors across different cell types. The top 10 chemotherapy agents with broad synergy with PF-05175157 across multiple breast cancer cell lines based on inhibit delta encompass lapatinib, vinorelbine tartrate, pazopanib hydrochloride, tamoxifen citrate, sunitinib, avapritinib, alectinib, enasidenib, gefitinib and nilotinib. To investigate the potential mechanism of PF05175157 affecting subfamily members of glycerophospholipids, MDA-MB-468 cells were treated with PF05175157 (10 μg/ml) for 24 and 72 hours. Lipid profiling revealed a decrease in phosphatidylglycerol, phosphatidylserine, phosphatidylinositol, and phosphatidylcholine levels treated with PF05175157 for 24 hours. PF05175157 also decreased the level of sphingomyelin, the most abundant sphingolipids in the plasma membrane. The levels of these fatty acids remained low at 72-hour treatment. Levels of long chain unsaturated fatty acids, triacylglycerols and cholesterol ester are increased after 72 hours treatment. UPR signaling is controlled by ER transmembrane-associated sensor proteins – IRE1α, PERK and ATF6.Treatment of MDA-MB-468 cells with PF-05175157 (10 μg/ml) for 6, 24 and 72 hours upregulated the protein levels of downstream signal transduction pathways of ER stress sensors: p-IRE1α, XBP-1S, p-EIF2 α, ATF4 and ATF6. Treating multiple breast cancer cell lines including MDA-MB-468, BT-20 and BT-474 with PF-05175157 (10 μg/ml) for 72 hours significantly inhibited cell viability.
Conclusion: PF05175157 treatment showed broad synergy with various anti-cancer therapies, alters cellular lipid composition and induces endoplasmic reticulum stress and cell death.

P2-05-24: Impact of the gut microbiome on immune-related adverse events (irAE) in HR+/HER2- locally advanced or metastatic breast cancer (MBC) patients (pts) receiving palbociclib, endocrine therapy, and pembrolizumab

Alexis LeVee, Keehoon Lee, Colt Egelston, Susan Yost, Nora Ruel, Paul Frankel, Christopher Ruel, Daniel Schmolze, Peter Lee, Christina Yeon, Yuan Yuan, James Waisman, Sumanta Pal, Joanne Mortimer

Background: Based on preclinical data demonstrating a synergistic effect of combining immune checkpoint inhibitors (ICIs) with CDK4/6 inhibitors, we conducted a phase I/II study of palbociclib, endocrine therapy, and pembrolizumab in patients (pts) with HR+/HER2- MBC. We previously reported that the gut microbiome can predict clinical response to this ICI combination. Emerging evidence also suggests that the gut microbiome is closely linked to the development of immune-related adverse events (irAE), and that the onset of irAE may be associated with improved ICI response. Here, we explore the role of the gut microbiome on the onset of severe irAE in this cohort of pts with HR+/HER2- MBC treated with palbociclib, endocrine therapy, and pembrolizumab.
Methods: Pts with stage IV HR+/HER2- MBC were enrolled and treated with palbociclib, endocrine therapy, and pembrolizumab. Baseline stool samples were collected at Day -28 to C1D1 (N=28 pts). Next on-treatment sample was used if baseline unavailable. Gut microbiota composition was assessed using deep metagenomic sequencing. Taxonomic profiling was conducted using MetaPhlAn4. Functional profiling was performed using HUMAnN3. Correlative studies assessed the association between the gut microbiome and severe (grade >3) irAE.
Results: Between March 2017 and May 2022, 40 pts (39 female/1 male) were accrued, with a median age of 51 (range 39-75). With a median follow-up of 35.8 months (mos) (95% CI: 26.1, 63.5), the median progression-free survival (PFS) was 27.8 mos (95% CI: 11.2, NR). The incidence of severe irAE was 11/40 (27.5%). There was no difference in PFS between pts with and without severe irAE (P=0.6). The median PFS was 27.8 mos (95% CI: 6.7, NR) and 27.1 mos (95% CI: 8.7, NR) in pts with and without severe irAE, respectively. ANCOM-BC (Analysis of compositions of microbiomes with bias correction) identified Dialister invisus (log fold change [LFC] 2.45 [P=0.02]), Blautia caecimuris (LFC 2.43 [P=0.01]), Flavonifractor plautii (LFC 2.40 [P=.01]), and Eisenbergiella massiliensis (LFC 2.12 [P=0.001]) in greater abundance in pts without severe irAE, while Coprococcus eutactus (LFC -3.94 [P=0.0009]) was in greater abundance in pts with severe irAE. Beta diversity using Bray-Curtis analysis showed significant differences in gut microbiome composition between irAE groups (P=0.04). Although alpha diversity using the Shannon diversity analysis showed no differences across irAE groups (P=0.3), Shannon diversity analysis showed significant differences in functional genetic pathways between irAE groups (P=0.03). ANCOM-BC identified several distinguishing metabolic pathways between irAE groups, including the CMP-pseudoaminate biosynthesis pathway which was enriched in pts without severe irAE (LFC 2.37 [P=0.0002]).

Conclusions: Certain gut bacteria can predict the development of severe irAE in a cohort of pts with HR+/HER- MBC treated with palbociclib, endocrine therapy, and pembrolizumab. Several metabolic pathways were enriched between irAE groups, which suggests differences in immune activation that can lead to the onset of irAE. This study suggests that the gut microbiome can serve as a risk factor and biomarker of severe irAE in breast cancer pts, which warrants further evaluation.

P2-05-25: Comparative Study of Droplet-digital PCR and Ultra-sensitive NGS Assay for ctDNA Profiling in Breast Cancer

Binggang Xiang, Amy Wang, Yong Huang, Shidong Jia, Pan Du

Background: The variant allele frequencies (VAF) of oncogenic mutations often correlate with drug response or resistance following treatments of tumors. However, the sensitivity of molecular diagnostic assays are limited by technological factors. For example, the lower report range of NGS-based assays for tissue FFPE and plasma samples are usually above 1% and 0.1%, respectively. In recent publications, our assays have been used to demonstrate that a more complete view of cancer development and drug resistance can be achieved if variants with VAF below the current resolution can be detected. In this study, we demonstrated the use of both PredicineCARE Ultra™ and ddPCR (droplet digital PCR) to push detection limit further lower down to 0.01%.
Methods: The NGS-based PredicineCARE Ultra™ assay sequences targeted regions with 100,000X coverage, identifying mutations in over 150 genes. ddPCR methods test specified mutation sites faster (same day) and at a lower cost. We applied both methods to multiple solid tumor studies, collecting whole blood samples from patients at baseline and follow-up time points. Cell-free DNA was extracted and tested with the PredicineCARE Ultra™ assay, analyzing over 150 genes with up to 100,000X read coverage to detect variants with VAF down to 0.01%. Tumor fraction estimation based on longitudinal samples provided higher detection sensitivity by tracing multiple mutations together. ddPCR achieved single molecule detection sensitivity, dependent on the input amount, with a limit of detection down to 0.01% for 100ng of input cfDNA.
Results: In this study, 216 plasma samples from 98 solid tumor (including 58 breast cancer) subjects were analyzed. Some samples also had baseline tissue samples sequenced separately for cross-reference. The PredicineCARE Ultra™ assay achieved 0.01% VAF sensitivity, providing significant insights into longitudinal tumor dynamics. For PIK3CA mutations, mutation frequencies were 23% (50/209) at the sample level and 28% (27/95) at the subject level at a 0.1% VAF threshold. With a VAF down to 0.01%, the frequencies increased to 29% (60/209) at the sample level and 34% (32/95) at the subject level. This allowed more detailed analysis of VAF changes in PIK3CA and other genes like ESR1, KRAS, and TP53. The ultra-sensitive assay detected 31.3% more mutations and 30.1% more CNVs compared against PredicineCARE ctDNA assays with 20,000x coverage in 46 patients. Hotspot variants were further validated using ddPCR, with over 95% concordance.
Conclusion: Using the high sensitivity of the ultra-deep cfDNA assay and the low-cost ddPCR

assay, the fraction of variants detectable in blood-based monitoring significantly increased, aiding therapy monitoring. Unlike personalized MRD assays, the PredicineCARE Ultra™ assay is tumor-agnostic and can detect novel mutations, crucial for drug resistance studies. The assay's longitudinal tumor fraction estimation offers higher sensitivity by tracing multiple mutations. While ddPCR is less efficient in exploring numerous mutations simultaneously, it provides a fast turnaround for pre-designed hotspots, complementing the PredicineCARE Ultra™ assay. Together, these methods enhance the detection of low VAF variants that are otherwise undetectable.

P2-05-26: Differential TROP2 expression patterns among inflamed tumor microenvironments in HER2-negative breast cancer

Mai Onishi, Tatsunori Shimoi, Shu Yazaki, Yuki Kojima, Taro Yamanaka, Rui Kitadai, Mai Hoshino, Munehiro Ito, Ayumi Saito, Shosuke Kita, Asuka Kawachi, Hitomi Sumiyoshi-Okuma, Aiko Maejima, Kazuki Sudo, Emi Noguchi, Yasuhiro Fujiwara, Masayuki Yoshida, Kan Yonemori

Introduction: The combination therapy of immune check point inhibitor (ICI) and antibody-drug conjugates (ADC) targeting trophoblast cell surface antigen 2 (TROP2) have recently been progressed. This study aims to evaluate the association between the status of the inflamed tumor microenvironment, as indicated by programmed death-ligand 1 (PD-L1) expression and tumor-infiltrating lymphocytes (TILs), and TROP2 expression in HER2-negative breast cancer.
Methods: We collected 227 archival paired samples of primary tumors and metastatic sites from 105 breast cancer patients treated at our hospital from 2000 to 2018. Surgical specimens and samples from one or more recurrent sites were required for inclusion. TROP2 was stained using Anti-Human TROP-2 (Clone77220) for IHC assays and results were categorized based on the histochemical score (H-score). PD-L1 expression was evaluated using the VENTANA SP142 assay. PD-L1 positive was defined as ≥1% of tumor-infiltrating immune cells staining positive for PD-L1. The following categories were used: IC1 (PD-L1 positivity in ≥1% and <5% of cells), IC2 (PD-L1 positivity in ≥5% and <10% of cells), and IC3 (PD-L1 positivity in ≥10% of cells).Stromal TILs were assessed according to international guidelines and scored using semi-continuous (10% increment) methods and TIL-high was defined as ≧30%.
Results: Among the samples, 140 were Estrogen receptor (ER)-positive and 87 wereER-negative (triple-negative, TN). Samples from primary sites(P) accounted for 49% and those from metastatic sites(M) accounted for 51%. The median TROP2 H-score was 10, with a mean of 37.5 (range: 0-265). PD-L1 positive was observed in 15% of samples and 13% were TIL-high.
TROP2 expression was higher in metastatic site (median TROP2 H-score: 2[range 2-200]in P, 30 [range 30-265] in M, $p<0.001$). However, there was no significant difference in PD-L1 positivity and TIL-high status between primary and metastatic sites (PD-L1 positive :19% in P, 11% in M, $p=0.138$; TIL-high:16% in P, 12% in M, $p=0.337$). There were no significant

difference in TROP2 expression between PD-L1 positive and negative samples or between TIL-high and TIL-low samples (median TROP2 H-score were 55[range:10-265] in PD-L1 negative and 44 [range 15-215] in PD-L1 positive, p=0.852; 54.25[range 10-265] in TIL-low and 53.5 [range 25-215, p=0.69]). However, among TN samples, TROP2 expression was higher in PD-L1 positive and TIL-high samples (median TROP2 H-score was 59[range:5-248] in PD-L1 negative and 80 [range 36-155] in PD-L1 positive, p=0.04; 59[range 10-248] in TIL-low and 88 [range 50-175, p=0.0153])
Conclusions: This study showed in TN, TROP2 expression is notably higher in PD-L1 positive and TIL-high samples, and no significant correlation was found between TROP2 expression and inflammatory markers in the overall HER2-negative breast cancer. It provides the insight of the combination therapy of ICI and ADC targeting TROP2 in TN. Further research is warranted to explore these associations and develop personalized treatment approaches.

P2-05-27: Revealing prognostic subtypes and related model of early-stage TNBC

Haixing Shen, Qing Chen, Jing Zhang, Shuqian Wang, Jing Zhao, Changbin Zhu, Xiaotian Zhang, Xing Li, Tianze Yu, Jinfei Ma, Yanyuan Li, Peifen Fu

Background: Triple-negative breast cancer (TNBC) is the most malignant subtype of breast cancer. Effective approach stratifying the risk of recurrence for early-stage TNBC patients is still lacking. This study aims to explore the molecular heterogeneity of early-stage TNBC yielding a practical tool evaluating the risk of disease recurrence.

Methods: This retrospective study included stage I-III TNBC patients treated at our institution between December 2013 and December 2019. RNA sequencing was performed on surgical samples, and correlations were analyzed with clinical data and prognosis.

Results: A total of 240 patients were included, with a median follow-up of over 5 years. Patients were categorized into two cohorts: recurrence-free within 3 years post-surgery (good prognosis, n=203) and recurrence within 3 years (bad prognosis, n=34). Differential gene analysis revealed 423 up-regulated and 1,818 down-regulated genes in patients with good prognosis. Consensus cluster analysis identified three clusters (C1, C2, C3). C1 had the worst prognosis for DFS (p=0.020) and OS (p=0.055). Further analysis of the three groups' characteristics showed that C1 patients exhibited significant upregulation of angiogenesis, hypoxia, and glycolysis signals. Differential gene analysis indicated that NOX1, HNF1A, CXCL8, TGFBI, and NT5E (CD73) were significantly upregulated in C1 patients. This suggests that tumors in these patients might create a hypoxic microenvironment through NOX1 upregulation, promoting glycolysis and adenosine metabolism, which in turn stimulates ATP and lactate release, angiogenesis, and immune evasion, creating a tumor growth-promoting microenvironment. Given the notably shorter DFS in this group, therapies targeting angiogenesis or CD73 may improve clinical outcome of C1 patients. C2

patients showed enrichment of canonical oncogenic pathways like WNT, NOTCH signaling. C3 patients displayed pro-inflammatory tumor microenvironment with elevated IFN-γ signatures. Additionally, potential infiltration of activated dendritic cells, activated CD8+ T cells, CD4+ T cells, and plasma cell signature (IGHV1OR15-2, IGKV1D-43, IGHV2-26) were observed in the C3 group. This deconvoluted estimation of TME indicated the presence of matured tertiary lymphoid structures (TLS) in the C3 group. Eight subtype and prognosis related genes (ABCD2, ACSM3, ADCYAP1, ADM, CXCL13, GLO1, PIGR, RRP8) were selected. A prognostic prediction model was constructed, categorizing patients into high-risk and low-risk groups. In the training set (n=166), high-risk patients had significantly lower OS than low-risk patients (P<0.0001), with an AUC of 0.874 for predicting 3-year recurrence. The validation set (n=71) showed an AUC of 0.844, with high-risk patients having significantly lower OS (P<0.0001). External validation with the GSE103191 dataset showed an AUC of 0.761 for predicting 3-year survival.
Conclusions: This study disclosed novel molecular subtypes with prognostic and therapeutic significance. A subtype-derived prognostic model was also constructed and validated to stratify recurrence risk for early-stage TNBC patients. Further validation via multi-center study was warranted.

P2-05-28: High throughput analysis in HER2 positive locally advanced breast cancer (BC): pathological complete response (pCR) and mutational status.

Ida Paris, Minucci Angelo, Giaco' Luciano, Generali Daniele, Nanni Simona, D'Angelo Tatiana, Pavese Francesco, Fabi Alessandra, De Bonis Maria, Cannita Katia, Piermattei Alessia, Fuso Paola, Ricozzi Valentina, Carbognin Luisa, Rotondaro Silvia, Nero Camilla, Giacomini Flavia, Pasciuto Tina, Marrazzo Maria, Mulè Antonino, Masetti Riccardo, Franceschini Gianluca, Garganese Giorgia, Rossi Alessandro, Giannarelli Diana, Scambia Giovanni

Background: Pathologic complete response (pCR) after neoadjuvant treatment (NAD) is a strong prognostic biomarker associated with improved survival in breast cancer patients, especially those with HER2-positive BC and Triple negative subtypes. PIK3CA is mutated in up to 20% of HER2 positive BC patients, contributes to anti-HER-2 resistance and may be predictive of the lack of response to anti HER2 NAD. PIK3CA mutations in breast cancer occur primarily at hotspots E545K at exon 9 and H1047R at exon 20. Next generation sequencing has improved our knowledge regarding the biology of the mechanisms behind treatment resistance. The aim of this study is to evaluate the genomic landscape of tissue samples obtained from locally advanced breast cancer patients treated in a neoadjuvant setting, to correlate the genomic analysis to response and clinical outcome.
Methods: DNA extracted from archival 84 formalin-fixed paraffin-embedded (FFPE) samples obtained by core needle biopsies was subjected to deep sequencing using the TruSight Oncology (TSO) 500 panel (Illumina, San Diego, USA; 523 genes, size: 1.94 Mb), following the manufacturer's protocol, which assesses microsatellite instability (MSI) status, tumor mutation burden (TMB), recurrent somatic copy number variations (sCNV),

somatic sequence variants as single nucleotide variants (SNVs) and Insertion/Deletion (InDel). Libraries were sequenced on a NovaSeq 6000 instrument (Illumina) to reach a minimum of 500× read depth. All samples were evaluated for RNA single cell transcriptional profile. 72 of 84 patients were treated with traditional neoadjuvant chemotherapy plus trastuzumab meanwhile 12 of 84 received neoadjuvant chemotherapy plus trastuzumab and pertuzumab. Statistical analysis was performed to detect the genes whose mutation involved in the progression and / or non-response of the disease using the Statistical Package for Social Science (SPSS), release 23.0. Continuous variables were expressed as median [range], categorical variables were displayed as frequencies and the X2-test or Fisher's exact test were used to assess significance of the differences between subgroups (patients with or without pCR). Molecular and histopathological data were uploaded to local instance of cBioPortal to provide a comprehensive overview of the molecular data in association with clinical data. Actionability of the mutations was annotated with OncoKB and the ESMO Scale for Clinical Actionability of Molecular Targets (ESCAT). ClinVar significance were used to assess the germline pathogenic variants in BC susceptibility genes.

Results: In total we analyzed samples from 82 of 84 patients, for 2 samples it was not possible to carry out reliable genomic analysis due to not adequate tissue material. The median age was 48 years. 20 of 82 (24%) were HER2 enriched, 62 of 82 (76%) were triple positive, 66 (80.5%) with G3 and 29 (35.3%) with stage III. 46 of 82 patients (56%) obtained pCR.

The most common frequently altered genes were TP53 (55/82, 67%) PIK3CA (25/82, 31%), GATA3 (21/82, 26%), CCND1 (17/82, 21%) cMYC (14/82, 17%), and BRCA1 (7/82, 7%). In tab. 1 is reported main clinical characteristics of patients and genomic alterations detected through the use of the cBioPortal.

73 out of 82 samples showed an HER2 amplification, one patient harbored an HER2 mutation. 10% of samples (8/82) were not HER2 amplified with discrepancy between immunohistochemistry (IHC) and genomics (Fig.1). Among patients with a mutated PI3KCA (31%), 32% (8/25) obtained a pCR versus 67% (17/25) who did not; PIK3CA wild type patients (57/82, 69.5%) obtained pCR in 58% of cases (33/57) compared to 24 of 57 patient (42%) did not (p=0.03). It is interesting to note the position of the mutations in the PIK3CA and p53 gene sequence based on pCR versus not pCR: the lollipop plots in Fig. 2 demonstrate how missense and truncating mutations are frequent in mutated patients with not pCR compared to patients with pCR after neoadjuvant chemotherapy.

Conclusions: In this preliminary report, genetic drivers such as PIK3CA and p53 may have a clinical implication for prognosis and treatment response after NAD in locally advanced HER2 positive breast cancer. PIK3CA and p53 altered patients have a lower pCR rate than not altered patients. More samples are needed to evaluate the significance of both single mutation and co-alteration in this patient setting. We are waiting for the results of the RNA single cell transcriptional profile of these samples. Event free survival data is not yet mature at this moment. We would like to acknowledge the contribution of Multispecialistic Biobank Research Core Facilty G-STeP, Fondazione Policlinico Universitario "A. Gemelli" IRCCS (Biobank-FPG) who provided the bioresources.

P2-05-29: Orally bioavailable cyclin A/B-RxL inhibitors elicit antitumor activity in breast cancer patient-derived xenograft models

Cristina Molina-Gutiérrez, Andreu Òdena, Li-Fen Liu, Bernard Levin, Mariana Paes Dias, Marta Guzmán, Olga Rodríguez, David J. Earp, Michael C. Cox, Evelyn W. Wang, Violeta Serra

Background: Complexes of cyclins and cyclin-dependent kinases (Cdk) regulate the activity of Rb and E2F to drive cell cycle progression. The association of some substrates and regulators of Cyclin/Cdk complexes is mediated by the interaction of their RxL motif with the highly conserved hydrophobic patch (HP) on the cyclins. Disruption of this interaction was previously shown to selectively drive lethality in cancer cells containing oncogenic alterations that drive high levels of E2F1 (Chen1999, Mendoza 2003), suggesting an opportunity for a targeted therapeutic approach. CID-078 is a novel, orally bioavailable, passively cell permeable, potent, and selective macrocycle that binds to the HP of cyclins A and B, preventing the RxL-motif mediated binding of both E2F1 with Cyclin A2-Cdk2 and Myt1 with Cyclin B1-Cdk1. This activity of CID-078 causes cell cycle arrest at G2M resulting in apoptotic tumor cell death. We have previously shown that CID-078 causes inhibition of cell cycle progression in multiple cancer cell lines. CID-078 is further associated with in vivo tumor regression in small cell lung cancer. We have previously shown in lung tumor models that phosphorylation of separase (ESPL1), a mitosis specific protein which is a direct substrate of Cyclin B1-Cdk1, at serine 1126 increases upon treatment with CID-078. Here, we explore the pharmacodynamic effect of CID-078 and show its anti-tumor activity in eight patient-derived xenograft (PDX) models from patients with triple negative breast cancer (TNBC), estrogen receptor-low (ERlow/HER2-) or ER+/HER2- breast cancer.
Methods: The models were chosen based on varying expression of E2F1, ESPL1, as well as hallmark pathway scores of E2F targets and G2M checkpoint. PDXs were treated with either vehicle or active therapy, including standard of care (cisplatin for TNBC and ERlow, and cisplatin alone or palbociclib in combination with the oral SERD elacestrant for ER+/HER2- models) or oral formulation of CID-078 at 100 mg/kg QD, BID or TID for at least 28 days. Tumor volume and body weight were measured biweekly. Biomarker analyses were conducted with or without treatment with CID-078 by mRNA and IHC for cyclin A2-Cdk2 and cyclin B1-Cdk1 and other targets including E2F1, pATM, cleaved caspase 3, cyclin B1 and phospho-separase.
Results: Treatment with CID-078 resulted in substantial tumor regression in 3/4 TNBC and ERlow models as a single agent, and in 1/4 ER+/HER2- models (either as a single agent or combined with elacestrant). All PDX models with higher E2F1 and ESPL1 expression levels (3/7) responded to CID-078 and all models with lower E2F1 expression (2/7) did not respond. The median E2F1 and ESPL1 expression trends higher in responders compared to non-responders. Oral treatment with CID-078 was well tolerated with no significant body weight changes. Pharmacodynamic evaluation of additional biomarkers including Cyclin B1 and phospho-separase by IHC and RNAseq is underway.
Conclusions: CID-078 exhibits potent anti-tumor activity in the TNBC, ERlow and ER+ preclinical models tested, consistent with the proposed mechanism of action and correlating well with E2F1 and ESPL1 expression. Given these compelling results, CID-078

may be a new treatment option for TNBC, ERlow/HER2-, or ER+/HER2- breast cancer. This hypothesis and the correlation of anti-cancer activity with biomarkers will be explored in the CID-078 first-in-human clinical trial CID-AB1-24001.

P2-05-30: Ki-67 dynamics during neoadjuvant treatment of breast cancer and their added prognostic value to the Neo-Bioscore model: a population-based cohort study

Maria Angeliki Toli, Louise Eriksson Bergman, Xingrong Liu, Caroline Boman, Christian Tranchell, Jonas Bergh, Alexios Matikas, Theodoros Foukakis

Introduction: Ki-67 is a commonly used proliferation marker in breast cancer. Although strongly prognostic, its role following neoadjuvant chemotherapy (NACT) is still evolving. We here investigate the prognostic implications of the changes in Ki-67 pre- and post-NACT, and the value of adding Ki-67 to the Neo-Bioscore prognostic model.
Methods: Patients with invasive breast cancer treated with NACT in the Stockholm-Gotland region between 2007 and 2020, were identified through the National Breast Cancer Register (n=2533). The register data were complemented with information from the electronic patient records. Individuals who only received neoadjuvant endocrine therapy and patients with stage IV or unknown disease were excluded (n=39). The efficacy endpoints of the study were defined in accordance with the NeoSTEEP definitions. Relative change (RC) of Ki-67 was defined in 4 subgroups: decreased (High-Low) if RC < -30%, unchanged (Low-Low) if -30% ≤ RC ≤ 30% and pre-NACT Ki-67 < 40%, unchanged (High-High) if -30% ≤ RC ≤ 30% and pre-NACT Ki-67 ≥ 40% and increased (Low-High) if RC > 30%. Multivariable analysis included covariates; adjuvant chemotherapy use, age at diagnosis, clinical tumor size and node status at diagnosis, Estrogen Receptor-status, Progesteron Receptor-status, HER2-status, grade, diagnosis year. The addition of Ki-67 to Neo-Bioscore staging system was examined by fitting Cox regression models. The improvement in fit was determined using the concordance index (C-index), the Akaike information criterion (AIC), and likelihood ratio test in the multivariable analysis.
Results: A total of 2494 patients were included. The median pre-NACT Ki-67 expression was 40% in the total population. Patients with higher pre-NACT Ki-67 had higher pathologic complete response (pCR) rates in ER+/HER2- (n=1091, 5.3% vs 21.4%, p<0.0001), TNBC (n=543, 26.2% vs 37.3%, p=0.0168) and HER2+ (n=820, 41.5% vs 54.0%, p=0.0013) subtype, when categorized by a Ki-67 threshold of 50%. Pre-NACT Ki-67 was prognostic for breast cancer specific survival (BCSS) (p=0.022). The median post-NACT Ki-67 expression in patients with residual disease (RD) was 12%. Post-NACT Ki-67 was associated with BCSS (p<0.0001), which was also observed for ER+/HER2-(p=0.0001) and TNBC (p=0.0007), but not for HER2+ (p=0.8223) subtype. Among patients with RD, those who had decreased (High-Low, 65.2%) or unchanged (Low-Low, 9.7%) RC had improved 5-year BCSS (p<0.0001) compared to those with increased (Low-High, 8.1%) or unchanged (High-High, 17.0%) RC. This trend was statistically significant in ER+/HER2- (p<0.0001), and TNBC (p<0.0001), but not in HER2+ (p=0.13) subtype. Neo-Bioscore was associated with BCSS

and identified distinct prognostic groups in all patients with well-defined Neo-Bioscore (n=1730, p<0.0001) and across subtypes. The prognostic performance of Neo-Bioscore improved with the addition of post-NACT Ki-67, increasing the C-index from 0.751 to 0.797 and reducing the AIC value from 1807.59 to 1781.59. The likelihood ratio tests were significant for all models with p<0.001 for both ER+/HER2- and TNBC, and p=0.029 for HER2+ subtype. Exploratory cut-off points for post-NACT Ki-67, based on median values, were explored to improve Neo-Bioscore and were found to be 10%, 12% and 55% for ER+/HER2- (p=0.00033), HER2+ (p=0.046) and TNBC (p<0.0001) subtype, respectively. Conclusion: In this large population-based cohort study our data indicates that the prognostic value of Neo-Bioscore can be further enhanced with the addition of post-NACT Ki-67. Ki-67 should be considered in clinical trials exploring post-neoadjuvant treatment strategies.

P2-06-01: CBP/P300 bromodomain inhibition reduces neutrophil accumulation and activates antitumor immunity in TNBC

Xueying Yuan, Xiaoxin Hao, Hilda Chan, Na Zhao, Diego Pedroza, Fengshuo Liu, Le Kang, Alex Smith, Sebastian Calderon, Nadia Lieu, Michael Soth, Philip Jones, Xiang Zhang, Jeffrey Rosen

Tumor-associated neutrophils (TANs) have been shown to promote immunosuppression and tumor progression, and a high TAN frequency predicts poor prognosis in triple-negative breast cancer (TNBC). Dysregulation of CREB binding protein (CBP)/P300 function has been observed with multiple cancer types. The bromodomain (BRD) of CBP/P300 has been shown to regulate its activity. In this study, we found that IACS-70654, a novel and selective CBP/P300 BRD inhibitor, reduced TANs and inhibited the growth of neutrophil-enriched TNBC models. In the bone marrow, CBP/P300 BRD inhibition reduced the tumor-driven abnormal differentiation and proliferation of neutrophil progenitors. Inhibition of CBP/P300 BRD also stimulated the immune response by inducing an IFN response and MHCI expression in tumor cells and increasing tumor-infiltrated cytotoxic T cells. Moreover, IACS-70654 improved the response of a neutrophil-enriched TNBC model to docetaxel and immune checkpoint blockade. This provides a rationale for combining a CBP/P300 BRD inhibitor with standard-of-care therapies in future clinical trials for neutrophil-enriched TNBC.

P2-06-02: Identification of Antigenic Determinants in SV-BR-1 derived Cellular Breast Cancer Vaccines

Miguel Lopez-Lago, Pravin Kesarwani, Timothy Kountz, Charles L. Wiseman, William W. Kwok, William V. Williams

Background: Identifying antigenic determinants is crucial for developing effective cancer vaccines. This study focuses on SV-BR-1 derived cellular breast cancer vaccines, aiming to delineate specific antigens that elicit an immune response. These vaccines rely on two key

concepts: tumor cells display immunogenic antigens activating T-cells via cross-presentation, and genetic engineering enhances their role as antigen-presenting cells, amplifying immune responses. Bria-IMT, the first version, is a genetically modified tumor cell line engineered to secrete granulocyte-macrophage colony-stimulating factor (GM-CSF). This vaccine has shown encouraging clinical outcomes, demonstrating its potential in cancer immunotherapy. Bria-OTS+, an advanced version, enhances tumor cells' ability to present antigens by expressing cytokines, co-stimulatory factors, and HLA alleles.
Methods: MHC-associated Peptide Profiling of Bria-IMT: Cell pellets were lysed, centrifuged, and clarified lysates were used for immunoprecipitation of MHC class I and II molecules. Peptides were eluted, analyzed by LC-MS/MS with a 2-hour gradient, and raw files processed using PEAKS software for peptide identification, including PTM and mutation analysis. Using class-specific peptide length, abundance, and -10logP values, we shortlisted ~130 peptides (class I, and class II) for further evaluation of antigen-specific responses. Class I and II antigen/epitope mapping: CD154-expressing T cells (Class II) and CD137-expressing T cells (Class I) were enriched using magnetic beads and flow sorted with activation and memory markers. The sorted T cells were expanded as oligoclones in 96-well plates with feeder cells, PHA, and IL-2. They were then stimulated with peptide pools, and positive responses were restimulated with individual peptides to identify the specific antigenic peptide.
Results: In our study, MHC class I analysis identified 6,932 peptides at a 1% PSM FDR using forward/decoy database searching, including Post-Translational Modified (PTM) and mutated peptides. Peptide length distribution showed a predominant length centered around specific motifs. In MHC class II analysis, 5,197 peptides were detected under similar conditions, with motif analysis highlighting two distinct motifs and a portion of peptides remaining unclustered. We conducted Class I and II antigen/epitope mapping to test a subset of candidate peptides post-vaccination in one individual, No CD4+ T cell epitopes were identified, but a specific Class I peptide was recognized as a CD8+ T cell epitope. These preliminary results suggest a specific CD8+ T cell response, warranting further investigation.
Conclusions: This study identified a wide array of antigenic determinants in SV-BR-1 derived cellular breast cancer vaccines using MHC-associated peptide profiling and antigen/epitope mapping. The analysis revealed diverse peptides, including PTM and mutated variants, in MHC class I and II molecules. These findings highlight the potential of vaccines like Bria-IMT and Bria-OTS+ to elicit strong immune responses by presenting a broad range of tumor-specific antigens, paving the way for improved personalized cancer immunotherapy strategies.

P2-06-03: Age Conditions the Tumor Microenvironment of Hormone Receptor Positive Breast Cancer

Mackenzie Hawes, Megan C. Benz, Sophie R. Dietrich, Jack D. North, Bruce A. Bunnell, Bridgette M. Collins-Burow, Van T. Hoang, Elizabeth C. Martin, Matthew E. Burow

Hormone receptor positive (HR+) breast cancer is the predominant molecular subtype in postmenopausal women. Although menopause decreases the concentration of estrogen in the body, HR+ breast tumors are sustained by local production of estrogens in the surrounding adipose tissue. The aged breast is characterized by an expansion of white adipose tissue, a phenomenon with unknown implications for breast cancer progression and treatment. Current clinical trials focused on HR+ breast cancer treatment fail to accurately represent aged women, with the average age of enrollment 7.76 years younger than the average age at diagnosis. It is important to understand how age-related changes to this environment impact disease progression, as breast adipose tissue both surrounds and bidirectionally communicates with cancer cells. Considering that age is not accurately represented in clinical trials, there remains a critical need for clinically relevant models of aged HR+ tumors and breast adipose in vitro. This project set out to characterize how age-based differences in the microenvironment alter HR+ tumor growth and disease progression, using a combination of in vivo analyses of age and in vitro conditioned media studies. Our results show that tumors from aged mice have a higher growth rate and overall total tumor volume at endpoint compared to young counterparts, indicating age as a driver in vivo tumorigenesis. In vitro proteomic analysis demonstrated that HR+ cancer cells exposed to conditioned media from aged breast adipose derived stem cells (brASC) have elevated expression of markers associated with adhesion, EMT, and angiogenesis at the mRNA and protein levels. Cytokine arrays of aged tumors show decreased expression of CXCL12/SDF1 and increased expression of SERPINE1, supporting possible changes in adhesion, EMT, and extracellular matrix with age. These findings suggest that age-educated components of the tumor microenvironment alter signaling within the tumor and promote tumorigenesis.

P2-06-04: Potential Impact of the Cancer-Associated Fibroblast Secretome in the Tumor Microenvironment

Anjali Agrawal, Elaine Stur, Emine Bayraktar, Sara Corvigno, Kirill Pevzner, Gali Arad, Yibo Dai, Sisy Chen, Robiya Joseph, Nitzan Simchi, Eran Seger, Cristina Ivan, Anil Sood

Background: Proteins secreted by cancer-associated fibroblasts (CAFs) can influence inflammation and recruit external immune cells to the tumor microenvironment. However, the cross[1]talk between CAFs and immune cells in the tumor microenvironment is not well understood. Therefore, in this study, we determined the association of proteins secreted by the CAF secretome with immune cell infiltration in patients diagnosed with breast cancer (BC) and ovarian cancer (OC).
Methods: The Human Protein Atlas was explored to identify potential gene targets associated with the CAFs secretome, including inhibin subunit beta A (INHBA), Dickkopf-related protein 3 (DKK3), and follistatin (FST). BC and OC patient data sets (n=14 samples) in the Gene Expression Omnibus were analyzed as discovery cohorts to compare CAFs and normal fibroblasts. Kaplan-Meier Plotter, Gene Expression Profiling Interactive Analysis, and Tumor Immune Estimation Resource bioinformatics databases were explored to

computationally understand relationships between gene expression, tumor prognosis, and immune infiltration. Single cell analysis datasets and opal multiple staining were used to validate the contribution of CAFs to overexpression of the gene targets in BC and OC cancer patients. Proteogenomic BC and OC data sets (n=46) from Clinical Proteomic Tumor Analysis Consortium were used for validation of the correlation between marker expression and immune cell infiltration.
Results: Increased expression of INHBA, DKK3, and FST correlated with shortened survival of patients with BC and OC. All three genes were negatively associated with multiple tumor-infiltrating immune cell types, both in RNA and protein levels. INHBA expression was positively correlated with the expression of T cell exhaustion markers. Pathway analysis demonstrates that INHBA's role in immune infiltration may be a result of its association with the Smad2 signaling pathway, which promotes the transition of fibroblasts to activated CAFs via an inflammatory response. In BC and OC, the three genes were generally positively correlated with immune cells characterized as "protumor", such as macrophages, CAFs, and neutrophils and negatively correlated with those considered as "antitumor," such as B cells.
Conclusion: INHBA, DKK3, and FST are candidate therapeutic targets for the treatment of breast, ovarian, and other cancers. Their therapeutic effect should be evaluated in the context of regulating infiltration and inflammation of the tumor microenvironment.

P2-06-05: Use of breast adipose-derived stromal cells in a 3D spheroid model to recapitulate the triple-negative breast cancer tumor microenvironment

Nicole Cullen, Khudeja Salim, Megan C. Benz, Jovanny Zabaleta, Bruce A. Bunnell, Van T. Hoang, Matthew E. Burow, Elizabeth C. Martin, Bridgette M. Collins-Burow

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer characterized by the absence of hormone receptors and human epidermal growth factor receptor 2. This subtype is difficult to treat due to lack of known protein targets, is often refractory to chemotherapy, and has a high rate of recurrence. Stromal components, like collagens in the extracellular matrix (ECM) in the TNBC tumor microenvironment (TME) can contribute to treatment resistance by altering the immune microenvironment. Identifying the drivers of immunosuppressive ECM will yield novel predictive biomarkers in TNBC and guide effective treatment options.
In the TME, different stromal cells secrete different proteins and breast adipose-derived stromal cells (BrASCs) produce different collagens than differentiated breast adipocytes. Thus adipogenesis in the TNBC TME can alter the ECM significantly. Furthermore, adipogenesis in TNBC is associated with increased pro-tumorigenic M2 macrophages. To determine the interplay between TNBC and components of the TME on immune recruitment, we performed spatial profiling of primary patient TNBC tumors with a specific focus on the transcriptome of tumor regions with macrophage infiltration compared to tumor regions without macrophage infiltration. Results demonstrated that in M2 macrophage infiltrated areas of TNBC tumor, expression of FN1 and COL5A1 was decreased

in both the tumor and the stromal compartments. In contrast regions without macrophage infiltration had enriched FN1 and COL5A1. To determine if TME stroma composition modulated the collagen type and thus macrophage phenotype, we next developed a 3D tumor spheroid model using either BrASCs or BrASCs differentiated to an adipocyte lineage.
Model analysis revealed a phenotypic change in differentiated and non-differentiated 3D BrASC spheroids. Post induction of differentiation with supplemented media, spheroids were measured for circularity, referenced to a perfect circle value of 1; induced spheroids retained compact circularity ~0.8, while non-induced controls were eccentric and irregularly shaped ~0.5. Spheroids in both conditions were viable on day 7, as assessed by staining with calcein AM and ethidium homodimer-1. Next spheroids were evaluated for adipogenesis and collagen production. Once validated, this model will be used as a platform to understand the impact TNBC ECM on immune regulation.

P2-06-06: The Role of iNOS Inhibition in Enhancing Chemotherapy Efficacy by Modulating the Tumor Microenvironment in Obese TNBC Models

Ivonne Uzair, Jenying Deng, Sean Hynes, Karina Ortega-Martinez, Kai Sun, Wei Qian, Jianying Zhou, Polina Matre, Jenny C Chang

Background: This study investigates the impact of obesity on the treatment outcomes of triple-negative breast cancer (TNBC), focusing on the modulation of the tumor microenvironment (TME) through inducible nitric oxide synthase (iNOS) inhibition. Obesity fosters an adverse TME characterized by immune suppression, metabolic alterations, and pro-tumoral cytokine release. Elevated nitric oxide (NO) levels associated with obesity can undermine vascular integrity and promote metastasis. We explore whether combining standard chemotherapy (docetaxel) with iNOS inhibitor L-NMMA can enhance antitumor efficacy in an obese mouse model of TNBC.
Methods: An orthotopic TNBC syngeneic mouse model was developed using C57BL/6 mice fed either with a normal diet (ND) or a high-fat diet (HFD) for 11 weeks before injecting the E0771 murine cancer cell line into the mammary fat pad. Once tumors reached 100 mm^3, mice were randomized into vehicle and L-NMMA treatment groups. Formalin-fixed, paraffin-embedded (FFPE) tumor tissue sections from ND, HFD, and HFD+LNMMA treated mice were analyzed for immune cell phenotypes and TME markers using a panel of 64 proteins by Digital spatial transcriptomics using NanoString™ GeoMx and nCounter platforms.
Results: Mice on a HFD exhibited significantly increased tumor growth compared to those on ND. Serum analysis revealed higher levels of pro-inflammatory cytokines (TNF-α, IL-6, IL-17) and the granulocyte-recruiting chemokine G-CSF in HFD mice, along with a downregulation of T-cell recruiting chemokines like Eotaxin and RANTES, suggesting a shift towards a pro-tumoral inflammatory state. Immunohistochemistry (IHC) analysis showed that HFD tumors had higher iNOS expression and increased markers for cytotoxic T cells (CD8), macrophages (F4/80), neutrophils (Ly6G), and exhaustion markers (FOXP3 and PD-

1) compared to ND tumors. Combining docetaxel with L-NMMA in HFD mice showed greater potency in slowing tumor growth and reducing lung metastasis incidence compared to either treatment alone, as demonstrated by smaller tumor volumes and fewer metastatic nodules in treated mice. Heatmap analysis of the expression of an immune panel revealed that HFD tumors clustered differently than ND and HFD+LNMMA tumors, indicating a distinct protein expression profile. L-NMMA treatment reduced the expression of exhaustion markers and immunosuppressive macrophages, aligning the TME closer to that of ND tumors. Furthermore, L-NMMA treatment in HFD tumors led to decreased expression of survival (p53) and proliferation (Ki67) markers, as well as phospho-AktSer473. These changes suggest that iNOS inhibition can modulate critical pathways involved in tumor growth and survival.
Conclusion: Our findings highlight the impact of obesity on the TME in TNBC, in promoting tumor growth and creating a pro-inflammatory, immunosuppressive environment. iNOS inhibition through L-NMMA, in combination with standard chemotherapy, effectively remodels the TME, reducing tumor growth and metastasis, and modulating pathways associated with cell proliferation and survival. These results underscore the potential of targeting iNOS as a therapeutic strategy to enhance the efficacy of TNBC treatments, particularly in obese patients.

P2-06-07: Function of NR4A1 in Natural Killer Cells

Kenneth Martinez-Algarin, Isaac S. Chan

Background: Natural killer (NK) cells are critical members of the innate immune system that control breast cancer growth and metastasis. Despite these anti-tumor characteristics, our lab has shown that NK cells exhibit functional polarity and can become reprogrammed directly by breast cancer cells to promote tumor metastasis. Single cell RNA-seq analysis of human breast tumor infiltrating NK cells revealed a reprogrammed subset which was characterized by overexpression of Nuclear Receptor 4 A1 (NR4A1). NR4A1 is an orphan nuclear receptor known to regulate immunologic activity and cellular apoptosis. While NR4A1 has been shown to regulate T cell activity, the function of NR4A1 in NK cells is not well understood. In our RNA seq data, NR4A1 negatively correlated with KLRG1. Previously, we showed when Killer cell Lectin-like Receptor G1 (KLRG1), an inhibitory receptor on NK cells, is blocked with a monoclonal antibody, reprogrammed NK cells more effectively kill breast cancer cells. Previous data suggests NR4A1 can regulate NK cell function, but mechanisms for this remain elusive. We hypothesized that NR4A1 regulates NK cell function through KLRG1 and sought to further characterize the role of NR4A1 and KLRG1 in NK cells in the breast tumor microenvironment.

Methods: To genetically overexpress NR4A1 in NK cells, we developed a transposon-containing vector and used electroporation to successfully introduce and overexpress NR4A1 in NK cells. To test the functional relevance of NK cells, we utilize in vitro co-culture models and measure cytotoxicity between NK cells and target breast cancer cells. Breast cancer cell lines were selected based on receptor-ligand pairing using bioinformatic

analysis and experimental validation of their sensitivity to NK cell cytotoxicity. To assess the impact of NR4A1 on NK cell apoptosis, we assessed NK cell viability after challenge with reduced IL-2 concentrations. We then characterized the expression of NK cell surface receptors in our models using flow cytometry. Cell cycle state of cancer cells in coculture with NK cells were also measured by flow cytometry.

Results/Discussion: Using NK cells isolated from patients with breast cancer, we found that NR4A1 is more highly expressed at the protein level when compared to NK cells from healthy volunteers. Functionally, NR4A1 overexpression (OE) in NK cells decreased their cytotoxicity to K562 cancer cells by 33%. When NR4A1 OE NK cells are co-cultured with BT474 breast cancer cell line, a cell line shown to be resistant to NK cell cytotoxicity, the amount of breast cancer cells in S phase is increased compared to co-culture with WT NK cells. Notably NR4A1 OE NK cells also expressed 50% less KLRG1. NR4A1 OE in NK cells also decreased NK cell death by 50% under conditions of IL-2 depletion. The data suggest NR4A1 plays a unique role in NK cells and drives them to a state of reduced cytotoxicity and a direct or indirect tumor promoting state. NR4A1 also regulates NK cell survival and proliferation, potentially through KLRG1. Future studies will focus on understanding the mechanistic relationship between NR4A1 and KLRG1. Understanding how NK cell function is regulated could lead to improved NK cell-based therapeutics for patients with breast cancer.

P2-06-08: A Novel SERM Reinvigorates Natural Killer Cells by Uniquely Downregulating DKK1 in Breast Cancer Cells

Kristen Young, Govinda Hancock, Steven Kregel, Sean W. Fanning

Although Estrogen Receptor positive (ER+) breast cancer has treatment options that have initial success, many women often experience disease recurrence and hormone therapy resistance. A subset of these resistant patients develop a distinct tyrosine to serine missense mutation at position 537 (Y537S) in ER, encoded by the ESR1 gene, that leads to allele-specific transcriptional programs that enhance metastasis. Probing unique ER structural features can reveal new transcriptional activities critical for therapeutic efficacy. Our lab developed a structurally novel Selective Estrogen Receptor Modulator (SERM), T6I-29, to better understand these structure-transcriptional relationships. T6I-29 shows effective anti-tumoral activities in Y537S ESR1 breast cancer xenografts. To examine the anti-tumoral mechanism of T6I-29 action, we performed RNA-sequencing on Y537S ESR1 mutant breast cancer cells. Compared to other clinically relevant compounds, our drug uniquely and significantly downregulated DKK1, a tumor secreted glycoprotein. Upregulation of DKK1 correlates with metastatic burden across multiple cancers but has not been evaluated in ESR1 mutant breast cancers. Furthermore, online database information is limited on the correlation of DKK1 with ER+ breast cancer. Using patient and donor plasma samples, we find that DKK1 levels are significantly elevated in 108 ER+ breast cancer patients compared to 100 matched healthy donors. Furthermore, in breast cancer cell lines, those with Y537S ESR1 mutation show constitutive expression and secretion of

DKK1, while DKK1 expression and secretion is estrogen-dependent in WT breast cancer cells. Intriguingly, WT cells show significant surface bound DKK1, which is secreted into the media upon hormone stimulation and blocked by T6I-29. Recent findings in triple negative breast cancer and lung cancer models show DKK1 induces Natural Killer (NK) cell dormancy to enhance metastatic capabilities of tumor cells. We find in co-culture experiments with human NK cells and ER+ breast cancer cells, treatment with specifically T6I-29 enhances killing ability of NK cells. Understanding the ER-dependence and functional importance of DKK1 secretion offers a novel approach to potentially reduce breast cancer metastatic burden.

P2-06-09: Impact of lipid composition on triple-negative breast cancer progression and survival.

Khudeja Salim, Elnaz Sheikh, Bridgette M. Collins-Burow, Van T. Hoang, Elizabeth C. Martin, Matthew E. Burow, Manas R. Gartia

Triple-negative breast cancer (TNBC) is an aggressive type of breast cancer, with high resistance to chemotherapy and low survival rates, and accounts for 10-15% of all breast cancer cases. TNBC incidence has been associated with obesity and fatty acids in the tumor microenvironment (TME) derived from lipids can induce obesity-driven metabolic inflammation and affect TNBC pathology. However, the unique impact of the TNBC subtype on lipid composition in the TME, and its subsequent role as an energy source for cancer cell metabolism and progression is unknown. Understanding lipid heterogeneity in the TME will provide novel insights to target TNBC. It is, therefore, crucial to understand the impact of TNBC-driven TME remolding in the context of lipid composition. Our study aims to decipher the role of lipid composition in the progression of TNBC. Spatial lipid profiling of hormone receptor-positive (HR+) and TNBC primary tumors was performed and compared to matched normal breast adipose tissue. Raman mapping of lipids showed a heterogeneous distribution of lipids across the TNBC tissues, including five omega-3 fatty acids, two omega-6 fatty acids, and one unsaturated fatty acid were upregulated in TNBC tumors compared to normal-matched adipose. To determine the unique impact of lipids elevated in TNBC, we next demonstrated that the uptake of lipid compounds (linoleic acid, docosahexaenoic acid, and oleate acid) by TNBC cells increased cell proliferation after 72 hours of treatment. Overall, our results suggest that lipid composition plays a key role in breast TME and may represent a novel therapeutic strategy to target TNBC by alternate sensitivity to therapeutic modalities including apoptosis and ferroptosis.

P2-06-10: The transcription factor HLF (Hepatic Leukemia Factor) : a potential therapeutic target in triple negative breast cancer

Ibrahim Bouakka,Tran Dien Alicia, Sirerol, Marine, Aymeric Silvin, Rocca Anna, Fabrice Andre

Pivotal role of immune response in the evolution of triple negative breast cancer has been largely reported in the last decade. Our previous study highlighted the role of HLF gene as part of a four-gene signature and was found to be negatively correlated with tumoral immune cells infiltration. We investigated more precisely its implication in the immune response and TNBC tumor development. Bioinformatics analysis of publicly available TNBC patient datasets revealed that, in mesenchymal tumor subtypes expressing low levels of HLF, upregulation of genes associated with neutrophil attraction and activation pathways was observed in comparison with those expressing high HLF levels. The implication of neutrophils in cancer is contentious, as they can function either as active anti-tumoral partners or as pro-tumoral agents promoting immunosuppression and tumor growth. This ambiguity stems from their high plasticity, which enables them to switch roles during tumor progression, influenced by signals from tumoral microenvironment, in particular those from surrounding tumor cells. In this study, we employed CRISPR/Cas9 technology to inactivate the HLF gene in TNBC cell lines, enabling us to elucidate the downstream effects on the chemokine and protease inhibitor landscape that governs neutrophil infiltration and function within the microenvironment of TNBCs, especially in mesenchymal subtypes. In vivo experiments using immunodeficient mouse models revealed that HLF downregulation in TNBC mesenchymal subtypes correlates with increased neutrophil infiltration into the tumor, leading to inhibit tumor growth. Altogether, our results suggest that a reduction of HLF expression can lead in the early steps of tumor development to the awakening of the anti-tumoral function of neutrophils to enforce the necessary immunological tone to tumor elimination. Thus, HLF emerges as a potential therapeutic target in order to favor infiltration and function of anti-tumoral neutrophils to restore an efficient immune response in the aggressive mesenchymal TNBC subtype.

P2-06-11: TBK1 Promotes Growth of Aggressive Breast Cancer by Modulating the Tumor Microenvironment

Lan Phi, Manuel Van Gijsel-Bonnello, James Long, Naoto T. Ueno, Xiaoping Wang

Background: Triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC) are the most aggressive breast cancer subtypes. TANK-binding kinase 1 (TBK1), a member of the IKK family, regulates innate immune responses to viruses and other pathogens and functions as an immune-evasion gene. Studying TBK1 is crucial in the context of aggressive breast cancer due to its potentially significant role in tumorigenesis driven by regulation of the tumor microenvironment (TME). However, the molecular mechanisms of TBK1 signaling in regulating the tumorigenesis of TNBC and IBC remain unclear. To address this knowledge gap, we tested the hypothesis that TBK1 signaling promotes the aggressiveness of breast cancer by generating an immunosuppressive TME.
Methods: We knocked out (KO) TBK1 expression in two human cancer cell lines [one IBC (SUM149) and one TNBC (HS578T)] and tested the effect on colony formation, migration, and invasion in vitro. Additionally, we performed RNA sequencing analysis on the control (Ctrl) and TBK1 KO clones to determine the underlying mechanism by which TBK1

regulates IBC and TNBC cell growth. Last, we inoculated Ctrl and TBK1 KO murine 4T1.2 TNBC cells into BALB/c mice and examined the effects of TBK1 KO on tumor growth and TME components.
Results: TBK1 KO significantly reduced colony formation, migration, and invasion in both SUM149 and HS578T cells. RNA sequencing analysis of TBK1 KO clones revealed downregulation of pathways associated with the inflammatory response, such as IL-17 signaling and NF-kB signaling. Furthermore, cytokine-mediated signaling pathways and cytokine-stimulated cellular response were downregulated in these TBK1 KO clones. In the syngeneic murine 4T1.2 xenograft model, tumors derived from TBK1 KO cells exhibited slower growth ($P = 0.0382$) and had fewer M2 macrophages ($P = 0.0068$) than Ctrl cells. Additionally, TBK1 KO tumor samples showed a reduction in protein expression of immunosuppressive cytokines, including CCL27, CXCL1, CXCL2, and CCL2, compared to Ctrl tumors. These results collectively suggest that TBK1 can modulate the TME, promoting aggressive breast cancer tumorigenicity.
Conclusion: TBK1 plays a critical role in the aggressiveness of aggressive breast cancers through generating an immunosuppressive TME. Further understanding TBK1's mechanisms can uncover novel therapeutic targets, potentially improving breast cancer treatment and patient outcomes.

P2-06-12: MGAT1-Mediated Glycosylation Orchestrates Immune Checkpoints and Antitumor Immunity

Junlong Chi

Despite the widespread application of immunotherapy, treating immune-cold tumors remains a significant challenge in cancer therapy. Using multiomic spatial analyses and experimental validation, we have identified MGAT1, a glycosyltransferase, as a pivotal factor governing tumor immune response. Overexpression of MGAT1 leads to immune evasion due to aberrant elevation of CD73 membrane translocation, which suppresses CD8+ T cell function, especially in immune-cold triple-negative breast cancer (TNBC). Mechanistically, addition of N-acetylglucosamine to CD73 by MGAT1 enables the CD73 dimerization necessary for CD73 loading onto VAMP3, ensuring membrane fusion. We further show that THBS1 is an upstream etiological factor orchestrating the MGAT1-CD73-VAMP3-adenosine axis in suppressing CD8+ T cell antitumor activity. Spatial transcriptomic profiling reveals spatially resolved features of interacting malignant and immune cells pertaining to expression levels of MGAT1 and CD73. In preclinical models of TNBC, W-GTF01, a newly developed inhibitor, specifically blocked the MGAT1-catalyzed CD73 glycosylation, sensitizing refractory tumors to anti-PD-L1 therapy via restoring capacity to elicit a CD8+ IFNγ-producing T cell response. Collectively, our findings uncover a strategy for targeting the immunosuppressive molecule CD73 by inhibiting MGAT1.

P2-06-13: HOXB13 Expression Induces an Immunosuppressive Tumor Microenvironment in Breast Cancer

Dennis Sgroi, Yun Xia, Marinko Sremac, Shawn Demehri

Background: Multiple studies has shown that HOXB13 gene expression is associated with poor prognosis for hormone receptor positive (HR+) post-menopausal breast cancer (BC) patients. However, the biological contribution of HOXB13 in such patients is unclear. Previous gene expression- and proteomic-based analyses of HOXB13-high and -low human breast cancers and breast cancer cell lines indicate that HOXB13 expression is associated with interferon gene signatures, suggesting that HOXB13 may modulate the tumor immune microenvironment (TIME). Herein, we investigate the role of HOXB13 expression in breast cancer development in two independent mouse mammary tumor transplant models.
Methods: Murine HOXB13 was ectopically expressed the ER+ SSM3 and the ER- PyMT mouse mammary tumor cell lines, and these cells along with non-HOXB13 expressing control cell lines were transplanted into the inguinal mammary fat pad of syngeneic wild-type (WT) mice on the 129S6/SvEv and C57BL/6 backgrounds, respectively. Tumor volumes and weight were monitored every other day and mice sacrificed at day 40. Tumor single-cell suspensions were prepared, and tumor infiltrating lymphocytes (TILs) were isolated using CD45+ Microbeads on magnetic columns. Cells were stained with the following surface antibodies: CD3, CD4, CD8α. After fixation and permeabilization, intracellular stains were performed using antibodies to TNF-a and TGF-b. Stained cells were assayed using a BD LSRFortessa flow cytometer, and data were analyzed using FlowJo software. To demonstrate that mature T and/or B cells lymphocytes play an important role in the modulation of tumor growth, PyMT-HOXB13 and -control cells were transplanted into Rag1 knockout (Rag1 KO) mice on the C57BL/6 background.
Results: The SSM3-HOXB13 and PyMT-HOXB13 cells exhibited significantly increased tumor growth rate compared with their corresponding control cells after implantation into the inguinal mammary fat pad of WT 129S6/SvEv and C57BL/6 mice, respectively (Figure 2A). Analysis of tumor-infiltrating lymphocytes revealed a marked decrease in CD3+ T and CD8+ T cells in both the ER+ SSM3-HOXB13 and the ER- PyMT-HOXB13 tumors, along with a significantly reduced percentage of activated (TNF-α+ and IFN-γ+) CD8+ T cells in these tumors. Importantly, PyMT-HOXB13 and PyMT-Ctrl tumors grew at a similar rate in the inguinal mammary fat pad of Rag1 KO mice lacking T and B lymphocytes.
Conclusions: HOXB13 expression in two independent mouse mammary tumor models confers tumoral growth advantage by impeding antitumor T cell immunity.

P2-06-14: Calcium-Sensing Receptor Agonist Enhanced Anti-Tumor Activity of Adoptive NK Cell Therapy in Triple-Negative Breast Cancer

Yu Shi, Qun Lin, Zhuxi Duan, Jinpeng Luo, Jieer Luo, Xiaolin Fang, Chang Gong

Triple-negative breast cancer (TNBC), characterized by the absence of estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER-2), often presents a higher infiltration of lymphocytes, suggesting a favorable immune microenvironment for immunotherapy. Recently, natural killer (NK) cells have emerged as a promising option for adoptive cell transfer in cancer immunotherapy. While adoptive NK cell therapy has shown promising efficacy in hematologic malignancies, its practical application in TNBC treatment remains uncertain and variable. Therefore, strategies to enhance the anticancer immune responses of adoptive NK cell therapy in TNBC are urgently needed to improve survival outcomes for TNBC patients. In this study, we explored a novel strategy that combines a calcium-sensing receptor (CaSR) agonist with adoptive NK cell therapy to improve anti-tumor activity in low-response-rate TNBC patient-derived xenograft (PDX) models. Mechanistically, an intracellular Ca2+ imbalance prompted the integration of HLA-DP molecules and circRNA-encoded 296aa, resulting in the retention of HLA-DP intracellularly. The CaSR agonist was observed to aggregate at photodamage sites, leading to ESCRT complex aggregation and membrane repair, which facilitated the budding of HLA-DP-enriched microvesicles. These microvesicles specifically targeted the activating receptor Nkp44 on NK cells, thereby enhancing their cytotoxicity. In vivo experiments further confirmed the efficacy and safety of this combined therapy. These results indicate the feasibility of using adoptive NK cell therapy in combination with a CaSR agonist as an efficient immunotherapy approach for TNBC patients who may be resistant to conventional poly adoptive NK cell therapy.

P2-06-15: DCIS-associated myoepithelial cells drive transcriptional alterations in macrophages through up-regulation of integrin αvβ6

Michael Allen, M. Reza Roozitalab, Stephen Murtough, Eleni Maniati, J. Louise Jones

Ductal carcinoma in-situ (DCIS) is a non-obligate precursor of invasive breast cancer, however, less than 50% of DCIS will ever progress to invasive cancer. There is therefore a need to understand how we can predict those DCIS cases that will progress. A key component in promoting tumour invasion is the immune microenvironment, though its role in DCIS is unclear. We previously have shown that up-regulation of integrin αvβ6 on DCIS-associated myoepithelial cells switches the tumour-suppressor properties of myoepithelial cells to tumour-promoter properties, leading to enhanced tumour cell invasion. We found that macrophages surrounding ducts positive for αvβ6; exhibited a more M2 tumour-promoter phenotype compared to DCIS ducts with myoepithelial cells negative for αvβ6. We therefore hypothesised that the altered phenotype of myoepithelial cells in DCIS may directly influence the peri-ductal immune infiltrate which could influence disease progression. Macrophages were isolated from fresh tissue from patients with DCIS. These were confirmed as either positive or negative for myoepithelial αvβ6. The macrophages were subjected to RNA sequencing. In parallel, primary myoepithelial cells were isolated from cosmetic mammoplasty samples and used to overexpress αvβ6 using a lentiviral inducible system. Conditioned Medium (CM) was collected and this was applied to

macrophages which then underwent RNA seq. RNA-seq analysis demonstrated novel transcriptomic profiles revealing upregulation of genes, e.g. AREG and FOSL2, with potential prognostic significance in DCIS. Utilising conditioned medium generated from primary myoepithelial cells with inducible expression of αvβ6, we demonstrate induction of immune checkpoint inhibitor - CD274 (PD-L1) in monocyte-derived macrophages in vitro. We identified a novel macrophage gene signature, outside of the usual M1/M2 dichotomy, pointing towards a macrophage spectrum which is driven by an in vivo αvβ6-dependent tumour progressive ME. This work thus suggest a panel of microenvironmental markers could be used to predict progressive DCIS cases and may represent novel therapeutic targets to influence a tumour suppressive immune response.

P2-06-16: Addressing Thermal and Battery Efficiency in AI Enhanced Portable Ultrasound Screening Protocols for Breast Cancer

Nusrat Zaman Zemi, Dustin Valdez, Arianna Bunnell, John Shepherd

Background: Breast cancer remains a significant cause of mortality in women, especially in rural and underserved communities where access to mammography is limited or nonexistent. The incidence of advanced-stage breast cancer is 66% higher in Hawaii than in the mainland US, and 5 – 9 times higher in the U.S. Affiliated Pacific Islands (USAPI). AI-enhanced point-of-care ultrasound (POCUS) breast imaging may be an effective method for detecting breast cancer while still in the early stages. The hypothesis is that AI detection and classification algorithms will increase the accuracy of POCUS such that it would approach that of mammography. Further, it may reduce the training levels needed to do the early detection POCUS scanning. One such candidate device is portable, wireless, and provides an SDK for inserting AI models before presenting the image to the user. We have been exploring a suitable protocol for using this POCUS device in remote conditions where infrastructure may be limited. Further, we asked if the portable battery-operated scanner could keep up with a scanning rate of 2 patients per hour for an indefinite amount of time. In this study, we seek to identify the performance parameters that need to be considered to use this and other POCUS systems in rural, remote, and underserved communities.
Methods: The POCUS system consists of a portable handheld scanner (Clarius L7 HD3 model; Clarius Mobile Health Inc, Vancouver, Canada), a tablet computer (Samsung Galaxy Tab S9 Ultra; Samsung Electronics Co., Ltd, South Korea), and a laptop (Dell XPS 15 running Windows 11; Dell Inc., Texas, US). The scanner communicates with the tablet and laptop via an ad hoc WIFI connection. A breast phantom (Gphantom, EDM Medical Solutions, Florida, US) was scanned continuously for 10 minutes, followed by a 20-minute charging period, and repeated. Pretrained AI models were inserted into the image stream using the Cast API. Scanner temperature and battery levels were monitored to determine their time characteristics utilizing the Clarius app. Longer scan and charging periods were used as well to capture the full extent of heating, cooling, and charging cycles. Probe temperature and charging/discharging characteristics were fit to exponential functions.
Results: The system was able to operate for 24 minutes continuously before hitting a

thermal protection temperature of 48°C. The probe was able to fully recharge from 0 to 100% within 60 minutes. For the 2-patient-per-hour protocol, the probe was able to regain its starting charge and temperature for back to back phantom scans over 4 hours. Time constants were found to be 16.1 minutes for temperature increase and 49.6 minutes for battery discharge. The user found it difficult to hold the probe for temperatures above 42°C. A shorter time between scans may not be feasible but being tested.
Conclusion: The findings show that the device can be used continuously for at least two patients per hour with 10 minutes of continuous scanning followed by 20 minutes of charging. However, the operating temperature of the probe is quite high and it may be difficult to handle. Healthcare workers can optimize usage protocol to maximize functional time without frequent recharging in remote areas. Future work will focus on refining AI models for real-time applications and exploring alternative devices with better thermal performance.

P2-06-17: An Integrated Analysis of Metastatic Gene Co-expression in Triple-Negative Breast Cancer via Bulk and Single-Cell Transcriptome Data

Melody Hong, Gábor Balázsi

Background: Triple-negative breast cancer (TNBC) is clinically significant for its high invasiveness (metastasis) and poor prognosis. The molecular classification of breast cancers and characterization of TNBC have been aided by the analysis of both bulk and single-cell RNA-sequencing data. Specifically, they have facilitated the study of the roles of various regulator and effector genes associated with pro-metastatic behaviors such as invasion, and drug resistance-related epithelial-to-mesenchymal transition (EMTI). Yet, it remains unknown how informative and consistent bulk and scRNA-seq TNBC data are in regards to co-expressions of EMTI genes.
Methods: Bulk TNBC RNA-seq data was retrieved from the TCGA-BRCA cohort of the TCGA-TARGET-GTEx Recompute Project, cleaned, and normalized. Single-nucleus TNBC tumor cell data curated by Pal et al. (2021) was separated into six datasets based on patient(s) of origin/cell cycling status and preprocessed. A list of 363 EMTI genes from the EMTome was defined for all gene-gene correlation analyses. Significantly correlated gene pairs with co-expressions concordant among TNBC dataset pairs and larger groupings were found. To identify possibly TNBC-specific correlations, co-expression analysis was repeated for both bulk normal breast from the GTEx cohort of the Recompute project and snRNA-seq normal breast epithelial data from Pal et al. (2021). EMTI regulatory networks were reconstructed using co-expression data between 26 key EMT genes for both TNBC and normal. Co-expression comparisons and differential co-expression analysis were performed between the TNBC and normal samples. Differential expression analysis was also performed between the bulk TNBC and normal to investigate the relationship between differential EMTI gene expression and co-expression.
Results: EMTI gene co-expression patterns exhibited greater similarity between TNBC single-cell datasets than between any single-cell and bulk TNBC. Moreover, the datasets

most concordant with each other were single-cell datasets originating from the same patient(s), indicating that EMTI gene co-expressions do not significantly differ with cell cycling status. The SPINT1 and LSR genes were significantly positively correlated in all TNBC samples but not in normal, revealing a previously undocumented link. Additionally, we found 11 TNBC single-cell-specific gene-gene correlations (7 positive, 4 negative), relationships that would not have been identified in heterogeneous bulk TNBC. We observed known interactions between EMTI genes, including an EpCAM-keratin-claudin link well preserved across both TNBC and normal breast. Out of the three breast epithelial lineages (luminal progenitor (LP), mature luminal (ML), basal), EMTI gene co-expressions in TNBC single-cell were most similar to those in LP; however, those in the bulk TNBC were most similar to basal. With the exception of 2 gene pairs common to the bulk datasets, there were no EMTI gene pairs with consistent co-expression patterns across the different TNBC/normal groupings. Interestingly, differential EMTI gene co-expression was weakly associated with differential gene expression; this applied for genes non-differentially expressed (KRT5), upregulated in TNBC (EPCAM), or downregulated (TGFB1I1) (Spearman's ρ: 0.139, 0.145, 0.0839; all $p < 10e-07$).
Conclusions: Our integrated analysis reveals that EMTI gene pairs are moderately concordant among TNBC or normal datasets, but not between the two. Moreover, we show both known and new interactions in reconstructed networks. We identify a TNBC single-cell-specific 11 gene pair signature that may be promising for further study. Finally, although contrary to previous work we find that differential EMTI gene co-expression can be partially explained by differential gene expression, the association is weak enough where the two remain complementary approaches.

P2-06-18: Deep learning-based tumor microenvironment signature predicts progression-free survival in early-stage hormone receptor positive and HER2 negative breast cancer

Firas Khader, Omar S. M. El Nahhas, Firas Khader, Evan Paul, Pavol Cekan, Nicoleta Antone, Daniel Truhn, Jakob Nikolas Kather

Molecular risk assays, such as OncotypeDX, have emerged as a robust method for guiding adjuvant chemotherapy alongside endocrine therapy in early-stage hormone receptor positive (HR+) and HER2 negative (HER2-) breast cancer (BC). However, these assays have limitations in that they lack the capability to capture the heterogeneity and complexity of the tumor microenvironment. They do not account for morphological features in routine hematoxylin and eosin (H&E)-stained histopathology slides—features that can provide insights into how the tumor cells are behaving in situ. Additionally, molecular assays are expensive and time-consuming, limiting their widespread use in clinical practice. Consequently, there is a need for alternative or complementary prognostic tools that can analyze tumor morphology and the TME from H&E slides.
Deep learning (DL) can predict cancer biomarkers directly from H&E slides, enabling the automated and consistent quantification of the tumor microenvironment (TME) for clinical

decision-making. Our study focuses on the prediction of TME signatures on a large international and multi-centric cohort for the prognostication of BC patients. We developed a weakly-supervised, transformer-based multi-task deep regression model to predict signatures of the TME directly from routine H&E-stained histology slides. We trained the model using 5-fold cross-validation on a large pan-cancer cohort of patients (n=2,690), and validated its prognostication performance on an external cohort of early-stage HR+/HER2- female BC patients (n=470).
The model predicted signatures of tumor cell proliferation and tumor infiltrating lymphocytes (TILs) as a continuous variable, which was carried forward for survival analyses as a composite interaction score. Using longitudinal data from the multi-centric external cohort (median follow-up = 133 months), survival analysis was performed using a Cox proportional hazards model with adjustment for age, nodal status, stage, administration of adjuvant chemotherapy, and a research-based molecular risk of recurrence score. Our AI-based TME signature was significantly associated with improved 12-year progression-free survival, with a hazard ratio = 2.28, (95% confidence interval; 1.19, 4.36), p=0.01.
Our new AI-based prognostication method, which we call SAIBR (StratifAI BReast), provides a cheap and readily available algorithm for analyzing digital pathology images of H&E sections of BC to quantify tumor cell proliferation and TILs. The data show that SAIBR is an informative prognostic marker for 12-year progression-free survival and that it provides prognostic information beyond standard clinicopathological factors and validated molecular risk assessment in early-stage HR+/HER2- breast cancer.

P2-06-19: The clinical relevance of infiltrating hematopoietic stem cells in the breast cancer tumor microenvironment

Masanori Oshi, Rongrong Wu, Akimitsu Yamada, Kazutaka Narui, Takashi Ishikawa, Itaru Endo, Kazuaki Takabe

Background: There are numerous types of cells in the tumor microenvironment (TME) that are known to affect breast cancer (BC) biology. However, the roles of cells that are rare in TME are vastly understudied. Recent advances in transcriptomic analyses enabled us to quantify and study the roles and clinical relevance of the extremely rare cells in TME, including hematopoietic stem cells (HSCs).
Material and Methods: In silico analyses was conducted on total of 5,176 breast cancer (BC) patients from large independent cohorts; SCAN-B and METABRIC, and single cell sequence data including GSE169246, GSE246613, GSE 161529, GSE167036, and GSE255107 from NCT03366844clinical trial. HSC was quantified using xCell algorithm for bulk tumor, and SingleR algorithm for single cell sequence data. High HSC patients were defined as more than the median in each cohort.
Results: Utilizing 5 single cell sequencing data, HSCs were less than 0.1 % of immune cells in ER+/HER2- as well as 0.1% in triple negative BC, and inversely related with pathological grade. HSCs did not collate with any of the lineages including lymphocyte, myeloid,stromal, nor stem cells in TME. BC patients with high HSCs was significantly associated with better

overall survival (OS) compared to low, particularly in ER+/HER2- BC in both SCAN-B and METABRIC cohorts (both p<0.02). Further, high HSCs ER+/HER2- BC was significantly associated with better disease-specific survival (DSS) in the METABRIC cohort (p=0.028). High HSC ER+/HER2- BC enriched several pro-cancerous gene sets, including TGF-β, KRAS signaling, NOTCH signaling, epithelial-to-mesenchymal transition, angiogenesis, and hypoxia. On the other hand, low HSC patients enriched cell proliferation-related gene sets; E2F targets, G2M checkpoint, MYC targets-v2, and mitotic spindle. High HSC ER+/HER2- BC was significantly associated with high fraction of dendritic cells, adipocytes, endothelial cells, pericytes, and fibroblasts, and with low fraction of Th1 cells, Tregs, NK T cells, memory B cells, M1-macrophages, and eosinophils consistently in both cohorts (all p<0.001). The level of HSC infiltration showed no association with response to neoadjuvant chemotherapy consistently with low Area Under the Curve, and neither OS nor DSS after chemotherapy in the METABRIC cohort (p=0.705 and 0.643, respectively). On the other hand, high HSC was significantly associated with lower risk of lung metastasis and with better survival.
Conclusion: In silico approach detects HSCs in the BC TME and revealed that it is inversely associated with cancer cell-proliferation, and better patient survival in ER+/HER2- BC. Given that HSCs was not associated with response to chemotherapy, but with risk of lung metastasis and survival, we speculate that it may have a role in the BC biology rather than chemotherapy resistance.

P2-06-20: Use of an AI Algorithm to Determine the Prevalence of Breast Arterial Calcifications in Women Undergoing Screening Mammograms Based on Race, Age and Cancer Status

Chirag Parghi, Jennifer Pantleo, Jeff Hoffmeister, Julie Shisler, Wei Zhang, Avi Sharma, Zi Zhang

Background: Breast arterial calcifications (BAC) on mammography has been historically overlooked and underreported as an “incidental finding”. Due to the success of mammography as a screening platform and known gaps in cardiac screening for women, BAC presence and extent can potentially identify women that may benefit from enhanced cardiac screening and medical optimization.
Methods: A set of 3558 Hologic Digital Breast Tomosynthesis (DBT) screening mammograms, including 394 cancer cases and 3164 noncancer cases from October 7, 2014 to April 16, 2021 across 3 healthcare systems were analyzed using a deep learning AI algorithm trained to detect BAC on 2D images from combo DBT or 2D synthetic images from DBT. Patients ranged from 35 to 94 years of age. The dataset was weighted relative to a screening population based on Breast Cancer Surveillance Consortium based on specific clinical characteristics, namely age, race, and mammographic density with a cancer incidence of 6/1000. The study assessed overall prevalence of BAC as well as distribution among women with cancer and without cancer and by race and age.
The AI model was trained using an internal dataset of 2D/synthetic mammograms to detect

BAC based on expert annotation and provides a BAC of present or absent. The accuracy of the AI model was validated on a data set of 2D mammograms from 8,881 women. Ther was no overlap in the training, validation and the 3558 women prospective study data sets.
Results: The unweighted overall prevalence of BAC in this cancer enriched dataset of screening exams is 17.7%. When normalized by standard age, mammographic density, and racial demographic data with a cancer incidence of 6/1000, the (weighted) prevalence of BAC changed to 15.0%, which was used for subsequent analyses. BAC is present in mammogram exams in 33.9% of women with cancer and 14.8% of women without cancer. BAC prevalence per race in the screening adjusted dataset is 14.6% White, 17.7% Black, 13.9% Asian and 17.4% in other races. BAC prevalence per age group in the screening adjusted dataset is 3.7% in women <50 years old, 8.6% in 50-59, 17.3% in 60-69 and 37.4% in women 70 and older. When the age deciles were consolidated into two groups above and below age 60, the weighted BAC prevalence was 25% in patients age 60 or above and 6.5% below the age of 60.
Conclusion: The weighted prevalence and distribution of BAC increases with age as expected in a screening population. Interestingly, BAC prevalence did not vary by race suggesting it could serve as an effective cardiovascular biomarker across racial groups. AI based BAC detection on mammography demonstrates high prevalence of BAC in women with mammographically detected breast cancer. Women with increased BAC and breast cancer may benefit from cardiovascular assessment in addition to undergoing oncological treatment. In that sense, a conventional mammogram can identify cardiac needs of patients prior to or at the time of breast cancer diagnosis.

P2-06-21: Preliminary validation of a multi-modal AI for stratification of early-stage breast cancer patients utilizing a foundation model for digital pathology

Jan Witowski, Ken Zeng, Joseph Cappadona, Jailan Elayoubi, Nancy Chan, Young-Joon Kang, Ugur Ozerdem, Freya Schnabel, Linda M. Pak, Khalil Choucair, Yu Zong, Lina Daoud, Waleed Abdulsattar, Francisco Esteva, Krzysztof J. Geras

Early breast cancers are risk-stratified based on clinicopathological characteristics and refined by genomic assays that predict the risk of recurrence. Clinical features alone are often insufficient for accurate predictions, while genomic assays are limited by long processing times, tissue exhaustion, and high costs.
Digital pathology is an imaging modality that captures information about tissue morphology and the tumor microenvironment, providing valuable insights into tumor biology and patient outcomes. However, the complexity of these images make it impractical to depend on pathologists for manual assessment. Whole slide image (WSI) analysis is labor-intensive, time-consuming, and subject to interobserver variability. However, recent advances in artificial intelligence (AI), specifically in self-supervised learning, have enabled researchers to train models to extract meaningful histopathological features by learning over large unlabeled datasets of pathology slides, providing a path to overcoming the limitations

presented by traditional assays.
We developed an AI model that integrates digital pathology with clinical information to predict risk of breast cancer recurrence. We extracted pathology imaging features using an AI foundation model trained on 500 million image patches derived from 80,000 WSIs. Imaging-based features were combined with routinely collected clinical information and used in time-to-event models to predict risk of an event. These models can assess patient risk in minutes, instead of the weeks it takes for genomic assays, and with a fraction of the labor. In this analysis, we have developed and trained models to predict disease-free interval (DFI).
We evaluated our model's performance on 992 stage I-III patients from TCGA's BRCA cohort. This dataset has not been used to train or optimize the model's hyperparameters. Additionally, we performed a subgroup analysis in 365 hormone receptor-positive (HR+) node-positive (N+) cases and 102 TNBC cases. Continuous risk scores between 0 and 100 generated by the multi-modal test accurately predicted DFI, achieving a C-index of 0.71 (95% CI 0.63–0.77) in the all-TCGA group, 0.69 (95% CI 0.59–0.76) in the HR+ N+ cohort, and 0.81 (95% CI 0.71–0.90) in the TNBC cohort. When categorized into low- and high-risk groups with a naive, non-optimized 90/10 threshold, we observed a statistically significant difference in DFI between high- and low-risk groups (log-rank tests $p<0.01$). The hazard ratio between high- and low-risk patients was 3.40 (95% CI 2.15–5.40) in the all-TCGA group, 3.28 (95% CI 1.59–6.79) in the HR+ N+ cohort, and 4.86 (95% CI 1.37–17.32) in the TNBC cohort.
Additionally, we conducted an analysis showing that the features generated by our AI foundation model provide independent information beyond the clinical data. In a Cox proportional hazards model, after adjusting for the clinical-only score, the digital pathology imaging-based score remained statistically significant with the log-rank test ($p<0.001$). Even accounting for the clinical score, the hazard ratio per 20-unit increase in our digital pathology score corresponds to a hazard ratio of 2.99 (95% CI 1.54–5.80).
Our model is prognostic in early-stage breast cancer, including in clinically meaningful groups such as HR+ N+ and TNBC patients. As the model is fully digital, it can significantly expedite the risk assessment process compared to molecular tests and can provide access to a wider population at a fraction of the cost. Finally, AI-derived imaging features provide novel prognostic information not captured through traditional clinicopathological features.

P2-06-22: PreciseBreast, an AI-enabled digital test predicting breast cancer recurrence is equivalent with Oncotype in an observational, retrospective study of patients from Baptist Health Miami Cancer Institute in partnership with COTA, Inc.

Reshma L. Mahtani, Ana Sandoval -Leon, Maria Abreu, Elysse Castro-Hall, Ching-Kun Wang, Chelsea Perelgut, Christina M. Zettler, Gerardo Fernandez, Marcel Prastawa, Jack Zeineh, Aaron Feliz, Juan Carlos Mejias, Alex Shtbasky, Xiaozhu Zhang, Abishek Sainath Madduri, Brandon Veremis, Michael J. Donovan, Manmeet S. Ahluwalia

Background: PreciseBreast (PDxBR) is an AI-enabled clinical grade digital test combining demographic and pathology data e.g. age, tumor size, anatomic stage and lymph node status with outcome-curated image features (biomarkers) from an H&E image of early-stage invasive breast cancer (IBC) to provide prognostic information regarding risk of recurrence within 6 yrs. PDxBR was previously evaluated on a cohort of patients (pts) with Oncotype (ODX) results from the Mount Sinai Health Care System, NY, NY and demonstrated improved risk discrimination when compared to ODX. We sought to extend these initial observations on a cohort from the Miami Cancer Institute and Baptist Health South Florida in partnership with COTA, Inc.

Methods: An early-stage retrospective cohort of IBC pts with ODX results and 6-yrs outcome data from Miami Cancer Institute were identified utilizing COTA's real-world database. H&E glass slides were scanned, and images processed with the PDxBR platform to generate an algorithm validated low (</=58) vs high (>58) risk score (scale 0-100) for predicting disease recurrence. Risk stratification, adjuvant treatment choice and event classification between PDxBR and ODX were evaluated using c-index/AUC and KM curves with hazards ratio, NPV, PPV, sensitivity (SE), specificity (SP). Adjuvant treatment decisions based on ODX were compared with PDxBR risk stratification and summarized descriptively. Subgroup analysis stratified by age and positive lymph node status was also performed.

Results: This cohort included 425pts with stage I-II, HR+, HER2- IBC, with a median age of 59 years (75%>50), 91% were White, and 60% Hispanic. 90% tumors <2.5cm, 50% clinical grade 2, 81% LN negative, with median 6-years of follow-up. 20% of patients had received adjuvant chemotherapy, 99% endocrine therapy and 56% radiation. There were 40 events (9.4% event rate: 11 deaths, 19 distant recurrences and 10 local-regional recurrences). ODX classified 87% (n=371) as low/intermediate risk with a RS </=25 vs PDxBR 79% (n=337) low risk score </=58 ; ODX AUC was 0.69 vs. PDxBR AUC 0.66 (Delong test p-value=0.3). The NPV for ODX vs PDxBR was 0.93,0.93; PPV 0.26, 0.17 and HR 4.26, 2.41 (p-value=0.22) with a SP of 0.90, 0.81, and SE 0.35, 0.38. The avoidance of adjuvant chemotherapy was comparable between both ODX (81%) low/intermediate and PDxBR (79%) low risk pts, respectively. Of the pts who developed an event, ODX correctly classified 14/40 (35%) as high risk (RS>25) vs PDxBR 15/40 (38%) as high risk (risk score >58). For the combined 29 distant metastasis and loco-regional events, the ODX identified 14/29 (48%) vs PDxBR 13/29 (45%). Similar results were obtained by conducting a subgroup analysis stratified by age >50 years. Due to the limited sample size, we were unable to conduct a comprehensive analysis on patients <50 years and positive lymph nodes.

Conclusion: The results support the equivalence of PDxBR vs. ODX in providing prognostic information regarding the risk of recurrence for pts with early stage IBC. The NPV of 93 along with comparable specificity, event classification and use of risk directed adjuvant therapy supports the use of this assay to provide a standardized AI-enabled grade and

phenotype of IBC. This information may enhance overall risk discrimination when used in conjunction with genomic assays which also provide important predictive results that aid in decisions regarding the use of adjuvant chemotherapy. Additional studies are underway to further confirm these proposed clinical applications.

P2-06-23: Using a Machine Learning Model for Prediction of Palbociclib Response in a Single Institution, Real-World Analysis of Patients with ER+ HER2- Advanced Breast Cancer

Xiaojie Zhang, Akshat Singhal, Safia Hassan, Kelly Gu, Trey Ideker, Kay T. Yeung

Introduction: CDK4 and 6 inhibitors (CDK4/6i) have transformed the treatment landscape of ER+ HER2- advanced breast cancer (ABC), significantly improving progression free survival in several phase III trials. Despite this, overall response rates hover around 50% in the 1st line setting, and development of resistance is nearly universal. To date, no established biomarkers predict sensitivity to CDK4/6i, emphasizing the need for a predictive tool for optimized CD4K/6i use. We recently published work (Park et al., Nature Cancer 2024) on an interpretable, 'visible' neural network model (VNN) based on a hierarchical proteomics map of 718 genes assessed by one or more clinical cancer gene panels. This model, validated in the metastatic breast cancer cohort from the AACR Project GENIE registry, predicts response to palbociclib (palbo). In this study, we successfully applied the palbo-VNN model in identifying patients with ER+ HER2- ABC who have palbo sensitive vs resistant disease in a single institution, retrospective analysis.
Methods: We conducted a retrospective study of patients with biopsy-proven ER+ HER2- ABC and available tissue-based genomic sequencing data treated with palbo between February 2016 and September 2023 at UC San Diego. Clinical data gathered included patient demographics, disease characteristics (de novo vs recurrent metastatic breast cancer), therapy line, treatment duration, and overall survival (from palbo start date to death). Tissue-based genomic sequencing data from commercially available vendors were used as input for the palbo-VNN model. Palbo-VNN is an ensemble of five models; tumors with a predicted score <0.645 (previously validated and described in our published work) in at least two models were categorized as palbociclib sensitive (palbo-VNNsen), with the rest categorized as palbociclib resistant (palbo-VNNres).
Results: A total of 139 patients met inclusion criteria. The median age was 63 (range 33-91) with a median ECOG performance status of 1 (range 0-3). Among the patients, 34% had de novo metastatic disease, 17% had prior localized disease with metastatic relapse within 2 years of adjuvant endocrine therapy (ET) initiation, and 41% had metastatic relapse after 2 years of adjuvant ET. Bone metastases were present in 71% of patients, visceral involvement in 66%, and central nervous system involvement in 9%. 75 out of 139 patients (54%) received palbo in the 1st line setting. In the 1st line setting, median therapy duration was 12.3 months (0.26-72). At a median follow-up of 72.5 months since palbo start, patients with palbo-VNNsen tumors (n=38) had a median treatment duration of 49.6 months compared to 15.6 months for those with palbo-VNNres tumors (n=37) (HR=0.63, p=0.01).

Patients with palbo-VNNsen and palbo-VNNres disease had a median overall survival of 79.3 vs 45.7 months (HR=0.68, p=0.03), respectively. Further subgroup analyses, such as stratification for de novo vs early relapsed disease, visceral vs bone only metastatic disease, and additional resistance pathways analysis, will be presented at the meeting.
Conclusion: This is one of the first real-world retrospective analysis using a machine-learning model to predict CDK4/6i therapy response in ER+ HER2- ABC. The palbo-VNN model effectively predicted sensitivity to palbo, correlating with longer therapy duration and overall survival in palbo sensitive disease. This highlights the clinical utility of the palbo-VNN model in optimizing patient selection for CDK4/6i therapy in the first line setting. Future research could explore the model's application in selecting patients for sequential CDK4/6i treatment and could enhance our understanding of CDK4/6i resistance mechanisms, potentially improving outcomes and quality of life for patients with ER+ HER2- ABC.

P2-06-24: Effect of an Image-Derived Short Term Breast Cancer Risk Score in the Analysis of Breast Cancer Prevalence in Screening Population by Race and Breast Density

Chirag Parghi, Jennifer Pantleo, Julie Shisler, Jeff Hoffmeister, Wei Zhang, Avi Sharma, Zi Zhang

Background: Screening with digital breast tomosynthesis (DBT) improves breast cancer detection and reduces false positives. Adding a short term breast cancer risk assessment model using image-derived artificial intelligence (AI) has shown higher performance than traditional lifestyle and family-based models in cohort studies. Although the image-based risk is reported as a discrete number across all patients, the predictive accuracy may vary across patients by race and/or amounts of breast density. Contextualizing image-based risk categories by race and density can potentially enhance clinical use during interpretation of subsequent screening mammograms.
Methods: A set of 3558 Hologic (DBT) mammograms, including 394 cancer cases and 3164 noncancer cases from October 7, 2014 to April 16, 2021 across 3 healthcare systems were analyzed with a deep learning AI Risk model. Patients ranged from 35 to 94 years of age. An imaging only AI risk model utilizes mammographic features, density and age at exam to provide a single risk score, identifying women more likely to be diagnosed with breast cancer at the next annual screening exam. Women are considered average risk with an absolute one year risk score of <0.34%, intermediate 0.34-<0.6% and high ≥ 0.6%. The dataset was analyzed adjusting to a screening population based on Breast Cancer Surveillance Consortium clinical characteristics of age and race for screening DBT exams with a cancer incidence of 6/1000. The study assessed the distribution of overall risk score as well as sub analysis by density and race.
Results: In women with an average risk score, the prevalence of cancer is 1 in 1369 within 68.7% of adjusted screening population, intermediate is 1 in 171 (13.1% of population) and high is 1 in 38 (18.2% of population). For women with non-dense breasts the prevalence of

cancer in the average risk score group is 1 in 1427 (39.5% of adjusted screening population), intermediate is 1 in 231 (8.4% of population) and high is 1 in 41 (10.3% of population). For women with dense breasts the prevalence of cancer in the average risk score group is 1 in 1297 (29.3% in adjusted screening population), intermediate is 1 in 118 (4.7% in population) and high is 1 in 36 (7.9% in population). When analyzing by race for women with high risk scores the prevalence of cancer in White is 1 in 38 (15.5% of adjusted high risk screening population), Black is 1 in 41 (1.4% in population), Asian is 1 in 34 (0.5% of population) and for all other race is 1 in 5 (0.8% of population).
Conclusion: An image-derived AI risk model is equally affective across race and density and can provide accurate insight on short-term breast cancer risk. Based on our results, image-based risk can potentially offset known gaps in breast cancer detection by traditional mammography in patients with dense tissue and address known disparities across races.

P2-06-25: Is Mammography Artificial Intelligence consistent across race and density?

Chirag Parghi, Jennifer Pantleo, Julie Shisler, Jeff Hoffmeister, Zi Zhang, , Avi Sharma, Wei Zhang

Background: Artificial intelligence (AI) is increasingly utilized as an interpretive adjunct for radiologists reading screening mammograms. The case score is a central feature of tomosynthesis-based AI applications as the combination of images for a single patient is consolidated into a single number. An increased case score may suggest the presence of breast cancer in select mammograms and a low score would imply the converse. Although the case score is currently provided as a single number, the clinical value of this score may vary with parameters such as patient race and breast density, which are known to affect the overall incidence of breast cancer. Therefore, offering context of the case score based on screening populations with a mix of racial and density distributions can guide radiologists for more accurate breast cancer detection.
Methods: A set of 3558 Hologic Digital Breast Tomosynthesis (DBT) mammograms, including 394 cancer cases and 3164 noncancer cases from October 7, 2014 to April 16, 2021 across 3 healthcare systems were analyzed with a deep learning AI detection system. Patients ranged from 35 to 94 years of age. The AI system based on deep convolutional neural networks processes the DBT images and provides a case score of 0-100 to indicate the algorithm's confidence that a case showed malignancy. The dataset was weighted relative to a screening population based on Breast Cancer Surveillance Consortium clinical characteristics of race and density for screening DBT exams with a cancer incidence of 6/1000. Breast tissue was categorized as non-dense (BIRADS A and B) or dense (BIRADS C and D). Scores were assigned to 3 categories based on suspicion of cancer: low 0-19, intermediate 20-69 and high 70-100. Statistical analysis was performed using a Mann-Whitney U Test and Chi-Squared Test utilizing Stata (v18.0) software. A p-value at or below 0.05 was defined as the threshold for statistical significance.
Results: When sub analyzed by race across all case scores, the frequency of cancer in white

women is 1 in 161, Black 1 in 187, Asian 1 in 220 and other races is 1 in 221. The cancer rates across race were consistent across the high, intermediate, and low Case Scores with no clear difference between racial subgroups.
Breast density sub analysis:
The overall analysis of case score showed the frequency of cancer differs significantly by breast density (p= 0.0006). The frequency of cancer in women with non-dense breast tissue for low case scores is 1 in 11,363, intermediate is 1 in 304[JS1] and high is 1 in 28. For women with dense breast tissue the frequency of cancer for low case scores is 1 in 1952, intermediate is 1 in 213 and high is 1 in 22. Yet, when individually analyzing frequency of cancer by case score categories and breast density, a statistical difference only appeared for the intermediate category in dense vs. non-dense breasts (p=0.0018).
Age sub analysis:
The mean age of women with a cancer detected in the low Case Score category is 63.3 years compared to 56.2 years in the non-cancer category (p=0.053). The mean age of women with cancer and intermediate Case Scores is 65.8 years compared to 60.2 in the non-cancer group ($p<0.05$). The mean age for women with cancer in the high Case Score category is 64.9 years compared to 64.0 in the non-cancer group (p=0.296).
Conclusion: AI generated case scores effectively stratify mammograms into categories with varying frequency of cancers. The case scores did not vary significantly across racial subgroups in our dataset suggesting the accuracy of the AI software was consistent across races. In women with non-dense, or fatty breast tissue on the mammogram, a low case score corresponded to a lower frequency of cancer (1 in 11,363) compared to those women with dense breast tissue and a low case score (1 in 1952). Although finding was not statistically significant by the Mann-Whitney U test, the difference between categories is notable and the lack of statistical confirmation is likely due to the low absolute number of cancer case in the low case score, non-dense cohort. Therefore, the negative predictive value of a low case score on a screening mammogram is presumably higher in women with non-dense breast tissue across a large data set.

P2-06-26: nf-hlamajority: a Nextflow pipeline for consensus MHC class I typing and its application to neoantigen identification in breast cancer stromal cells

Kevin Ryan, Domhnall O'Connor, Barry Digby, Laura Barkley, Pilib Ó Broin

Introduction: Cancer-associated fibroblasts (CAFs) are a heterogeneous cell type found in the tumour microenvironment (TME). CAFs can support tumour growth and metastasis and contribute to therapeutic resistance. They can also impact immune infiltration and immune responses in the TME. Therefore, therapeutic targeting of CAFs is potentially a viable strategy to treat cancer. Here, we aim to identify somatic mutations in CAFs, that may give rise to neoantigens. HLA genotyping is an important step for neoantigen prediction. This can be carried out in silico using DNA sequencing data, with numerous tools available for this purpose. Claeys et al. (PMID: 37161318) benchmarked several HLA typing tools,

finding that a majority voting approach using a combination of four tools resulted in superior performance for each HLA gene. No end-to-end pipeline currently exists to apply this majority voting approach, making it difficult for non-informaticians to implement. The objectives of this work were to: 1) develop a Nextflow bioinformatics pipeline implementing majority voting for MHC class I typing from DNA sequencing data, and 2) use HLA calls from this pipeline to identify potential neoantigens in cancer-associated fibroblasts.
Materials and Methods: CAFs and corresponding tumour-associated normal fibroblasts (TANs) were cultured from tissue of 12 breast cancer patients (11 Luminal A and one triple-negative). Bulk RNA-sequencing was carried out on all samples and whole-exome sequencing (WES) was carried out on CAFs and TANs from eleven patients. The Nextflow pipeline developed, nf-hlamajority, was used to determine HLA genotypes using WES from each breast cancer patient and 12 NCI-60 Human Tumor Cell lines. nf-hlamajority takes FASTQ files and performs HLA typing using Optitype, Polysolver, HLA-LA and Kourami. For each HLA gene, it then assigns the HLA genotype called by the highest number of tools. In the case of a tie, the HLA genotype called by the tool with the highest accuracy for that HLA gene, as determined by Claeys et al., is assigned to the sample. HLA calls made by nf-hlamajority in the samples from breast cancer patients were used as input to Landscape of Effective Neoantigens Software (LENS) to identify CAF-specific neoantigens (PMID:37184881).
Results and Discussion: In the NCI-60 dataset, 68/70 (97%) nf-hlamajority HLA calls matched the ground-truth PCR genotyping call, demonstrating the high accuracy of the pipeline. nf-hlamajority was then used for the automated high-confidence HLA typing of all breast cancer patients. Using HLA alleles called using nf-hlamajority, LENS identified a number of potential neoantigens resulting from missense mutations, all of which were private to each patient. Interestingly, genes with these mutations included CAF markers and genes implicated in lipid metabolic pathways. CAFs contribute to lipid metabolism within the TME, thus impacting cancer progression and tumour immunogenicity.
In this study, we have developed an automated pipeline for consensus HLA typing which we envisage will be useful to the research community. nf-hlamajority has helped us identify candidate neoantigens in breast cancer CAFs. Future work will focus on validation using T-cell immunogenicity assays, improving our understanding of the potential of targeting CAF neoantigens to enhance the efficacy of anti-cancer therapy.

P2-06-27: Mapping APOBEC Profiles in Breast Cancer Microenvironments: Bridging Bulk and Single-Cell RNA-seq Data

Jake Lehle, Mohadeseh Soleimanpour, Diako Ebrahimi

The apolipoprotein B mRNA editing enzyme, catalytic polypeptide- like 3 (APOBEC3 or A3) family of cytosine deaminases has been implicated in some of the most prevalent mutational signatures in cancer. A3-associated mutational signatures have been identified in more than 70% of cancer types and around 50% of all cancer genomes, with prominence

in breast cancer as well as other cancer types. Many tumors are hypermutated by C-to-T/G mutations induced by A3 within TCW (W:T,A) motifs, accounting for many driver mutations in genes such as PIK3CA, ERBB2, and PPP2R1A. The genome and transcriptome of tumor tissue biopsies contain a wealth of information about these A3-associated signatures. However, quantification of A3 expression changes in tumor cells is confounded by the ubiquitous expression of these enzymes in infiltrating immune cells. To overcome this we will utilize single-cell RNA-seq analysis across a wide range of publicly available breast cancer datasets in order to follow the relative changes of A3 expression within individual cell types. Results from this analysis will give our lab insights into to changes in A3 expression in tumor cells which will be helpful in unveiling the complex relationships among breast cancer cells, stromal elements, and immune cells, facilitating the development of personalized therapies and prognostic markers, while also shedding light on breast cancer heterogeneity and potential vulnerabilities.

P2-06-28: AI-driven feature discovery enables accurate identification of breast cancer biomarkers and histology

Joseph Cappadona, Ken Zeng, Jan Witowski, Krzysztof Geras

The advent of foundation models in artificial intelligence presents a transformative opportunity for oncology. These large-scale models, trained via self-supervised learning on large repositories of unlabeled data, can learn to recognize complex patterns within images and can easily be adapted to downstream tasks with minimal additional training. Additionally, foundation models excel at downstream tasks with relatively few training data, which is especially important within oncology where obtaining large and diverse labeled datasets is challenging, time-consuming, and expensive.
We demonstrate the potential of foundation models for oncology by training a pathology foundation model and evaluating it on a diverse suite of clinically relevant downstream tasks. The model, based on a vision transformer architecture (ViT-L), was pretrained using state-of-the-art self-supervised learning method DINOv2 on 500 million image patches from 80,000 H&E-stained whole slide images. We evaluated the model on 12 slide-level and patch-level tasks identifying breast cancer tumor and patient characteristics based solely on digital pathology. The datasets comprised over 2000 patients across all tasks and entailed identifying major histological subtypes (ILC, IDC, etc.), hormone receptor statuses (ER and PR), and genomic characteristics. For all downstream evaluations, we keep the foundation model frozen and train regressors or classifiers on top of embeddings obtained by passing slide patches through the model.
The model learned to identify patients with ILC with an AUC of 0.84±0.03 in the TCGA cohort (n=1033) and 0.79±0.05 in the PLCO cohort (n=1011). For IDC, the model achieved an AUC of 0.80±0.03 in TCGA and 0.82±0.04 in PLCO. The model also learned to classify breast tumors as ER/PR-positive versus -negative. For ER classification, the model obtained an AUC of 0.80±0.04 in TCGA (n=983) and 0.83±0.05 in PLCO (n=848), and for PR classification, the model obtained an AUC of 0.70±0.04 in TCGA (n=980) and 0.80±0.04 in

PLCO (n=842).
Additionally, the model, when trained on 938 patients from TCGA and evaluated out-of-distribution on 116 patients from CPTAC, learned to identify mutations in genes associated with endocrine resistance, including TP53 (AUC=0.76±0.04) and PIK3CA (AUC=0.61±0.04), and in genes associated with lobular breast cancer, such as CDH1 (AUC=0.89±0.02).
We also evaluated our foundation model on 5 patch-level tasks identifying spatially resolved histological features. We demonstrate that the model can learn to predict tumor cellularity (Kendall's tau of 0.78±0.01), classify metastatic regions (balanced accuracy of 0.98±0.00), and identify areas with various histologies, including dysplasias, adenomas, and lobular carcinomas (AUCs of 0.74±0.03, 0.92±0.01, and 0.97±0.00 in three independent datasets).
Following these evaluations, we analyzed the effect of varying model size and pretraining dataset size. In particular, we looked at the differences in performance between ViT-S (21M parameters), ViT-B (85M parameters), and ViT-L (303M parameters) when trained on 130 million patches from 11,000 slides versus 500 million patches from 80,000 slides. We find that larger model sizes and pretraining dataset sizes yield significantly better downstream models, yielding up to 8% relative improvement in performance depending on the task.
In this study, we have demonstrated that our AI foundation model can be used to infer a wide range of breast cancer characteristics from a single H&E-stained slide, including histological subtypes and clinically relevant gene mutations. The unique strengths of our approach—leveraging small amounts of supervised data along with large-scale unsupervised pretraining—create significant opportunities for advancements in pathology research and clinical applications.

P2-06-29: Automated Breast Density Assessment on Chest CT with a Deep-Learned 3D Ordinal Regression Model

Artur Wysoczanski, Elsa D. Angelini, Sachin S. Jambawalikar, Andrew F. Laine, Mary M. Salvatore

Introduction: Breast cancer is the most common malignancy and the second-leading cause of cancer mortality in women. Breast density, defined as the extent of fibroglandular tissue within the breast, is assessed semi-quantitatively on a four-grade scale, from mostly fatty (grade 1) to extremely dense (grade 4), with a severalfold increase in prospective cancer risk between the lowest and highest grades. Millions of chest CT studies are performed annually in patients eligible for routine mammographic screening, representing a significant opportunity for incidental density reporting and risk stratification. While automated density grading on mammography is robust and widely deployed, assessment on CT remains limited by comparison. To facilitate the efficient and standardized assessment of breast density on chest CT, we train and evaluate a 3D convolutional neural network (CNN) model to predict breast density grade from chest CT volumes using a retrospective dataset of patients at Columbia University Irving Medical Center.
Methods: A retrospective, IRB-approved chart review identified female patients at CUIMC

who underwent both mammography and chest CT acquired less than one year apart from January 2010 through March 2019. All cases were reviewed by a faculty radiologist, recording both CT breast density and whether the entire breast was present within the scanner field of view (FOV). All CT scans with or without IV contrast, with axial soft-tissue reconstruction and no breast malignancy, prosthesis or prior mastectomy were included. CT volumes were downsampled to isotropic 2.5 mm resolution and 80x80x80 voxel volumes of interest (VOIs) were extracted containing each imaged breast. Scans were randomly allocated to training, validation, and test sets in a 3:1:1 ratio with stratification by density grade.
Our 3D CNN model consists of five blocks containing 3D convolutional layers with ReLU activation, convolutional block attention modules (CBAM), and batch normalization, interleaved with pooling operations. Rank-consistent ordinal regression (CORN) was applied to the final fully-connected layer to predict the density grade for each image. The model was trained to minimize ordinal cross-entropy with L2 regularization, using training batches balanced across density grades and train-time augmentation, over 60,000 training steps with early stopping conditioned on validation ordinal cross-entropy. Patient-level predictions were generated on the test cases by averaging predictions over the right- and left-breast VOIs.
Results: Of 503 scans which met the inclusion criteria, 86 (17.1%) were assigned breast density grade 1, 244 (48.5%) were grade 2, 131 (26.0%) were grade 3, and 42 (8.3%) were grade 4. One or both breasts were partially outside the FOV in 134 scans (26.6%). On prediction of high (grades 3-4) versus low breast density, the optimized model achieved test-set accuracy of 90.1%, receiver-operating characteristic AUC of 0.935, and Cohen kappa of 0.787 with respect to radiologist-assessed ground truth, comparable to reported values for inter-radiologist agreement. One-vs-all accuracy for breast density grade was 67.3%, with 98.0% of predicted grades at most one level off from the ground truth. ROC AUC and Cohen kappa improved to 0.955 and 0.873, respectively, on the subset of test cases (N=80) where both breasts were contained within the FOV.
Conclusions: We have introduced a 3-D CNN model for automated ordinal regression of breast density on chest CT using a retrospective clinical CT dataset, with performance relative to ground-truth comparable to published inter-reader agreement among trained radiologists. Estimating breast density grade independently of threshold-based volumetric percent density is a direct precursor to deep-learning on chest CT to improve on image-based breast cancer risk stratification.

P2-06-30: A Machine Learning Platform for In Silico Design of DNA Targeting Cancer Therapeutics Using SwRI's Rhodium® Docking Software

Tristan Adamson, Dillon Cao, Shawn T. Blumberg, Jonathon Bohmann

DNA is a classic target of small molecule cancer therapeutics due to the rapid rate of replication in cancer cells and compromised DNA repair machinery, which makes them more susceptible to DNA damage than healthy cells. Unfortunately, DNA-targeting drugs are

notorious for adverse side effects and can even increase the risk of future cancer themselves. Therefore, the design, testing, and development of safer, more selective DNA-targeting drug derivatives remains an important challenge in cancer therapeutic research and development. To date, SwRI's Rhodium™ docking platform has been successfully used for the identification of several potent antiviral and medical countermeasure therapeutics, including therapeutics for filoviruses, SARS-CoV-2, and organophosphate nerve agent antidotes. However, Rhodium™ and other reported docking programs have only been statistically validated for studying protein-ligand interactions. To address the need for a machine learning guided platform for the in silico design of DNA-targeting therapeutics, SwRI recently completed an internal research and development project to adapt Rhodium™ for the screening of DNA-targeting small molecules. This was achieved through a meticulous review of published data to identify highly trustworthy DNA crystal structures as well as unbiased small molecule datasets for training machine learning models to predict DNA binding pose, affinity, and anticancer activity. Finally, the efficacy of this technology was demonstrated by rank ordering the potency of compounds that exhibit anti-cancer activity in several cancer cell models, including breast cancer, leukemia, and liver cancer. In each case, Rhodium™ was able to rank order actual potent compounds above inactive ones with statistical confidence levels ranging from 96% to 99.95%.

P2-07-02: Predicting and validating up to 5-year risk of triple-negative breast cancer using mammogram images.

Graham Colditz, Shu (Joy) Jiang, Debbie L Bennett, Bernard A Rosner

Triple-negative breast cancer (TNBC) drives excess mortality from breast cancer, particularly in Black women. Neither lifestyle variables, mammographic breast density, nor polygenic risk scores—individually or combined—adequately identify at-risk women. Therefore we aimed to identify women undergoing mammographic breast screening at risk for TNBC for appropriate risk management.
We draw on a prospective mammography screening service in an urban health system covering all women regardless of ability to pay. The training cohort included 350 TNBC cases and 10,461 women free from breast cancer (27% of non-cases and 46% of cases were non-Hispanic Black women). The mean age at TNBC diagnosis was 54.6. External validation includes 45 cases and 731 controls. We use full-field digital mammogram images and a generated mammogram risk score. The outcome is discrimination measured by AUC and calibration of TNBC risk.
Established breast cancer risk factors did not differ between TNBC cases and cancer-free women, though more cases had history of pregnancy than non-cases. The mammogram risk score on the first available digital mammogram was substantially higher for women who developed TNBC compared with those who remained cancer-free. The odds ratio for each standard deviation increase in mammogram risk score is 7.1 (95% CI, 6.3, 7.9). In the external validation, the AUC for 5-year risk was 0.85 (95% CI 0.79, 0.91) when including cases diagnosed from the screening mammogram and 0.73 (95% CI 0.65, 0.81) when

excluding cases diagnosed within 6 months of screening. Calibration between predicted and observed risk across quintiles of TNBC risk show good performance. We then plotted the estimated TNBC risk score using mammograms only and observed substantial separation of the baseline risk distribution for women who developed TNBC and those who remained cancer-free.
We assessed predictive performance over time starting from the initial digital mammogram and noticed a slight decrease in AUC as the prediction horizon was extended. In the external validation excluding cases diagnosed <6 months from screening mammogram, the AUC decreased from 0.75 (95% CI 0.67, 0.84) for a 1-year risk to 0.72 for a 2-year risk, and to 0.72 (95% CI, 0.64, 0.80) for a 5-year risk.
Conclusion: The mammogram risk score derived from a diverse mammography screening population offers a tool to identify women at high risk specifically for TNBC. It can be calibrated to population incidence rates allowing consistent classification across screening services. This can open the way for precision management of TNBC risk and recruitment to prevention trials. Evidence-based strategies to reduce TNBC risk are urgently needed.

P2-07-03: Noninvasive imaging of breast cancer and metastasis using TROP2-targeting radiotracer 68Ga-TTP

Yifei Pei, Jingwen Bai, Guojun Zhang

Objective: Molecular imaging technology, such as PET/CT, is of great value for accurate and individualized diagnosis of early tumors and non-invasive target location. Currently, targeted nuclide probes for breast cancer primarily include 18F-FES (ER targeting), 18F-FFNP (PR targeting), and 68Ga-ABY-025 (HER2 targeting). However, these probes are limited to specific types of breast cancer. Therefore, there is an urgent need to develop new targets for all kinds of breast cancer imaging. Human trophoblastic cell surface antigen 2 (TROP2) is a glycoprotein distributed on cell membranes. Researchers have found that TROP2 expression is low or absent in breast tissues but significantly elevated in breast cancer, especially in 93% of triple-negative breast cancer. Based on the successful ASCENT Phase III clinical trial and TROPiCS-02 study, Trodelvy, an antibody-conjugated drug that targets TROP2, - has been approved by the U.S. Food and Drug Administration and the China Drug Administration for treating triple-negative breast cancer or HR+/ HER2- advanced breast cancer. The efficacy of Trodelvy in breast cancer treatment highlights the viability of TROP2 as a reliable marker for breast cancer cells imaging.
Methods: Based on phage libraries, we innovatively screened TTP (TROP2-targeted peptide), a polycyclic peptide with high affinity for TROP2. The peptide was conjugated with the bifunctional chelating agent DOTA-NHS and labeled with 68Ga to obtain the radiotracer 68Ga-TTP. We examined its physicochemical and pharmacokinetic properties, followed by micro-PET/CT imaging to assess its potential for tumor imaging. Then, we evaluated the probe's ability to detect in situ tumors and metastatic tumors using mouse models of breast cancer in situ, lymph node metastasis, and lung metastasis. Additionally, we compared the targeting efficiency of this imaging probe with that of 18F-FDG, the most commonly used

radiotracer in clinical practice.
Results: The radiochemical purity of probe 68Ga-TTP exceeds 95% and demonstrates excellent stability in both vivo and vitro settings. The results from biological distribution and pharmacokinetic experiments indicate rapid clearance and predominant renal metabolism of the probe in mice, with minimal uptake and fast metabolism observed in normal tissues and organs. PET/CT imaging reveals high tumor tissue uptake of 68Ga-TTP in mouse models expressing high levels of TROP2, such as MDA-MB-231-TROP2 and 4T1-TROP2 tumor cells. However, in mouse models carrying MDA-MB-231 and 4T1 tumors with relatively low TROP2 expression, the uptake of 68Ga-TTP in tumor tissues is significantly lower, which can be further blocked by excessive non-radioactive injection. Furthermore, the constructed 68Ga-TTP accurately identifies lymph nodes with tumor metastasis as well as lung metastatic lesions, exhibiting superior clarity and signal-to-noise ratios compared to conventional 2-fluorodeoxyglucose PET/CT imaging techniques. Overall, these findings demonstrate that the developed 68Ga-TTP exhibits excellent targeting capabilities for breast cancer.
Conclusion: This study proposes that TROP2-targeted PET imaging holds potential as a diagnostic tool for breast cancer and metastasis, thereby facilitating its clinical application in PET/CT and PET/MR imaging for breast cancer detection and therapeutic response evaluation to Trodelvy.

P2-07-04: [18F]FluorThanatrace PET imaging correlates with response to PARP inhibitors in breast cancer: a pilot study

Austin R. Pantel, Kara Maxwell, Anthony Young, Daniel A. Pryma, Michael D. Farwell, Fang Liu, Quy Cao, Sophia R. O'Brien, Amy S. Clark, Payal D. Shah, Elizabeth S. McDonald

Introduction: PARP inhibitors (PARPi) are approved for BRCA-mutant HER2- breast cancer, and there is clinical interest in expanding indications to include homologous recombination deficient (HRD) breast cancers. Yet, response in these populations remains variable, suggesting clinical utility in developing a better biomarker to select patients for PARPi and predict response. Here, we evaluated the 18F-labeled PARPi, [18F]FluorThanatrace (FTT), as a functional biomarker of PARPi response in breast cancer.

Methods: A single-arm prospective observational trial was conducted at the University of Pennsylvania from May 2017 to March 2022 (NCT03083288, NCT03846167). Subjects ≥18 years of age with known or suspected breast cancer, at least one lesion ≥1 cm on conventional imaging, and willing to undergo an FTT-PET prior to treatment initiation were enrolled. Participants provided written informed consent.

Subjects were scanned on an Ingenuity TF PET/CT (Philips Healthcare) following injection of FTT. To evaluate if FTT uptake associated with PARPi response, primary and metastatic target lesions were selected based on anatomic CT imaging and RECIST 1.1 criteria. Maximum standardized uptake values (SUVmax) were recorded from the tumor with reference to CT scans. Spearman correlation estimated the strength of association

between FTT uptake and progression free survival (PFS). Mann-Whitney test compared FTT uptake in subjects with < or ≥ 5-month PFS. For HRD correlation, somatic sequencing of the index tumor and germline sequencing were utilized and compared with SUV from the index malignancy on PET/CT.

Participants: Twenty-four subjects with primary breast cancer underwent a baseline FTT-PET/CT scan prior to standard of care therapy. FTT uptake and genomic mutations were previously reported and showed a broad range of FTT uptake independent of genomic data. Here, untreated biopsy specimens were sequenced and HRD was calculated for correlation analysis with FTT uptake.
A second cohort of 10 women with stage IV breast cancer underwent a baseline FTT-PET/CT scan prior to the start of a PARPi, and eight women received a second optional scan after a short interval after initiating PARPi treatment. Subjects ranged from 35 to 72 years of age and 3 self-reported as Black and 7 as White. All subjects had a germline or somatic pathogenic mutation in HR repair genes identified by a CLIA certified assay.

Results: Baseline FTT-PET uptake did not correlate to HRD score, supporting that FTT provides distinct information from genetic features. In the PARPi cohort, 22 target lesions were identified across the 10 subjects. Target lesion diameter averaged 2.8 cm (range 1-6.5) and baseline FTT-PET imaging showed variable uptake (SUVmax range 0.5-6.9, mean 4.8). SUVmax did not correlate to tumor CT measurements, supporting that PARP expression or binding of PARPi to its target is not directly related to lesion size.
Baseline average lesion uptake correlated to PFS ($r=0.74$, $P=0.023$, $n=8$), suggesting subjects with greater [18F]FTT uptake had longer survival. Dichotomizing subjects between those with a PFS >5 months and those with <5 months showed subjects with longer survival had higher SUVmax at baseline ($P=0.04$). All eight subjects imaged by FTT-PET/CT post-PARPi had a decline in FTT uptake (13%-61%), indicating variable drug-target engagement. A correlation was seen between PFS and subject-level percent change in SUVmax from baseline to post-PARPi imaging ($r=-0.86$, $P=0.012$, $n=7$), indicating larger declines in FTT uptake were associated with longer times-to-progression.

Conclusion: These early results suggest the potential of FTT-PET to select patients for PARPi treatment and monitor in vivo pharmacodynamics after therapy start. The absence of association with HRD score supports FTT uptake as a novel measure from genomic biomarkers. Larger multicenter trials to evaluate FTT-PET as a biomarker of PARPi response in breast cancer are warranted.

P2-07-05: Performance of the BCSC and MammoRisk (MR) scores with and without PRS313 to predict invasive breast cancer (iBC) risk in the UK Biobank cohort

Elie Rassy, Suzette Delaloge, Mojgan Karimi, Thérèse Truong, Emilien Gauthier, Stéphane Ragusa, Damien Drubay, Stefan Michiels, Maryam Karimi

Background: As risk-based iBC screening and prevention strategies emerge as promising avenues, the international validation of iBC risk prediction scores becomes increasingly important. BCSC and MR scores have been developed on the US BCSC cohort. We evaluated their performance in predicting iBC risk in the UK Biobank cohort with and without PRS313.

Methods: We included the data from female participants of European ancestry who were enrolled in the UK Biobank cohort (application number 69901) and excluded women with prevalent iBC, history of other malignancy except for non-melanoma skin cancer, and a history of mastectomy or breast augmentation surgeries. The primary endpoint was the diagnosis of iBC. Participants were censored at diagnosis of another malignancy, death, last follow-up, or administratively at 5 years whichever came first. Mammographic density was not reported in this cohort, thus a sensitivity analysis was performed using different strategies for imputing the density of all participants: 1) by B, 2) by C, 3) by the mean prediction of all densities weighted by their respective frequencies reported by Tice et al (JCO 2015) [ongoing]. Both models were calibrated for age and the national incidence of iBC in UK. Their discrimination and calibration were assessed using respectively the time-dependent ROC AUC (tdAUROC), and the calibration curves, observed to expected ratio (O/E) and the integrated calibration index (ICI) for the 5-year iBC risk prediction.
Results: Among the 273,476 women enrolled in UK Biobank, 196,317 were eligible for the present analysis. Most women were ≥ 50 years (77%), postmenopausal (60.8%) and had no reported history of breast biopsy (99.8%). 10.8% had a first-degree relative with iBC. At 5 years, 2,951 participants had a reported diagnosis of iBC.
For mammographic density imputed by density B, BCSC showed an O/E of 1.196 (95% CI 1.191-1.202), ICI of 0.00256 (95% CI 0.0020-0.0031), and tdAUROC of 0.556 (95% CI 0.545-0.566). The addition of PRS313 yielded an O/E of 1.177 (95% CI 1.172-1.182), ICI of 0.00235 (95% CI 0.0019-0.0029), and tdAUROC of 0.638 (95% CI 0.625-0.648). MR showed an O/E of 1.222 (95% CI 1.216-1.227), ICI of 0.00282 (95% CI 0.0023-0.0034), and tdAUROC of 0.558 (95% CI 0.547-0.569). Adding PRS313 to the MR model resulted in an O/E of 1.203 (95% CI 1.197-1.208), ICI of 0.00263 (95% CI 0.0021-0.0032), and tdAUROC of 0.642 (95% CI 0.630-0.652).
For mammographic density imputed by density C, BCSC showed an O/E of 0.848 (95% CI 0.845-0.852), ICI 0.00327 (95% CI 0.0027-0.0038), and tdAUROC of 0.557 (95% CI 0.546-0.566). Adding PRS313 to BCSC yielded an O/E of 0.835 (95% CI 0.831-0.839), ICI of 0.00301 (95% CI 0.0024-0.0036), and tdAUROC of 0.640 (95% CI 0.627-0.650). MR showed an O/E of 0.794 (95% CI 0.790-0.797), ICI of 0.00456 (95% CI 0.0040-0.0051), and tdAUROC of 0.550 (95% CI 0.536-0.560). The addition of PRS313 to MR resulted in an O/E of 0.782 (95% CI 0.778-0.785), ICI of 0.00420 (95% CI 0.0036-0.0048), and tdAUROC of 0.637 (95% CI 0.625-0.646).
Conclusions: PRS313 had a significant additional value for the prediction of the iBC risk for both models which performed similarly. The addition of the PRS to the BCSC and MR scores provided a significant improvement in discrimination and calibration. The mammographic density is essential to provide a reliable prediction for stratified interception with

calibration showing that the BC density imputation impacted the predictions. The clinical utility of PRS313 in combination with MR is being evaluated in the MyPeBS (NCT03672331) trial.

P2-07-06: ClearCoast® MRI System - Intraoperative Magnetic Resonance Imaging for Margin Assessment of Ductal Carcinoma In Situ (DCIS) and Invasive Breast Cancer in Breast Conserving Surgery. MRO - A Controlled Post-Market Study

Marc Thill, Iris Szwarcfiter Brand, Katharina Kelling, Viviane van Haasteren, Petia Kiene, Josefa Nölke, Tina Schnitzbauer, Samantha Natanzon, Zachi Peles Ben David, Saul Stokar, Steffi Marzotko, Bianca Boening, Rubina Hafizi, Sebastian Aulmann, Vesna Bjelic-Radisic

Introduction: Breast cancer accounts for 12.5% of all new annual cancers worldwide. Ductal Carcinoma in Situ (DCIS) has increased its incidence more than fivefold in western countries and alone accounts for up to 25% of all newly detected breast cancers. The primary treatment modality for local breast cancer is breast-conserving surgery (BCS), which aims at balancing adequate pathologic margins while minimizing removal of excess breast tissue. However, unaddressed positive margins occur in 20-40% of cases, often requiring re-excision, which is a strong predictor of local and distant recurrence. The ClearCoast™ MRI System (ClearCut. Ltd., Israel) is a CE-marked adjunctive intraoperative margin assessment tool for distinguishing normal and suspected cancerous tissue based on Diffusion-Weighted Imaging (DWI).
Method: A prospective, controlled, non-randomized study conducted in the AGAPLESION MARKUS KRANKENHAUS (AMK), Frankfurt, Germany and in the Helios University Clinic Wuppertal compared patients undergoing BCS with the ClearCoast™ for real-time margin assessment to an historical control group under standard-of-care (SoC) methods. The focus was the system's impact on re-excision rate, feasibility, diagnostic ability, and conservation of breast tissue volume.
Results: 116 patients were included in the trial, 50 patients in Frankfurt, 66 patients in Wuppertal. The results presented in the abstract are focussing on an interim analysis of the 50 patients of the AMK, and 150 margins were evaluated per study group. The ClearCoast™ was associated with a 40% reduction in re-excision rates among the treatment group, and potentially 80% compared to control group. The ClearCoast™ presented highly accurate diagnostic performance of sensitivity 81% and specificity 70% compared to SoC 36% and 86%, respectively. Particularly for DCIS, ClearCoast™ detected 92% compared to Control's 18%, resulting in a significantly lower rate of unaddressed intra-operative positive margins compared to SoC (15% vs. 64% accordingly). More conservative removal of breast tissue was achieved by the ClearCoast™ (69.9cm3 vs. 153.2 cm3) without any increase in operation time.
Conclusions: The ClearCoast™ MRI System showed potential to improve BCS outcomes, by offering surgeons a real-time, accurate approach to intraoperative margin assessment. It decreases the likelihood of unaddressed residual tumor, thus reducing the burden of re-

excision for patients and the health care system without trading time for precision. Further analysis together with the data from the Helios Universitätsklinikum Wuppertal can be awaited for end of 2024.

P2-07-07: Multiparametric Whole-Body MRI for Reclassification of Oligometastatic Disease in Metastatic Breast Cancer Patients: A Prospective Study

Filippo Merloni, Michela Palleschi, Andrea Prochowski Iamurri, Emanuela Scarpi, Danila Diano, Caterina Gianni, Domenico Barone, Marianna Sirico, Giandomenico Di Menna, Chiara Casadei, Roberta Maltoni, Alice Rossi, Ugo De Giorgi

Background: Almost half of patients with metastatic breast cancer (BC) present with oligometastatic disease (OMD), currently defined as the presence of a maximum of 5 metastases safely treatable with metastases-directed therapy (MDT). MDT aims to eradicate visible metastatic lesions, bringing patients to a state of non-evident disease. However, data regarding survival benefit are conflicting and the correct management of OMD remains a matter of debate. Possible explanations include the lack of biological criteria and advanced imaging methodologies for oligometastatic status definition. The aim of our study is to investigate whether multiparametric whole-body magnetic resonance imaging (WB-MRI) may provide a more precise definition of OMD compared to standard imaging modalities (SIT) as computed tomography (CT) and positron emission tomography (PET-CT).
Methods: In our prospective study, WB-MRI was used as an additional staging tool in patients defined as oligometastatic based on SIT. We aimed to assess how often MRI was able to redefine the number of metastases in patients formerly defined as oligometastatic. Here we report the preliminary results of this ongoing study.
Results: Eighteen patients with 1 to 5 metastases detected by standard imaging techniques underwent WB-MRI: 9 patients were staged with CT and 9 with PET. In 11 cases, only one metastasis was detected by SIT. Ductal or lobular histology was found in 9 and 5 cases, respectively. The majority of patients had HR+/HER2-negative disease (14 patients), 3 patients were triple-negative, and only 1 patient was HER-2 positive. WB-MRI revealed additional metastases (bone and liver metastases in 89 % and 11% of cases respectively) in 9 patients compared to SIT. In 8 cases, the oligometastatic status was redefined: 3 patients were reclassified as disease-free, and 5 patients as polymetastatic (having more than 5 metastases).
Conclusions: WB-MRI has proven to be useful in reclassifying OMD, primarily due to higher detection of additional bone metastases compared to SIT. Missing some metastatic lesions with imaging could hamper the complete eradication of the disease sought with MDT. WB-MRI is therefore strongly recommended for the definition of OMD both in clinical practice and clinical trials.

P2-07-08: MRI screening for brain metastases versus SYMptom-directed brain imaging for Patients with Triple neg or HER2+ Metastatic breast cancer: updated primary outcome analysis and preliminary quality of life data from a randomized phase II pilot study

Katarzyna J. Jerzak, Megan Shum, Gregory Pond, Orit Freedman, Gur Chandhoke, Tatiana Conrad, Priscilla K. Brastianos, Gregory Stanisz, Arjun Sahgal, Ellen Warner

Background: The role of MRI screening to detect asymptomatic brain metastases (BrM) among patients with HER2+ or triple negative (TN) metastatic breast cancer (MBC) continues to be debated. While early detection and intervention for BrM has potential to improve patients' outcomes, evidence to confirm utility of screening is still lacking.
Methods: We conducted a multicentre phase II pilot study randomizing patients with TN or HER2+ MBC to 1 year of BrM screening (contrast enhanced brain MRI at baseline, 4, 8, and 12 months) versus symptom directed brain imaging (MRI only if symptoms of BrM develop). The primary goal of this study was to determine the feasibility of a future randomized trial of BrM screening versus symptom-directed imaging in this patient population. Key inclusion criteria were age ≥18; TN MBC diagnosed ≤12 weeks prior to study entry or HER2+ MBC with no restrictions regarding time of diagnosis; no symptoms of BrM or known asymptomatic BrM; ECOG ≥ 1 and no MRI contraindications. Overall and neurologic-specific quality-of-life (QoL) as well as cancer-related anxiety were assessed at baseline, 6 and 15 months.
Criteria rendering a future trial "not feasible" were defined a-priori as: <30% of eligible patients enroll in the study, <50% complete the study protocol, and/or >50% of patients allocated to the control arm during the 1 year study period are screened for asymptomatic BrM with CT or MRI.
Results: Between 2018 and 2024, 50 patients from 3 cancer centres enrolled in the study. Metrics regarding the proportion of eligible patients who enrolled in the study were collected from the Sunnybrook Odette Cancer Centre site; of 70 patients approached, 44 (63%) enrolled in the study. Forty (80%) had HER2+ and 10 (20%) had TN MBC. The median age was 52.7 (13.2) years. Twenty-four patients (48%) were randomized to the MRI screening arm and 25 (52%) were randomized to standard of care (SOC) surveillance. So far, 42 patients (84%) have either completed the study (n= 23, 46%) or withdrawn early (n= 18, 36%); 8 (16%) continue on study. 10 patients (42%) in the MRI screening arm withdrew a median of 2.5 months after enrollment and 8 (31%) in the SOC arm withdrew a median of 6.7 months after enrollment; the most common reasons for withdrawal were patients' discontent with their randomised arm (n=6) and claustrophobia (n=5). To-date, 9 patients (18%) developed BrM, 4 (17%) in the screening arm and 5 (19%) in the SOC arm. Eighteen patients (69%) in the SOC arm had brain imaging, 7 (27%) in the absence of neurological symptoms.
Baseline scores for overall QoL (EORTC QLQ BN20) and neurologic-specific QoL (FACT-BR tools) as well as cancer-related anxiety (NCI PRO-CTCAE) were similar in patients in both study arms. Only 5 (24%) of patients in the MRI arm and 8 (36%) in the SOC arm

experienced anxiety frequently at baseline. At 6 month follow-up, the majority of patients [14 (93%) in the MRI arm and 8 (62%) in the SOC arm] had either improved or unchanged level of anxiety compared to baseline (p=0.069). There was no significant difference between baseline and 6-month scores in any of the assessed QoL domains. Data regarding 15-month QoL measures will be reported during the abstract presentation, when longer follow-up is available.
Conclusion: A large, multi-center randomized trial to investigate the utility of MRI-based surveillance for asymptomatic detection of BrM in the proposed patient population is likely feasible based on a-priori criteria. However, a high rate of brain imaging in the control arm of this pilot study and increasing uptake of BrM screening in daily practice need to be taken into consideration. Anxiety scores were similar among patients in both arms of the trial.

P2-07-09: Breast cancer diagnosis using artificial intelligence algorithms

Yumi Kim, Sungsoo Kim, Chan-seok Yoon, Jeng-min Park, Dong-young Noh

Background: In our previous study, we developed a 3-protein signature blood marker using a proteomics technique for early detection of breast cancer. This study is to evaluate the breast cancer diagnosis performance of a newly developed 7-protein signature blood marker with artificial interlligence techniques to improve breast cancer diagnosis.
Meterial and methods: From July 2022 to March 2024, 300 breast cancer patients and 150 health controls were enrolled prospectively. The subjects regularly collected blood at regular intervals of 6 months or 1 year. The peptides that are optimal for MS/MS detection were selected through the development of the PepQuant library, a biomarker detection library. The selected proteins were chemically synthesized and then quantified by a multi-reaction monitoring (MRM) method. After discovering and verifying breast cancer biomarkers, algorithms were developed using five types of machine learning techniques for seven candidate proteins (APOC1, CHL1, FN1, vWF, PRG4, CLU, and MMP9). To evaluate the perfomance of breast cancer diagnosis, performance evaluation was conducted based on the sensitivity, specificity, accuracy, false positive rate, false negative rate, positive predictive value, and negative predictive value.
Result: The sensitivity, specificity, and accuracy of the 7-protein signature analyzed using a new machine learning algorithm were 87.6%, 89.7%, and 88.0%, respectively, which outperformed the previous 3-protein markers. The false positive and false negative rates were 20% and 15.4%, indicating a 33% improvement in false negatives over previous markers. In addition, positive and negative predictive value were also recognized to be improved to 85.2% and 87.0%.
Conclusion: Breast cancer diagnosis using a 7-protein signature developed with aritificial intelligence models shows that breast cancer detection can be significantly improved compared to before.

P2-07-10: The role of [18F]16Î±-Fluoro-17Î²-Fluoroestradiol (FES) Positron Emission Tomography (PET) in Predicting Response to Endocrine Therapy (ET)

Nicholas DiGregorio, Hannah Linden, Jennifer Specht, Dan Hippe, Jasper van Geel, Song Shaoli, Liu Cheng, Christine Brand

Background: Seventy percent of breast cancers (BC) are estrogen receptor-positive (ER+). ET improves clinical outcomes in ER+ BC; however, ET effectiveness relies on functional ER. While immunohistochemistry (IHC) is routinely used to quantify ER presence in sampled tissue, its clinical utility has inherent limitations. ER+ by IHC does not confirm function of ER, as illustrated by up to 50% of patients experiencing disease progression while on ET. FES is a radiolabeled form of estrogen and quantification of functional ER binding via FES PET may render important guidance on potential response to ETs, thus optimizing patient management, avoiding futile therapy or associated toxicities, and reducing financial burden. FES PET quantification, as measured by standardized uptake value (SUV), informs on functional ER and ER heterogeneity. This meta-analysis evaluated FES SUVmax and heterogeneity with clinical outcomes following ET.
Methods: A systematic review identified five studies with comparable FES SUV and progression-free survival (PFS) measures; patient-level data was obtainable from three studies. All patients had advanced ER+ BC and received ET (n = 53, Palbociclib + ET; n = 48, Fulvestrant monotherapy); all patients were scanned on a Siemens PET/CT. Using Syngo software, two board-certified nuclear medicine physicians measured FES SUVmax per lesion. The number and percentage of FES-positive (FES+) lesions were calculated per patient. A lesion with FES SUVmax > 1.8 was defined as ER+ and heterogeneity as 1-99% of lesions FES+; other thresholds for FES SUVmax and % heterogeneity were considered. PFS was defined as time from initiating ET until disease progression / death from any cause and was censored at last follow-up. PFS was estimated via the Kaplan-Meier method. Cox proportional hazards regression was used to evaluate associations between FES+ and PFS, summarized via hazard ratios (HRs). HRs were estimated using different thresholds to define FES+ lesions (SUVmax from 1.8-6) and different thresholds for heterogeneity (e.g., 1-X% vs. (X+1)-100% FES+ lesions, X from 50-99%).
Results: The individual-level data was merged, resulting in 101 distinct patients with 878 quantified lesions (median lesions/patient [inter-quartile range]: 7 [4 - 12]). By FES PET, 40% had only visceral lesions; 31% bone and soft tissue; 16% bone only; and 14% soft tissue only.
Lesions were homogeneous (100% FES+) in 75% of patients and heterogeneous in 25%. Overall, 64% of patients progressed or died over follow-up (median PFS: 13.1 months). mPFS was less in the heterogeneous vs. homogeneous group (5.5 vs. 21.6 months), with a corresponding HR for progression or death of 5.4 (95% confidence interval [CI]: 3.2-9.4, $p < 0.001$). When the SUVmax threshold for FES+ was raised from 1.8, the HR for heterogeneous vs. homogeneous decreased, ranging from 1.1 (95% CI: 0.6-2.0) to 3.3 (95% CI: 2.0-5.5). Similarly, when the heterogeneity threshold was lowered from 99%, the HR also tended to decrease compared to when 1-99% vs. 100% was used, ranging from 1.8

(95% CI: 0.4-7.3) to 5.2 (95% CI: 3.0-8.9). No combination of SUVmax or heterogeneity thresholds resulted in a higher HR than the original combination.
Conclusion: To our knowledge, this analysis is the largest individual-level data cohort to date assessing the predictive value of FES in patients receiving ET. FES was strongly predictive of PFS using a threshold of SUVmax > 1.8 for FES+ and 1-99% for heterogeneity threshold. Raising the threshold for SUVmax or heterogeneity did not improve risk stratification. Any amount of heterogeneity was associated with shorter PFS with ET compared to patients with homogeneous FES+ expression. The results support the utility of FES in predicting clinical benefit to ET but warrant further analysis to support more routine use in clinical practice.

P2-07-11: The value of baseline staging tests in early stage breast cancer: A retrospective study from the Antwerp University Hospital

Christophe Van Berckelaer, Alice Esposito, Katrijn Vandyck, Mathias Van Geyt, Peter Van Dam, Xuan Bich Trinh, Julie Verhaegen, Wiebren Tjalma

Background: Breast cancer, the most common cancer among Belgian women, impacts almost 1/8th of the female population. Prognosis of breast cancer patients largely depends on disease stage and the presence of (occult) metastases, therefore many patients undergo imaging to detect distant metastasis as part of their diagnostic work-up. Furthermore, the detection of distant disease will have major therapeutic consequences. However, it is unclear whether the detection of oligometastatic disease before surgery has an impact on survival and numerous international guidelines suggest not to do screening in the early stage setting because of the very low a priori probability of a patient presenting with metastatic disease. Despite these guidelines many Belgian women still undergo baseline staging test with a bone scan (BS), a liver ultrasound (LUS) and chest radiography (CXR), when presenting with early stage breast cancer. This study aims to assess the benefit of staging tests by examining the incidence of metastatic disease in early-stage breast cancer detected by baseline staging tests.
Methods: We conducted a single-center retrospective cohort study including all newly diagnosed invasive breast cancer patients, who had their initial diagnosis and complete treatment at Antwerp University Hospital (Edegem, Belgium) between 1 January 2012 and 31 Augustus 2023. The hospital records were reviewed to obtain clinical-pathological information and data about the baseline staging. Confirmatory investigations and biopsy (anatomopathological confirmation) were conducted after an initial positive result. For each staging procedure, we analyzed the 'prevalence' and a 'false positive rate'. Relationships between staging results and clinicopathological variables were assessed in R studio.
Results: A total of 1589 patients were evaluated in this study of which 1090 had early-stage breast cancer (cT1/2N0). Only 2 patients out of 857 had a positive CXR (0.2%) and 2 out of 902 patients had a positive LUS (0.2%). A positive BS was seen in 12 out of 968 cases (1.2%). Interestingly, false-positive results leading to additional examinations were seen respectively in: 31/857 (CXR), 41/902 (LUS) and 18/968 (BS) cases. Clinicopathological

parameters associated with a positive staging in the early setting were a larger tumor size (P= 0.009) and an elevated CA15.3 (P< 0.001).
In contrast with a negative nodal status, cT1/2 patients that had cN1 disease (230) had more often positive screening results: 7.2% versus 1.5%, P<0.001. Although the prevalence of metastic disease in this cohort was also still low: CXR: 0/147 (0%), LUS: 2/173 (1.1%) and BS: 12/192 (6.3%).
Conclusion: In this real-life university hospital setting, a very low prevalence of metastases in early-stage breast cancer (T1/2N0) was seen. These findings are in line with previous studies and support the omission of routine baseline staging. Although staging can be considered in larger tumors and patients with an elevated CA15.3. Furthermore, our results reveal a substantial number of false positive staging results, leading to psychological distress among patients and increasing the public health care expenses.

P2-07-12: Associations between demographic and clinicopathologic characteristics and convolutional neural network-derived breast cancer risk scores among women with hormone receptor-positive breast cancer.

Julia McGuinness, Juliet Rowe, Simukayi Mutasa, Vicky Ro, Samuel Pan, Jianhua Hu, Meghna S. Trivedi, Melissa K. Accordino, Kevin Kalinsky, Dawn L. Hershman, Richard S. Ha, Katherine D. Crew

Introduction: Deep learning tools applied to standard surveillance mammograms could serve as noninvasive pharmacodynamic biomarkers of response to adjuvant breast cancer (BC) therapies, including endocrine therapy (ET). We previously demonstrated that a convolutional neural network (CNN)-based model applied to surveillance mammograms is an accurate, independent predictor of BC risk, and that short-term change in a CNN-derived BC risk score with adjuvant ET was also associated with breast cancer relapse. We evaluated demographic and clinicopathologic characteristics associated with baseline CNN risk score and with change in CNN risk score over time on adjuvant ET among women with early-stage HR+ breast cancer.
Methods: We conducted a retrospective cohort study among women diagnosed with stage I-III unilateral hormone receptor-positive (HR+) BC at Columbia University Irving Medical Center (CUIMC) from 2007-2017, who received adjuvant ET (tamoxifen, aromatase inhibitors [AIs) and had mammograms of the contralateral breast at diagnosis (baseline) and at 1-2 years on adjuvant ET (follow-up). We extracted demographics, body mass index (BMI, kg/m2), clinicopathologic characteristics including tumor stage and grade, and BC treatments from the electronic health record (EHR) and the New York-Presbyterian Hospital Tumor Registry. We applied the CNN risk model to baseline and follow-up mammograms to estimate baseline CNN BC risk score (range, 0-1, with 1 indicating highest risk), and to calculate absolute change in CNN risk score from baseline to 1-2 years on ET. We conducted multivariable linear regression models to evaluate for potential associations between baseline CNN risk score and change in CNN risk score and prognostic factors including age, race/ethnicity, BMI, tumor stage and grade, and BC treatments.

Result: Among 749 evaluable women, mean age was 59.4 years (standard deviation [SD], 12.4 years), and 38% were non-Hispanic White, 14% non-Hispanic Black, 38% Hispanic, and 10% Asian. Thirty-six percent of women were obese (BMI >30 kg/m2), and three-quarters were postmenopausal at diagnosis. The majority of patients had stage I cancer (59.4%), and received adjuvant aromatase inhibitors (68.1%). After adjustment for covariates, baseline BMI was not significantly associated with baseline CNN risk score (regression slope estimate [ß]=0.001; p=0.424). However, increasing age (ß=0.001; p<0.001), Black race (ß=0.023; p<0.001), tumor stage III (ß=0.023, p=0.005) were associated with higher baseline CNN score, while high tumor grade was inversely associated with baseline CNN score (ß= -0.0150; p=0.028). In multivariable analysis, absolute change in CNN risk score from baseline to follow-up was inversely associated with change in BMI over that period (ß= -0.002; p=0.007) and with high tumor grade (ß -0.014; p=0.039), while older age (ß=0.001; p<0.001), Black race (ß=0.024; p<0.001), tumor stage III (ß=0.023; p<0.001), and low tumor grade (ß=0.022; p=0.024), had significant positive associations with change in CNN score.
Conclusions: We found that poor prognostic factors such as advanced tumor stage and Black race were associated with higher baseline CNN risk score and increase in CNN score on adjuvant ET. However, factors typically associated with more favorable BC diagnosis, including lower tumor grade, older age, and a decrease in BMI on adjuvant ET, were also associated with higher baseline CNN score and an increase in CNN risk score. These associations should be further evaluated in future studies utilizing larger, diverse patient cohorts of patients with early-stage HR+ BC.

P2-07-13: USE OF INDIGO CARMINE FOR DETECTING SENTINEL LYMPH NODES IN BREAST CANCER: INTERIM RESULTS OF A STUDY ON EFFICACY AND SAFETY

Mikhail Voronov, Soynov A.V., Abdugafforov S.A., Mchedlidze T.G., Vorotnikov V.V., Kopytich I.V., Tsalko S.E., Pakhomova R.A., Sharavina M.V., Mukueva M.I., Andreeva V.A., Tkachenko A.V.

Abstract: Sentinel lymph node biopsy (SLNB) is the standard staging procedure for early breast cancer (BC). Various markers are currently used to detect sentinel lymph nodes, including radioisotopes, methylene blue-based dyes, and fluorescent agents.
Relevance: the reference and most studied method remains the use of radioactive colloid: technetium-99mTc. In addition to the high cost, a limitation of the method is its technical complexity and lack of availability in most clinics due to radiation safety requirements. Therefore, the search for alternative techniques remains relevant.Indocyanine green (ICG) also has high sensitivity and has been recommended as an alternative to radioisotopes. After intradermal injection, ICG binds to albumin, an integral component of lymph, and is therefore an excellent means of visualizing lymphatic vessels and lymph nodes. The disadvantages of this method are the high cost of the dye, the need for expensive additional

equipment (near-infrared camera), and indirect visualization of the surgical field.
Indigo carmine is an affordable and safe dye that has been successfully used in urology to study the excretory function of the kidneys, including the renal pelvis and ureters. In surgery, it is used for visual detection of integrity violations of hollow organs and the extent of fistulous passages. The use of indigo carmine during endoscopic chromoendoscopy has shown high efficiency in visualizing esophageal, gastric, and colorectal neoplasms. The low volume of dye (<2 ml) and intradermal injection have low rates of anaphylaxis (0.031%). In experimental animal studies, with daily administration of indigo carmine at doses 10 times higher than the recommended human dose, it did not have a harmful effect on the main organ systems and tissues (nervous, cardiovascular, hematopoietic, excretory, respiratory), metabolism, general condition, and important physiological homeostasis parameters, which also demonstrates the complete absence of cumulative properties of this dye. However, despite the potential advantages, there is currently insufficient data confirming the efficacy and safety of indigo carmine for lymph node marking in SLNB.
Purpose: The aim of this study was to evaluate the efficacy of performing "sentinel" lymph node biopsy using indigo carmine in patients with breast cancer and to assess the safety and tolerability of indigo carmine for the "sentinel" lymph node biopsy procedure in patients with breast cancer.The objective of this study was to identify lymph nodes marked using indigo carmine, identify lymph nodes marked using the radiopharmaceutical technetium-99mTc, and compare the number of cases of detection of "sentinel" lymph nodes using indigo carmine with the number of cases of detection of "sentinel" lymph nodes using the technetium-99mTc preparation and gamma probe.
Materials and methods: Over 6 months, 117 patients with a diagnosis of breast cancer who were indicated for the sentinel lymph node biopsy procedure underwent sentinel lymph node biopsy using a combined method with the use of indigo carmine and the radiopharmaceutical technetium-99mTc. Indigo carmine and the technetium-99mTc radiopharmaceutical were injected intradermally into the areola of the affected breast in each patient. The "sentinel" lymph nodes stained with indigo carmine were visible to the naked eye without the use of additional equipment, then detected with a gamma probe, and then removed. The frequency of detection of "sentinel" lymph nodes was analyzed and the presence of complications was investigated.
